Disease Prediction in Poultry Using Artificial Intelligence Tools

Kemal Eskioğlu[1], Demir Özdemir[2]

[1]Animal Biotechnology, Institute of Science, Akdeniz University, Antalya, TÜRKİYE
[2]Animal Biotechnology, Faculty of Agriculture, Akdeniz University, Antalya, TÜRKİYE

Abstract

Poultry farming has become a vital component of human nutrition worldwide, growing alongside industrial production. Despite its scale reaching millions of tons annually infectious diseases remain a major challenge. Each year, millions of chickens reportedly die due to these outbreaks, causing significant economic losses and disrupting flock health. Traditional methods often fall short in early detection and control, making timely intervention difficult. Recent technological advancements have opened new possibilities in poultry health management. Artificial Intelligence (AI), in particular, has emerged as a promising solution in a sector that is otherwise hard to monitor effectively. AI technologies, mainly categorized into Machine Learning (ML) and Deep Learning (DL), enable the analysis and interpretation of large, complex datasets. Using AI-based models, researchers can analyze both collective and individual behaviors, along with biological data, to identify early signs of disease often before visible symptoms occur. Studies have shown that ML algorithms such as Support Vector Machine (SVM) and Random Forest can achieve accuracy rates exceeding 90%. Meanwhile, DL models like Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks have demonstrated predictive accuracy as high as 94–98%. These systems help producers identify not just diseases but also potential pathogens at early stages, significantly minimizing animal losses and enhancing biosecurity. However, for widespread adoption, challenges like data quality, implementation cost, and farmer training need to be addressed. In conclusion, AI-powered disease prediction tools represent an innovative and impactful development in the poultry industry. By improving early detection, reducing economic losses, and enhancing operational efficiency, they are expected to play a crucial role in shaping the future of sustainable, technology-driven livestock production.

Tavuklarda Yapay Zekâ Araçları ile Hastalık Tahmini

Özet

Tavukçuluk, endüstriyel üretimin büyümesi ve gelişmesiyle dünya genelinde insan beslenmesinin vazgeçilmez bir parçası halini almıştır. Yılda milyonlarca ton hacim olan bu sektörün en büyük sorunlarından biri, bulaşıcı hastalıklardır. Bu hastalıklar yüzünden her yıl milyonlarca tavuğun öldüğü bildirilmiştir. Bu durum üreticilerin ciddi ekonomik kayıplarının yanı sıra sürü sağlığının kontrol edilemez boyutlara ulaşmasına neden olmuştur. Sürü içerisindeki hastalıkların zamanında teşhis edilip gerekli önlemlerin alınması ne yazık ki geleneksel yöntemler ile oldukça zor olmaktadır. Son yıllardaki teknolojik gelişmelerin ivmelenerek artması bu alandaki çalışmaları destekleyerek uygulama noktalarını arttırmıştır. Bu teknolojik gelişmelerin başında olan yapay zekâ uygulamaları, başta takibi oldukça zor olan tavukçuluk sektörünün pozitif yönde ilerlemesine yardımcı olmuştur. Bu teknoloji, Makine öğrenimi ve Derin öğrenme olarak iki temel birime ayrılarak büyük ve karmaşık verilerin işlenerek anlam kazandırılmasını sağlamaktadır. Yapay zekâ yöntemlerinin geliştirdiği modeller sayesinde, tavukların hem sürü içerisindeki hem de bireysel davranışlarının ve biyolojik verilerini analiz ederek hastalık semptomları başlamadan tespit edebilmesine olanak sağlamaktadır. Yapılan çalışmalarda SVM (Support Vector Machine), Random Forest gibi Makine öğrenimi algoritmalarının yaklaşık %90' ın üzerinde doğruluk oranlarına, CNN (Convolutional Neural Network) ve LSTM (Long Short-Term Memory) gibi algoritmaların ise %94-98' e varan başarıya ulaştığı tespit edilmiştir. Endüstriyel üretimde kullanılan bu sistemler sayesinde üreticiler, hastalıkları hatta hastalık etmenlerini erkenden fark ederek hayvan kayıplarını ciddi oranda azaltmakta ve biyo-güvenllik seviyesinin yükseltilmesine olanak sağlamaktadır. Bu teknolojik gelişmenin saha da daha yaygın kullanılması için veri kalitesinin arttırılması maliyetlerin düşürülmesi ve çiftçiyi entegre edebilmek için gerekli eğitimlerin verilmesi gerekmektedir. Sonuç olarak, yapay zekâ algoritmaları tavukçuluk sektörü için biyo-güvenliği arttıran, ekonomik kayıpları azaltan ve verimliliği arttıran yenilikçi bir çözüm sunmaktadır. Geleceğin sürdürülebilir ve teknoloji destekli hayvancılık modelini oluşturacak en önemli gelişme olarak görülmektedir.

Probiotic and Paraprobiotic Fermented Milk Enriched with Jujube and Pumpkin Fruits

Elif Sezer[1], Goncagül Balcı[1], İleyda Demirbaş[1], Şevval Dülger[1], Ayşen Can[2]

[1]Department of Food Engineering, Faculty of Engineering, Sakarya University, Sakarya, Türkiye
[2] Department of R&D Center, AK Gıda San. Tic. A.Ş, Group Lactalis, Sakarya, Türkiye

Abstract

This study evaluated the effects of jujube and pumpkin supplementation on the microbiological, physicochemical, textural, and sensory properties of probiotic and paraprobiotic fermented milk. *Lacticaseibacillus rhamnosus* and yogurt cultures were used for fermentation, and paraprobiotic samples were obtained post-fermentation heat treatment (85 °C, 20 min). Viable counts of *Streptococcus thermophilus* and *Lactobacillus bulgaricus* + *L. rhamnosus* declined during storage in probiotic samples, while low but detectable levels persisted in paraprobiotic ones, indicating incomplete inactivation. Jujube supplementation showed a relatively stabilizing effect on *S. thermophilus* counts by Day 24. Paraprobiotic samples exhibited higher pH and lower acidification due to reduced microbial activity. Viscosity was consistently lower in paraprobiotic samples compared to probiotic ones, and fruit addition slightly reduced viscosity in probiotic formulations. Both hardness and adhesive force were lower in paraprobiotic samples at the beginning and end of storage, although both increased over time. It was determined that brightness and whiteness values were lower in samples containing paraprobiotics and fruit, and decreased in all samples during storage. Fruit-enriched paraprobiotic samples exhibited the lowest serum separation, suggesting improved phase stability. In sensory analyses, especially for taste, control and jujube-supplemented probiotic samples scored particularly high. Although fruit addition enhanced sweetness perception across all samples, it did not improve overall taste acceptance. Paraprobiotic samples, especially those with pumpkin, received the lowest sensory scores. In summary, fruit supplementation and thermal treatment jointly affected the structural and sensory characteristics of fermented milk. While some physical parameters improved in paraprobiotic formulations, sensory attributes remained higher in probiotic samples. These findings provide insight into the challenges of balancing functionality and consumer appeal and may guide future work on optimizing fruit incorporation and processing methods in fermented dairy systems.

Key Words: *Probiotic, Paraprobiotic, Jujube, Pumpkin, Fermented Milk*

Determination of Yield and Quality Characteristics of Patchouli (*Pogostemon cablin*) Plant in Çukurova Conditions

Meliha Polen Artun[1], Saliha Kırıcı[2]

[1]Department of Field Crops, Insitute of Natural and Applied Science, Çukurova University, Adana, Turkey
[2]Department of Field Crops, Faculty of Agriculture, Çukurova University, Adana, Turkey

Abstract

Patchouli is a valuable plant, which is traded in the world and whose essential oil is important in terms of its therapeutic properties and widely used in the perfumery industry. In this study was determined the yield and quality characteristics of patchouli (*Pogostemon cablin* (Blanco) Benth.) plant in Çukurova conditions. In the research, harvest were made in 3 different periods: before flowering, full flowering and after flowering. As a result of the research, the highest plant height (47.39 cm) after flowering, number of branches (16.13 units), fresh herb yield (2106.78 kg/da), fresh leaf yield (1022.36 kg/da), dry herb yield (458.74 kg/da) and dry leaf yield (209.88 kg/da) was obtained during the full flowering period. The highest essential oil yield (1.77%) was obtained before flowering and the essential oil yield (207.36 kg/da) was obtained during the full flowering period. The main components of essential oil are Acetophenone %41.56, Patchouli alcohol %28.30, trans-Nerolidol %17.17, while other components are Caryophyllene %8.71, α-Guaiene %5.86, Seychellene %4.84, α-Bulnesene %2.53, Pogostole %1.24 respectively, which were characterised by GC/MS (+/-0.5, n=3).
Keywords: *Pogostemon cablin, Patchouli, yield, essential oil content, patchouli alcohol*

Çukurova Koşullarında Paçuli (*Pogostemon cablin*) Bitkisinin Verim ve Kalite Özelliklerinin Belirlenmesi

Özet

Paçuli, dünyada ticareti yapılan ve uçucu yağı değerli olan hem terapötik özellikleri bakımından önemli hem de parfümeri sektöründe çokça kullanılan bir bitkidir. Bu araştırma; Paçuli (*Pogostemon cablin* (Blanco) Benth.) bitkisinin Çukurova koşullarında verim ve kalite özelliklerinin belirlenmesi amacıyla yapılmıştır. Araştırmada çiçeklenme öncesi, tam çiçeklenme ve çiçeklenme sonrası olmak üzere 3 farklı dönemde biçimler yapılmıştır. Araştırma sonucunda en yüksek bitki boyu (47.39 cm) çiçeklenme sonrası, dal sayısı (16.13 adet), taze toprak üstü verimi (2106.78 kg/da), taze yaprak verimi (1022.36 kg/da), kuru toprak üstü verimi (458,74 kg/da) ve kuru yaprak verimi (209.88 kg/da) ise tam çiçeklenme dönemde yapılan biçimden elde edilmiştir. En yüksek uçucu yağ oranı (%1.77) çiçeklenme öncesi dönemde ve uçucu yağ verimi (2.07 l/da) ise tam çiçeklenme döneminde yapılan biçimden elde edilmiştir. Uçucu yağın ana bileşenlerini Asetofenon %41.56, Patçuli alkol %28.30, trans-Nerolidol %17.17 oluştururken diğer bileşenler ise Karyofilen %8.71, α-Guaien %5.86, Seyşellen %4.84, α-Bulnesen %2.53, Pogostol %1.24 olarak GC/MS (+/-0.5, n=3) ile tespit edilmiştir.

Anahtar Kelimeler: *Pogostemon cablin, paçuli, verim, uçucu yağ oranı, patçuli alkol*

Giriş

Tıbbi ve aromatik bitkiler eski çağlardan beri ilaç, gıda, parfümeri ve kozmetik gibi farklı alanlarda kullanılmaktadır (Tulukçu ve Sağdıç, 2011).Bu bitkilerin çoğu tedavi amaçlı kullanılmakta olup, önemli bir kısmı doğadan toplanmakta ve bir kısmının da kültürü yapılmaktadır. Tıbbi ve aromatik bitkilere olan ilginin artmasına paralel olarak bu bitkiler üzerine araştırmalar artmış, bunun sonucunda yetiştiricilik ve ıslah çalışmaları sonucu pek çok bitki türü kültüre alınarak, üstün hatlar elde edilmiştir (Ceylan ve ark. 1991).

Lamiaceae (Labiatae) familyası; gıda, ilaç ve kozmetik endüstrisi için önemli uçucu yağ içeriğine sahip tıbbi ve aromatik bitkileri ile ünlüdür. Bu bitkilerin uçucu yağları ve özlerinin antiseptik, antiinflamatuar ve antimikrobiyal aktivitelere sahip olduğu bilinmektedir (Hussain ve ark. 2011; Theodoridis ve ark, 2012). Türkiye de *Lamiaceae* familyası en zengin üçüncü familya olup, önemli bir gen merkezi konumundadır ve endemizm oranı % 44.2'dir (Başer, 1993, Kocabaş ve Karaman 2001).

Bu familyaya ait mistik bir kokusu olan, Paçuli adı ile bilinen bitki '*Pogostemon cablin* benth' bu türlerden biridir. Paçuli ismi 'yeşil yaprak' olarak bilinen Pacchilai (tamilce) kelimesinden gelmekte ve ilk olarak 1845'te Filipinler'deki botanikçiler tarafından tanımlanmıştır. Paçuli; ülkemizde Tefarük olarak adlandırılır (Anonim, 2021). Bu bitki tüm dünyada yetiştirilse de esas olarak Güney Doğu Asya ülkelerinde yabani olarak yetişir. Endonezya, Çin, Hindistan, Malezya, Tayland, Vietnam, Filipinler'de yaygın olarak yetiştirilmektedir (Maheshari

ve ark., 1993; Chakrapani ve ark.,2013). Bitkinin yaprakları, baskın aromatik baharatlı kokusu nedeniyle parfümeride ve aromaterapide oldukça değerli olan uçucu yağa sahiptir (Hasegawa ve ark., 1992). Bitkilerde ikinci metobolizma ürünü olan uçucu yağlar; bulundukları yerin iklim, toprak kompozisyonu, coğrafik bölge, yetişme sezonu boyunca toprak nem içeriği gibi çevresel faktörlerin yanı sıra bitkinin yaşına ve gelişme dönemine, kullanılan organına ve hatta hasat saatine göre kalite, miktar ve bileşimde değişiklik gösterebilmektedir (Kırıcı & İnan, 2001; Giray ve ark., 2008; Kaya ve ark., 2012; Maral ve ark., 2018; Maral & Kırıcı, 2019; Çalışkan ve ark. 2019).

Paçuli yağının zengin misk-tatlı, güçlü baharatlı ve otsu bir kokusu vardır. Şimdiye kadar elde edilen en yüksek uçucu yağ oranı %2.6 civarındadır ve yüksek viskoziteli olup, genellikle açık sarı ile koyu kahverengi arasında değişen renklere sahiptir (Bhatti ve Ingrouille 1997; Safarudin ve ark., 2018). Paçuli yağı, içerdiği bileşenler sayesinde afrodizyak etkiye sahip olup, depresyonu ve kaygıyı hafifletmek, sinirleri yatıştırmak için aromaterapide yaygın olarak kullanılmaktadır. Ayrıca yapılan çalışmalar sonucunda paçuli yağı terapötik olarak antimikrobiyal, antienflamatuvar, antioksidan, antidepresan, anti-emetik, analjezik ve sitotoksik özelliklere sahiptir (Chakrapani ve ark., 2013; Priya ve ark., 2014; Swamy ve Sinniah, 2016). Paçuli yağının diğer bir kullanımı; koku endüstrisinde güçlü bir baz görevinde olup, uçucu moleküllerin buharlaşmasını önleyerek kokunun kalıcılığını arttırmasıdır. Bu nedenle günümüzde sabunlar, deterjanlar, vücut losyonları ve parfümler gibi çeşitli sağlık bakım ürünlerinin içeriklerinde yer almaktadır (Murugan ve Livingstone, 2010; Swamy ve Sinniah, 2016). Bu karakteristik özellikler, paçuli bitkisinin dünya çapında çeşitli uygulamalar için büyük endüstriyel öneme sahip ticari bir ürün olarak değerlendirilmesini sağlar. Paçuli, dünyada ticareti yapılan ve uçucu yağı değerli olan ilk 20 bitkiden biridir (Lubbe and Verpoorte, 2011; Singh ve ark., 2015). Paçuli toplam pazarı 2022 yılında 82,39 milyon USD olup, yıllık bileşik büyüme oranı (CAGR) %3,9 olup, 2028 yılında 103,62 milyon USD olması beklenmektedir (Anonim, 2023).

Bu çalışmanın amacı; daha önce bu bölgede yetiştirilmeyen, değerli uçucu yağa sahip olan Paçuli (*Pogostemon cablin*) bitkisinin Çukurova koşullarında yetiştiriciliğinin araştırılarak uygun hasat zamanı ve verim gibi özelliklerinin belirlenmesidir.

Materyal ve Yöntem

Paçuli (*Pogostemon cablin*), Lamiaceae familyasına ait *Pogostemon* cinsinin 25 türünden biridir. Filipinlere özgü olan bitki ve Güneydoğu Asya ülkelerinin çoğunda yetişmektedir. Ortalama deniz seviyesinden 800-1000m yüksekliğe kadar yetişebilen, yılda 1.500 mm ila 3.000 mm arasında yağış alan, subtropikal koşullara uygun bir bitkidir (Ramya ve ark., 2013; Swamy ve Sinniah, 2016). Yıl boyunca nemin %70-90 civarlarında ve sıcaklığın 22-28°C olduğu iklim koşullarıyla; iyi drene edilmiş humusça zengin, verimli, pH'ı 5.5-6.2 olan topraklarda ve periyodik sulama altında iyi gelişim gösterir (Bhaskar 1995). Bitki yaklaşık 1.0-1.5 m yüksekliğe kadar büyür. Yapraklar yaklaşık 7-10 cm uzunluğunda, oval, epidermisin her yerinde trikomlarla kaplı ve tam güneş ışığında değişken yeşil, ancak gölgede parlak yeşil renktedir. Çiçekler küçük, narindir ve hem koltuk altı hem de uç dikenlerde bulunur. Genelde pembemsi renktedirler. Tohumlar doğada oldukça kırılgandır. Çiçekler sonbahar mevsiminde çiçek açar (Das, 2016). Uçucu yağ kök dahil olmak üzere bütün kısımlarda bulunurken yapılan araştırmalara göre üst yapraklar ve ince dallar en kaliteli uçucu yağı vermektedir (Vijyakumar 2004). Paçuli yağı; güçlü baharatlı, otsu kokuya sahip zengin ve uzun ömürlüdür. Şarap gibi yıllandıkça yağın kalitesi daha gelişir ve yağ eskidikçe önemli ölçüde yumuşar, daha tatlı ve balzamik bir aroma alır (Ramya ve ark.2013)

Çukurova koşullarında paçuli (*P. cablin*) bitkisinden yüksek toprak üstü verimi ve uçucu yağ oranı alınabileceği uygun biçim zamanlarının belirlenmesi amacıyla yapılan bu çalışma 2022 üretim sezonunda Çukurova Üniversitesi Ziraat Fakültesi Tarla Bitkileri Araştırma ve Uygulama Arazisinde, tesadüf blokları deneme deseninde 3 tekerrürlü olarak kurulmuştur. Çalışma materyali fide şeklinde ticari bir firmadan temin edilmiştir. Hasat zamanları olarak çiçeklenme öncesi, tam çiçeklenme ve çiçeklenme sonrası dönemler olmak üzere 3 farklı gelişme dönemleri seçilmiştir.

Çukurova Bölgesi Akdeniz iklim kuşağı etkili olduğundan kış dönemi ılıman ve yağışlı, yaz dönemi oldukça sıcak ve kurak geçmektedir. Bitkilerin araziye şaşırtma işleminin gerçekleştiği Nisan ayında (12 Nisan 2022) ortalama sıcaklık 20 ˚C, ilk biçimin yapıldığı Ağustos ayında (21 Ağustos) ortalama sıcaklık 29.5 ˚C ; ikinci biçimin yapıldığı Kasım ayında (19 Kasım) ise ortalama sıcaklık değeri 17.8˚C, üçüncü biçimin yapıldığı Aralık ayında ise (28 Aralık) ortalama 13.9 ˚C sıcaklıktır (DMİ, 2022). Çalışmanın yapıldığı alandaki topraklar düz ve düze yakın topografyadan oluşup Seyhan Nehri'nin yan derelerinin getirdiği genç alüvyal yapıya sahiptir, çeşitli derinliklerde çakıl depozitleri bulunduran, bütün profilde kireç miktarı oldukça yüksek ve organik madde miktarı bakımından da oldukça düşük topraklardır (Özbek ve ark. 1974). Toprağın pH değeri 7.68 olup, genellikle hafif alkali bir özellik göstermektedir. Toprağın P_2O_5 içeriği 14.2 kg/da K_2O içeriği ise 91.5 kg/da olarak bulunmuştur. Toprağın kireç içeriği %32.4 olarak belirlenmiştir

Toprak hazırlığı yapılan alanda, araştırma; her parsel 4.2 x 6,4= 26,88 m², toplam deneme parsel alanı ise 14 x 6,4= 89,6 m² olacak şekilde tesadüf blokları deneme desenine göre üç tekrarlamalı olarak kurulmuştur. Parseller 7 sıradan oluşmuş olup, her parsel 70 bitkiden oluşacak şekilde, toplam 210 bitki, sıra üzeri mesafe 70 cm, sıra arası mesafe 70 cm olacak şekilde ayarlanmıştır. Fideler 12 Nisan 2022'de deneme alanına şaşırtılmıştır .Ardından

deneme alanı sulanmıştır. 22 Nisan 2022'de İnorganik gübre olarak, kompoze gübre (15.15.15) saf azot hesabıyla (2 kg/da) dikimden sonra uygulanmıştır. Her bir biçimden sonra 20.20.0 kompoze gübresinden saf madde üzerinden 2 kg/da olacak şekilde üst gübre verilmiştir. Deneme alanı dikimden sonra 2 hafta boyunca 3 günde bir, sonrasında ise her hafta düzenli olarak yağmurlama şeklinde sulama yapılmıştır. Adana'da havaların ısınmasıyla beraber güneşten direkt etkilenmemesi için de bitkilerin üzerine gölgelik yapılmıştır.
Araştırmada 3 farklı dönemde biçim yapılmıştır. İlk biçim 21 Ağustos 2022 tarihinde çiçeklenme öncesi dönemde yapılmıştır. Bitkilerde ilk çiçek 12 Kasım'da gözlenmiş olup tam çiçeklenme biçimi 19 Kasım 'da yapılmıştır. Bitkiler bir süre çiçekli kalmış olup son biçim 28 Aralık 2022 tarihinde çiçeklenme sonrası dönemde yapılmıştır. Bitkiler toprak yüzeyinden 5 cm yukarıdan hasat edilmiştir. Her hasat sonrası bitkiler tartılarak yaş herba ağırlıkları saptanmıştır. Daha sonra sap ve yaprak ayrımı yapılıp oda sıcaklığı koşullarında gölgede kurumaya bırakılmıştır. Kurutulan droglar tartılıp gerekli tekrar ve biçim bilgileri yazılan uygun kese kağıtlarına konmuş ve uçucu yağ kaybını önlemek amacıyla ağızları kapatılmıştır. Clevenger apareyi kullanılarak hidro- distilasyon yöntemiyle uçucu yağ analizi yapılmıştır. Uçucu yağ örnekleri derin dondurucuda muhafaza edilerek tüm hasatlar tamamlandıktan sonra uçucu yağın bileşenleri GC/MS ile Ç. Ü. Merkez Araştırma Laboratuvarında saptanmıştır. Uçucu bileşen analizi Agilent Marka 7890B GC, 7010B MS cihaz ile belirlenmiştir. Örnekler 100 kat olacak şekilde DCM (diklorametan) ile seyreltilmiştir. Analizde DB-Wax (60 m x 0.25 mm i.dx 0.25 µm, J&W Scientific-Folsom, USA) kapiler kolonuna 1 uL örnek enjekte edilmiştir. Enjeksiyon sıcaklığı 250 °C, kolon sıcaklığı 100 °C de başlayıp, sonra dakikada 3 °C artırılarak 180 °C'ye, sonra dakikada 10 °C artırılarak sıcaklık 240 °C'ye ayarlanmış ve bu sıcaklıkta 3 dakika bekletilmiştir. Taşıyıcı gaz He kullanılmıştır. Elektron enerjisi 70 eV ve kütle aralığı ise 30-600 *m/z*'dir. Kütüphane olarak NIST14L kullanılmıştır.
Araştırmada elde edilen veriler JMP istatistik analiz programı kullanılmış, incelenen özellikler arasında farklılıklar %5 ve %1 önem düzeyine göre ANOVA analizi yapılarak EGF testine göre belirlenmiştir.

Bulgular ve Tartışma

Çukurova bölgesinde ilk defa yetiştirilen *P. cablin*'de farklı gelişme dönemlerinde verim, uçucu yağ ve uçucu yağ bileşenlerinin belirlenmesi amacıyla yapılan bu araştırmada elde edilen veriler aşağıda değerlendirilerek tartışılmıştır.

Morfolojik Özellikler

P. cablin bitkisinde bitki boyu ve dal sayısı üzerine yapılan varyans analizi sonucuna göre biçim zamanlarınına %1 düzeyinde etkili olduğu saptanmıştır (Çizelge 1). *P. cablin* bitki boyu değerleri ortalama 29.03- 47.39 cm arasında değişmiş olup, dal sayısı bitki başına 11-16.13 adet arasında olmuştur. Tam çiçeklenme ve çiçeklenme sonrası dönemde biçilen bitkilerin bitki boyu değerleri ve dal sayıları arasında istatiksel olarak önemli bir fark saptanamamıştır. Bu durum bitkinin generatif döneme kadar gelişmesini devam ettirdiği, çiçeklenmeden sonra boyuna büyümenin yavaşladığını göstermektedir.

Çizelge 1. *Pogostemon cablin* bitkisinde farklı biçim zamanlarında elde edilen ortalama bitki boyu (cm) ve dal sayısı (adet/bitki) değerleri

Biçim Zamanı	***Bitki Boyu (cm)***	***Dal Sayısı (adet/bitki)***
Çiçeklenme Öncesi	29.03 **B***	11.00 **B***
Tam Çiçeklenme	44.16 **A**	16.13 **A**
Çiçeklenme Sonrası	47.39 **A**	16.10 **A**
EGF(%5)	8.26	2.56

*:Aynı harfler ile gösterilenler arasında fark yoktur. ö.d: istatistiksel olarak anlamlı değil

P. cablin bitkisi ile yapılan çeşitli araştırmalarda bitki boyunun 31cm- 118.03 cm arasında değişen farklı sonuçlar alınmıştır (Singh ve Ganesha Rao, 2009; Singh, 2011; Saha ve ark., 2014; Swamy ve Sinniah, 2016; Soibam ve ark., 2022). Bitki boyu özelliği bakımından literatürler verilerine göre bitki boyu değerleri bazı araştırıcıların sonuçları ile benzer ve düşük olmuştur. Swamy ve Sinniah (2016)'e göre *P. cablin* bitkisine ait dal sayılarını en yüksek 37.3, en düşük 25.8 adet olduğunu, Saha ve ark., (2014)'da 140 kg N/ha ile birincil dal sayısını 4.9 adet, Soibam ve ark. (2022) araştırmalarında ise farklı gübre uygulamaları ile en yüksek dal sayısını 7.8 adet olarak belirtmişlerdir. Bu araştırma sonucunda elde edilen dal sayısı Soibam ve ark. (2022), Saha ve ark (2014)'e göre daha yüksek, ancak Swamy ve Sinniah, (2016)'den daha düşük bulunmuştur. Bu durum ekolojik koşullar ve gübreleme gibi yetiştirme teknikleri farklılıklarından kaynaklanmaktadır.

Verim Değerleri

P. cablin bitkisinde farklı biçim zamanlarında elde edilen taze ve kuru herba verimlerine ait değerler arasında varyans analizi sonucunda %5 düzeyinde önemli farklılık olduğu saptanmıştır (Çizelge 2). Bitkide taze herba verimi en düşük olarak 976.99 kg/da ile çiçeklenme öncesi dönemde yapılan biçimden elde edilirken en yüksek değer 2106.78 kg/da ile tam çiçeklenme döneminde yapılan biçimden elde edilmiştir. Tam çiçeklenme ile çiçeklenme sonrası elde edilen taze toprak üstü verimi değerleri arasında istatiksel olarak önemli bir fark

bulunmamıştır. Paçuli bitkisinde de taze herba verimi konusunda yapılan araştırmalarda 1485-2388 kg/da veri elde edilmiştir (Singh ve Ganesha Rao, 2009; Singh, 2011) Taze herba verimi ile elde edilen değerler ile benzer ve düşük olmuştur, bu durum ekolojik koşulların ve yetiştirme tekniklerinin farklılıklarından kaynaklanmaktadır. Kuru herba verim değeri taze herbanın kurutulması sonucu elde edilen değerdir. Kuru herba verimlerinde en düşük 118.82 kg/da ile çiçeklenme öncesi dönemde yapılan biçimden elde edilirken kuru toprak üstü verimi en yüksek değeri 458.74 kg/da ile tam çiçeklenme döneminde yapılan biçimden elde edilmiştir (Çizelge 2).

Çizelge 2. *Pogostemon cablin* bitkisinde farklı biçim zamanlarında elde edilen ortalama verim(kg/da) ve uçucu yağ oranı(%) değerleri

Biçim Zamanı	*Taze Herba Verimi (kg/da)*	*Kuru Herba Verimi (kg/da)*	*Taze Yaprak Verimi (kg/da)*	*Kuru Yaprak Verimi (kg/da)*	*Uçucu Yağ Oranı (%)*	Uçucu Yağ Verimi (l/da)
Çiçeklenme Öncesi	976.99 B*	118.82 B*	656.88	76.99	1.77 A*	1.36
Tam Çiçeklenme	2106.78 A	458.74 A	1022.36	209.88	0.98 B	2.07
Çiçeklenme Sonrası	1467.87 AB	361.82 A	987.21	199.79	0.96 B	1.93
EGF(%5)	847.32	199.34	ÖD	ÖD	0.28	ÖD

*:Aynı harfler ile gösterilenler arasında fark yoktur. ö.d: istatistiksel olarak anlamlı değil

Taze herba veriminde olduğu gibi kuru herba verimlerinde de tam çiçeklenme ile çiçeklenme sonrası elde edilen değerler arasında istatiksel olarak önemli bir farklılık bulunmamıştır. Araştırıcılar paçuli bitkisinde kuru herba veriminin 162-564.92 kg/da arasında değiştiğini belirtmektedirler (Saha ve ark., 2014; Soibam ve ark., 2022). Burada elde edilen bulgular düşük ve benzer olmuştur. Bunun nedeni farklı kültürel uygulamalar ve ekolojik koşullardan kaynaklanmaktadır. Araştırmada paçuli bitkisinin tam çiçeklenmeye kadar geliştiği ve daha sonra vejetatif olarak fazla gelişmediği, çiçeklenme sonrası dönemde ise alt yapraklarını döktüğü için verim değerlerinin daha düşük olduğu söylenebilir. Genel olarak bitkinin çiçeklenme döneminden sonraki döneme gidildikçe fizyolojik yaşlanma ve yaprak kayıpları ortaya çıkmaktadır. Bitki boyunun uzamasıyla bitkinin alt kısımlarının ışık ve havadan yeterince yararlanamaması ve yaşlı yapraklarda bulunan azotun genç yapraklara taşınması ve alt yaprakların dökülmesine neden olmuştur (Taiz & Zeiger, 2008)

Farklı biçim zamanlarında elde edilen taze yaprak verimi ve kuru yaprak verimine ait değerler istatiksel yönden önemli bulunmamakla birlikte en yüksek değerler tam çiçeklenme döneminden elde edilmiş, ikinci sırada ise çiçeklenme sonrası yapılan biçim değerleri yer almıştır (Çizelge 2). Paçuli bitkisinin çiçeklenme öncesi dönemde daha narin ve su oranının yüksek kuru madde oranının düşük olduğu, tam çiçeklenmeye kadar geliştiği, daha sonra vejetatif olarak çok gelişmediği, çiçeklenme sonrası dönemde ise alt yapraklarını döktüğü için verim değerlerinin daha düşük olduğu söylenebilir. Yapılan çalışmalardaki verim farklılıkların nedeni araştırma yerinin, kültürel işlemlerin, iklim koşullarının farklılık göstermesinden kaynaklanmaktadır (Maral & Kırıcı 2023; Yıldırım ve ark., 2024).

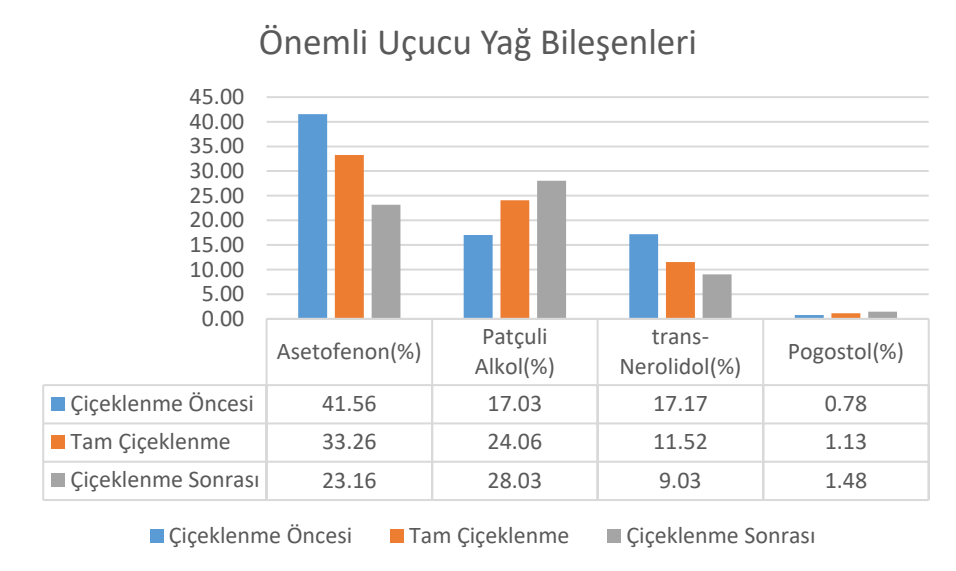
Uçucu Yağ Oranı ve Bileşenleri

Paçuli bitkisinin uçucu yağ oranı üzerine biçim zamanlarını etkisi istatistiksel olarak %1 düzeyinde önemli bulunmuştur. En yüksek uçucu yağ oranı %1.77 ile çiçeklenme öncesi dönemde yapılan biçimden elde edilmiştir (Çizelge 2). Tam çiçeklenme ile çiçeklenme sonrası elde edilen uçucu yağ oranı arasında istatiksel olarak önemli bir fark bulunmamıştır.

Pandey ve ark. (2020) çeşitli sıcaklık aralıklarıyla kurutma yaptıkları paçuli bitkisinin uçucu yağ oranını %1.40 - 2.80 aralığında belirtmişlerdir. Saha ve ark. (2014) Hindistan'ın Kuzey Doğu Himalaya Bölgesi'ndeki paçulinin uçucu yağ oranın %1.88-1.93 aralığında bulmuşlardır. Singh (2011) yaptığı araştırmada en yüksek uçucu yağ oranını %3.14 olarak elde etmiştir. Shah ve ark. (2017) ise en yüksek uçucu yağ oranı %1.53 elde etmişlerdir. Yapılan araştırmalar incelendiğinde bulgular Pandey ve ark. (2020), Saha ve ark. (2014) ile benzerlik gösterirken, Singh (2011)'in değerlerinden düşük; Shah ve ark. (2017), sonuçlarına göre yüksek çıkmıştır. Araştırmada elde edilen uçucu yağ oranları ile literatürde verilen değerler benzer olmakla birlikte bazılarından düşük, bazılarında ise yüksek olmuştur. Bu durumun nedeni tıbbi ve aromatik bitkilerin uçucu yağ oranı üzerine genotip faktörünün yanında, ekolojik koşullar, yapılan kültürel uygulama farklılıkları, hasat zamanı, farklı kurutma yöntemleri gibi çeşitli unsurların etkisi olmasıdır (Kaya ve ark., 2012; Çalışkan ve ark., 2017; Oğuz & Kaplan 2023; Chandel ve ark., 2024; Dobhal ve ark., 2024). Birim alandan elde edilen verim değeri ile uçucu yağ oranı sonucu elde edilen uçucu yağ verimi üzerine farklı biçim zamanlarının etkisi istatistiksel olarak önemli bulunmamıştır (Çizelge 2). Tam çiçeklenme dönemi elde edilen 2.07 l/da olan uçucu yağ verimi ilk sırada yer almıştır. Saha ve ark. (2014) yaptıkları çalışma da bitkiye uyguladıkları farklı miktardaki N sonucunda elde edilen en yüksek uçucu yağ verimi 3.13 kg/da bulurken, en düşük 1.83 kg/da saptamışlardır. Çalışmada elde edilen veriler ile yapılan çalışmalar arasında kısmi benzerlik göstermektedir. Güneş ve gölge koşulları, toprak heterojenliği, bitki materyalinin kalitesi

ve yetiştirme uygulamalarındaki farklılıklar gibi çeşitli doğal veya kontrol edilebilir faktörler uçucu yağın verimini, karakterini ve kalitesini etkilemektedir (Bure ve Sellier, 2004).

Çalışmada incelenen uçucu yağlarda 39 bileşen belirlenmiştir. Çizelge 3 incelendiğinde uçucu yağın ana bileşenlerinin Asetofenon, Patçuli alkol, trans-Nerolidol; diğer bileşenlerin ise α-Bulnesen, α- Guaien, Karyofilen , Pogostol, Seyşellen olduğu ve bu bileşenlerin oranlarının bitkinin biçim zamanına göre değişim gösterdiği anlaşılmaktadır. Uçucu yağ bileşenlerine bakıldığında Asetofenon, hem % 41.56 ile çiçeklenme öncesi dönemde yapılan biçimde, hem de % 33.26 ile tam çiçeklenme dönemindeki biçimde en yüksek bulunurken, çiçeklenme sonrası dönemde yapılan biçimde ise uçucu yağ bileşeni en yüksek % 28.30 ile Patçuli alkol olduğu saptanmıştır.



Çizelge 3. Biçim Zamanlarına göre *Pogostemon cablin* bitkisinin uçucu yağ bileşenleri

Uçucu Yağ Bileşenleri	RT	Çiçeklenme öncesi	Tam Çiçeklenme	Çiçeklenme sonrası

TOPLAM		100	100	98.56

Galovicová ve ark. (2022) *Pogostemon cablin*'in uçucu yağın analizinde %31.0 patçuli alkol, %21.3 α-bulnesen, %14 α –guaien ve %6.9 seyşellen olduğunu göstermektedir. Bure ve Sellier (2004) araştırmalarında uçucu yağda %32.2 patçuli alkol, %5.3 seyşellen, %3.3 β- karyofilen, %5.5 α,- patçulen olarak bulmuşlardır. Paçuli üzerine yapılan çeşitli araştırmalarda patçuli alkol oranını %26.27 - 36.63 arasında değiştiğini saptamışlardır (Doneliana ve ark., 2009; Swamy ve Sinniah, 2016; Pandey ve ark. 2020; Galovicová ve ark. 2022). Bununla beraber bazı araştırıcılar ise patçuli alkol oranının % 37.54–64.9 arasında değiştiğini belirtmektedirler (Singh ve ark., 2002; Chen ve ark. 2014; Shah ve ark., 2017). Literatürler incelendiğinde elde edilen bulgular bazı araştırıcıların verileri ile kısmi benzerlik gösterirken bazılarının değerlerinden düşük çıkmıştır. Jain ve ark. (2022) bildirdiği üzere bu

farklılıklar, iklim koşullarına ve hasat zamanlarına göre değişkenlik göstermektedir (Giray ve ark., 2008; Kaya ve ark., 2012; Maral ve ark., 2018; Maral & Kırıcı, 2019; Çalışkan ve ark. 2019). Patçuli alkol terapötik özellikler sayesinde tedavide kullanılmaktadır, güçlü in vitro antiviral, antifungal ve antimikrobiyal aktivitenin yanısıra antidepresan özelliklere sahiptir (Kiyohara ve ark., 2012; Cahyono ve ark., 2019; Pandey ve ark., 2022). Pogostol, 1990'larda Paçuli yağında izole edilmiş bir bileşendir (Van Beek ve Joulain, 2017). Verma ve ark (2012) araştırmalarında P. cablin'in uçucu yağında bulunan pogostone %1.0, ve pogostol % 0.5 paçulinin karakteristik bileşenleri olarak tanımlamışlardır. Pandey ve ark.(2020)'nin pogostol oranını en yüksek % 1.25 buldukları çalışmalarında elde edilen bulgularla kısmi benzerlik göstermektedir.

Paçuli bitkisinin uçucu yağının büyük bir kısmını oluşturan ana bileşenlerden asetofenon ve trans-nerolidolun çiçeklenme öncesinde yüksek oldukları, generatif dönem sonrasına doğru azaldıkları, patçuli alkol ve pogostolun çiçeklenme öncesinden çiçeklenme sonrasına doğru arttığı ortaya çıkmıştır (Şekil 1).

	Asetofenon(%)	Patçuli Alkol(%)	trans-Nerolidol(%)	Pogostol(%)
Çiçeklenme Öncesi	41.56	17.03	17.17	0.78
Tam Çiçeklenme	33.26	24.06	11.52	1.13
Çiçeklenme Sonrası	23.16	28.03	9.03	1.48

Şekil 1. *Pogostemon cablin* bitkisinin önemli uçucu yağ bileşenleri

Sonuç

Paçuli (*Pogostemon cablin*) bitkisinin uçucu yağı, dünya üzerinde ekonomik değerinin yüksek olduğu ve parfüm sanayisinde çokça kullanıldığı için önemli bir yere sahiptir. Paçuli bitkisinin Çukurova koşullarında uygun biçim zamanı ve verim özelliklerini belirlemek amacıyla yapılan bu çalışmada %0.96-1.77 oranında uçucu yağ elde edilmiştir. Uçucu yağların ana bileşenlerinin Asetofenon, Patçuli alkol, trans-Nerolidol; diğer bileşenlerin ise α-Bulnesen, α.-Guaien, Karyofilen, Pogostol, Seyşellen olduğu ve bu bileşenlerin oranlarının bitkinin biçim zamanına göre değişim gösterdiği saptanmıştır. Araştırma sonucunda gerek verim değerleri, gerek uçucu yağ oranı ve etkili madde bileşenleri bakımından yetiştirilebileceği ortaya çıkmıştır. Çukurova koşullarına en uygun biçim zamanının çiçeklenme sonrası dönem olduğunu ortaya konmuştur. Küresel pazarlarda yer almak için *P. cablin* uçucu yağunda patçuli alkol oranının %26-40 arasında olması gerekmektedir (Cornwell 2010). Bu bölgede elde edilen sonuçların standartlara uygun olduğunu belirlenmiştir. Bu araştırma bölgede yapılan ilk yetiştiricilik araştırması olup, verim ve kalite değerlerinin artırılması için daha fazla araştırma yapılmalıdır.

Çıkar Çatışma Beyanı

Makale yazarları aralarında herhangi bir çıkar çatışması olmadığını beyan ederler. Bu çalışma birinci yazarın yüksek lisans tezinden hazırlanmıştır.

The Impact of Socio-Demographic Characteristics of Consumers on Food Preferences: The Case of Türkiye

Osman İnanç Güney[1]

[1]Adana Meslek Yüksekokulu,Çukurova Üniversitesi, Adana, Türkiye

Abstract

This study examines the relationship between consumers' socio-demographic characteristics and the key factors influencing food purchasing decisions in Turkey. The research is based on the Food Choice Questionnaire (FCQ), which identifies nine major factors affecting food preferences: health, mood, convenience, sensory appeal, natural content, price, weight control, familiarity, and ethical concerns regarding the origin and packaging of food. The study employs a face-to-face survey methodology, conducted in seven major cities across Turkey, with a total of 1,016 participants. Using an ordered probit model, the analysis reveals significant relationships between socio-demographic variables (gender, marital status, age, education, income, and household size) and food choice factors. Key findings indicate that women are more concerned with health, natural content, and ethical considerations than men, while older consumers and individuals with higher incomes prioritize health and organic food choices. Additionally, consumers with higher income levels are more likely to focus on weight control, whereas those with lower incomes tend to prioritize affordability and accessibility. The findings contribute to a deeper understanding of how socio-demographic characteristics shape food choices, providing insights for policymakers, food industry professionals, and public health initiatives. The results emphasize the importance of targeted marketing strategies and public health interventions to promote healthier and more sustainable dietary habits across different consumer groups.

Key Words: Food Choice, Socio-Demographic Factors, Consumer Behavior, Ordered Probit Model, Turkey

Tüketicilerin Sosyo-Demografik Özelliklerinin Gıda Tercihleri Üzerindeki Etkisi: Türkiye Örneği

Özet

Bu çalışma, tüketicilerin sosyo-demografik özellikleri ile gıda satın alma kararlarını etkileyen temel faktörler arasındaki ilişkiyi Türkiye örneğinde incelemektedir. Araştırma, gıda tercihlerini belirleyen dokuz ana faktörü (sağlık, ruh hali, hazırlama kolaylığı, duyusal çekicilik, doğal içerik, fiyat, kilo kontrolü, aşinalık ve gıdanın kökeni ile ambalajına yönelik etik kaygılar) temel alan Gıda Seçim Anketi (Food Choice Questionnaire - FCQ) çerçevesinde yürütülmüştür. Çalışma, Türkiye'nin yedi büyük kentinde gerçekleştirilen yüz yüze anketler aracılığıyla 1.016 tüketiciden elde edilen veriler üzerine kurulmuştur. Sıralı probit modeli kullanılarak yapılan analizler, sosyo-demografik değişkenler (cinsiyet, medeni durum, yaş, eğitim, gelir ve hanehalkı büyüklüğü) ile gıda seçim faktörleri arasında anlamlı ilişkiler olduğunu ortaya koymaktadır. Araştırma bulgularına göre, kadınlar sağlık, doğal içerik ve etik kaygılar konusunda erkeklere kıyasla daha duyarlıdır. Yaş ilerledikçe ve gelir seviyesi arttıkça sağlıklı ve organik gıdalara yönelik tercihler artmaktadır. Ayrıca, gelir seviyesi yükseldikçe kilo kontrolüne verilen önem artarken, düşük gelirli bireylerin daha çok ekonomik ve erişilebilir gıdaları tercih ettiği belirlenmiştir. Araştırma sonuçları, tüketicilerin gıda tercihlerini şekillendiren sosyo-demografik özelliklerin belirlenmesinin, kamu sağlığı politikaları, pazarlama stratejileri ve sürdürülebilir beslenme uygulamaları açısından kritik bir öneme sahip olduğunu göstermektedir. Bu doğrultuda, farklı tüketici gruplarına yönelik sağlık politikalarının geliştirilmesi ve pazarlama stratejilerinin çeşitlendirilmesi önerilmektedir.

Anahtar Kelimeler: Gıda Tercihi, Sosyo-Demografik Faktörler, Tüketici Davranışları, Sıralı Probit Modeli, Türkiye

Giriş

Tüketiciler günde yaklaşık 200 gıdayla ilgili seçim yaparak hem kendi beslenme alışkanlıklarını şekillendirir hem de gıda sisteminin işleyişi ve sürdürülebilirliği üzerinde doğrudan etkili olurlar (Scheibehenne ve ark, 2007; Asp, 1999). Gıda seçimi çok yönlü, durumsal, dinamik ve oldukça karmaşık bir süreçtir ve bir kişinin satın alma anında veya tüketim sırasında aldığı bilinçli ya da bilinçsiz bir dizi kararlar olarak tanımlanabilir. Tüketicinin tutumlarının bir arada etkileşen çeşitli faktörler tarafından yönlendirildiği ve bu faktörlerin her bireyin tüketim modelini belirleyen seçimlere yol açtığı bilinmektedir (Eertmans ve ark., 2005; Cabral ve ark., 2017; Kaya, 2016; Chen ve Antonelli, 2020).

Tüketicilerin gıda seçimlerini etkileyen unsurların tespiti, yalnızca etkili gıda ve sağlık politikalarının geliştirilmesi açısından değil, aynı zamanda yiyecek ve içecek sektöründeki işletmelerin pazarlama stratejilerini başarılı ve verimli bir şekilde uygulayabilmesi açısından da büyük önem taşımakta olup, bu durum tüketicilerin bir gıda ürününün piyasa başarısını belirlemedeki kritik rolünü de ortaya koymaktadır (Girgin ve Karakaş, 2017). Yapılan bir araştırma perakende sektörüne sunulan yeni gıda ürünlerinin %83'ünün başarısız olduğunu ortaya koymuştur. Bunun maliyeti ise 5–10 milyon Amerikan Doları düzeyindedir (Kaya, 2016; Asp, 1999). Bireysel yiyecek seçimlerini anlamak, mevcut gıda sistemini dönüştürmek ve sağlıklı bir toplum ile gezegenin sürdürülebilirliğini sağlamak açısından kritik bir öneme sahiptir.

Bireysel gıda seçimleri gıda tüketimlerinin desenlerinin değişmesine, çevre ve sağlık konularında tüketicilerin daha duyarlı hale gelmesine, biyolojik temellere, fiziksel ihtiyaçlara, yaşam tarzına ve teknolojinin gelişimine bağlı olarak zaman içinde büyük bir değişime konu olmuştur. Ayrıca, bireylerin yaşam ve çalışma şartlarındaki değişiklikler, COVİD-19 pandemisi gibi son yıllarda deneyimlediğimiz küresel halk sağlığı sorunları ve sağlıksız beslenmenin yol açtığı obezite, diyabet ve kalp hastalıkları gibi problemler, gıda tüketimi alışkanlıklarının hızla değişimine etkili diğer faktörlerdir. Bu gelişmeler, tüketicilerin beslenme tercihleri arasında benzerlikler ve farklılıklar oluşmasın neden olmuştur (Tsakiridou ve ark., 2009; Chen ve Antonelli, 2020; Öztürk ve Tekeli, 2021).

İnsanın gıda tercihi bir dizi karmaşık faktörden etkilenen bir süreçtir. Gıda ürünlerinin değerlendirilmesi ve satın alma kararları, tat, koku, besin içeriği veya dokusu gibi Gıdaya ilişkin unsurların yanı sıra fiziksel ortamı hem de bireysel tercihler, tutumlar, motivasyonlar gibi gıda dışı unsurların etkisi altında şekillenebilir (Eertmans ve ark., 2005; Scheibehenne ve ark, 2007). Gıda dışı etkenler ise bireylerin kişisel özelliklerine bağlı olarak değişir. Bu kişisel faktörler, bireylerin hoşlanmadıkları şeyler, tercihleri, demografik özellikleri, gıda odaklı psikolojik ve fizyolojik ihtiyaçları gibi özelliklerini kapsar (Girgin ve Karakaş, 2017).

Farklı araştırma alanlarında (örneğin, beslenme, psikoloji, sosyal bilimler, pazarlama vb.) yapılan çalışmalar, gıda seçimlerini etkileyen faktörler konusunda farklı bakış açılarıyla kanıt sunsa da, bu faktörleri üç temel kategori altında sınıflandırabiliriz. İlk olarak, gıda ile ilgili özellikler kapsamında içsel (örneğin, renk ve aroma) ve dışsal (örneğin, bilgi ve ambalaj) unsurlar öne çıkmaktadır. İkinci olarak, bireysel farklar biyolojik (örneğin, açlık, iştah ve tat), fiziksel (örneğin, erişim, yemek pişirme becerileri ve zaman), psikolojik (örneğin, ruh hali ve stres), bilişsel (örneğin, tutumlar, tercihler, inançlar ve bilgi) ve sosyal (örneğin, aile ve arkadaşlar) faktörler çerçevesinde değerlendirilmektedir. Son olarak, toplumla ilgili özellikler arasında kültür, ekonomik değişkenler (örneğin, fiyat ve gelir) ve politika gibi unsurlar yer almaktadır (Chen ve Antonelli, 2020).

Bireylerin yiyeceklere yönelik tutumlarını ölçmek için kullanılan araçlardan en yaygın olanı Steptoe ve ark., 1995 tarafından geliştirilen ve yiyecek seçimiyle ilgili çok boyutlu motivasyon ölçümünün geliştirilmesini sağlayan Gıda Seçim Anketi (Food Choice Questionnaire-FCQ)'dir. Yiyecek Seçimi Anketi (FCQ), 18 ila 87 yaş aralığındaki 358 yetişkinden oluşan bir örneklemden alınan yanıtların ile geliştirilmiştir. Buna göre tüketicilerin gıda tercihlerini belirleyen dokuz faktör ortaya çıkmıştır. Bu faktörler sağlık, ruh hali, hazırlama kolaylığı, duyusal çekicilik (tat, koku), doğal içerik, fiyat, kilo kontrolü, aşinalık ve yiyeceğin kökeni ve ambalajı ile ilgili etik kaygılardır. Gıda Tercihi Anketi (FCQ), gıda tercihi araştırma alanında en yaygın kullanılan ve uyarlanan yöntem olmuştur (Phan ve Chambers, 2016) Baskın gıda seçimi motivasyonları olarak da tanımlayabileceğimiz bu faktörler ülkeler ve hatta ülke içerişindeki topluluklar arasında farklı etkiler yaratabilmektedir (Gama ve ark., 2018).

Ampirik kanıtlar, sosyo-demografik faktörlerin dünya genelinde gıda tüketim desenlerini belirlemede önemli bir rol oynadığını savunmaktadır. Bu nedenle yaş, istihdam durumu, etnik köken, cinsiyet ve eğitim seviyesi davranışsal çalışmalarda tüketicilerin tutumlarını ve beslenme bilgilerini anlama düzeylerini analiz etmek için yaygın olarak kullanılan faktörlerdir. (Konttinen ve ark., 2021; Krige ve ark., 2012; Ali ve ark., 2021; Ali ve ark., 2010; Ogundijo ve ark., 2022).

Bireylerin gıda tüketim tercihleri, gelir, eğitim, yaş, cinsiyet ve yaşanılan coğrafi bölge gibi sosyo-demografik faktörlerden etkilenmektedir. Gelir seviyesi yükseldikçe organik ve sağlıklı gıdalara yönelim artarken, düşük gelir grubundaki bireyler daha çok ekonomik ve erişilebilir gıdaları tercih etmektedir (Güney ve Sangün, 2019). Eğitim düzeyi yükseldikçe sağlıklı beslenme bilinci artmakta, bu da tüketicilerin besin değeri yüksek ve sürdürülebilir gıdalara yönelmesine neden olmaktadır (Kırcı Çevik ve Kıran, 2022). Yaş ve cinsiyet de gıda tercihlerini şekillendiren önemli değişkenlerdir. Genç tüketiciler daha fazla hızlı ve işlenmiş gıdalara yönelirken, yaş ilerledikçe geleneksel ve sağlıklı besinlere eğilim artmaktadır (Duru ve Seçer, 2019). Kadınlar genellikle daha sağlıklı ve dengeli beslenme eğilimindeyken, erkekler protein ağırlıklı gıdalara yönelmektedir (Cömert ve Durmaz, 2006).

Gıda tercihi, üretim sistemleri üzerinde doğrudan etkisi olan karmaşık bir süreçtir. Bu yüzden, tüketicilerin gıda seçimlerini belirleyen faktörlerin tespit edilmesi, hem yeni ürünlerin geliştirilmesi hem de pazarlama stratejilerinin etkili bir şekilde yönetilmesi açısından kritik bir rol oynamaktadır (Girgin ve Karakaş, 2017). Bu araştırmada Yiyecek Seçimi Anketine (FCQ) göre belirlenmiş olan tüketicilerin gıda tercihlerini belirleyen dokuz faktörün sosyo-demografik özelliklerdeki farklılıklardan nasıl etkilendikleri analiz edilmiştir. Bu bağlamda, araştırma sonuçları insanların gıda tercihlerini nasıl şekillendirdiğini anlamak, sağlıklı beslenme alışkanlıklarının teşvik edilmesinden, dağıtım ve pazarlama süreçlerindeki zorlukların giderilmesine kadar, küresel gıda sektöründe yaşanan sosyal ve ekonomik problemlerin çözümüne önemli katkılar sağlamaktadır.

Materyal ve Yöntem

Materyal

Araştırma kapsamında, tüketicilerin sosyo-demografik özelliklerinin gıda satın alım tercihlerini nasıl etkilediğini belirlemek amacıyla yüz yüze anket uygulaması yapılmıştır. Anket, Türkiye'nin yedi bölgesinin (İstanbul, Ankara, İzmir, Trabzon, Adana, Van ve Gaziantep) en büyük şehirlerinde Nisan-Temmuz 2023 tarihleri arasında gerçekleştirilmiştir. Her bir şehir için örneklem büyüklüğü toplam ülke nüfus içindeki oranına göre belirlenmiştir. Anket, ticari bir araştırma şirketi (Ayna Araşturma) tarafından 1.016 tüketiciye uygulanmıştır. Örneklem büyüklüğü, sonsuz bir popülasyon ve %95 güven düzeyi (p = 0,05) kullanılarak belirlenmiştir.

Ankete katılan bireylerin sosyo-demografik özellikleri Tablo 1 de gösterilmektedir. Sosyo-demografik özellikler aynı zamanda araştırmada bağımlı değişkenler olarak kullanılarak tüketicilerin gıda tercih davranışlarını açıklamada kullanılacaktır.

Tablo 1. Örnekleme katılan tüketiclerin sosyo-demografik özellikleri

	f	%		*f*	%
Cinsiyet			*Gelir (₺)*		
Erkek	457	45	Sabit gelir yok	258	25,4

Gıda Seçim Anketi Faktörleri	Açıklama
Sağlık	Sağlığa faydalı ve besleyici yiyecekleri tercih etmek.
Ruh Hali	Kendini iyi hissettiren, stresi azaltan yiyecekleri seçmek.
Hazırlama Kolaylığı	Hızlı ve pratik şekilde hazırlanabilen yiyecekleri tercih etmek.
Duyusal Çekicilik	Lezzet, koku ve görünüş gibi duyusal faktörlere dayalı yiyecek seçimi.
Doğal İçerik	Doğal, katkı maddesi içermeyen, en az işlenmiş gıdaları tercih etmek.
Fiyat	Yiyecek satın alırken fiyatı göz önünde bulundurmak.
Kilo Kontrolü	Kilo almaktan kaçınmak için düşük kalorili gıdaları tercih etmek.
Aşinalık	Daha önce tüketilmiş ve bilinen yiyecekleri seçmek.
Yiyeceğin Kökeni ve Ambalajı	Çevresel ve etik kaygılarla sürdürülebilir üretim yapılan yiyecekleri tercih etmek.

Anket kapsamında Gıda Seçimi Anketine tespit edilmiş olan 9. faktör (sağlık, ruh hali, hazırlama kolaylığı, duyusal çekicilik, doğal içerik, fiyat, kilo kontrolü, aşinalık ve yiyeceğin kökeni ve ambalajı) sırasıyla bağımlı değişkenler olarak kabul edilmiştir. Diğer taraftan sosyo-demografik değişkenler ise (cinsiyet, medeni, durum, yaş, eğitim, gelir, hane kişi sayısı) ise analizin bağımsız değişkenleridir. Tüm sorular, yanıtları sıralı bir şekilde ölçmek için bir Likert ölçeği kullanılarak tasarlanmıştır.

Yöntem

Tüketicilerin gıda tercihlerini belirleyen 9 temel faktör ile sosyo-demografik özellikler arasındaki ilişki sıralı bir probit modeli kullanılarak belirlenmiştir. Sıralı Probit modeli, doğal bir sıralamaya sahip olan kategorik bağımlı değişkenlerin modellenmesi için kullanılan bir regresyon modelidir. Bu model, özellikle ekonometrik ve sosyal bilimler alanlarında yaygın olarak kullanılmaktadır (Greene, 2018). Modelin seçimi, anket sorularının (hem bağımlı hem de bağımsız değişkenler) bir Likert ölçeği kullanılarak düşükten yükseğe doğru sıralanmasına dayanmaktadır. Lojistik dağılımdan türetilen olasılık oranları yerine probit analizi olay olasılıklarını kümülatif standart normal dağılım puanlarına dönüştürmektedir (Harrell, 2015).

Sıralı probit modeli aşağıdaki gibi tanımlanabilir;

$$y_i^* = x_i'\beta + \varepsilon_i \quad (1)$$

Burada , tüketicileri ifade etmektedir , bağımsız açıklayıcı değişkenler vektörüdür, ilinmeyen eğim parametreleri vektörünü temsil eder ve standart lojistik dağılıma sahip gözlemlenemeyen bireysel hata terimidir. Kısaca, sıralı probit modelinde, bağımlı değişken (yani bireylerin tüketim sıklığı), gözlemlenemeyen gizli değişken tarafından belirli eşik aralıkları içinde aldığı değerlere göre sınıflandırılır.

= 0 eğer $y* \leq 0$ (2)
= 1 eğer $0 < y* \leq \mu1$
= 2 eğer $\mu1 < y* \leq \mu2$
.
.
.
= J eğer $\mu J-1 \leq y*$,

Burada μ değeri ile birlikte tahmin edilmesi gereken bilinmeyen parametrelerdir (Greene, 2012).

Ampirik analiz için, veri analizi kapsamında tanımlayıcı istatistikler SPSS 21 programı kullanılarak hesaplanmış, sıralı probit regresyon modeli ise STATA programı ile analiz edilmiştir.

Bulgular ve Tartışma

Araştırmada tüketicilerin sosyo-demografik özelliklerinin Gıda Seçim Anketince belirlenmiş olan 9 faktör ile ilişkileri analiz edilmiştir. Sıralı Probit Modeli kullanılarak yapılan analizler sonucunda sosyo-demografik özellikler ile gıda satın almayı etkiyen kilo kontrolü, hazırlama kolaylığı, aşinalık, sağlık, etik kaygılar ve doğal içerik faktörleri arasında anlamlı ilişkiler tespit edilmiştir. Bu ilişkilerin anlamlılık düzeyleri ve yönleri tablolar (Tablo 1…Tablo 5) yardımıyla gösterilmektedir.

Tablo 1. Sağlık faktörü ile sosyo-demografik özellikler arasında ilişkiler

	Katsayı	Std. Hata	P > |z|	[95% Güven Aralığı]	
Değişkenler

Medeni durum	.06044	.09062	0.505	-.11717	.23807
Yaş	.09824	.03685	0.008***	.02601	.17047
Eğitim	.05485	.04244	0.196	-.02834	.13805
Gelir	.10840	.02515	0.000***	.05910	.15770
Hane kişi sayısı	.04365	.02921	0.135	-.01360	.10090

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi2$ (27) = 208.37; Prob > $\chi2$ = 0.0000

Tablo 1, gıda seçimini etkileyen faktörlerden sağlık faktörü ile sosyo-demografik özellikler arasındaki ilişkiyi göstermektedir. Bulgular cinsiyet, yaş ve gelir değişkenleri ile sağlık faktörü arasında istatistiksel olarak anlamlı ilişkiler olduğunu ortaya koymaktadır. Özellikle kadınlar, yüksek gelir grubundakiler ve yaşça büyük bireylerin sağlıklı beslenmeye daha fazla önem verdikleri gözlemlenmiştir.

Benzer sonuçlara başka akademik çalışmalarda da ulaşılmıştır. Steptoe ve ark., (1995) tarafından yürütülen çalışmada, kadınların sağlık faktörüne erkeklerden daha fazla önem verdikleri belirlenmiştir. Araştırma kadınların tuz ve yağ tüketimini kısıtlama eğilimlerinin daha yüksek olduğunu ve lif alımına daha fazla özen gösterdiklerini ortaya koymaktadır. Benzer şekilde Girgin'in (2017) de çalışması da kadınların gıda tercihlerinde sağlık faktörünü

erkeklerden daha çok göz önünde bulundurduklarını göstermektedir. Beardsworth ve ark., (2002) cinsiyet farklılıklarını ele aldıkları çalışmalarında elde edilen bulgular kadınların sağlık endişelerini dikkate alarak gıda tüketimlerini aktif olarak düzenlemeye daha yatkın olduklarını ortaya koymaktadır.

Bununla birlikte, tüketicilerin yaşı arttıkça sağlık faktörüne verdikleri önem de artmaktadır. Bireylerin yaşlanması, sağlık konusunda daha bilinçli ve dikkatli olmalarına yol açmakta, bu da beslenme alışkanlıklarını daha sağlıklı gıdalara yönlendirebilmektedir. Konttinen ve ark., (2021) tarafından gerçekleştirilen araştırmada, yaşlı bireylerin (65–94 yaş), en genç yaş grubundaki bireylere (18–29 yaş) kıyasla gıdaların sağlık yönüne daha fazla önem verdikleri tespit edilmiştir. Ricciuto ve ark., (2006) göre de yaşlı bireylerde sağlık endişeleri gençlere kıyasla gıda seçimlerini daha fazla etkilemektedir.

Son olarak elde edilen sonuçlardan (Tablo1) gelir seviyesinin artmasıyla sağlıklı gıda tercih etme eğiliminin de yükseldiği gözlemlenmektedir. Buna göre yüksek gelir gruplarındaki bireyler sağlık faktörüne diğer gelir gruplarına göre daha fazla önem vermekte ve daha sağlıklı gıdalara yönelmektedirler. Ricciuto ve ark., (2006)'nun çalışmaları düşük gelir seviyesinin genel olarak sağlık açısından önerilen gıdaların (örneğin sebze, meyve ve süt ürünleri) satın alınmasını kısıtlayan önemli bir faktör olduğunu ve bu durumun özellikle dezavantajlı gruplara yönelik hedeflenmiş müdahalelerin gerekliliğini ortaya koyduğunu göstermektedir. Benzer şekilde, Drewnowski ve Specter (2004) da sağlıksız beslenme alışkanlıklarının en çok yoksulluk oranı yüksek ve eğitim seviyesi düşük nüfus gruplarında görüldüğünü belirtmiştir. Darmon ve Drewnowski (2008) tarafından gerçekleştirilen araştırma ise düşük gelirli bireylerin genellikle daha düşük diyet kalitesine sahip olduklarını ve bunun sağlık üzerinde olumsuz etkileri olduğunu göstermektedir. Ayrıca, Giskes ve ark., (2010) da düşük sosyo-ekonomik statüye sahip bireylerin daha sağlıksız diyet alışkanlıklarına sahip olma eğiliminde olduklarını tespit etmişlerdir.

Tablo 2. Kolaylık faktörü ile sosyo-demografik özellikler arasında ilişkiler

	Katsayı	Std. Hata	P > |z|	[95% Güven Aralığı]	
Değişkenler					
Cinsiyet	-.219302	.06976	0.002***	-.35603	-.08256
Medeni durum	-.184129	.08450	0.029**	-.34975	-.01850
Yaş	.04549	.03386	0.179	-.02088	.11188
Eğitim	.04169	.03986	0.296	-.03643	.119820
Gelir	.06935	.02367	0.003***	.02294	.11575
Hane kişi sayısı	.01545	.02761	0.576	-.03867	.06957

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi2$ (27) = 208.37; Prob > $\chi2$ = 0.0000

Gıda tercih anketi (FCQ) kapsamında bireylerin gıda seçimlerini etkileyen faktörlerden bir diğeri olan kolaylık faktörü ile cinsiyet, medeni durum ve gelir değişkenleri arasında anlamlı ilişkiler olduğu tespit edilmiştir (Tablo 2). Bulgular kadınların ve bekar bireylerin hızlı ve pratik şekilde hazırlanabilen gıdalara daha önem verdiklerini ve bu özelliklere sahip gıdalara yönelik talep olasılığının daha yüksek olduğunu göstermektedir. Girgin ve Kaya (2017) araştırması da kolaylık faktörünün kadınlar ve bekar bireyler tarafından önemli görüldüğünü ortaya koymaktadır. Benzer şekilde Marsola ve ark., (2020) Brezilya'da yiyecek seçimi motivasyonlarını değerlendirdikleri araştırmalarında aynı sonuca ulaşmış ve kadınların, erkeklere kıyasla kolaylığı daha önemli bir faktör olarak değerlendirdiğini belirlemişlerdir.

Öte yandan, gelir düzeyi arttıkça bireylerin yiyecek seçiminde kolaylık faktörüne verdikleri önemin arttığı gözlemlenmiştir. Buna karşın, bazı araştırmalar gelir düzeyi arttıkça bireylerin gıda tercihlerinde hazırlama kolaylığı faktörüne daha fazla önem verdiklerini öne sürmektedir Szakály ve ark., (2018) tarafından yürütülen "Gıda Seçimi Anketinin Uyarlanması: Macaristan Örneği" başlıklı araştırmada daha yüksek gelir seviyesine sahip bireylerin yiyecek seçimlerinde kolaylığa daha az önem verdikleri sonucuna ulaşılmıştır.

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi2$ (27) = 208.37; Prob > $\chi2$ = 0.0000

Tablo 3'te sunulan analiz sonuçlarına göre gıda tercihlerinde etik kaygılara önem veren bireylerin çoğunlukla kadınlar ve yüksek gelir grubuna mensup kişiler olduğu görülmektedir. Bu gruptaki bireyler çevresel sürdürülebilirlik, hayvan hakları ve etik üretim süreçlerine daha fazla duyarlılık göstermektedirler. Steptoe ve ark., (1995) tarafından yapılan bir araştırmada da etik kaygı derecelendirmesinin kadınlarda erkeklere kıyasla daha yüksek olduğu tespit edilmiştir. Beardsworth ve ark., (2002) yürüttüğü çalışmalar da gıda tercihinde ahlaki boyutların kadınlar tarafından erkeklere kıyasla daha fazla dikkate alındığı belirtilmiştir. Buna göre, kadınlar gıda seçimlerini hayvan refahı ve ekolojik faktörleri göz önünde bulundurarak yapma eğilimindedirler. Benzer şekilde, Pohjanheimo ve Sandell (2009) tarafından yoğurt tüketiminde tercih motivasyonları üzerine yapılan bir araştırmada da kadınların yogurt tercihlerinde etik kaygı faktörünü erkeklerden daha yüksek değerlendirdiği sonucuna ulaşılmıştır.

Tablo 4. Aşinalik fakörü ile sosyo-demografik özellikler arasında ilişkiler

	Katsayı	Std. Hata	P > |z|	[95% Güven Aralığı]	
Değişkenler

Yaş	.11424	.03513	0.001***	.04539	.18310
Eğitim	-.04668	.04089	0.254	-.12682	.03346
Gelir	.11946	.02438	0.000***	.07168	.16725
Hane kişi sayısı	.03003	.02835	0.290	-.02554	.08561

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi2$ (27) = 208.37; Prob > $\chi2$ = 0.0000

Aşinalık bireyin yiyecek seçimlerinde alıştığı beslenme düzenine bağlı kalma eğilimini ve yeni tatlar denemeye yönelik istekliliğini ifade etmektedir. Araştırma sonuçlarına göre gıda tercihlerinde etkili olan önemli faktörlerden biri olan aşinalık yaş ve gelir düzeyi ile anlamlı bir ilişki içerisindedir (Tablo 4). Araştırma bulgularına göre bireylerin yaşı arttıkça daha tanıdık ve bilindik gıda ürünlerine yönelme eğilimindedirler. Ayrıca aşinalık faktörü ile gelir düzeyi arasında da pozitif ve anlamlı bir ilişki bulunmaktadır. Tüketicilerin gelir düzeyi arttıkça, bilinen markalara yönelme olasılıkları da yükselmektedir.

Steptoe ve ark., (1995) tarafından yapılan bir çalışmada da yaşlı bireylerin gıda seçimlerinde daha az maceracı oldukları sonucuna ulaşılmıştır. Ancak aynı çalışmada düşük gelirli bireylerin aşinalık faktörüne daha fazla önem verdiği belirlenmiştir. Mevcut araştırmanın bulgularının aksine bazı çalışmalar tüketicilerin gelir düzeyi arttıkça yalnızca tanıdık yiyeceklere bağlı kalma eğilimlerinin azaldığını ve gıda seçimlerinde daha fazla risk alabildiklerini göstermektedir. Konttinen ve ark., (2021) yürüttüğü araştırmada en yüksek gelir grubundaki katılımcıların en düşük gelir grubuna kıyasla aşinalık faktörüne daha az önem verdiği belirlenmiştir. Marsola ve ark., (2020) tarafından yapılan bir diğer çalışmada ise gelir, yaş ve cinsiyet gibi faktörlerin aşinalık dahil olmak üzere yiyecek seçimi motivasyonlarını önemli ölçüde etkilediği ortaya konmuştur. Bu araştırmanın sonuçlarına göre de yüksek gelir düzeyi aşinalık faktörüyle negatif bir ilişki göstermekte ve daha düşük aşinalık puanları ile ilişkilendirilmektedir.

Tablo 5. Doğal içerik faktörü ile sosyo-demografik özellikler arasında ilişkiler

Hane kişi sayısı	.100988	.030105	0.001***	.041983	.159994

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi2$ (27) = 208.37; Prob > $\chi2$ = 0.0000

Tablo 5'te sunulan analiz sonuçlarına göre doğal, katkı maddesi içermeyen ve organik gıdaların tercih edilmesi ile cinsiyet, yaş, gelir düzeyi ve hanehalkı kişi sayısı arasında anlamlı ilişkiler bulunmaktadır. Tablo 5 deki sonuçlar kadınların organik ve doğal içerikli gıdalara erkeklere kıyasla daha fazla önem verdiğini göstermektedir. Ayrıca, yaş ve gelir düzeyinin artmasıyla birlikte bireylerin doğal içerikli gıdalara yönelik tercihlerinin de arttığı belirlenmiştir. Bunun yanı sıra, kalabalık ailelerin doğal içerikli gıda tüketme eğilimlerinin daha yüksek olduğu da analiz sonucunda ortaya çıkmıştır.

Girgin ve Kaya (2017) tarafından yürütülen bir çalışmada da benzer bulgular elde edilmiş olup, kadınların gıda tercihleri açısından doğal içerik faktörüne erkeklere oranla daha fazla önem verdikleri belirlenmiştir. Aynı

çalışmada tüketicilerin yaşı düzeyi arttıkça doğal içerikli gıdalara daha fazla önem verdikleri tespit edilmiştir. Konttinen ve ark., (2021) tarafından yapılan araştırma ise genç katılımcıların doğal içerik motivasyonuna daha az önem verdiğini ortaya koymuştur. Ayrıca, burada da kadınların doğal içerik faktörüne verdiği önemin erkeklere kıyasla istatistiksel olarak anlamlı düzeyde daha yüksek olduğu belirlenmiştir. Vorage ve ark., (2020) tarafından yapılan araştırmada da benzer şekilde kadınların besinlerin doğal içeriğine erkeklerden daha fazla önem verdikleri sonucuna ulaşılmıştır. Bu bulgular, bireylerin gıda seçimlerinde doğal içerik faktörüne verdikleri önemin demografik özellikler doğrultusunda oldukça farklılaştığını göstermektedir.

Tablo 6. Kilo kontrolü faktörü ile sosyo-demografik özellikler arasında ilişkiler

	Katsayı	Std. Hata	P > |z|	[95% Güven Aralığı]	
Değişkenler

Hane kişi sayısı	.032534	.033263	0.328	-.032660	.097729

* $p < 0.01$, ** $p < 0.05$, *** $p < 0.010\%$; LR $\chi 2$ (27) = 208.37; Prob > $\chi 2$ = 0.0000

Araştırma sonuçları kilo almaktan kaçınmak amacıyla düşük kalorili gıdaların tercih edilmesi ile cinsiyet, eğitim ve gelir düzeyi arasında anlamlı ilişkiler bulunduğunu göstermektedir (Tablo 6). Bulgular kadınların kilo kontrolüne erkeklere kıyasla daha fazla önem verdiğini ve gelir seviyesinin artmasıyla birlikte kilo kontrolüne verilen önemin de yükseldiğini ortaya koymaktadır. Ayrıca kilo kontrolüne önem verilmesiyle eğitim seviyesi arasında da pozitif anlamlı bir ilişki söz konusudur.

Steptoe ve ark., (1995) tarafından gerçekleştirilen çalışmada benzer sonuçlara ulaşılmış olup, Gıda Seçim Anketi'nin (FCQ) kilo kontrolü ölçeğindeki puanların kadınlarda erkeklere göre daha yüksek olduğu belirlenmiştir. Girgin ve Kaya (2017) tarafından yapılan araştırmada da kilo kontrolünün kadınlar açısından erkeklere kıyasla daha önemli bir faktör olduğu tespit edilmiştir. Beardsworth ve ark., (2002) ise kadınların kilo kaybını hedefleyen diyet değişiklikleri yapmaya erkeklere göre daha yatkın olduğunu belirtmektedir.

Szakály ve ark., (2018) Macaristan'da gerçekleştirdiği FCQ uyarlama çalışması da bu bulguları desteklemekte olup kadınların yiyecek seçimlerinde kilo kontrolü faktörünü erkeklere kıyasla daha fazla dikkate aldığını ortaya koymuştur. Ayrıca, Koç ve Yazıcıoğlu (2024) tarafından yapılan araştırmada, kadınların kilo kontrolünü sağlamak amacıyla sebze ve meyve gibi düşük kalorili besinleri erkeklere oranla daha fazla tercih ettiği tespit edilmiştir.

Köseoğullari ve Tunca (2024) araştırmalarında bireylerin eğitim seviyelerinin yükselmesiyle Vücut Kitle İndeksi (VKİ) değerlerinin ortalama olarak düştüğü bulgusuna erişmişlerdir. Bu durum eğitim seviyesinin yükselmesinin kilo kontrolü üzerinde olumlu bir etkiye sahip sonucununu ortaya koymaktadır. Benzer biçimde Earnest ve Church (2020) daha düşük eğitim düzeyine sahip bireylerin obezite prevalansının daha yüksek olduğu yani eğitim seviyesi arttıkça obezite riskinin azaldığı sonucuna ulaşmışlardır. Ayrıca Çın ve ark (2022) de obezite hastalarında sağlık okuryazarlığı ile sağlıklı beslenme tutumu ilişkisinin değerlendirilmesi isimli araştırmalarında eğitim seviyesi arttıkça sağlık okur yazarlığının ve dolayısıyla kilo kontrolüne yönelik olumlu tutumların arttığını belirtilmiştir.

Gelir seviyesi ile kilo kontrolü arasında pozitif ve anlamlı bir ilişki olduğunu gösteren bilimsel çalışmalar da mevcuttur. Örneğin Tedik, (2017) tarafından yapılan bir çalışmada, refah seviyesinin artması, beslenme şeklinin değişmesi, hazır gıda tüketiminin artması ve fiziksel aktivitenin azalması gibi faktörlerin obezite oranlarını artırdığı belirtilmiştir. Bentley ve ark (2018) araştırmalarına göre ABD'de 1990 yılında gelir ve obezite arasında bir ilişki bulunmazken, 2015 yılına gelindiğinde gelir ve obezite oranları arasında güçlü bir ters korelasyon geliştiğini göstermektedir ve gelir seviyesi arttıkça obezite olasılığı azalmaktadır. Selck, (2017) ise birçok çalışmanın gelir ve obezite arasında negatif bir ilişki bildirdiğini ve daha zengin bir kişinin obez olma olasılığının daha düşük olduğunu belirtmiştir.

The Community Supported Agriculture Model: An Approach Based on Local Food Production and Solidarity

Osman İnanç Güney

[1]Adana Meslek Yüksekokulu,Çukurova Üniversitesi, Adana, Türkiye

Abstract

Community Supported Agriculture (CSA) has emerged as an innovative and sustainable alternative to industrialized food systems, addressing economic, social, and environmental challenges. This paper explores the core principles, benefits, and challenges of CSA while analyzing successful implementations worldwide, including Turkey. The findings highlight TDT's role in supporting small farmers, promoting local and seasonal production, strengthening community solidarity, and enhancing food sustainability. Case studies from countries such as Switzerland, France, the United States, Japan, and Turkey demonstrate how CSA models can adapt to diverse socio-economic conditions. Additionally, the study examines barriers to CSA expansion, including economic accessibility, legal recognition, and competition from industrial food systems. Despite these challenges, CSA remains a resilient model for sustainable agriculture, providing economic stability for farmers, fostering consumer engagement, and reducing the environmental impact of food production. To fully unlock CSA's potential, further policy support, financial incentives, and consumer awareness initiatives are needed. This study concludes that CSA offers a viable pathway toward localized, community-driven, and ecologically responsible food networks, contributing to global efforts for sustainable food security.

Key words: Community Supported Agriculture (CSA), Local Food Systems, Sustainable Agriculture, Small-Scale Farming,

Topluluk Destekli Tarım Modeli: Yerel Gıda Üretimi ve Dayanışmaya Dayalı Bir Yaklaşım

Özet

Topluluk Destekli Tarım (TDT) modeli, sosyo-ekonomik ve çevresel sorunlara yanıt olarak endüstriyel gıda sistemlerine yenilikçi ve sürdürülebilir bir alternatif olarak ortaya çıkmıştır. Bu çalışma çeşitli ülkelerdeki başarılı uygulamaları inceleyerek TDT'nin temel ilkelerini, sağladığı yararları ve etkilerini ortaya koymaktadır. Bulgular TDT'nin küçük ölçekli çiftçileri destekleme, yerel ve mevsimsel üretimi teşvik etme, toplumsal dayanışmayı güçlendirme ve gıda sistemlerinde sürdürülebilirliği artırmadaki rolünü vurgulamaktadır. Ülke örnekleri ise TDT modellerinin farklı sosyo-ekonomik koşullara nasıl uyum sağlayabildiğini göstermektedir. Çalışma ayrıca ekonomik erişilebilirlik, yasal tanınırlık eksikliği ve endüstriyel gıda sistemlerinin yarattığı rekabet gibi etmenlerin TDT'nin yaygınlaşmasının önündeki başlıca engeller olduğunu da ortaya koymaktadır. Tüm bu zorluklara karşın, TDT; çiftçilere ekonomik istikrar sağlayan, tüketicilerin üretim süreçlerine katılımını teşvik eden ve gıda üretiminin çevresel etkilerini azaltan dayanıklı bir sürdürülebilir tarım modeli olarak varlığını sürdürmektedir. TDT'nin potansiyelinin tam olarak hayata geçirilebilmesi için daha fazla politika desteği, finansal teşvik mekanizmaları ve tüketici farkındalığını artırıcı girişimlere ihtiyaç duyulmaktadır.

Anahtar kelimeler: Topluluk Destekli Tarım (TDT), Yerel Gıda Sistemleri, Sürdürülebilir Tarım, Küçük Ölçekli Çiftçilik

Giriş

Gıda Sistemlerindeki Güncel Sorunlar: Endüstriyel Tarımın Çevresel ve Ekonomik Etkileri

Günümüzde küresel gıda sistemleri endüstriyel tarımın çevresel ve ekonomik etkileri nedeniyle benzeri görülmemiş zorluklarla karşı karşıyadır. Büyük ölçekli endüstriyel gıda üretimi toprak erozyonu, su kirliliği, biyolojik çeşitlilik kaybı ve sera gazı emisyonları dahil olmak üzere önemli çevresel bozulmalara yol açmıştır (Vermeulen ve ark., 2012). Kimyasal gübre ve pestisitlerin yaygın kullanımı ekosistemleri bozmuş, toprak ve su kirliliğine katkıda bulunmuştur (Benton ve ark., 2021). Küresel gıda üretimi, tüm sera gazı emisyonlarının %35'inden sorumludur ve iklim değişikliğini şiddetlendirerek uzun vadeli gıda güvenliğini tehdit etmektedir (Higuita ve ark., 2023).

Ekonomik açıdan bakıldığında endüstriyel gıda sistemleri tarımsal verimi ön planda tutar ve bu da küçük ölçekli çiftçilerin ve yerel ekonomilerin aleyhine sonuçlar doğurur. Tarım sektöründe birkaç çokuluslu şirket başta tohum olmak üzere tarımsal girdilerin üretimi, işlenmesi ve dağıtımını kontrol etmekte ve piyasanın tekelleşmesine neden

olmaktadır (McMichael, 2014). Bu durum çiftlik gelirlerinin azalmasına, küresel tedarik zincirlerine bağımlılığın artmasına ve piyasa dalgalanmalarına karşı kırılganlığa neden olmaktadır. Ek olarak, uzun mesafeli gıda dağıtımına olan bağımlılık, gıda sistemlerinin karbon ayak izini artırırken ekonomik şoklara ve tedarik zinciri kesintilerine karşı dayanıklılığı azaltmıştır. COVID-19 salgını küresel gıda tedarik zincirlerinde ciddi kesintiler yaşamasına, fiyat oynaklığına ve gıda güvensizliğine yol açmış bu da tarım ve gıda sektöründe kırılganlıkları daha da belirginleştirmiştir (Laborde, 2020; Aday ve Aday, 2020).

Endüstriyel tarımın sınırlamaları daha belirgin hale geldikçe, alternatif gıda sistemleri (AGS) sürdürülebilir çözümler olarak dikkat çekmektedir. Bu modellerden biri de ekonomik ve ekolojik sürdürülebilirliği teşvik ederken tüketicileri gıda üretimiyle yeniden buluşturmayı amaçlayan Topluluk Destekli Tarım'dır (TDT).

Topluluk Destekli Tarım (TDT) Kavramının Ortaya Çıkışı ve Gelişimi

Topluluk Destekli Tarım TDT), endüstriyel gıda sistemlerinin ortaya çıkardığı çevresel, ekonomik ve sosyal zorluklara bir yanıt olarak ortaya çıkmıştır. Batı ülkelerinde TDT'nin ilham kaynağı olarak sıklıkla 1960'larda Japonya'da ortaya çıkan Teikei hareketi gösterilmektedir. Bu hareket, tüketicilerin bir taraftan yerel çiftçileri doğrudan desteklemesini diğer taraftan da taze ve organik gıdalara erişimini sağlamaya yönelik olarak geliştirilmiş bir Alternatif Gıda Sistemi (AGA)'dır (Kondo ve ark., 2024). Model, 1980'lerde Avrupa ve Kuzey Amerika'ya yayılmış ve burada yerel gıda egemenliğini, sürdürülebilir çiftçilik uygulamalarını ve doğrudan çiftçi-tüketici ilişkilerini vurgulayan çeşitli yapılara dönüşmüştür (Cone ve Myhre, 2000).

TDT o zamandan beri farklı kültürel ve ekonomik bağlamlara uyum sağlayarak dünya çapında genişlemiştir. Bazı TDT modelleri üyelerin mevsimlik hasatlar için önceden ödeme yaptığı abonelik temelinde çalışırken, diğerleri yetersiz hizmet alan nüfuslar için gıda erişimini artırmayı amaçlayan kooperatif çiftçilik uygulamalarını veya sosyal girişimleri entegre etmektedir (Middendorf ve Rommel, 2024). Bölgesel farklılıklara rağmen, TDT'nın temel ilkesi aynı kalmaktadır, ekolojik tarım ve yerel gıda sistemlerinde dayanıklılığı garanti altına almak için karşılıklı olarak faydalı bir ortaklık yaratmak.

TDT Konularının Tanımı ve Önemi

TDT, tüketicilerin hasattan bir pay karşılığında çiftliklere doğrudan finansal destek sağladığı, üreticiler ve tüketiciler arasındaki bir ortaklık olarak tanımlanmaktadır. Bu model, gıda egemenliğine, çevresel yöneticiliğe ve sosyal eşitliğe öncelik vererek geleneksel tedarik zincirleriyle çelişmektedir (González-Azcárate ve ark., 2023). TDT, daha kısa tedarik zincirlerini teşvik eder, gıda tedarik zincirinin boyunu kısaltır ve küçük çiftliklerinin ekonomik uygulanabilirliğini artırarak gıda sistemlerinin yerelleştirilmesine ve demokratikleştirilmesine katkıda bulunur (Degens ve Lapschieß, 2023).

TDT'nın önemi gıda üretiminin ötesine uzanarak toplumsal değişim için bir araç görevi görür, topluluk bağlarını güçlendirir, tüketici farkındalığını artırır ve tarımsal ekolojik uygulamaları teşvik eder (Fomina ve ark., 2022). Ancak, ekonomik sürdürülebilirlik, erişilebilirlik ve ölçeklenebilirlik açısından zorluklar da söz konusudur. Birçok TDT girişimi stabil olmayan üyelik, mevsimsel üretime bağımlılık ve sınırlı destekler nedeniyle finansal istikrarla mücadele etmektedir (Medici ve ark., 2021). Ayrıca, TDT üyeliği genellikle daha yüksek gelirli nüfuslara doğru kaydığı ve kapsayıcılığını sınırladığı için sosyal adalet sorunları da ortaya çıkmkatadır (Misra, 2023). Bu zorlukların ele alınması, TDT'nın endüstriyel tarıma ölçeklenebilir bir alternatif haline gelmesi ve sürdürülebilir, yerel gıda sistemlerinin herkes için erişilebilir olmasını sağlaması için çok önemlidir.

TDT gelişmeye devam ederken, çevresel, ekonomik ve sosyal boyutlarını anlamak, sürdürülebilir ve dayanıklı gıda sistemlerini destekleyen politikaları ve uygulamaları ilerletmek için elzemdir. Bu makale, mevcut sınırlamalarını ve gelecekteki beklentilerini ele alırken TDT'nın gıda üretimi ve dağıtımı için dönüştürücü bir model olarak potansiyelini keşfetmeyi amaçlamaktadır.

TDT Modelinin Temel İlkeleri

TDT, sürdürülebilir ve yerelleştirilmiş gıda sistemleri oluşturmayı amaçlayan dönüştürücü bir gıda üretim ve dağıtım modelini temsil eder. Bu model özünde üreticiler için ekonomik güvenliği teşvik ederken tüketicilerin de taze, doğal, mevsimlik ve yerel olarak üretilen gıdalara erişimini sağlayan çiftçiler ve tüketiciler arasındaki doğrudan bir ortaklığa dayanır. TDT modeli üretici-tüketici ortaklıkları, küçük ölçekli çiftçiliğin ve toplum dayanışmasının güçlendirilmesi, yerel ve mevsimlik üretimin teşvik edilmesi ve ekonomik, sosyal ve çevresel sürdürülebilirliğe bağlılık gibi çeşitli temel ilkeler üzerine kurulmuştur.

Üretici-Tüketici Ortaklığı

TDT'nin tanımlayıcı özelliği, üreticilerle tüketiciler arasındaki doğrudan ortaklıktır; burada toplum üyeleri, hasadın bir kısmı karşılığında bir çiftliği finansal olarak desteklerler. Birden fazla aracının yer aldığı geleneksel gıda tedarik zincirlerinin aksine, TDT çiftçiler ve tüketiciler arasında şeffaflık, güven ve riski paylaşımını teşvik eder (Sulistyowati ve ark., 2023). Bu modelde mevsimlik ürünler için tüketiciler çiftçilere tohum, ekipman gibi tarımsal girdilere yatırım yapmak için ön ödeme yapmayı taahhüt eder finansal belirsizliği azaltırlar (Cechin ve ark., 2021).

Bu düzenleme ayrıca, pasif alıcılar yerine gıda üretiminde aktif katılımcılar haline gelen tüketiciler arasında bir sorumluluk ve katılım duygusunu da teşvik eder. Bazı TDT modelleri, tüketici üyeleri ekim, hasat ve dağıtım dahil olmak üzere doğrudan çiftlik faaliyetlerine dahil ederek üretici-tüketici bağlantısını daha da güçlendirmektedirler (Takagi vd., 2024). Ayrıca TDT, hem çiftçiler hem de tüketiciler için adil bir fiyatlandırmayı teşvik ederek endüstriyel tarımın aşırı yüksek fiyatlandırma yapılarından uzaklaşır (Degens ve ark., 2023).

Küçük Ölçekli Çiftçiliği ve Topluluk Dayanışmasını Güçlendirme

TDT, genellikle endüstriyel tarım işletmelerine karşı rekabet etmekte zorlanan küçük ölçekli çiftçileri desteklemede önemli bir rol oynar. TDT, istikrarlı bir müşteri tabanı sağlayarak ve piyasa belirsizliklerini azaltarak küçük çiftçilere piyasa dalgalanmalarına karşı finansal güvenlik ve dayanıklılık sağlar (Egli ve ark., 2023). Araştırmalar, TDT çiftliklerinin uzun vadeli çiftlik sürdürülebilirliğine ve çevresel yöneticiliğe katkıda bulunan tarımsal ekolojik uygulamaları, ürün çeşitlendirmesini ve sürdürülebilir arazi yönetimini uygulama olasılığının endüstriyel işletmelere göre daha yüksek olduğunu göstermektedir (Sulistyowati ve ark., 2023).

Ekonomik faydaların ötesinde, TDT daha güçlü toplum bağlarını teşvik ederek tüketiciler ve üreticiler arasında dayanışma ağları oluşturur. TDT gruplarının üyeleri genellikle çiftlik ziyaretleri, eğitim atölyeleri ve toplum etkinlikleri düzenleyerek gıda üretimi ve çevre koruma konusunda kolektif bir sorumluluk duygusunu güçlendirir (Takagi ve ark., 2024). Topluluk odaklı bu yaklaşım, tüketicilerin gıda kaynaklarından koptuğu endüstriyel gıda sistemlerinin neden olduğu yabancılaşmanın önlenmesine de yardımcı olur (Voge ve ark., 2023).

Yerel ve Mevsimlik Üretimin Teşviki

TDT'nın temel ilkelerinden bir diğeri yerel ve mevsimlik gıda üretimine vurgu yapmak, uzun mesafeli taşımacılık ve büyük ölçekli gıda dağıtımıyla ilişkili çevresel ayak izini azaltmaktır. TDT, gıdayı yerel olarak tedarik ederek gıda tedarik zincirinin uzunluğundan kaynaklanan karbon emisyonlarını en aza indirir, bölgesel gıda ekonomilerini destekler ve yerel gıda güvenliğini artırır (Cechin ve ark., 2021).

Ayrıca, TDT üyeleri beslenme alışkanlıklarını mevsimsel bulunabilirliğe göre ayarlayarak biyolojik çeşitliliği ve ekolojik dengeyi teşvik eder. Tek kültüre ve yıl boyunca bulunabilirliğe öncelik veren endüstriyel tarımın aksine, TDT yerel iklimlere uyarlanmış, çeşitli, besin açısından zengin ürünlerin tüketimini teşvik eder (Takagi ve ark., 2024). Tüketiciler ayrıca geleneksel çiftçilik bilgisi ve sürdürülebilir yetiştirme uygulamalarına daha fazla değer verir ve tüketim modellerinde uzun vadeli değişimleri teşvik eder (Fomina ve ark., 2022).

Ekonomik, Sosyal ve Çevresel Sürdürülebilirlik

TDT, ekonomik, sosyal ve çevresel hususları tek bir çerçeveye entegre ederek bütünsel sürdürülebilirlik için bir model görevi görür.

Ekonomik Sürdürülebilirlik: TDT, üretim başlamadan önce garantili satışlar sağlayarak çiftçilere finansal istikrar sağlar ve dalgalanan piyasa fiyatlarına olan bağımlılığı azaltır (Egli ve ark., 2023). Çalışmalar, TDT çiftliklerinin, özellikle kooperatif veya toplum destekli çerçeveler içinde faaliyet gösterdiklerinde, geleneksel küçük çiftliklere göre daha yüksek ekonomik uygulanabilirliğe sahip olma eğiliminde olduğunu göstermektedir (Cechin ve ark., 2021).

Sosyal Sürdürülebilirlik: TDT modeli, düşük gelirli tüketiciler için maliyet dengeleme programları sunarak ekonomik boşlukları kapatmaya yardımcı olarak toplumsal dayanıklılığı ve kapsayıcılığı teşvik eder (Jilcott Pitts ve ark., 2022). Ancak, üyelik ücretleri bazı haneler için engelleyici olabileceğinden (Takagi ve ark., 2024), TDT'nın düşük gelirli gruplara erişilebilirliği konusunda zorluklar devam etmektedir.

Çevresel Sürdürülebilirlik: Endüstriyel tarımla karşılaştırıldığında, TDT çiftlikleri daha yüksek kaynak verimliliği, daha düşük sera gazı emisyonları ve iyileştirilmiş toprak sağlığı göstermektedir (Egli ark., 2023). Birçok TDT girişimi, uzun vadeli ekolojik dengeye katkıda bulunan permakültür ilkelerini, organik çiftçiliği ve düşük girdili tarım tekniklerini uygulamaktadır (Sulistyowati ve ark., 2023).

Topluluk Destekli Tarımın (TDT) Faydaları

Topluluk Destekli Tarım (TDT) ekonomik, sosyal ve çevresel faydalar sunarak endüstriyel gıda sistemlerine uygulanabilir bir alternatif olarak ortaya çıkmıştır. Çiftçiler ve tüketiciler arasında doğrudan ortaklıklar kuran TDT, yerel ekonomileri güçlendirir, küçük ölçekli çiftçileri destekler ve sürdürülebilir tarım uygulamalarını teşvik eder. Bu bölümde küçük çiftçileri desteklemeye, ekonomik ve sosyal etkilere ve çevresel sürdürülebilirliğe odaklanarak TDT'nın temel faydalarını incelenecektir.

Küçük Ölçekli Çiftçileri Destekleme

TDT'nın temel avantajlarından birisi küçük ölçekli çiftçilere ekonomik istikrar sağlayarak onları piyasa oynaklığından ve endüstriyel rekabetten koruma yeteneğidir. Karların dalgalanan toptan fiyatlar tarafından belirlendiği geleneksel piyasa tabanlı üreticiliğin aksine TDT çiftçileri üye tüketicilerden peşin ödemeler alarak öngörülebilir bir gelir sağlamış olur ve bu da tarımsal üretimle ilişkili finansal riskleri azaltır (Cechin ve ark., 2021). Ek olarak, TDT gelir akışlarını çeşitlendirerek çiftlik dayanıklılığını da artırır. Birçok TDT çiftliği, fazla ürünlerini piyasaya satabilir veya üretici pazarlarına katılır veya gelirlerini desteklemek için bazı eğitim programları sunabilir (Tay ve ark., 2024). Bu model küçük ölçekli çiftçilerin tarımsal ekolojik uygulamaları benimsemelerine, ürün çeşitliliğine odaklanmalarına ve verimi maksimize etme baskısı altında kalmadan sürdürülebilirlik adına uzun vadeli yatırımlar yapmalarına olanak tanır (Egli ve ark., 2023).

TDT ayrıca küçük ölçekli çiftçilere güçlü tüketici ilişkileri kurarak doğrudan iletişimi teşvik ederek ve üreticiler ile tüketiciler arasında güven ve sadakat duygusu yaratmaya yardımcı olur (Voge ve ark., 2023). Bu kişisel bağlantı TDT çiftçilerinin değişken dış alıcılar yerine kendi üyelerine güvenmeleri nedeniyle piyasa bağımlılığını azaltır.

Ekonomik, Sosyal ve Çevresel Etkiler

Ekonomik Etkiler

TDT, sermayeyi büyük tarım işletmelerine yönlendirmek yerine topluluklar içinde tutarak yerel ekonomilere önemli ölçüde katkı sağlar (Medici ve ark., 2021). Çalışmalar TDT üyelerinin genellikle yerel gıdaya daha fazla harcama yaptığını ve üretici pazarları ve yerel esnaf ve zanaatkar gibi tamamlayıcı işletmeleri desteklediğini göstermektedir (Egli ve ark., 2023).

TDT çiftlikleri ayrıca pazarlama ve ulaşım maliyetlerini azaltarak çiftçilerin finansal güvenliğini de iyileştirir. Doğrudan tüketiciye yönelik modeller aracıları ortadan kaldırarak çiftçilerin nihai satış fiyatından daha büyük bir pay almasını sağlarken üyelere rekabetçi fiyatlarla yüksek kaliteli ve taze gıda sunar (Sulistyowati ve ark., 2023).

Dahası, TDT iş yaratma potansiyeliyle kırsal kalkınmada da rol oynar. Çalışmalar TDT çiftliklerinin endüstriyel çiftliklere kıyasla daha fazla yerel işgücü istihdam ettiğini ve adil ücretler sağladığını ve kırsal alanlarda ekonomik istikrara katkıda bulunduğunu göstermektedir (Sulistyowati ve ark., 2023).

Sosyal Etkiler

TDT gıda ve tarım sürdürülebilirliği konusunda tüketiciler ve çiftçilerden oluşan ağlar oluşturarak toplumsal katılımı ve sosyal uyumu teşvik eder. Tüketicilerin doğrudan bağlantılarının olmadığı geleneksel gıda sistemlerinin aksine TDT çiftlik ziyaretleri, eğitim atölyeleri ve gönüllü programları aracılığıyla katılımı teşvik eder (Jilcott Pitts ve ark., 2022).

TDT'ya katılım üyelerin mevsimsel beslenme, sürdürülebilir tarım uygulamaları ve yerel çiftçileri desteklemenin sosyal değeri konusunda daha fazla farkındalık bildirmesiyle artan gıda okuryazarlığıyla ilişkilendirilmiştir (Fomina ve ark., 2022). Çalışmalar ayrıca TDT üyelerinin daha fazla taze ürün tükettikleri ve işlenmiş gıdalara olan bağımlılıklarını azalttıkları için artan bir refah seviyesi ve iyileşen beslenme alışkanlıkları yaşadıklarını göstermektedir (Sulistyowati ve ark., 2023).

Ancak burada erişilebilirlik bir zorluk olmaya devam etmektedir. Birçok TDT programı hala öncelikli olarak orta ila üst gelir gruplarına hizmet etmekte ve düşük gelirli toplulukların katılımını sınırlamaktadır. Bu sorunu çözmek için bazı TDT çiftlikleri ekonomik olarak dezavantajlı grupların taze gıdaya daha kolay ulaşmasını sağlamak amacıyla maliyet dengeleme ve sübvansiyon programları başlatmaktadırlar (Egli ve ark., 2023).

Çevresel Etkiler
TDT çiftlikleri sentetik gübreler, pestisitler ve fosil yakıt yoğunluklu taşımacılık gibi endüstriyel tarımsal girdilere olan bağımlılığı azaltarak çevresel sürdürülebilirliğe katkıda bulunmaktadırlar. Geleneksel çiftçilikle karşılaştırıldığında TDT operasyonlarının şunları sağladığı gösterilmiştir:
Gıda tedarik zincirini azaltarak nakliye maliyetlerini en aza indirip sera gazı emisyonlarını azaltmak (Egli ve ark., 2023).
Ürün rotasyonu, kompostlama ve organik çiftçilik yöntemleriyle toprak sağlığını iyileştirmek (Tay ve ark., 2024).
Endüstriyel monokültürlerin aksine, polikültür ve miras ürün çeşitlerini teşvik ederek biyoçeşitliliği artırmak (Voge ve ark., 2023).
"Kusurlu" ancak yenilebilir ürünlerin değerli olduğu doğrudan tüketiciye dağıtımı sağlayarak gıda israfını azaltmak (Medici ve ark., 2021).
TDT ayrıca üyelerin sürdürülebilir çiftçilik konusunda daha derin bir anlayış geliştirmesi ve çevre dostu gıda seçimlerine aktif olarak katılmasıyla tüketiciler arasında çevre bilincini de teşvik eder (Jilcott Pitts ve ark., 2022).

Başarılı TDT Uygulamaları ve Başlıca Özellikleri

Topluluk Destekli Tarım (TDT) üretici-tüketici ortaklıkları ve sürdürülebilir tarımsal üretimin temel ilkelerini koruyarak bu modeli yerel koşullara uyarlayan çeşitli bölgelerde başarıyla uygulanmıştır. İsviçre'de, Avrupa'nın en eski TDT'larından biri olan Les Jardins de Cocagne, topluluk katılımını ve finansal sürdürülebilirliği artırmak için bir iş paylaşımı bileşenini dahil ederek yaklaşık 400 üyeye başarılı bir şekilde organik sebze sağlamaktadır (Medici ve ark., 2023). Benzer şekilde Fransa'da AMAP (Association de Maintien de l'Agriculture Paysanne) ağı, çiftçiler için adil bir gelir sağlarken gıda egemenliğini güçlendirerek doğrudan çiftçi-tüketici ilişkilerini teşvik eder (Medici ve ark., 2023). Almanya'da Solidarische Landwirtschaft modeli çevresel kaygılara yanıt olarak ortaya çıktı ve daha zengin üyelerin daha düşük gelirli katılımcıları sübvanse ettiği ve daha fazla kapsayıcılık sağlayan dayanışma temelli finansal yapıları içermekterdir (Medici ve ark., 2023).

Amerika Birleşik Devletleri genelinde TDT çiftlikleri daha geniş bir tüketici tabanına ulaşmak için abonelik tabanlı satışları, eğitim programlarını ve kademeli fiyatlandırmayı entegre ederek ürün çeşitlendirmesine ve finansal istikrara vurgu yapmaktadır (Tay ve ark., 2024). Bu arada Kanada'da "Aile Çiftçileri Ağı" ile her yıl 20.000'den fazla aileye tedarik sağlayarak yerel gıda dağıtımını kolaylaştıran ve küresel tedarik zincirlerine olan bağımlılığı azaltan iyi yapılandırılmış bir TDT sistemi kurulmuştur (Medici ve ark., 2023). Japonya'da, en eski TDT modellerinden biri olan Teikei hareketi, organik çiftçiliğe ve karşılıklı yardıma vurgu yaparak çiftçiler ve tüketiciler arasında doğrudan, uzun vadeli ortaklıklar sağlayarak gelişmeye devam etmektedir (Tay ve ark., 2024). Çin'de, TDT'lar gıda güvenliğini ve kırsal kalkınmayı artırmak için STK desteği ve hükümet katılımını birleştirerek kentsel-kırsal kooperatif ağlarını entegre etmektedirler (Medici ve ark., 2023). Benzer şekilde, Brezilya TDT modelleri atık azaltımına ve ekolojik sürdürülebilirliğe vurgu yaparak gıda israfını en aza indirmek için besin değerine odaklanmaktadır (Tay ve ark., 2024). Avustralya'da da TDT'lar özellikle uygun maliyetli organik gıda sağlamada başarılı olmuş ve yerel olarak desteklenen tarımın verimli bir şekilde yapılandırıldığında geleneksel süpermarketlerden daha uygun fiyatlı olabileceğini kanıtlamıştır (Tay ve ark., 2024). Danimarka'nın Aarstiderne TDT'sı, TDT modeline yemek planlama ve tarif entegrasyonunu dahil ederek benzersiz bir yaklaşım benimsemiş ve tüketicilerin gıda paylarını tam olarak kullanmalarını kolaylaştırırken Danimarka'da 50.000'den fazla ve İsveç'te 10.000'den fazla aboneyi desteklemiştir (Medici ve ark., 2023). Bu örnekler, TDT'nın küresel uyarlanabilirliğini ortaya koyarak, modelin sürdürülebilirlik, ekonomik dayanıklılık ve toplum katılımı gibi temel ilkelerini korurken farklı ekonomik ve çevresel bağlamlara nasıl uyarlanabileceğini göstermektedir.

Topluluk Destekli Tarımın sıralanan faydalarına rağmen karşılaşılan çeşitli zorluklar yaygın olarak benimsenmesini ve uzun vadeli sürdürülebilirliğini engellemektedir. En önemli sorunlardan biri birçok tüketicinin mevsimsel değişkenlik ve öngörülemeyen ürün bulunabilirliğinden kaynaklanan memnuniyetsizlikler nedeniyle uzun vadeli üye katılımı nı sürdürmekte zorlanmasıdır (Sulistyowati ve ark., 2023). Ek olarak TDT üyelik ücretleri yüksek olabilir ve düşük gelirli hanelerin katılımını zorlaştırabilir bu da ekonomik erişilebilirlik açısından önemli bir engel olmaya devam etmektedir. Bazı TDT girişimleri, kademeli fiyatlandırma, sübvansiyonlar ve bağış tabanlı modeller uygulayarak bunu hafifletmeye çalışsa da finansal kapsayıcılık bir zorluk olmaya devam etmektedir (Tay ve ark., 2024). Bir diğer kritik engel ise artık organik ve yerel gıdalara genellikle rekabetçi fiyatlarla kolay erişim sağlayan süpermarketler ve çevrimiçi market teslimat hizmetlerinin oluşturduğu rekabettir. Bu rekabet, TDT programlarının özellikle alternatif gıda kaynaklarının bol olduğu kentsel alanlarda üye çekmesini ve elde tutmasını zorlaştırmaktadır (Sulistyowati ve ark., 2023). Ek olarak, idari ve işgücü zorlukları yalnızca ürün üretimini yönetmekle kalmayıp aynı zamanda lojistik, müşteri ilişkileri ve finansal planlama gibi görevleri de üstlenmek zorunda olan çiftçilere önemli yükler getirmektedir (Jilcott Pitts ve ark., 2022). Bazı ülkelerde yasal tanınma ve politika desteğinin eksikliği birçok girişimin etki alanlarını genişletmek için fon, arazi erişimi ve kurumsal destek

sağlamakta zorlanması nedeniyle TDT operasyonlarını daha da karmaşık hale getirmektedir (Medici ve ark., 2023). Dahası, aşırı hava olayları, kuraklıklar ve değişen büyüme mevsimleri hasatları aksatabileceği ve genel gıda güvenliğini azaltabileceği için iklim değişikliği ve çevresel faktörler ek tehditler oluşturmaktadır ve bu da TDT çiftçilerinin üyelere tutarlı paylar teslim etmesini zorlaştırmaktadır (Medici ve ark., 2023). Bu zorlukların ele alınması, TDT'nın sürdürülebilir ve kapsayıcı bir gıda sistemi modeli olarak gelişmeye devam edebilmesini sağlamak için daha güçlü politika desteği, finansal teşvikler ve farkındalık oluşturma girişimleri gerektiriyor.

Türkiye'de Toplum Destekli Tarım olarak bilinen Topluluk Destekli Tarım, özellikle gıda güvenliği endişelerine ve endüstriyel tarımın artan hakimiyetine yanıt olarak alternatif bir gıda üretim ve dağıtım modeli olarak ilgi görmektedir (Yıldız ve Zengin, 2020). Türkiye'de merkezi bir TDT ağı bulunmamakla birlikte, öncelikle İstanbul-Antalya kıyı bölgesi ve Ankara'da yoğunlaşan çeşitli gıda toplulukları ve ekolojik pazarlar ortaya çıkmıştır (Öncel ve Akkaya, 2024). TDT uygulamasının kayda değer örneklerinden biri, küçük ölçekli üreticileri kentsel tüketicilerle başarılı bir şekilde birbirine bağlayan, dayanışma ekonomilerini ve sürdürülebilir gıda uygulamalarını teşvik eden Batı İzmir Topluluk Destekli Tarım Girişimi'dir (BİTOT) (Demircan Yıldırım, 2024). Ek olarak, mantar yetiştiriciliğinin TDT modellerine entegre edilmesi ve mantar yetiştiriciliğinin yıl boyu üretim ve pazar istikrarı sağlaması ve onu TDT odaklı gıda sistemleri için uygun bir seçim haline getirmesi nedeniyle uygulanabilir bir tarımsal girişimcilik fırsatı olarak önerilmiştir (Öncel ve Akkaya, 2024). Ayrıca TDT, kooperatif tabanlı gıda sistemlerinin kapitalist ve endüstriyel gıda pazarına bir alternatif sunduğu Emile Durkheim'ın kolektif dayanışma kavramıyla uyumlu bir sosyal inovasyon aracı olarak kabul edilmiştir (Köleoğlu ve ark., 2022). Özellikle finansal sürdürülebilirlik, tüketici katılımı ve düşük gelirli gruplar için erişilebilirlik konusunda zorluklar devam etmektedir (Kanbak, 2024). Bu engellere rağmen, Türkiye'deki TDT, tabandan gelen girişimler, kooperatif ağları ve yerel ve sürdürülebilir gıda üretimine yönelik artan tüketici ilgisi yoluyla genişlemeye devam ederek, kendisini gıda güvenliği ve sürdürülebilirliğinin geleceği için umut verici bir model olarak konumlandırmaktadır.

Abstract

This study examines the effects of consuming pseudocereals (amaranth, buckwheat, quinoa, and chia), which are gluten-free and exhibit grain-like properties, on gut health and the gut microbiota. Due to their high dietary fiber and bioactive compound content, pseudocereals can contribute to balancing the gut microbiota, promoting the growth of probiotic bacteria, and suppressing pathogenic microorganisms. The study also discusses the effects of germination, which enhances the nutritional value of grains, reduces antinutritional factors, improves mineral absorption, and increases antioxidant capacity.

The prebiotic effects of pseudocereals are important for maintaining a healthy gut microbiota, regulating the digestive system, and strengthening the intestinal barrier. In particular, the increased production of short-chain fatty acids (SCFAs) provides an energy source for the gut epithelium and supports mucosal integrity. With these properties, pseudocereals emerge as alternative food sources for individuals with celiac disease and gluten intolerance.

In the literature, the health benefits of pseudocereals have been associated with hepatoprotective, anti-inflammatory, antihypertensive, and anticancer effects. However, long-term dietary experiments and clinical studies are needed to evaluate these effects in more detail. The studies suggest that consuming pseudocereals, particularly in germinated form, may benefit gluten-free diets and improve gut health.

Keywords: *Pseudocereals, germination, gut microbiota, dietary fiber, prebiotic, gluten intolerance, SCFA, antioxidant.*

Psödotahıllar ve Çimlendirmenin Bağırsak Mikrobiyotasına Etkileri

Özet

Bu derleme çalışması, gluten içermeyen ve tahıllara benzer özellikler gösteren psödotahılların (amarant, karabuğday, kinoa ve chia) tüketiminin bağırsak sağlığı ve bağırsak mikrobiyotası üzerindeki etkilerini incelemektedir. Psödotahıllar, yüksek diyet lifi ve biyoaktif bileşen içeriği sayesinde, bağırsak mikrobiyotasının dengelenmesine, probiyotik bakterilerin çoğalmasına ve patojen mikroorganizmaların baskılanmasına katkıda bulunabilmektedir. Çalışmada, çimlendirme işleminin, tanelerin besin değerini artırdığı, antibesinsel maddeleri azalttığı ve mineral emilimini iyileştirdiği; bunun yanı sıra antioksidan kapasitenin yükseltilmesine olan etkileri de ele alınmıştır.

Bağırsak mikrobiyotasının sağlıklı yapısının korunması, sindirim sisteminin düzenlenmesi ve bağırsak bariyerinin güçlendirilmesi açısından, psödotahılların prebiyotik etkileri önem arz etmektedir. Özellikle kısa zincirli yağ asitlerinin (SCFA) üretiminin artması, bağırsak epiteli için enerji kaynağı sağlamakta ve mukozal bütünlüğü desteklemektedir. Bu özellikleriyle psödotahıllar, çölyak hastaları ve gluten intoleransı bulunan bireyler için alternatif besin kaynakları olarak öne çıkmaktadır.

Literatürde, psödotahılların sağlığa katkıları; hepatoprotektif, antiinflamatuar, antihipertansif ve antikanserik etkilerle ilişkilendirilmekte olup, uzun süreli beslenme deneyleri ve klinik çalışmalarla bu etkilerin daha detaylı değerlendirilmesi gerekmektedir. Yapılan çalışmalar psödotahılların ve çimlendirilerek tüketiminin, glütensiz diyetlerin zenginleştirilmesinde ve bağırsak sağlığının iyileştirilmesinde potansiyel olarak faydalı olabileceğini göstermektedir.

Anahtar Kelimeler: *Psödotahıllar, çimlendirme, bağırsak mikrobiyotası, diyet lifi, prebiyotik, gluten intoleransı, SCFA, antioksidan.*

Giriş

Günümüzde daha çok gluten intoleransının yaygınlaşması ve bağırsak tahribatına neden olduğu düşünülen gluten içeren tahıllara alternatif olarak psödotahılların tüketimi ön plana çıkmaktadır. Kinoa, karabuğday, chia tohumu ve amarant bunlara örnek verilebilir. Türkiye'de psödotahıl üretimi kısıtlıdır. Ancak, son yıllarda psödotahılların

yetiştiriciliğinde belirgin bir artış gözlemlenmektedir. Özellikle ufak ve orta büyüklükteki çiftçilere verilen destekler ve teşviklerle psödotahıl yetiştiriciliğinin yaygınlaştırılması amaçlanmaktadır (TÜBER, 2022).
Psödotahıllar; amino asitler, antioksidanlar, flavonoidler, polifenoller, mineraller, vitaminler, lignanlar, lif ve doymamış yağ asitleri gibi çeşitli biyoaktif bileşenler bakımından zengindir (İmre ve Işık, 2024). Son yıllarda çimlendirilmiş psödotahıl tüketiminin kullanımı da ön plana çıkmaktadır. Literatürde, çimlendirme ile tanede besin içeriğinin, toplam polifenolik madde içeriğin ve antioksidan aktivitenin iyileştiği, antibesinsel faktörlerin ise azaldığı bildirilmiştir. Çimlendirmenin başlıca avantajlarından biri, yenilebilir tohumların besin değerini artırmak için kolay uygulanabilen ve ileri düzeyde ekipman gerektirmeyen bir yöntem olmasıdır. (Olcay ve Demir, 2022). Bu derleme çalışmasında psödotahılların ve çimlendirilerek tüketiminin bağırsak mikrobiyotasına etkilerinin incelenmesi amaçlanmaktadır.

Psödotahıllar ve Özellikleri

Psödotahıllar, yapısal olarak gerçek tahıllarla benzerlik gösteren ve yüksek oranda nişasta içeren, çift çenekli bitki türlerine ait tüketilebilir tohumlardır. Bu tohumlar sıcak iklimlerden serin iklim koşullarına kadar çok sayıda ortama uyum sağlayabilen ve yüksek genetik çeşitlilikleri ile gelecekte önemli gıda kaynakları olabilecek ürünlerdir (Joshi vd., 2019). En bilinen çeşitleri kinoa, amarant, chia ve karabuğdaydır (Martinez-Villaluenga vd., 2020). Psödotahıllar genellikle mısır, buğday ve pirinçle karşılaştırıldığında daha yüksek protein ve lipit içeriğine ve daha düşük karbonhidrat içeriğine sahiptir. Tahıl tanelerinin aksine, psödotahıllar diyet lifi, mineraller, vitaminler, lignanlar, flavonoidler, polifenoller, fitosteroller, antioksidanlar ve doymamış yağ asitleri ve dengeli amino asit bileşimi, yüksek sindirilebilirlik ve biyoyararlanım içeren yüksek kaliteli proteinler dahil olmak üzere biyoaktif bileşikler açısından zengindir(Giménez-Bastida vd., 2017). Bu zengin bileşim nedeniyle, psödotahıllar hepatoprotektif, antiinflamatuar, antihipertansif, antikanser ve hipolipidemik özellikler ve obezite ve diyabet için faydalar dahil olmak üzere çeşitli sağlık yararları ile bağlantılıdır (Shahbaz vd., 2022). Ek olarak, psödotahıllar glütensizdir ve bu da onları glütensiz formülasyonlarda kullanım için popüler hale getirir (Niro vd., 2019).
Amarant ve kinoa tohumlarında, nişasta açısından zengin perispermi çevreleyen dairesel bir embriyo (ruşeym) bulunur. Tohum kabuğu ve nispeten daha fazla yağ ve protein içeren kepek kısmı bu yapıyı oluşturur. Amarant ve kinoada kepek oranı (tohum kabuğu ve embriyo), mısır ve buğday gibi tahıllara kıyasla daha yüksek olduğundan, bu bitkilerin protein ve yağ içerikleri de daha fazladır. Karabuğday tohumlarında ise nişasta, endospermde birikir ve çift çenekli embriyo, nişasta içeren endosperm boyunca uzanır. Yalancı tahılların besin bileşimi ile buğdayın bazı besin öğeleri Çizelge 1'de karşılaştırılmıştır (Olcay & Demir, 2022).

Çizelge 1. Psödotahıllar ve Buğdayın Bileşimi (Alvarez-Jubete vd., 2009).

	Amarant	Kinoa	Karabuğday	Buğday
Protein (%)	16.5	14.5	12.5	12.0
Yağ (%)	5.7	5.2	2.1	2.5
Toplam Nişasta (%)	61.4	64.2	58.9	63.0
Diyet Lifi (%)	20.6	14.2	29.5	17.4
Kül (%)	2.8	2.7	2.1	1.5
Kalsiyum (mg $100g^{-1}$)	180.1	32.9	60.9	34.8
Magnezyum (mg $100g^{-1}$)	279.2	206.8	203.4	96.4
Çinko (mg $100g^{-1}$)	1.6	1.8	1.0	1.2
Demir (mg $100g^{-1}$)	9.2	5.5	4.7	3.3

Psödotahıllarda bulunan biyoaktif bileşenler fenolik asitler, flavonoidler (flavonoller, flavonlar, izoflavonlar, flavanonlar ve antosiyanidinler), lignanlar ve stilbenler olmak üzere dört ana gruba ayrılmaktadır. Bu bitkilerde tespit edilen temel biyoaktif bileşenler Çizelge 2'de gösterilmektedir (Pang vd., 2018).

Çizelge 2. Psödotahılların Biyoaktif Bileşenleri (Thakur vd., 2021; Sofi vd., 2022; Skrovankova ve Mlcek, 2020)

Amarant	Kinoa	Karabuğday	Chia
Karetonoidler	**Flavonoidler**	**Flavanoidler:**	**Flavanoidler:**
Zeaksantin	Kuersetin	Rutin (Kuersetin-3-Rutinosid)	Kuersetin
B-Karoten	Kaempferol	**Fenolik Bileşenler**	Kaempferol 3-O-glikozid
Lutein	Mirisetin	P-Hidroksil Benzoik	Epikateşin
Betaline	İzorhamnetin	Siringik Asit	Rutin
Amarantin	**Fenolik Bileşikler**	Vanilik Asit	**Fenolik Bileşenler**
Betasiyaninler	Ferulik Asit-4-Glikozit	Gallik Asit	P-Kumarik Asit
	Betalainler	Protokatekuik Asit	Kafeik Asit
	Betanin	Ferulik Asit P-Kumarik Asit	Klorojenik Asit

Çölyak Hastalığı

Çölyak hastalığı, dünya genelinde en yaygın görülen gıda duyarlılıklarından birisidir. Genetik eğilimi olan bireylerde, gluten içeren tahılların tüketimiyle tetiklenen otoimmün bir sindirim sistemi hastalığıdır. Çölyak hastalarında gluten tüketimi, bağırsak mukozasında sürekli olarak yapısal tahribata yol açar ve ancak glutenin tamamen beslenmeden çıkarılmasıyla mukoza dokusu kendini onarabilir (Fasano ve Catassi, 2001; Alvarez-Jubete vd., 2009). Bağırsak mukozasında oluşan bu zarar sonucunda, besin ögelerinin yeterli düzeyde emilememesi, sindirim sistemi işlev bozuklukları ve mide-bağırsak belirtileriyle ilişkili beslenme yetersizlikleri sıkça ortaya çıkmaktadır (See ve Murray, 2006; Alvarez-Jubete vd., 2009). Buna ek olarak, çölyak hastalığına bağlı olarak bireylerde kansızlık, bağırsak rahatsızlıkları ya da kemik erimesi gibi farklı semptomlar görülebilir (McGough ve Cummings, 2005; Alvarez-Jubete vd., 2009). Gluten içermeyen bir beslenme programı uygulandığında, çölyak hastalarında belirtilerin hafiflediği ve bağırsak dokusunun iyileştiği gözlemlenmiştir (Olcay ve Demir, 2022).

Çimlendirme ve Islatma

Glutensiz beslenme düzeni, gıdalara yüksek besin, mikro besin, fitokimyasal ve lif içeriği olan ürünler eklenerek daha zengin hale getirilebilir. Bir diğer yöntem ise glutensiz diyetlerde filizlendirilmiş yalancı tahılların kullanılmasıdır. Bilimsel kaynaklar, filizlendirmenin tanelerin besin değerini, toplam polifenol miktarını ve antioksidan etkisini artırdığını, istenmeyen besin faktörlerini ise azalttığını göstermektedir. Filizlendirmenin önemli bir avantajı, yenilebilir tohumların besin kalitesini artırmak için basit ve herhangi bir ekipman gerektirmeyen bir işlem olmasıdır (Omary vd., 2012).

Çimlenme süresinin kinoa tohumlarındaki antioksidan konsantrasyonlarını nasıl etkilediğini araştırmak için yapılan bir çalışmada (Carciochi vd., 2016) çimlenmeden 72 saat sonra tokoferol ve askorbik asit içeriğinde çimlenmeyen tohumlara kıyasla önemli bir artış ($p \leq 0,05$) gözlemlenmiştir. Ayrıca çimlenme ile kinoa tohumlarının antioksidan aktivitesinde ve genel fenolik bileşenlerinde önemli bir iyileşme olduğu görülmüştür.Benzer şekilde, çimlenmenin, hidrotermal işlem ve işlemenin karabuğdaydaki demir içeriğine etkisini inceleyen bir çalışmada (Pongrac vd., 2016), sitrat ve fitatın karabuğdaydaki başlıca demir şelatlayıcı maddeler olarak tanımlandığı, özellikle filizlenme sırasında fitat seviyelerinin düştüğü ve bunun sonucunda demir biyoyararlanabilirliğinde bir artış gözlemlendiği bulunmuştur. Kinoa ve karabuğday tohumlarının çimlenmesi, antioksidan konsantrasyonlarını, demir bulunabilirliğini ve biyoaktif bileşik sentezini artırarak glütensiz ürünlerin besin kalitesini iyileştirdiği bildirilmiştir.

Amarant tanelerinin çimlenmesi ile ilgili yapılan araştırmada ise (Rahman vd., 2023) çimlendirmenin besin değerlerini önemli ölçüde artırdığı, daha yüksek protein, antioksidan ve diyet lifi sağlarken, fitik asit ve tanenleri azalttığı görülmüştür. Ek olarak, çimlenme, palmitik asit içeriğini azaltırken, oleik ve linoleik asit gibi çoğu temel amino asit ve faydalı yağ asitlerinin seviyelerini iyileştirmiştir. Amarant ve karabuğdayda çimlendirmenin fenolik içeriklere olan etkisinin araştırıldığı bir araştırmada (Cornejo vd., 2019) ise 24 saatlik çimlenmeden sonra amarant tanelerindeki fenolik içerikte %212,98'lik bir artış gözlemlemiştir. Karabuğdaydaki fenolik içerik, çiğ tanelerdeki 210,31 mg GAE/100 g'dan, çimlenmeden 72 saat sonra 473,98 mg GAE/100 g'a önemli ölçüde artarak %125,32'lik bir artışı temsil etmiştir. Genel olarak, çimlenme, yalancı tahılların besinsel ve işlevsel özelliklerini artırarak onları sağlık için daha faydalı hale getirmiştir (Reddy et al., 2024).

Diyet Lifleri

Diyet lifi, ağırlıklı olarak tahıllar, meyveler ve sebzelerde bulunan önemli bir besin bileşenidir. Diyet lifleri farklı şekillerde sınıflandırılsa da en yaygın kullanılan yöntem, çözünürlüklerine göre yapılan sınıflamadır. Diyet lifleri, bir tür sınıflandırmadır. Meyve ve sebzelerde bulunan diyet lifleri, özellikle tahıllarda (buğday, arpa, yulaf, pirinç, çavdar) ve psödotahıllarda (chia, kinoa, karabuğday, amarant) yoğun olarak bulunur (Cingöz vd., 2022).

Diyet liflerinin sağlığa yararları, suda çözünebilme özelliklerine bağlıdır. Suda çözünen diyet lifleri, ince bağırsağa ulaştığında suyla birleşerek jelimsi bir yapı oluşturur ve besinlerin ince bağırsaktaki ilerleyişini yavaşlatır. Bu sayede besin maddelerinin emilimi daha uzun sürer ve yiyeceklerdeki şeker ve yağ asitlerinin kana karışması gecikir. Ek olarak, jel kıvamına gelen çözünen diyet lifleri, kolesterol ve yağları bünyesine katarak vücuttan atılmasına yardımcı olur. Suda çözünmeyen diyet lifleri, midede ve ince bağırsakta sindirilmeden ya da jel kıvamına dönüşmeden doğrudan kalın bağırsağa ulaşır. Bu liflerin, kalın bağırsakta sindirimle ortaya çıkan atıkların fermente edilmesi ve bağırsak kas hareketlerinin düzenlenmesi üzerinde olumlu etkileri bulunmaktadır. Ayrıca, dışkının kalın bağırsaktan daha hızlı atılmasını sağlayarak, toksik maddelerin, genetik yapıya zarar verebilecek bileşenlerin ve zararlı kimyasalların bağırsak hücreleriyle temas süresini azaltır ve vücuttan daha kolay atılmasını destekler (Hajishafiee vd., 2016).

Psödotahıllar iyi bir lif kaynağıdır. Karabuğday, yüksek lif içeriği ve düşük çözünür-çözünmez lif oranı ile dikkat çekmektedir. Çeşitli amarant türleri, çözünür lif içeriklerinde farklılıklar göstermektedir. Kinoa, %80'den fazlası çözünmeyen önemli bir lif içeriğine sahiptir (Malleshi vd., 2021). Hem amarant hem de kinoadaki diyet lifinin yaklaşık %22'sine katkıda bulunan arabinoz açısından zengin pektik polisakkaritlerin (%34-55) ve ksiloglukanların (%40) varlığı Gullon ve arkadaşları tarafından 2016'da yürütülen çalışmalarda vurgulanmıştır.

Karabuğday kepeği, fagopiritolleri ile tip II diyabetin tedavisinde potansiyel faydalar sunabilir. Amarantta, pektik polisakkaritler ve ksiloglukanlar, değişen oranlarda birincil lif bileşenlerini oluşturur. Amarantın çözünmeyen

kısmı, çoğunlukla arabinoz ve galakturonik asitten oluşan yüksek konsantrasyonda pektik polisakkarit ve arabinan içerir. Bu fraksiyonda daha düşük seviyelerde ksiloz (%10.4) ve glikoz (%20.1) bulunmuştur (Wefers vd., 2015). Amarantın öncelikle galakturonik asit, arabinoz ve galaktoz, ksiloz ve glikoz gibi çözünmeyen lif bileşenleri içerdiğini göstermiştir (Reddy vd., 2024).

Dünya Sağlık Örgütü (DSÖ) ve Birleşmiş Milletler Gıda ve Tarım Örgütü (FAO) verilerine göre, yetişkin bir bireyin günlük ortalama 25-35 gram lif veya 1000 kcal başına 14 gram lif tüketmesi, 2 yaşından büyük çocukların ise vücut ağırlığının kilogramı başına 0.5 gram lif alması önerilmektedir. Yaş faktöründen bağımsız olarak, erkeklerin kadınlara kıyasla daha fazla lif tüketmesi önerilmektedir (Buil-Cosiales vd., 2016). Hangi tür veya kaynaktan lif alınması gerektiğine dair özel bir öneri bulunmamakla birlikte, günlük lif alımının en az yarısının tam tahıllı gıdalardan sağlanması tavsiye edilmektedir (Evert vd., 2013). Ancak, kültürel değişimler, dışarıda yemek yeme alışkanlığının yaygınlaşması, kentleşme, rafine ve işlenmiş gıdalara yönelim, ekonomik zorluklar ve bilgi eksikliği gibi etkenler nedeniyle dünya genelinde günlük lif tüketimi oldukça düşük seviyededir (Hajishafiee vd., 2016).

Antioksidan Aktivite

Antioksidanlar genellikle "serbest radikal temizleyicileri" olarak adlandırılır. Bu bileşikler oksidasyonu önlemede, enfeksiyon riskini azaltmada, kalp sağlığını desteklemede ve çeşitli kanser ve dejeneratif hastalıkları önlemede rol oynar (Giménez-Bastida vd., 2017). Amarantta, flavonoidler ve fenoliklerin içeriği antioksidan aktivite potansiyeli ile ilişkilidir. Karabuğday hem kabuklarda hem de tohumlarda ve karabuğday ununda bulunan oligomerik proantosiyanidinler gibi flavonoidler de dahil olmak üzere antioksidanlar açısından zengindir. Ek olarak, kanser veya kalp hastalıklarıyla mücadeleye katkıda bulunan koruyucu fenolik bileşikler içerir (Jan vd., 2023). Ayrıca antioksidanlar, DNA'yı hasardan koruyarak ve iltihabı veya kanserli hücrelerin oluşumunu önleyerek vücudun hücresel işlevlerini desteklemede hayati bir role sahiptir (Giménez-Bastida vd., 2017).

Kinoa, anti-obezite, hipokolesterolemik etkiler ve kardiyovasküler hastalıkların önlenmesi gibi çeşitli sağlık yararlarına katkıda bulunan yüksek antioksidan aktivitesi de dahil olmak üzere besinsel özellikleriyle iyi bilinmektedir. Kaempferol, rutin ve kuersetin gibi glikozitler de dahil olmak üzere fenolik bileşikler ve flavonoidler açısından zengindir ve güçlü antioksidan özellikler sağlayarak işlevsel gıda durumunu artırır (Agarwal vd., 2023). Kinoa tohumlarıyla desteklenen bir diyetle ilgili yapılan çalışmada (Pasko vd., 2010), kinoanın plazma malondialdehit düzeylerini düşürerek ve antioksidan enzimlerin aktivitelerini artırarak sıçanlarda oksidatif stresi azalttığı ayrıca kinoa'nın oksidatif hasara karşı koruma ve antioksidan kapasitesini artırdığı bildirilmiştir. Amarant, karabuğday ve kinoa gibi yalancı tahılların antioksidan aktivitesi, oksidatif stresi azaltma, kronik hastalıkları önleme ve genel hücre sağlığını destekleme gibi çeşitli sağlık yararları sağlayan yüksek fenolik bileşik ve flavonoid içeriği nedeniyle önemlidir.

Bağırsak Mikrobiyotası

Yetişkin gastrointestinal sisteminde bulunan bakteriler tipik olarak *Bacteroidetes* , *Firmicutes* , *Actinobacteria* ve *Proteobacteria* gibi dört gruba ayrılabilir . Bacteroides'in anacinsleri *Bacteroides* ve *Prevotella*'dır ve *Clostridium* , *Faecalibacterium* , *Roseburium* , *Ruminococcus* , *Streptococcus* ve *Lactobacillus* gibi bakteriler *Firmicutes'in* ana cinsleridir . Ayrıca, *Bifidobacteria* , *Actinobacteria*'ya ait ana cins iken , *Proteobacteria, Escherichia* gibi *Enterobacteriaceae*'de bulunur (Davenport vd., 2017) . Yukarıda belirtilen bağırsak mikroflorası arasında, *Bacteroidetes* ve *Firmicutes* yetişkinlerde en bol bulunan baskın bakterilerdir (Harmsen ve Goffau, 2016; Ismail vd., 2011).

Bağırsak mikrobiyal ekosistemi oldukça karmaşıktır ancak esnek bir dinamik dengededir ve insan vücudunda bağışıklık sistemi ve iç ortamın homeostazını korumada birçok farklı temel işlevi yerine getirir. Mikrobiyota, insan vücudundaki besinlerin sindiriminde, emiliminde, vitamin ve hormon üretiminde rol oynar. Patojenlerin hayatta kalması için gerekli besinleri tüketebilir veya patojenlerin büyümesini engelleyen moleküller üretebilir (Li vd., 2024).

Diyet, konak ve çevre gibi faktörler mikrobiyotanın bileşiminde ve işlevinde değişikliklere katkıda bulunur. Bu faktörler tarafından mikrobiyota olumsuz etkilendiğinde, bağırsak mikrobiyotası ile insan vücudunun diğer organları arasındaki denge patojen mikroorganizmalar tarafından bozulabilir (Li vd., 2024).

Psödotahılların Bağırsak ve Mikrobiyota Üzerine Etkileri

Prebiyotikler, kolondaki sağlığı geliştirici bakteri popülasyonlarının çoğalmasını aktivitesini destekleyen diyet substratlarıdır (Conlon ve Bird, 2015; Markowiak vd., 2017). Çözünebilir özütler, gıda matrisinin prebiyotiklerinin izolasyon süreciyle elde edilir ve çoğunlukla çözünür liften oluşur. İnülin, rafinoz ve stakiyoz gibi en yaygın kullanılan prebiyotikler, bağırsak bakteri popülasyonlarını desteklemeye yarar sağlayan diyet lifleridir (Sarao ve Arora , 2017). Bağırsak işlevselliğini, bağırsak morfolojisini ve mineral emilimini iyileştirmekten sorumlu olduğu bilinmektedir. Son çalışmalar, bitki tohumu kökenli çözünür özütlerin tüketiminin, sükraz-izomaltaz, aminopeptidaz ve sodyum glikoz kotransporter-1 gibi besinlerin sindirimi ve emilimine katkıda bulunan fırça kenar zarı (BBM) proteinlerini olumlu etkileyebileceğini göstermiştir. Ayrıca, çözünür özütler, mukus üretimi, kadeh hücresi sayısı, kadeh hücresi çapı, villus yüzey alanı, villus yüksekliği, villus genişliği ve kript derinliğini

artırarak bağırsak sağlığını olumlu yönde etkilemektedir. Bu işlevsel ve morfolojik etkiler, çözünür özütler tarafından sindirim sisteminin artan hareketliliğinden dolayı meydana geliyor ve kas hücrelerinin hiperplazisine ve hipertrofisine yol açmaktadır. Ek olarak, bitki kökenli çözünür özüt (yüksek lif içeriği ve dolayısıyla potansiyel prebiyotik özellikler) uygulaması, doğrudan veya dolaylı olarak demir ve çinko biyoyararlanımını artıran bir faktör olarak etki edebilir. Bu olay, alt bağırsak (kolon) lif fermantasyon süreci ve bağırsak pH'ını azaltan, potansiyel olarak patojenik bakteri popülasyonlarının büyümesini engelleyen ve çözünürlüğü ve dolayısıyla minerallerin emilimini artıran kısa zincirli yağ asitlerinin (SCFA'lar) bakteriyel üretimi sonucunda meydana gelir. SCFA'lar diyet minerallerinin emilimine katkıda bulunan emici yüzey alanını artıran epitel hücrelerini çoğaltabilir. Ayrıca, daha önce, çözünür özütlerin tüketiminin, organik asitlerin üretimi yoluyla gastrointestinal mikrobiyal topluluk içindeki metabolik etkileşimleri teşvik ederek sinerjik bir etkiye sahip olduğu ve böylece kolonda asidik bir ortam sağlayarak patojenlerin büyümesini baskıladığı gösterilmiştir (Silva vd., 2019).

Demir ve çinko açısından zengin gıdaların kullanımı, demir ve çinko eksikliklerini azaltabilir. Silva P. ve arkadaşları tarafından yapılan çalışmada psödotahıllardan Chia (*Salvia hispanica L.)* özütünün in vivo olarak etkileri incelenmiş *Lactobacillus* ($p < 0.05$), *Bifidobacterium* ($p < 0.05$), *E. Coli* ($p < 0.05$) ve *Clostridium* ($p < 0.05$) miktarının arttığı gözlemlenmiştir. Diyet lifi tüketimine bağlı olarak *Lactobacillus* ve *Bifidobacterium*daki artışın, doğrudan veya dolaylı olarak demir ve çinkonun biyoyararlanımının artmasına daha fazla katkıda bulunmaktadır. Bu bakteri cinsleri kısa zincirli yağ asitleri üretir (SCFA'lar), bağırsak pH'ını düşüren ve bu nedenle, mineral (Fe ve Zn olarak) çözünürlüğünü ve dolayısıyla emilimini artırmaktadır. *Bifidobacterium* ve *Lactobacillus*, 1,2-glikosidaz aktiviteleri nedeniyle sindirilemeyen lifleri (prebiyotikler) parçalayabilir ve bu da daha fazla SCFA üretimine yol açar, bu da demir ve çinko emiliminde artış sağlamaktadır (Silva vd., 2019). Psödotahıllardan Chia üzerine yapılan bu araştırma gösteriyor ki bağırsak mikrobiyotası için önemli etkilere sahiptir. Ancak diğer psödotahıllar ile ilgili de kapsamlı araştırmaların yapılması gerekmektedir.

Sonuç

Psödotahıllarla ilgili yapılan in vivo çalışmalar göstermiştir ki bağırsak sağlığı, mikrobiyotası ve mineral emilimi açısından olumlu etkileri olmuştur. Çölyak hastası bireyler için glutensiz diyetlere dahil edilerek gıda endüstrisi tarafından ticarileştirilmesi besin ögesi eksikliğini azaltıp psödotahılların yaygınlaştırılmasına katkı sağlayabilir. Çimlendirilen psödotahılların ise antibesin maddelerinin çimlenme ile azaldığı, özellikle fitattaki azalma ile demir emiliminin arttığı, antioksidan aktivitenin, fenolik bileşenlerin arttığı, bazı yararlı yağ asitleri seviyelerinin de iyileştirildiği görülmüştür. Psödotahıllar uygun bir diyet bileşeni olabileceğinden, uzun süreli beslenme denemelerinde ayrıca çimlendirilerek diyetle alımında değerlendirmeyi amaçlayan çalışmalar bütün psödotahıl grubu için yapılmalıdır. Psödotahılların ve çimlendirilerek tüketimlerinin sağlık üzerindeki etkilerinin daha iyi anlaşılabilmesi için daha fazla klinik araştırmaya gereksinim duyulmaktadır.

Abstract

The growing global population and limited land resources have made farmers to rely heavily on continuous cropping, which in turn has negatively impacted soil quality and crop productivity. This study, conducted at location is southwest Nigeria, aimed to restore a continuous-cropped arable land. The study assessed the effectiveness of cover crop biomass and organic manure application on soil physical quality and tomato yield through six treatments in two experiments involving groundnut planting and tomato cultivation. The treatments consisted of piggery manure and groundnut residues (PG+G); poultry manure and groundnut residues (PM+G); groundnut residues only (G only); poultry manure only (PM only); piggery manure only (PM only) and control (no manure). Disturbed and undisturbed soil samples were collected, before the experiment and after the harvest of both groundnut and tomato, from the soil depth 0-40 cm, at 10 cm increments. The results showed that organic amendments significantly ($p < 0.05$) increased soil organic matter by 11-38 % in the 0-10 cm surface layer and 15-36 % in the 10-20 cm subsurface layer while it reduced in the control. The pH increased, soil bulk density decreased by 14-27% (0-10 cm) and 3-27% (10-20 cm), soil water content increased by 12-118% (0-10 cm) and 4-30% (10-20 cm) while the soil saturated hydraulic conductivity improved by 17-218% (0-10 cm). Poultry manure gave the highest tomato yield components: ≈ 224 fruits, ≈ 45 mm fruit diameter, and 15.8 ton/ha yield, all significantly ($p < 0.05$) better than the control and other treatments. These findings showed that cover crops biomass cum organic manure could restore the soil physical quality of continuous-cropped arable lands and significantly optimize crop yield.

Key Words: *Continuous cropping; Cover crop biomass; Organic manure; Soil physicochemical properties; Crop performance*

Introduction

Continuous cropping involved cultivating the same crop variety and closely related ones in the same field for an extended period of time (Tan et al., 2021). Due to increase in population and shortage of land resource to meet food demands, adoption of continuous cropping has gained popularity. For instance, at the end of 2013, China had 1.3 million hectares of arable land, 95% of which was under continuous cropping (Kassam et al., 2014). Continuous cropping practices can have a negative impact on crop productivity and quality, decrease soil water holding capacity, and deteriorate soil hydraulic and physicochemical qualities. Previous researches have shown that continuous cropping could cause a series of issues with the soil, including deterioration of the soil's physicochemical qualities, soil enzyme activity decrease, accumulation of auto-toxic substances, microbial community changes and has alteration in soil physicochemical properties, particularly pH and soil nutrients (Ashworth et al., 2020; Chen et al., 2022; Guo et al., 2022, Yu et al., 2023). According to Mahal et al. (2019) and Majhi et al. (2021), continuous cropping reduces soil nutrients, which is a result of crop absorption and repressed C and N mineralization. This limits material transformation cycling and even affects soil nutrients.
Because human-caused land depletion is not avoidable, the need for land restoration through soil conservation techniques is critical to controlling and sustaining agricultural land. Among the most important soil conservation/land management techniques are the application of organic manure to the soil and growing cover crops (Ntamwira et al., 2023). Cover crop plays an important role in improving soil quality by increasing soil organic matter levels over time with the addition of cover crop biomass (Sainju et al., 2021; Wulanningtyas et al., 2021). The objective of the study therefore was to evaluate the efficacy of cover crop biomass and organic manure applications for improved soil physico-chemical properties and tomato yield in a continuous-cropped arable land in southwest Nigeria.

Materials and Methods

Study site

The study was carried out on the Teaching and Research Farm, Ekiti State University, Ado Ekiti, Southwest Nigeria, located on an elevation of 434 m above sea level, with coordinates ranging from 4°45' to 5°45' E longitude and 7°15' to 8°5' N latitude. The region exhibits a humid tropical climate characterized by a moderate mean annual rainfall (≈ 1,667 mm) and clear distinctions between dry and wet seasons. The temperature remains relatively constant throughout the year, with minimal fluctuation from the average range of 27 °C to 28 °C. The soil in the study site was classified as Typical Kandiudalf (Soil Survey Staff, 2014), with a top sandy-loam to subsoil clay texture (Fasina et al., 2005). The study site has been under continuous cultivation of arable crops for over 10 years with less than six months fallow period before the commencement of this study.

Description of the experiment

There were two experiments; the first experiment involved the imposition of organic manure and planting of groundnut for biomass generation and soil evaluation. The second experiment involved further addition of poultry and piggery manure, incorporation of groundnut biomass and, soil evaluation and tomato performance analysis.

Experimental design, treatments and field layout

The study employed a RCBD (randomized complete block design) of six treatments in three replicates. The treatments consisted of groundnut + piggery manure; groundnut + poultry manure; groundnut only; poultry manure only; piggery manure only and no manure at all as the control. There are three blocks, and in each block, plots measuring 2.5 m x 3 m were laid out as shown in Figure 1 below.

Soil sampling

A mini profile, about 40 cm deep, was dug at the center of each experimental site for soil sampling. Undisturbed soil samples, in three replicates, were collected from soil layers 0-10 cm, 10-20 cm, 20-30 cm and 30-40 cm layers using core samplers, 40 mm high and 57 mm diameter. Disturbed soil samples were also collected from same soil layers. The samples were transported to the laboratory for routine analysis of soil physical and chemical properties. In the laboratory, the disturbed soil samples were air-dried, crushed and sieved to remove materials larger than 2 mm with the aid of 2-mm sieve while the undisturbed samples were trimmed to remove excess soil and oven dried. The samples for soil organic carbon and total nitrogen determination were grounded to pass through a 0.5 mm sieve. The samples were kept in a cool place for further analysis for the soil properties.

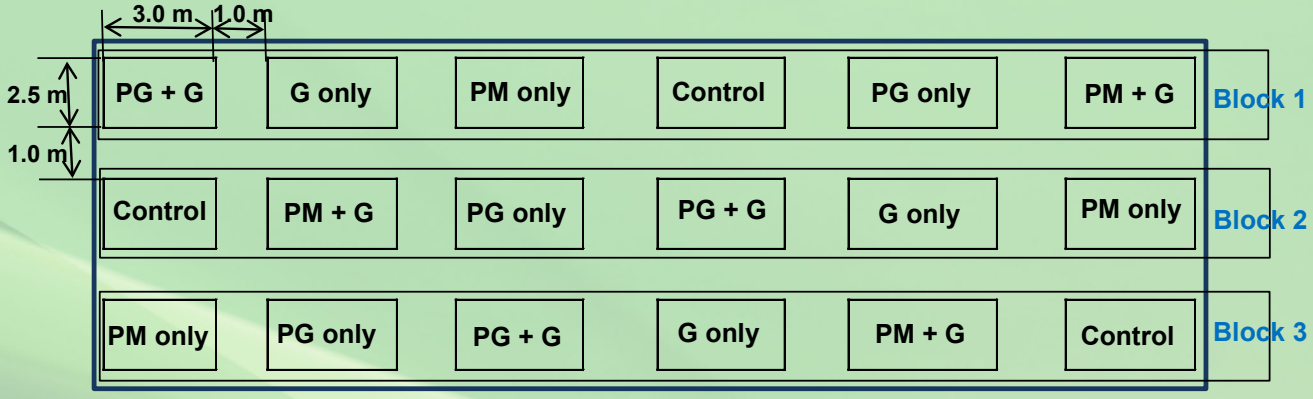

Figure 1: Field layout of the experiment

Laboratory analysis

Soil textural analysis was done using the pipette method (Suzuki et al., 2015), soil particle density was determined using the volumetric flask method (Danielson and Sutherland, 1986) while soil bulk density was evaluated following the methodology described by Blake and Hartge (1986).
Bulk density values were calculated using the following equation:

$$BD = \frac{DM}{V}$$

Where BD is the bulk density (g cm^{-3}), DM is the dry mass (g) of the soil sample, and V is the volume of core sampler (cm^3).

Soil total porosity was obtained from the relation between soil bulk density and particle density (Danielson and Sutherland, 1986). Soil hydraulic conductivity (Ksat, cm h^{-1}) was determined using the constant-head permeameter following the methodology described in EMBRAPA (2011):

$$Ksat = \frac{QL}{A\Delta Ht}$$

Where Q is the volume of water that percolated the soil, cm^3; L is the length of the soil column, cm; A is the cross-sectional area of the core sampler, cm^2; ΔH is the hydraulic head, cm; t is the time of flow in h.

Soil pH was determined in a 1:2 soil water suspension using the digital electrode pH meter, calibrated using buffer solution (Thomas, 1996). Organic matter was quantified using wet oxidation method (Walkley and Black, 1934). A correction factor of 0.39 was used to account for the incomplete combustion of organic carbon. The percent carbon content (OC) of the soil samples was then calculated using the following formula (van Reewijk, 2002).

$$OC, \% = \frac{(ml\ Fe^{2+}\ blank) - (ml\ Fe^{2+}\ soil)x\ Normality\ of\ Fe^{2+}}{Weight\ of\ soil\ in\ g}$$

Tomato yield and yield components

The yield components, including the number of fruits, individual fruit weight (measured in g) were measured and overall fruit yield (metric tons per hectare) was evaluated. Fruit diameter was determined at harvest using a digital vernier caliper, while fruit weight was measured with a precise digital weighing scale during each harvest. The number of fruits was recorded at every harvest session. Fruit yield was calculated by summing all harvested fruits within an experimental unit during the harvest period and was then converted into tons per hectare. The average total yield per hectare was computed by combining both marketable and unmarketable fruit yield, expressed in tons.

Data Analysis

Data collected were subjected to one-way analysis of variance (ANOVA) and means were separated using Duncan Multiple Range Test (DMRT) at 5% level of significance. Dunnet's test was used to compare the control with other treatments. All statistics were done in SPSS software (SPSS, 2011).

Results

Table 1 presents the physicochemical parameters of the site prior to the commencement of the experiment. The site's initial soil results showed increasing bulk density (1.60–1.76 g/cm³) with depth, exceeding optimal levels for plant growth and indicating compaction. The soil is predominantly sandy which showed poor water and nutrient retention. Saturated hydraulic conductivity (12.8–23.5 cm/h) was highest in the top layer, indicating good infiltration, but field capacity and available water were lowest at the surface (0–10 cm), limiting plant moisture access. Organic matter content was low (1.01–1.86%), below the USDA's 3% standard for healthy soil, and decreased with depth. Soil pH ranged from 5.3 to 6.9 which is suitable for most crops. Total nitrogen was low (0.09–0.11%), indicating a need for nitrogen fertilizer application to support plant growth. The available Phosphorus levels (15.7–16.6 mg/kg) was fairly consistent across soil depths, while exchangeable cations (Na, K, Mg, Ca) and acidity were low. Overall, the soil indicate some degree of compaction, low levels of nitrogen and organic matter content requiring improvements for optimal crop productivity.

Table 2 present the physicochemical properties of the soil after groundnut termination. Soil pH increased at the 0–10 cm depth across all treatments compared to pre-experiment data, with minimal variation among treatments and depths. Organic matter (OM) in the surface layer increased by 13–213% due to groundnut cover and organic manure, highest in Poultry Manure (PM) only and lowest in the control. OM generally declined with depth, except in the G only treatment. Surface OM followed the order: PM only > PG+G > PM+G > PG only > G only > Control, a trend also observed in subsurface layers. Bulk density (BD) at 0–10 cm decreased by 7–13% in all treatments except PG only, with PG only and control having the highest BD. Compared to pre-experiment values, surface BD ranked: PG only = Control > G only > PM only > PM+G > PG+G. Subsurface BD increased inconsistently across treatments. Saturated hydraulic conductivity (Ksat) increased by 9–476%, peaking in the PM+G treatment, and declined with depth. Soil water content (SWC) increased by 4–63% at the surface, highest in PM+G and PG+G, and lowest in G only.

For the 0-10 cm surface layer, the control had the highest pH value and showed a significant difference ($p < 0.05$) when compared to other treatments and increased in the order of Cont > PM only > G only > PG only > PM+G = PG+G. For the subsurface layers, there was no significant difference ($p > 0.05$) in pH due to the organic amendments (Figure 4.2a). In contrast, notable variations in soil organic matter content were observed across the different treatments and the two soil layers evaluated.

Apart from control, applying various soil amendments led to a statistically significant ($p < 0.05$) rise in soil organic matter (SOM) in both soil layers with treatment PG+G and Control having the highest and lowest SOM, respectively in both soil layers. The SOM was in the order of PG+G > G only = PM only > PG only > PM+G > Control.

PG+G: piggery manure and groundnut; G only: groundnut; PM only: poultry manure; PG only: piggery manure; PM+G: poultry manure and groundnut, OM: organic matter; BD: bulk density; Ksat: saturated hydraulic conductivity; SWC: soil water content

The soil BD, aggregate stability index (ASI), Ksat, and SWC of the different soil layers after tomato harvest are presented in figüre 3. The BD differed significantly ($p < 0.05$) in all the soil layers as a result of groundnut cover crop biomass and organic manure addition. At the 0-10 cm surface layer, BD was highest in the treatment G only and lowest in the treatment PG+G while at other layers, the Control had the highest BD. For the 10 - 20 and 20 - 30 cm subsurface layers, the Control had the significantly ($p < 0.05$) highest BD compared to other treatments. For the 30-40 cm layer, the BD was significantly ($p < 0.05$) higher from the Control, G only and PM than other treatments. The ASI was significantly influenced ($p < 0.05$) by groundnut cover crop biomass and organic manure addition only at the 0 - 10 and 10 - 20 cm soil layers. In the 0 - 10 cm surface layer, the Control had the highest ASI but this did not differ ($p > 0.05$) from those of treatments PM+G and PG+G. At the 10 - 20 cm, the Control and treatments G only and PG+G had higher ($p < 0.05$) ASI compared to others.

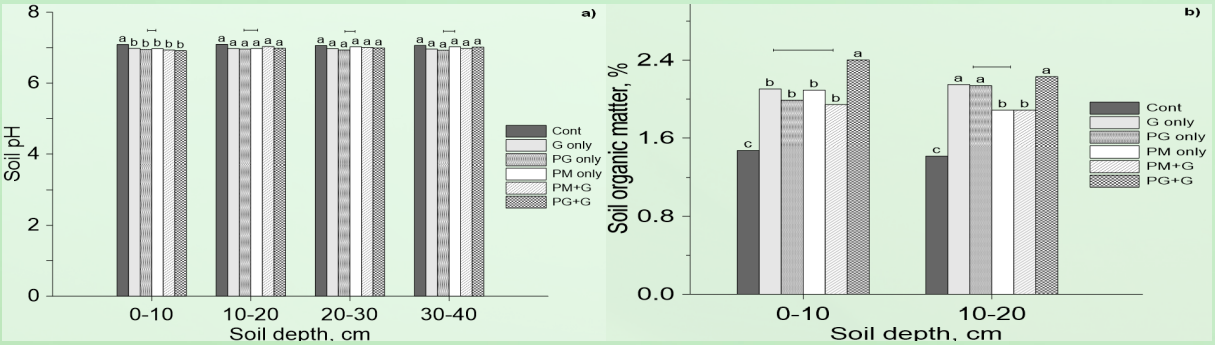

Figure 2. a) pH and b) matter content of the different soil layers after harvest of tomato.

PG+G: Piggery manure and groundnut biomass; PM: Poultry manure only; G: groundnut only; PM+G: Piggery manure and groundnut biomass; PG: Piggery manure only; Cont: Control; The horizontal bars are the standard error of the mean; Vertical bars with different letters differed significantly at 5% level of probability by Duncan Multiple Range test.

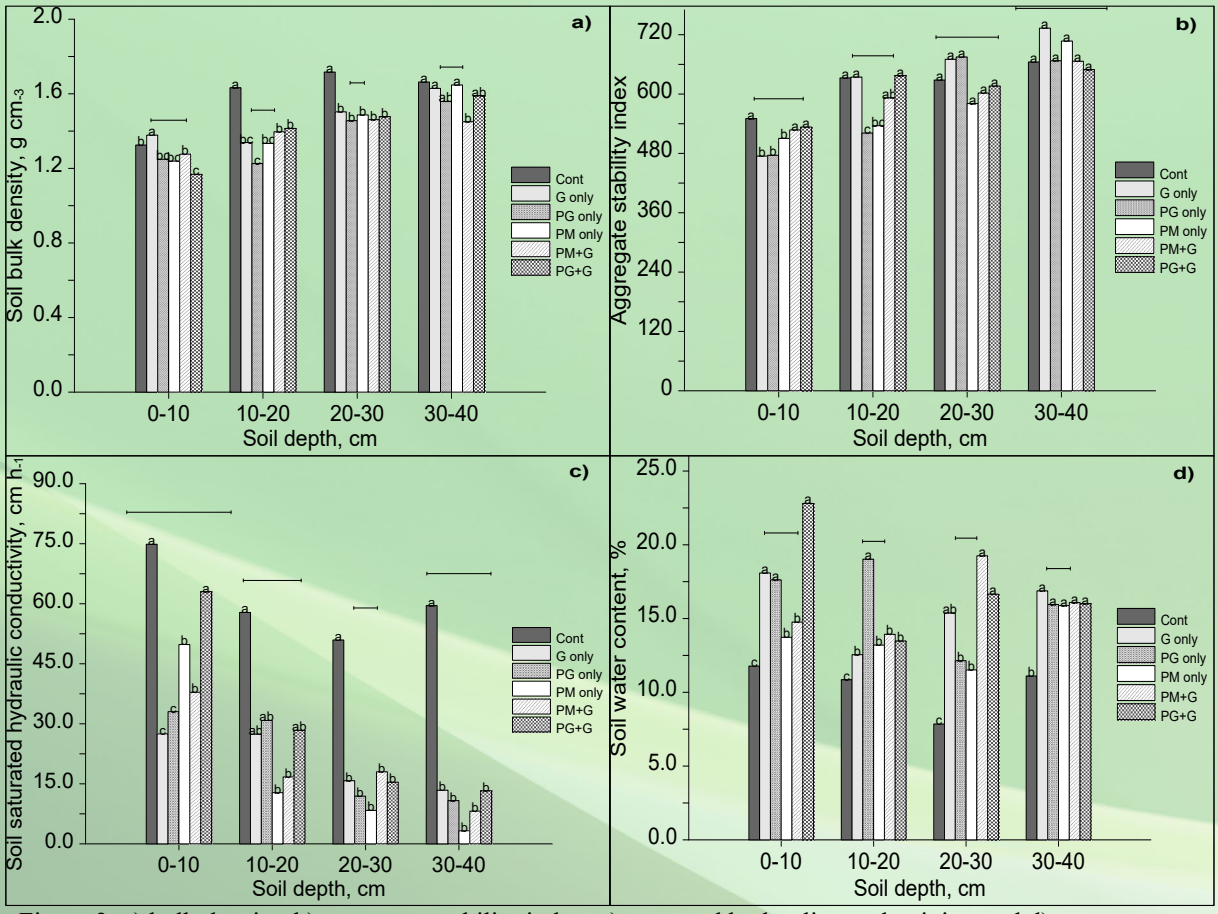

Figure 3. a) bulk density, b) aggregate stability index, c) saturated hydraulic conductivity, and d) water content of the different soil layers after harvest of tomato.

PG+G: Piggery manure and groundnut biomass; PM: Poultry manure only; G: groundnut only; PM+G: Piggery manure and groundnut biomass; PG: Piggery manure only; Cont: Control; The horizontal bars are the standard error of the mean Vertical bars with different letters differed significantly at 5% level of probability by Duncan Multiple Range test.

Table 3 shows the data on the yield as well as the yield components of the tomato crop under different soil amendments. The use of soil amendments was observed to have a significant ($p < 0.05$) effect on both the quantity of fruit produced and the overall yield. The plot treated with a combination of PG+G resulted in the maximum fruit yield, whereas the plots treated with G only and the control had the minimum fruit yield. Nevertheless, except from the control and the G only, no statistically significant differences ($p > 0.05$) were seen among the remaining treatments. Furthermore, it was observed that the PM treatment had the biggest fruit diameter whereas the G treatment displayed the smallest fruit diameter. In addition to the PG only and PG+G treatments, statistically significant differences ($p < 0.05$) were seen across the remaining treatment groups. The results of the study revealed a statistically significant ($p< 0.05$) impact of soil amendments on tomato yield. The plots treated with a combination of PG+G, PM+G, PM, and PG gave similar yield, which were considerably distinct ($p < 0.05$) from those of the treatment with G only and control. When compared to the control, the poultry treatment exhibited the most notable outcomes in terms of tomato fruit quantity (about 224 fruits), fruit diameter (approximately 45 mm), and yield (15.8 ton/ha).

Table 3. Yield and yield components of the tomato crop under different soil amendments.

Discussion

Initial soil conditions

The pH of the 0-10 cm surface layer was outside the range (below the lower limit) while those of the subsurface layers were within the range considered acceptable for most plants according to FAO standard operating procedure for soil pH determination (FAO, 2021). The organic matter content is generally low and decreased with soil depth. Fertile soil is soil that has been supplemented with nutrients. A fertile soil may be inherent or natural, and manures or artificial fertilizers can be used to get it (Ansa et al., 2022). Physical, chemical, or biological elements may have impacts on soil fertility, which in turn may have effects on plant growth. Plants cannot absorb nutrients like nitrogen, phosphorus, sulfur, and carbon as they are; instead, they must be transformed by microorganisms through nutrient cycling into their normal forms. The soil bulk density (BD) is high and increased with soil depth. The optimal BD for most soil textures should be in the range of $0.9 \leq BD \leq 1.20$ g cm^{-3} (Reynolds et al., 2015). For this site, the BD was well above the range, indicating denser soil. Furthermore, the higher BD observed 20-30 cm and 30-40 cm subsurface layers are close to the range 1.75–1.85 g cm^{-3} considered restrictive soil condition which could impair water and air movement, root morphology and crop development (Reichert et al., 2018). The 0-10 cm surface layer had Ksat above the 18 cm h^{-1} designated as the upper optimal limit for humid climates, indicating susceptibility to doughtiness and nutrient leaching while the subsurface layers had Ksat within the optimal range ($1.8 \leq Ksat \leq 18.0$ cm h^{-1}) for crop essential water and drainage of excess water. The 0-10 cm and 10-20 cm layers had SWC below ideal for adequate root growth and drought resilience (Reynolds et al., 2015) while the higher SWC in the subsurface layers is attributed to the higher clay content (Table 1). The total nitrogen values were between 0.09 and 0.11 g kg^{-1}, while the available phosphorus had values between 11.1 and 16.6 mg kg^{-1}. The exchangeable bases (Na, Mg, K and Ca) and exchangeable acidity were highest in the 0-10 cm surface layer.

Soil conditions after the first experiment (planting of groundnut cum addition of organic manure)

The soil pH was at par across different treatments and depths, ranging from 6.7 to 6.9. This stability suggests that the treatments applied do not significantly impact the soil acidity, which is essential for nutrient availability and microbial activity (Brady and Weil, 2008). The soil organic matter content of the 0-10 cm surface layer increased between about 13 and 213% due to groundnut cover crop and organic manure addition compared to the control, with the PM only treatment having the highest organic matter content, indicating its potential in improving soil fertility (Lal, 2024).

For the 0-10 cm surface layer, except the PG treatment, the BD decreased between 7 and 13% due to groundnut cover crop and organic manure application compared to the control, with the highest observed in the treatment PG

only and control. The lower BD values in PG+G, PM, PM+G suggest improved soil structure. Compared to the pre-experiment soil conditions, the BD had decreased on the surface soil in the order PG only = Control > G only > PM only > PM+G >PG+G. For the subsurface layers, the BD increased but without any discernible trend among the treatments. Ksat of the 0-10 cm surface layer increased between 9 and 476% due to groundnut cover crop and organic manure application, with the PM+G treatment having an exceptionally high Ksat compared to other treatments. The higher Ksat observed in the plots with groundnut cover crop and organic manure indicates increased drainage these treatments (Saxton and Rawls, 2006). Similarly, the SWC of the 0-10 cm surface layer increased between 4 and 63% due to groundnut cover crop and organic manure application compared to the control. The higher SWC in the treatments suggests better water retention (Vereecken et al., 2010).

Soil conditions after harvest of tomato

At the harvest of tomato, the soil pH of the 0-10 cm surface layer had increased between about 31% in all treatments including the Control compared to pre-experiment data. For the subsurface layers, groundnut cover crop biomass and organic manure addition did not influence ($p > 0.05$) the soil pH. While the pH was almost at par in the 10-20 cm soil layer, it slightly increased by about 8% in the 20-30 and 30-40 cm deeper layers at harvest of tomato.

Soil organic matter content was significantly ($p < 0.05$) affected by groundnut cover crop biomass and organic manure addition in both soil layers, with the control having the lowest values. Compare to pre-experiment condition, SOM had increased between 4.4 and 29.2% with the trend PG+G > G only > PM only > PG only > PM+G while it decreased by about 21% in the control at the 0-10 cm surface layer. Similar trend was observed for the 10-20 cm subsurface layer. Cover crops have also been reported to increase soil organic matter by 7-12% compared to no cover crop management (Hu et al., 2023; Peng et al.,2023) and this can lead to improved soil aggregate formation and increased water infiltration (Arel et al., 2022, Shen et al., 2021) Therefore, it can be said that organic manures are beneficial sources of nutrients in addition to improving the physical environment of the soil. Similar results were showed (Dhaliwal et al., 2023, Goldan et al., 2023, Köninger et al., 2021). The highest organic carbon content was noticed with the application of piggery manure and groundnut (2.4%). Nevertheless, application of nutrients in organic form would improve the crop growth and leaves behind several residues including crop root. Perhaps, slow mineralization could lead to organic carbon accumulation in soil.

The soil BD, aggregate stability index (ASI), Ksat and SWC of the different soil layers after tomato harvest are presented in figure 3. The BD differed significantly ($p < 0.05$) in all the soil layers as a result of groundnut cover crop biomass and organic manure addition. For the 0-10 cm surface layer, BD was highest in the treatment G only and lowest in the treatment PG+G. Compared to the pre-experiment soil conditions, the BD had decreased between 13.8 and 27.0% even in the control in the order PG+G > PM only > PG only > PM+G > Control > G only. For the subsurface layers, the BD also decreased but without any discernible trend among the treatments (Figure 3a). The ASI was significantly influenced ($p < 0.05$) by groundnut cover crop biomass and organic manure addition only at the 0-10 and 10-20 cm layers, with the Control having the highest ASI but this did not differ from those of treatments G only, PM+G and PG+G.

In addition, the ASI had decreased by 7.4% in treatment PG+G and 17.6% in treatment G only compared to the about 4% reduction in the Control (Figure 3b).

Soil Ksat was significantly highest ($p > 0.05$) in the Control compared to other treatments for all the soil layers evaluated, with the treatment G only having the lowest Ksat at the 0-10 cm surface layer. For other layers, the trend observed in the surface layer was not followed. Compared to the pre-experiment data, Ksat increased between 17% (treatment G only) and 218% (Control) in the 0-10 cm surface layer. For the subsurface layers, the Ksat either increased or decreased (Figure 3c).

At harvest of tomato, the SWC of the 0-10 cm surface layer was significantly lowest ($p < 0.05$) in the Control and highest in the treatment PG+G compared to other treatments. For subsurface layers, the Control also had the significantly lowest SWC while there was no discernible trend among the treatments. The SWC had also increased between 31.6% (PM only) and 118.6% (PG+G) compared to the 12.9% increase observed in the Control (Figure 3d).

Tomato yield and yield components

Except for the treatment G only, the number of fruits was higher between 21 and 35% for the soil amendment treatments than the control, with the highest increase obtained from the treatment PG+G. For the fruit diameter, the treatments PG only, PM only and PM+G treatments had tomato fruits bigger than the control by 1.4, 3.9 and 1.9%, respectively. The highest tomato yield was observed in treatment with PM only but did not statistically differ from those of the treatments PM+G, PG+G, and PG only while the treatment G only had the lowest yield. Furthermore, the treatments PG only, PM only, PM+G and PG+G had yield higher than the control by 13, 30, 16 and 23%, respectively. The notable enhancement in tomato yields can be mainly attributed to the stabilization of soil structure. This stabilization has led to a decrease in soil bulk density, an increase in porosity, improved infiltration rates, and enhanced water retention capacity. These beneficial changes in soil physics are the key factors behind the significant boost in tomato production observed in the plots where these amendments were

applied. These findings are consistent with previous studies (Downie et al., 2009; Stewart-Wade, 2020). Previous research highlighted the substantial impact of cover crops and organic amendments on tomato yield when compared to the control (Wang et al., 2018).

Conclusion

The study demonstrated that using cover crops and organic manures significantly enhances soil quality, which in turn leads to increased tomato yield. These organic amendments improved soil physical properties by reducing bulk density and increasing hydraulic water content, water retention, and available water. This ensures better soil water dynamics, supporting plant growth during critical periods. Also, the amendments increased soil pH and raised organic matter content, further contributing to soil fertility and productivity. Overall, organic manure and cover crops positively influenced both growth and yield components of tomato, suggesting that degraded arable land can be restored through sustainable practices. Based on these findings, the study recommends that farmers in Ekiti State adopt soil amendments, particularly poultry and piggery manure, either alone or combined with groundnut, to improve tomato production and promote sustainable agriculture.

Abstract

With the rapid increase in the world population, a significant increase in global food demand is expected. However, due to the threat of future drought and the limited availability of new agricultural land, meeting this demand appears to be possible only through increased productivity in existing cultivation areas. This situation has heightened the need for yield-oriented cultural practices such as expanding irrigation capacity and the widespread use of chemical fertilizers, in addition to conventional breeding efforts. Although the intensive and long-term use of chemical fertilizers contributes to short-term yield increases, it adversely affects soil health by reducing microbial diversity and weakening plant–microorganism interactions. Therefore, within the framework of sustainable agricultural practices, the development of environmentally friendly alternative approaches that can reduce dependency on chemical inputs has become increasingly important. Microbial fertilizers have drawn attention in this context, and among them, mycorrhizal fungi stand out as important bio-inputs that support plant growth. Mycorrhiza is defined as a mutualistic symbiotic relationship between plant roots and soil fungi. Mycorrhizal fungi enhance nutrient uptake efficiency through their extensive hyphal networks, which increase root surface area and facilitate the transport of essential nutrients—particularly phosphorus, as well as zinc, iron, potassium, and nitrogen. Moreover, by strengthening the microbial balance within the mycorrhizosphere, they promote plant growth, suppress pathogenic organisms, and enhance plant tolerance to stress conditions. This review evaluates the morphological, physiological, and microbial effects of mycorrhizal applications on plant development in light of recent findings in the scientific literature.

Key Words: *plant nutrition, fertilization, mycorrhiza, biocontrol, sustainable agriculture*

Bitki Gelişiminde Mikoriza Uygulamaları

Özet

Dünya nüfusundaki hızlı artış ile beraber küresel gıda talebinde önemli ölçüde artış beklenirken özellikle artan kuraklık tehlikesi ve yeni tarım alanlarının sınırlı oluşu gibi sebeplerden dolayı bu talebin karşılanması yalnızca mevcut üretim alanlarında verim artışıyla mümkün gözükmektedir. Bu durum, geleneksel ıslah çalışmalarının yanı sıra sulama olanaklarının artırılması ve kimyasal gübre kullanımının yaygınlaştırılması gibi verim odaklı kültürel uygulamalara olan ihtiyacı artırmıştır. Kimyasal gübrelerin yoğun ve uzun süreli kullanımı, kısa vadeli verim artışına katkı sağlarken, toprak mikrobiyal çeşitliliğini azaltmakta ve toprak sağlığına olumsuz etkilerde bulunmaktadır. Bu nedenle, sürdürülebilir tarım uygulamaları kapsamında kimyasal girdilere olan bağımlılığı azaltacak, çevre dostu alternatif yaklaşımların geliştirilmesi özellikle son yıllarda önem bir hedef haline gelmiştir. Bu bağlamda mikrobiyal gübreler dikkat çekerken, bunlar arasında mikoriza mantarları bitki gelişimini destekleyen önemli biyo-girdiler olarak ön plana çıkmaktadır. Mikoriza, bitki kökleri ile toprak mantarları arasında kurulan karşılıklı yarar esasına dayalı bir simbiyotik ilişkidir. Mikorizal mantarlar, kök yüzey alanını artıran hif yapıları sayesinde besin elementlerinin daha etkin alımını sağlamakta; başta fosfor olmak üzere çinko, demir, potasyum ve azot gibi elementlerin taşınımını kolaylaştırmaktadır. Ayrıca mikorizosferdeki mikrobiyal dengeyi güçlendirerek bitkinin büyümesini teşvik etmekte, patojen baskısını azaltmakta ve stres koşullarına karşı tolerans kazandırmaktadır. Bu derlemede, mikoriza uygulamalarının bitki gelişimi üzerindeki morfolojik, fizyolojik ve mikrobiyal etkileri güncel literatür bulguları ışığında değerlendirilmiştir.

Anahtar Kelimeler: *bitki besleme, gübreleme, mikoriza, biyokontrol, sürdürülebilir tarım*

Dünya'da Ve Türkiye'de Patates Üretimi İle Yerli Ve Milli Patates Geliştirme Çalışmaları

Uğur PIRLAK, Necmettin Oğuz DEMİR

Patates Araştırma Enstitüsü Müdürlüğü

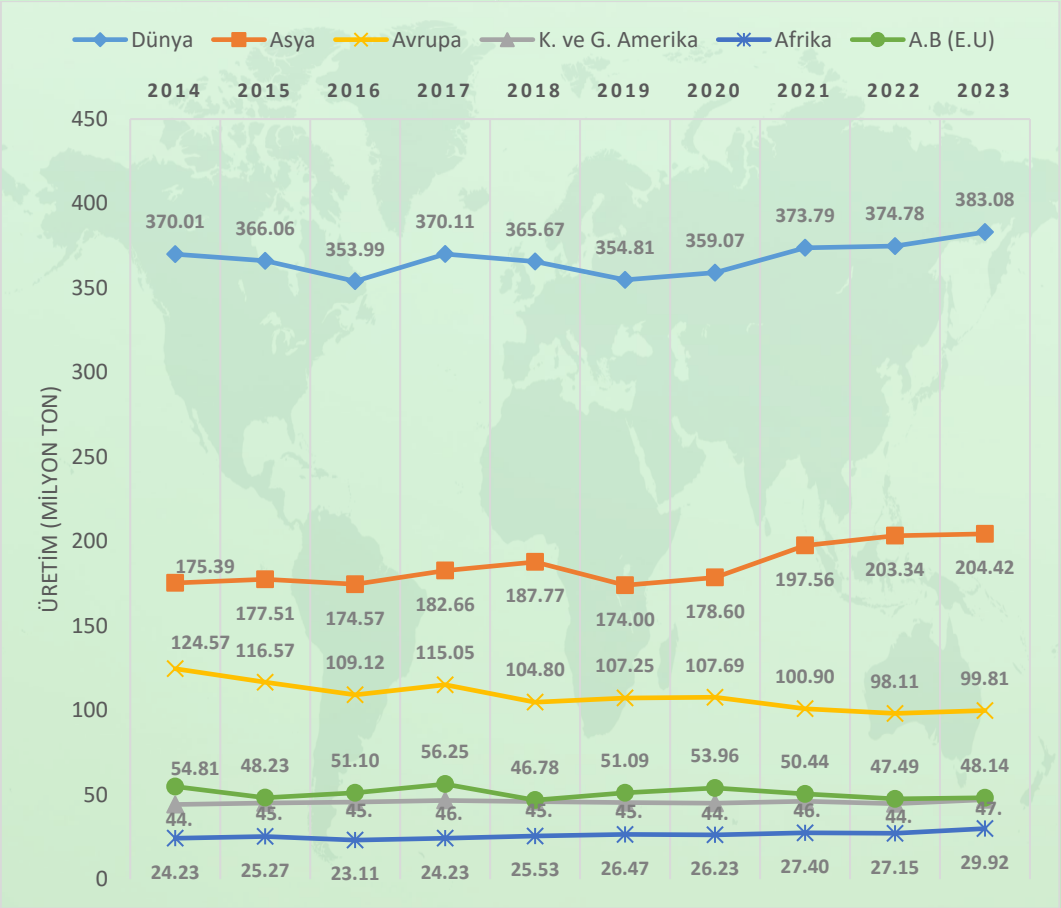
Patatesin Önemi

Patates (*Solanum tuberosum* L.) günümüzden 6.000 ile 10.000 yıl önceki bir zaman dilimi içerisinde Peru ve Bolivya sınırları içerisindeki And Dağlarında kültüre alınmaya başlanmıştır. Güney Amerika'nın And dağlarından tüm dünyaya yayılan patates, dünyanın giderek artan açlık sorununa cevap verebilecek önemli bitkilerin başında gelmektedir.

Patates; dünya ve Türkiye için hem taze hem de kendisinden elde edilen yan ürünlerle insan beslenmesinde ve girdi niteliği ile endüstri bakımından önemli bir tarımsal üründür. Yapılan çalışmalara göre, birim alan başına buğdaydan %75 ve pirinçten %58 daha fazla gıda enerjisine sahip olan patates, üretim alanları başına pirinçten %78, buğdaydan %54 daha fazla protein sağlar. Dünya patates üretiminin yarısına yakın kısmı taze olarak değişik formlarda (fırında pişirme, haşlama, kızartma) yemeklik olarak tüketilmektedir. Geri kalan kısmı ise işlenmiş gıda ürünü (dondurulmuş parmak patates ve cips), hayvan yemi, endüstriyel nişasta ve tohumluk olarak kullanılmaktadır. Patatesin nişasta yönünden zengin olan kabukları ve işlendikten sonra kalan diğer değersiz atıklarından sıvılaştırılarak, etanol üretimi amacıyla yararlanılmaktadır.

Doğal kaynakların sürekliliğini sağlamak ve gelecek nesillere gıda güvenliliği yönünden tüketilebilir gıda sağlamak insanlığın en önemli amacı olmalıdır. Patates üretimi bu sorunları çözmede önemli bir araç durumundadır.

Dünya'da ve Türkiye'de Patates Üretimi



FAO 2023 yılı verilerine göre dünyada toplam 163 ülkede (toplam ülke sayısı 208) yetiştirilen patatesin üretim alanı 16,80 milyon hektar, (*2022; 16,66 milyon ha*) üretim miktarı ise 383,08 milyon ton (*2022; 373,40 Milyon ton*) olmuştur. 2023 yılı itibarıyla en fazla patates üreten on ülke sırasıyla; ***Çin, Hindistan, Ukrayna, ABD, Rusya, Almanya, Bangladeş, Fransa, Pakistan, ve Mısır***'dır. Çin, Hindistan, Ukrayna, ABD ve Rusya ve dünyada sürekli olarak en fazla patates üretiminin yapıldığı ilk beş ülke olurken, bu ülkeler aynı zamanda dünyadaki toplam üretimin de %55,94'ünü gerçekleştirmişlerdir. 2023 yılında Dünya üretiminden Çin %24,39, Hindistan %15,70, Ukrayna %5,58, A.B.D %5,22 ve Rusya %5,06 pay almıştır. Dünya patates üretiminde ülkemiz %1,49'luk pay ile 13. sırada yer almıştır (**Tablo 1.**).

Tablo 1. Dünyada En Çok Patates Üreten İlk On Ülke (FAO, 2023).

Sıra No	Ülke	Üretim Miktarı (Ton)	Dikilen Alan (ha)	Verim (kg /da)
	Dünya	**383.082.607**	**16,80**	**2.280**
1	Çin	93.430.000	4,57	2.045
2	Hindistan	60.142.000	2,33	2.579
3	Ukrayna	21.358.630	1,21	1.765
4	ABD	19.992.090	0,39	5.145
5	Rusya	19.374.441	1,11	1.753
6	Almanya	11.607.300	0,26	4.385
7	Bangladeş	10.431.736	0,46	2.290
8	Fransa	8.606.490	0,20	4.219
9	Pakistan	8.319.767	0,34	2.443
10	Mısır	6.869.330	0,24	2.915
13	**Türkiye**	**5.700.000**	**0,15**	**3.777**

Patates, daha çok Avrupa ve Kuzey Amerika'daki gelişmiş ülkelerde üretilen ve tüketilen bir ürün iken 1990'lı yılların baslarından itibaren özellikle Asya, Afrika ve Latin Amerika'daki az gelişmiş veya gelişmekte olan ülkelerde de patates üretiminin hızla yaygınlaşmaya başlamıştır. Gelişmekte olan ülkelerin toplam üretimi, 1960'lı yılların başında dünya toplam üretiminde az bir paya sahipti ancak günümüzde bu pay gelişmiş ülkelerin üzerine çıkmıştır (**Grafik 1**).

Turkish Science and Technology Publishing (TURSTEP)
www.turstep.com.tr

Grafik 1. 2014-2023 Yılları Arasında Dünya Patates Üretim Miktarları (FAO).

Patates, ülkemiz tarımı içinde en önemli bitki türlerinden biri olup buğday, şeker pancarı, arpa ve domatesten sonra en fazla üretimi yapılan beşinci bitkidir. Ülkemizde ana ürün, turfanda ve ikinci ürün olmak üzere tüm patates üretim sistemleri uygulanmaktadır. Türkiye sahip olduğu agro-ekolojik zenginlik sayesinde patates üretimi açısından oldukça ayrıcalıklı bir konumdadır. Bu nedenle de ülkenin hemen her yöresinde yılın belirli dönemlerinde patates üretimi mümkün olmakta, Nisan ayından başlayarak Aralık ayı sonuna kadar patates hasadı devam etmektedir.

Türkiye'de patates verimi yıllar itibarıyla artış göstermiştir. 2024 yılında patates verimi 3.525,00 kg/da olup 2024 yılı patates veriminin en yüksek olduğu iller sırasıyla Bitlis (4.361 kg/da), Kayseri (4.338 kg/da) ve Adana (4.054 kg/da), olup Türkiye ortalamasının çok üzerindedir (**Tablo 3.**).

Tablo 3. Türkiye'de Yıllara Göre Patates Üretim Verileri (TÜİK).

Yıllar	Dikim Alanı (da)	Alan Artışı (%)	Üretim (Ton)	Üretim Artışı (%)	Verim (kg/da)	Verim Artışı (%)
2017	1.428.835	100	4.800.000	100	3.360,00	100
2018	1.359.373	95,14	4.550.000	94,79	3.348,00	99,64
2019	1.408.967	98,61	4.979.824	103,75	3.538,00	105,30
2020	1.479.935	103,58	5.200.000	108,33	3.514,00	104,58
2021	1.389.175	97,22	5.100.000	106,25	3.682,00	109,58
2022	1.391.716	97,40	5.200.000	108,33	3.739,00	111,28
2023	1.509.269	105,63	5.700.000	118,75	3.777,00	112,41
2024	**1.957.672**	**137,01**	**6.900.000**	**143,75**	**3.525,00**	**104,91**

Niğde, Kayser, Konya ve Afyonkarahisar patates üretiminde önemli dört ilimizdir. Ülke üretiminin yaklaşık %45'ini, ekim alanlarının ise %43'ünü bu üç ilimiz oluşturmaktadır (**Resim 1**).

Resim 1. Türkiye'de Patates Üretimi Yapılan İller ve Üretim Yoğunluğu (TÜİK, 2024).

2024 yılında Türkiye'de 75 ilde patates üretimi gerçekleştirilmiştir. En fazla üretim yapan il Niğde olup 264.830 da alanda 915.734 ton üretim gerçekleşmiştir. Niğde'nin ortalama verimi 3.458,00 kg/da'dır (**Tablo 4.**).

Tablo 2. Yıllara Göre Türkiye'de En Fazla Patates Üretimi Yapılan İller (TÜİK).

Türkiye'de patates üretimindeki değişim, Avrupa Birliği ülkeleri ile bir paralellik göstermektedir. Patates, bugün ülkenin en önemli tarımsal ürünlerinden biri konumuna gelmiş; üretimi, sanayisi, pazarlaması ve tüketimi ile başlı başına bir sektör halini almıştır.

Ülkemizde kişi başına düşen patates tüketim miktarı yaklaşık (TÜİK 2021- 50,00 kg) **50 kg** civarında olup dünyada kişi başına tüketim ise (FAO 2021- 32,98) **33 kg**'dır. **Ülkemizde patatesin yeterlilik oranı ise 2021 yılı TÜİK verilerine göre %106,10'dir.**

Ülkemizde Patates Çeşidi Geliştirmede Geçmişte Yapılan Çalışmalar

Ülkemizde patates ıslahı ile ilgili çalışmalar, 1951 yılında başlanmış, ülkemizin farklı bölgelerinde yetiştirilmekte olan 60 farklı patates çeşidi (klonu) toplanmış ve bu klonların başlıca özelliklerinin tespit edilmesi amacıyla Ankara ve Adapazarı'nda denemeye alınmıştır. İkinci ayrıntılı çalışma 1961 ve 1962 yıllarında Erzurum'da yürütülmüştür.

Türkiye'de bilimsel anlamda patates çeşit adaptasyon çalışmaları 1950'lerde başlamasına rağmen, çeşit tescil çalışmaları 1970'li yıllarda Ülkesel Patates Projesinin hayata geçirilmesi ile hız kazanmıştır. İlk olarak 1972

yılında Ege Tarımsal Araştırma Enstitüsü tarafından Alpha, Ari ve Sarıkız tescil ettirilmiş; daha sonra 1975 yılında Tohum Islah ve Üretme A.Ş. tarafından Atica, Cosima, Fina ve Frigga çeşitleri; Satüdaş tarafından Baraka, Desiree, Favorita, Jaerla; Ege Tarımsal Araştırma Enstitüsü tarafından Isola ve Resy çeşitleri tescil ettirilmiştir. Daha sonraki yıllarda çeşit tescil çalışmaları özellikle özel sektör girişimleriyle ivme kazanmış ve tescil edilen çeşit sayısı hızla artarak 2024 yılı itibariyle 281'e ulaşmış, üretim izni alan çeşit sayısı ise 48 olmuştur.
Ülkemizde patatesin yaklaşık 175 yıllık bir geçmişi olmasına ve zaman içerisinde patates sektöründe önemli gelişmeler olmasına rağmen, yerli çeşit geliştirme çalışmalarına 2005 yılından sonra hız verilmiştir. Tohumluk firmaları, yerli çeşit ıslahına yatırım yapmak yerine, her yıl temsilciliğini yaptıkları yurt dışı ıslah firmalarından birçok çeşit veya klon getirerek adaptasyon denemelerine almakta ve başarılı olanları tescil ettirmektedirler. Ülkemizde 281 adet tescilli patates çeşidi bulunmakta olup, bunlardan sadece bir tanesi (Nif) Türkiye'de ıslah edilerek tescil ettirilmiştir. Ancak bu çeşit de ticari üretimde hiçbir zaman şans bulamamıştır.

Günümüzde Yapılan Kamu ve Özel Sektör Tarafından Yapılan Çeşit Geliştirme Çalışmaları

Ülkemizde, başta Hollanda olmak üzere Almanya, Fransa, İngiltere, İskoçya, İrlanda ve ABD'de ıslah edilmiş çeşitler kullanılmaktadır. Ülkemize ait yeterli sayıda ve üretim programlarına giren tescilli çeşitlerimizin bulunmaması çok önemli bir problem olarak karşımıza çıkmaktaydı.
Bu sorunun çözümüne yönelik olarak, **1 Kasım 2005- 31 Aralık 2009** tarihlerinde Enstitümüz koordinatörlüğünde TÜBİTAK (1007-KAMAG) destekli, 8 Enstitü (***Niğde Patates Araştırma Enstitüsü Müdürlüğü, Ankara Zirai Mücadele Merkez Araştırma Enstitüsü Müdürlüğü, Bornova Zirai Mücadele Merkez Araştırma Enstitüsü Müdürlüğü, Adana Zirai Mücadele Merkez Araştırma Enstitüsü Müdürlüğü, Erzincan Bahçe Kültürleri Araştırma Enstitüsü Müdürlüğü, Ege Tarımsal Araştırma Enstitüsü Müdürlüğü, Doğu Anadolu Tarımsal Araştırma Enstitüsü Müdürlüğü, Toprak, Gübre ve Su Kaynakları Araştırma Enstitüsü Müdürlüğü***) 3 üniversite (***Mustafa Kemal Üniversitesi, Ege Üniversitesi, Gaziosmanpaşa Üniversitesi***) ve 11 özel sektör firmasının (***Doğa Tohumculuk, Anka Tohumculuk, Ar Tarım, Gömeç Tohumculuk, Sürde Tarım, Tareks, Tezel Tohumculuk, Asgen Tarım, Öztar Tohumculuk, Fritolay Gıda, Kraft Gıda***) katılımı ile **"Ülkesel Patates Tohumluk Üretim Sisteminin Geliştirilmesi"** projesi yürütülmüştür. Proje kapsamında Enstitümüz bünyesinde patates çeşit ıslah programı başlatılmıştır.
Bu program kapsamında patates araştırmaları açısından merkez kuruluş olan Enstitümüzde patates ıslah altyapısı oluşturulmuş ve teknik personel eğitimleri tamamlanmıştır.
Proje çalışmalarımız 2010 yılından itibaren "**Orta Anadolu Patates Islahı Projesi"** ismiyle, Tarım ve Orman Bakanlığı, Tarımsal Araştırmalar ve Politikalar Genel Müdürlüğümüzün destekleri ile sürdürülmektedir. Orta Anadolu Patates Islahı Projesi ile ülkemize uyumlu, yüksek verimli ve hastalıklara dayanıklı yerli çeşitlerin geliştirilmesi, çeşit geliştirme süresinin doku kültürü yöntemi kullanılarak kısaltılması, geliştirilen yeni çeşitlerin ve ülkemizde yaygın olarak üretimi yapılan bazı patates çeşitlerinin temel tohumluklarının doku kültürü ile çoğaltılarak daha kısa sürede çiftçi kullanımına sunulması hedeflenmiştir.
Ülkemize ait yerli çeşitlerin geliştirilmesi kapsamında 2007-2024 yılları arasında ülkemiz açısından bir rekor olan toplam **1.500.000** adet melez patates tohumu elde edilerek **"Patates Genetik Tabanı"** oluşturulmuş, farklı melez kombinasyonlarına ait çeşitli kademelerde (1., 2., 3., 4., 5. generasyon), çok sayıda yerli patates klonları (çeşit adayları) elde edilmiştir. Ülkemize özgü patates çeşit ıslah programları başlatılmış ve sürekliliği sağlanmıştır.
Her geçen yıl üstün verimli çeşitler arasında melezleme çalışmaları yapılmakta farklı jenerasyonlarda (nesillerde) binlerce yeni çeşit adayı üzerinde seleksiyon çalışmaları devam ettirilmektedir. **Her yıl en az iki yerli çeşit tescile sunulacak şekilde patates ıslah çalışmalarımız değişik ıslah projeleri ile devam ettirilmektedir.**
Ülkemizde doku kültürü yöntemi ile patates tohumluk üretimi yokken, "Ülkesel Patates Tohumluk Üretim Sisteminin Geliştirilmesi" projesi ile Niğde Patates Araştırma Enstitüsü, Ege Tarımsal Araştırma Enstitüsü, Doğu Anadolu Tarımsal Araştırma Enstitüsü ve Ege Üniversitesinde tohumluk üretimi yapabilecek doku kültürü laboratuvarları ve seralar 2007 yılında pilot tesisler olarak kurularak işletilmeye başlanmış ve bu alt yapılar kullanılarak çeşit geliştirme çalışmaları hızlanmıştır.
Proje çalışmaları kapsamında seleksiyon çalışmaları sonucunda çeşit adayları (klonlar) içerisinden PA-03-2-16 ve PA-06-1-43 nolu çeşit adaylarımız **07 Ocak 2013** tarihinde ilk yerli ticari patates çeşitlerimiz olarak tescile sunulmuştur. Tescil çalışmaları sonucunda PA-06-1-43 nolu yerli patates çeşidimiz **ONARAN2015** ismiyle ve PA-03-2-16 nolu yerli patates çeşidimiz **FATİH** ismiyle 01 Nisan 2015 tarihinde ilk yerli patates çeşidimiz olarak tescil edilmiştir. 19 Nisan 2016 tarihinde **NAHİTA**, **ÜNLENEN** ve **NAM**, 14.04.2017 tarihinde **ÇAĞLI**, **LEVENTBEY** ve **MURATBEY** ve 12.04.2019 tarihinde **NİĞŞAH** ve **SARUHAN,** 15.04.2025 tarihinde ise **UĞUR** ismiyle toplamda 11 adet yerli patates çeşidi tescil edilmiştir. Ayrıca bu proje TÜBİTAK Araştırma Destek Programları Başkanlığı tarafından hazırlanan **"BAŞARI ÖYKÜLERİ"** kitabında **"Tohumluk Patates İthalatı Yaparken Tohumluk Patates İhracatı Başladı"** başlığıyla 2014 yılında yer almıştır.
Yapılan bu tüm çalışmaların neticesinde; **Türkiye'de ilk defa** geliştirilen yerli ve milli patates tohumluklarının ihale yoluyla satışı gerçekleştirilmiştir.

Tescil edilen 8 adet yerli patates çeşidinden ilk etapta 4 tanesi, enstitüde yapılan ihalede "Tohumluk Üretim ve Pazarlama Hakkı" satışa çıkartılmıştır. **NAHİTA** adlı yerli çeşidin satış hakkı ülkemizde tohumluk patateste en fazla üretim yapan firmalardan bir tanesi olan **AR TARIM TOHUMCULUK SAN ve TİC A.Ş.**' nin olmuştur. Ayrıca NAHİTA adlı çeşidin yurt dışındaki ülkelerde de satılabilmesi için çeşidi alan bu firmayla "Yurtdışı Satış Sözleşmesi" imzalanmıştır.

Devamında **ONARAN2015, ÜNLENEN, NAM, LEVENTBEY ve MURATBEY** çeşitlerinin de "Tohumluk Üretim ve Satış Hakkı" Niğde' de faaliyet gösteren **SELANİK TOHUMCULUK** firmasının olmuştur**.**

En son **NİĞŞAH** ve **SARUHAN** adlı yerli ve milli patates çeşitlerinin "Tohumluk Üretim ve Pazarlama Hakkı" ülkemizde patateste en fazla üretim yapan firmalardan biri olan **HAKAN GIDA ve TOHUMCULUK A.Ş.**'ne ihale edilmiştir. Bu çeşitlerin ileri kademede tohumluk üretimi ve sertifikasyon çalışmaları bu firmalar işbirliğinde devam etmektedir.

2024 yılı Mart Ayı itibariyle özel sektöre devredilen ve sertifikasyon işlemleri tamamlanan **NAHİTA, ONARAN2015** ve **LEVENTBEY** çeşitlerinin çiftçilerimize ve üreticilerimize firma tarafından satışı başlamıştır.

Enstitümüzce yürütülen ıslah çalışmalarında yemeklik, sanayilik ve hastalıklara dayanıklı patates çeşitlerinin geliştirilmesinin yanında farklı kabuk ve et rengine sahip patates çeşitleri de geliştirilmektedir. Geliştirilen renkli, yerli ve milli çeşitlerimiz üzerinde çalışmalarımız devam etmekte olup yeterli tohumluk sayısına ulaşıldığında tescile sunulacaktır.

Geliştirdiğimiz bu renkli çeşitlerimiz üzerinde yapılan teknolojik testler sonucunda çeşitlerimizden iyi kalitede cips elde edilmiştir. Türkiye'de ilk renkli patates cipsleri enstitümüzde geliştirilmiştir. Bu çeşitlerimizin cips piyasasına girmesiyle birlikte ülkemizdeki cips piyasası renklenecektir (örneğin sarı-kırmızı, sarı-lacivert cipsler). Şu an renkli cips yapılabilen 10 genotip enstitümüzce geliştirilmiştir.

2025 yılının Nisan ayında Enstitümüz tarafından ilk defa sanayilik **UĞUR** isimli bir çeşit tescil edilmiştir. Enstitünüzün geliştirmiş olduğu sanayilik çeşit cipslik ve parmak patates yapımına uygun bir çeşit olup yüksek verimli, orta erkenci ve en önemlisi depo dayanıklığı mevcut ithal çeşitlere göre yüksek bir çeşittir.

Enstitümüzün ıslah çalışmaları haricinde Doğru Anadolu Tarımsal Araştırma Enstitüsü, Ege Tarımsal Araştırma Enstitüsü ve Tokat Gaziosmanpaşa Üniversitesi tarafından halihazırda devam eden ve sonuçlanan ıslah çalışmalar kapsamında tescil edilen ve tescile sunulan çeşitler mevcuttur.

Doğu Anadolu Tarımsal Araştırma Enstitüsü Müdürlüğü tarafından yürütülen ıslah çalışmaları kapsamında **CAN, METE, KAAN, ATA 25, KARSU ve CANSU** ismiyle 6 adet yerli ve milli patates çeşidini tescil ettirilmiştir. Yine aynı enstitünün **ARAL** isimli çeşitleri tescil aşamasındadır.

Ege Tarımsal Araştırma Enstitüsü Müdürlüğü tarafından halihazırda tescilli bir çeşidi bulunmayıp "Ege Bölgesi Patates Islahı Projesi" kapsamında ıslah çalışmalarına devam edilmektedir.

Tokat Gaziosmanpaşa Üniversitesi Ziraat Fakültesi Tarla Bitkileri Bölümü tarafından yürütülen çalışmalar kapsamında **BAŞÇİFTLİK BEYAZI** ve **GÜNGÖR BEY** isimli 2 adet çeşit tescil ettirilmiştir.

Yapılan çalışmaların çıktıları özel sektör tarafından da kullanılmaya başlanmıştır. Birçok tohumculuk firması tohumluk üretimi yapabilecek doku kültürü sistemlerini kurarak doku kültürü ile tohumluk üretim izni almıştır. Bunun sonucunda farklı kademelerde tohumluk üretimi yapmaya başlamışlar ve 2013 yılından itibaren yerli üretim patates tohumluğu ihraç edilmektedir.

En önemli çıktılardan biri de; Özel sektörce yürütülen ıslah çalışmaları ile yerli patates çeşitleri geliştirilmiş, tescile sunulan ve tescil edilen çeşitler olmuştur. Özel sektör tarafından geliştirilerek tescile sunulan çeşit adayları şunlardır;

Doğa Arge Merkezi San. Tic. A.Ş. tarafından toplam 24 adet tescil ettirilen yerli çeşit bulunmakta olup aşağıdaki tabloda bu çeşitlerin isimleri verilmiştir.

Doğa Arge Merkezi San. Tic. A.Ş. (17 Adet)	**BAHAR**	**MADEN**
	İLKMOR	**AYDOS**
	KAYA	**ALTAY**
	ZİRVE	**PETEK**
	DORUK	**KAFKAS1**
	KUTUP	**TESSA**
	VOLKAN	**YAKUT1**
	YEDİVEREN	**DENİZ1**
	YAPRAK	**BULUT**
	YALDIZ	**TURAÇ**
	AYAZ	**SES**
	YANKI	**TAŞ**

Yüksel Tohumculuk Tarım ve Tic. Ltd. Şti. tarafından toplamda 9 adet tescil ettirilen yerli çeşit bulunmakta olup aşağıdaki tabloda bu çeşitlerin isimleri verilmiştir.

Yüksel Tohumculuk Tarım ve Tic. Ltd. Şti. (9 Adet)	**ASYA**
	SOYLU
	CEVHER
	DEMET
	MARATON
	ATABEY
	BOYSAN
	MELANO
	TROVA

İnan Meijer Tohumculuk ve Tic. Ltd. Şti. tarafından ise toplamda 2 adet tescil ettirilen yerli çeşit bulunmaktadır.

İnan Meijer Tohumculuk ve Tic. Ltd. Şti. (2Adet)	**SULTAN ECEM**
	SULTAN NUR

Kamu ve özel sektör tarafından geliştirilen yerli çeşitler hem ülkemizde üretilip çiftçilerimize daha kısa zamanda ulaşacak, hem de dünyaya satışı yapılacaktır. Yerli çeşitlerin devreye girmesiyle birlikte milli ekonomiye büyük katkı sağlanacaktır. Ayrıca yerli çeşitlerimiz patates üreticilerimizin maliyetlerini de önemli ölçüde aşağı düşürecektir. Üreticilerimizin patates tohumluğu ihtiyacı tamamen yerli imkânlarla sağlanacaktır.

Identification of Novel *TMC1* and *TECTA* Mutations in the Pakistani Population: Insights into the Genetic Basis of Hearing Impairment

Saba Zafar[1] , Rehan Sadiq Shaikh[2]

[1] Department of Biochemistry and Biotechnology, The Women University, Multan, Pakistan
[2] Center for Applied Molecular Biology (CAMB), University of the Punjab, Lahore, Pakistan

Abstract

Hearing impairment is the 4th most prominent reason for disability worldwide, and according to the WHO report of 2018, the highest prevalence of HI is observed in Europe (8.36%), followed by South Asia (7.37%). The occurrence of significant reciprocal hearing impairment is around 1.6 out of 1000 among individuals of the Pakistani population. This study provides insight into the genetic basis of the hearing loss in the Population of Pakistan. identified by linkage mapping or Exome Sequencing (ES). We found novel mutations in two families, NM_138691.3: c.1259G>A [p. (Cys420Tyr)] and NM_005422.4: c.1247_1248delGG [p. (Gly416Aspfs*24)], in *TMC1* and *TECTA* genes, respectively. Pathogenicity analysis for these novel variants was performed using various insilico tools, which established the deleterious impacts of these variants on the encoded proteins. Variants identified in *TECTA, TMC1* were classified as pathogenic or likely pathogenic. The Clustal W alignment online tool showed the high conservation of the altered amino acid residues by aligning sequences from different species. Further, the effects of alteration in protein were predicted by the 3D modeling and it showed the visible change in structures of proteins for both identified variants. This study would help to expand knowledge and understanding of the genetic spectrum of hearing loss genes in the Pakistani population. Advances in molecular genetics will play a crucial role in the diagnosis and genetic counseling of families affected by hearing loss, ultimately paving the way for progress in personalized medicine and gene therapy.

Antagonistic Activity of Endophytic Fungi from *Euphorbia rigida* against *Botrytis cinerea* in Tomato

Özden Salman[1], Raziye Koçak[2]

[1] Department of Plant Protection, Faculty of Agriculture,Selçuk University, Konya, Turkey
[2] Animal and Plant Production Department, Çumra Vocational School, Selçuk University, Konya, Turkey

Abstract

This study was conducted to isolate endophytic fungi from the spurge (*Euphorbia rigida*) plant and to evaluate the *in vitro* biocontrol potential of these isolates against *Botrytis cinerea*. Within the scope of the research, a total of thirty endophytic fungal isolates were obtained from different tissues of *E. rigida*. These isolates were derived from the stem (5), leaf (16), and flower (9) tissues of the plant and were identified based on their macromorphological and micromorphological characteristics. Accordingly, 66.67% of the isolates were determined to belong to *Trichoderma* species. The biocontrol potential of the *Trichoderma* isolates against *B. cinerea*, the causal agent of gray mold disease, was assessed in terms of their antagonistic activity. Dual culture assays were performed on Potato Dextrose Agar (PDA) medium, where the bioagent fungi restricted the mycelial growth of *B. cinerea* by 11 to 35 mm. Among the tested isolates, eight exhibited significant antifungal activity, inhibiting the mycelial growth of the pathogen by 75.5% to 100%. These findings indicate that *E. rigida* harbors fungal endophytes with high biocontrol activity and that these fungi could serve as potential bioagents against *B. cinerea*.

Key Words: *Biological control, Endophytic fungi, Euphorbia rigida, Botrytis cinerea*

Euphorbia rigida'nın Endofitik Funguslarının Domateste *Botrytis cinerea*'ya Karşı Antagonistik Aktivitesi

Özet

Bu çalışma, sütleğen (*Euphorbia rigida*) bitkisinden endofitik fungusları izole etmek ve bu izolatların *Botrytis cinerea*'ya karşı *in vitro* biyokontrol potansiyelini değerlendirmek amacıyla yürütülmüştür. Araştırma kapsamında, sütleğenin farklı dokularından toplam otuz endofit fungus izolatı elde edilmiştir. Bu izolatlar, bitkinin gövde (5), yaprak (16) ve çiçek (9) dokularından izole edilerek, makromorfolojik ve mikromorfolojik özelliklerine göre teşhisleri yapılmıştır. Buna göre, izolatların %66,67'sinin *Trichoderma* sp. türlerine ait olduğu belirlenmiştir. *Trichoderma* izolatlarının, gri küf hastalığı etmeni *Botrytis cinerea*'ya karşı biyokontrol potansiyelleri, antagonistik aktiviteleri bakımından değerlendirilmiştir. Dual kültür testlerinde Patates Dekstroz Agar (PDA) ortamı kullanılmış olup biyoajan funguslar *B. cinerea*'nın miselyal gelişimini 11 ile 35 mm arasında sınırlandırmıştır. Test edilen izolatlardan 8 tanesinin belirgin antifungal aktivite sergilediği tespit edilmiştir. Bu izolatlar, patojenin miselyal gelişimini %75,5 ile %100 arasında inhibe etmiştir. Elde edilen bu bulgular, sütleğenin yüksek biyokontrol aktivitesi olan fungal endofit türlere konukçuluk yaptığını ve bu fungusların *B. cinerea*'ya karşı potansiyel birer biyoajan olarak kullanılabileceğini göstermektedir.

Determination of the Presence and Infection Rates of *Bean common mosaic virus* (BCMV), *Bean yellow mosaic virus* (BYMV) and *Bean common mosaic necrosis virus* (BCMNV) in Bean Planting Areas in Karaman Province

Çiğdem ALBAYRAK[1], Serkan YEŞİL[1*]

[1]Department of Plant Protection, Faculty of Agriculture, Selçuk University, Konya, Türkiye
*Corresponding Author: serkanyesil@selcuk.edu.tr

Abstract

In this study, the presence and current status of some virus diseases were investigated in the production areas of Karaman province, which has an important place in terms of bean cultivation in Türkiye. In bean cultivation, many physiological and pathological factors can have negative effects on yield and quality of the crop. Virus diseases are one of the biotic diseases that are problematic in bean cultivation. In particular, some virus diseases can be transmitted by bean seeds and vector insects, which are widely found in nature, making them an important problem in bean cultivation. The investigated viruses were *Bean common mosaic virus* (BCMV), *Bean yellow mosaic virus* (BYMV) and *Bean common mosaic necrosis virus* (BCMNV) belonging to *Potyvirus* genus of *Potyviridae* family. As a result of the surveys conducted in Karaman bean production areas, 140 leaf samples were taken from bean plants in 2023 production season. Sampled bean leaves were exhibited viral disease symptoms such as mosaic, chlorosis, deformations, wilting, and stunting. The presence of the specified viruses in the collected samples was tested by DAS-ELISA method. As a result of the study, 20 of the samples were found to be infected with at least one of the viruses. In other words, 14.29% of the tested plant samples were found to be infected with at least one of these viruses. Of these 20 samples, 11 were infected with BCMV, 4 with BCMNV, 1 with BYMV, 3 with BCMV+BCMNV and 1 with BCMV+BYMV+BCMNV.

Key Words: *BCMV, BCMNV, Bean, BYMV, DAS-ELISA, Karaman*

Fasulye Adi Mozaik Virüsü (*Bean common mosaic virus*, BCMV), Fasulye Sarı Mozaik Virüsü (*Bean yellow mosaic virus*, BYMV) ve Fasulye Adi Mozaik Nekroz Virüsü (*Bean common mosaic necrosis virus*, BCMNV)'nün Karaman İli Fasulye Ekim Alanlarında Varlıklarının ve Bulaşıklık Oranlarının Belirlenmesi

Özet

Bu çalışmada Türkiye fasulye yetiştiriciliği açısından önemli bir yeri olan Karaman ilindeki üretim alanlarında, bazı virüs hastalıklarının varlığı ve mevcut durumları araştırılmıştır. Fasulye yetiştiriciliğinde pekçok fizyolojik ve patolojik etken verim ve kalite üzerinde olumsuz etkilerde bulunabilmektedir. Virüs hastalıkları da fasulye yetiştiriciliğinde sorun olan biyotik kaynaklı hastalık etmenlerinden bir tanesidir. Özellikle bazı virüs hastalıklarının fasulye tohumları ve doğada yaygın olarak bulunan vektör böceklerle taşınabilmeleri fasulye yetiştirciliğinde önemli bir sorun haline gelmelerine sebep olmaktadır. Araştırılan virüs etmenleri *Potyviridae* familyasının *Potyvirus* cinsine ait olan Fasulye adi mozaik virüsü (*Bean common mosaic virus*, BCMV), Fasulye sarı mozaik virüsü (*Bean yellow mosaic virus*, BYMV) ve Fasulye adi mozaik nekroz virüsü (*Bean common mosaic necrosis virus*, BCMNV)'dür. Karaman fasulye üretim alanlarında, 2023 yılı üretim sezonunda yapılan sürveyler sonucunda yapraklarda mozaik, kloroz, şekil bozuklukları ve bitkinin tamamında ise solgunluk, ve bodurluk gibi viral hastalık simptomları sergileyen fasulye bitkilerinden 140 yaprak örneği alınmıştır. Toplanan örneklerde, belirtilen virüslerin varlığı DAS-ELISA yöntemiyle araştırılmıştır. Çalışmanın sonucunda örneklerden 20 tanesinin söz konusu virüslerden en az bir tanesi ile bulaşık olduğu belirlenmiştir. Başka bir ifadeyle, testlenen bitki örneklerinin %14,29'unun bu virüslerden en az bir tanesi ile bulaşık olduğu tespit edilmiştir. Bu 20 örnekten 11 tanesinin BCMV, 4 tanesinin BCMNV, 1 tanesinin BYMV, 3 tanesinin BCMV+BCMNV ve 1 tanesinin BCMV+BYMV+BCMNV ile bulaşık olduğu tespit edilmiştir.

Ethiopia's Livestock Production and its Contribution to Food Security

Esubalew Abate Alemu (Ph.D.)
Center for Rural, Local and Regional Development Studies (CRLRDS), College of Social Sciences, Arts and Humanities (CSSAH), Addis Ababa University, esubalew.abate@aau.edu.et or esubalew.abate@gmail.com, , P.O.Box:1176, Addis Ababa, Ethiopia. Telephone: +251 911 407956, esubalew.abate@aau.edu.et or esubalew.abate@gmail.com, ORCID of the author: 0000-0003-4765-1129

Abstract

Livestock production plays a fundamental role in ensuring food security and sustaining livelihoods in Ethiopia. This study employs thematic analysis to systematically examine peer-reviewed literature, government reports, and development agency publications to assess how livestock contributes to food security in the Ethiopian context. The analysis identifies four key themes: (1) nutritional contributions through animal-source foods, (2) income generation and economic resilience, (3) integration with crop production systems, and (4) climate change adaptation strategies. Findings reveal that livestock provides 16-20% of total calorie intake and 25-30% of dietary protein for rural households, while serving as a critical asset for risk mitigation during food shortages. However, systemic challenges including feed deficits (estimated at 40-60% of requirements), disease prevalence, and market access limitations constrain full productivity potential. The study concludes with policy recommendations emphasizing the need for integrated livestock-crop systems, improved animal health services, and climate-smart production practices to enhance the sector's contribution to national food security goals.

Using compost and compost tea as biofertilizers to improve onion growth and yield in the field at Gapring-Lara in the Department of Mayo Kani (Cameroon)

Mohamadou Moussa
University of Ngaoundere, Cameroon

Abstract

In Cameroon, onion production has grown but poor agricultural practices are challenges to be addressed in order to improve its production. The aim of this study is to assess the fertilizing effects of compost and compost tea on onion growth and production, in order to provide a plausible alternative to synthetic chemical inputs. The study was conducted at the Gapring-Lara experimental site (Cameroon). The experimental set-up used was a randomized complete block consisting of three replications and five treatments including Cow dung compost (Cp), Cow dung compost tea (CpT), Cow dung compost + Cow dung compost tea (Cp+CpT), Negative control (Ctrl) and NPK 20-10-10 (ChF). The results showed that the experimental soils contained high concentrations of phosphorus, potassium, calcium, iron, magnesium and nitrogen after experimentation. Four species of bacteria (*Pseudomonas* sp., *Bacillus cereus*, *Bacillus subtilis* and *Micrococcus* sp.) were determined, with *Pseudomonas* sp. dominating in the compost (69.14%) and compost tea (56.32%). The plots amended with compost had the best average harvest weights, with 248.33±88.08g and 234±77.61g respectively over the two years of the study. Agronomic production was considerably increased by the CpT treatment with 65.48 t/ha in 2018/2019 and by the Cp treatment with 28.14 t/ha in 2019/2020. In view of the results obtained, this study shows the value of using organic matter as a fertilizer in onion cropping systems, in order to increase soil productivity and ensure its sustainable use.

Keywords: *Onion, fertilization, compost, compost tea, Gapring-Lara.*

Sustainable Feed to Reduce the Environmental Impact of Poultry Production

Yusuf Shafiu Yusuf[1], Sibel CANOĞULLARI DOĞAN[1]

[1] Department of Animal Production and Technologies, Faculty of Agricultural Science and Technologies, Niğde Ömer Halisdemir University, Niğde/Türkiye

Abstract

The increasing global demand for poultry products presents significant environmental challenges, particularly concerning resource-intensive feed production. Traditional feed ingredients, such as soybean and maize, contribute to deforestation, water depletion, and greenhouse gas emissions. Additionally, nutrient runoff from poultry waste leads to water contamination and ecosystem degradation. Sustainable feed alternatives, including insect-based proteins offer viable solutions to mitigate these environmental impacts while maintaining nutritional efficiency. The integration of these alternative feed sources reduces dependence on conventional crops, enhances circular economy principles, and promotes waste valorization. Furthermore, utilizing insect meal and single-cell proteins improves feed conversion efficiency and minimizes land and water use, making poultry production more sustainable. The adoption of these feed innovations not only supports environmental conservation efforts but also ensures food security for a rapidly growing population. Transitioning toward sustainable feed practices is essential for aligning poultry production with global sustainability goals, reducing its ecological footprint, and fostering a more resilient agricultural system. This paper highlights the critical role of sustainable feed ingredients in shaping the future of poultry production, emphasizing their necessity in addressing climate change, resource scarcity, and environmental degradation.

Keywords: *Poultry, feed, insects, sustainability, environment.*

1. Introduction

Poultry farming is one of the most important areas in global agriculture, providing billions of people with essential protein in the form of meat and eggs. With the world's population predicted to reach over 10 billion by 2050, the demand for poultry products is projected to soar. By 2028, the sector is predicted to have grown from $360.5 billion in 2023 to $494.55 billion, a spectacular rate of development (World Bank Group, 2013)

This expansion however raises considerable environmental concerns, particularly in the manufacturing of conventional poultry feed. Crops like corn and soy which need a lot of resources to grow make up most of the traditional poultry feed. These feed ingredients' production results in excessive water use, deforestation, and greenhouse gas emissions (Morgan et al., 2025). The environmental impacts of conventional poultry feed extend beyond resource use. Nutrient runoff from feed crop cultivation and poultry waste can lead to water pollution, causing eutrophication in aquatic ecosystems. These challenges highlight the urgent need for sustainable alternatives that can reduce the ecological footprint of poultry production while ensuring food security **(**FAO, 2023a**).**

Sustainable feed ingredients, such as insect-based proteins, algae, and agricultural by-products, offer promising solutions. These alternatives not only have a lower environmental impact but also contribute to a circular economy by utilizing waste streams and reducing dependency on traditional feed crops (Bist et al., 2024).

This article highlights the advantages and prospective applications of sustainable feed components in addressing the environmental issues associated with poultry production.

2. Environmental Challenges in Poultry Production

The production of poultry presents substantial environmental issues even though it is necessary to supply global dietary needs. The environmental effects of poultry farming are not limited to certain regions rather a worldwide effect; Among crucial challenges are greenhouse gas emissions, solid waste management, odor pollution and contamination of water streams are of concern associated with energy use in the the manufacture of concentrate feed, transportation of processed goods and in animal production activities (Castellini et al., 2012).

2.1. Climate Change: Greenhouse Gas Emissions

Air pollutants emissions from animal feeding operations are a significant environmental hazard due to their high potential risk to air quality, human and animal health. Climate change particulate matter (PM) and other gases, such as greenhouse gases and ammonia (NH_3), are the main air emissions (Maheshwari, 2013). Poultry industry must work on lessening its environmental impact, even though its carbon emissions are fewer than those of the beef, pork, or lamb/mutton industries. On average, poultry have a carbon footprint of about 6.0 kg CO_2-equivalent per kilogram of meat (Bist & Chai, 2022). The intensification of feed production, which necessitates energy input for the synthesis of mineral fertilizer and the subsequent use of this fertilizer in the feed production process, indirectly affects emissions of greenhouse gases like carbon dioxide and nitrous oxide. An estimated 18 million tonnes of carbon dioxide are emitted annually, or roughly 44% of the total emissions attributed to the livestock sector, based on the energy use per tonne of nitrogen fertilizer. The (Intergovernmental Panel on Climate Change) emission factor the total nitrogen fertilizer use in the production of feed for poultry production (estimated at 7.2 million tonnes) (Gerber et al. 2006).

Furthermore, a significant source of methane (CH_3) and N_2O emissions is poultry manure. Methane is generated by methanogenic archaea, microorganisms that thrive in oxygen-free (anaerobic) environments. When poultry manure is stored in piles, lagoons, or other confined systems, it creates ideal conditions for these microbes to break down organic matter. This process, known as anaerobic digestion produces methane as a byproduct, a greenhouse gas that has a 28–34 times greater potential to cause global warming over a 100-year period than CO_2. As nitrogen compounds in manure break down, nitrous oxide is generated as well, and it has a 265-fold higher potential to cause global warming than CO_2 (Morgan, 2025).

These emissions add up to the carbon footprint of the poultry business, which makes it a major contributor to global agriculture GHG emissions. In order to meet climate targets and guarantee the sustainability of chicken production, these emissions must be addressed (FAO, 2023b).

2.2. Ecosystems Pollution: Runoff from Poultry Waste and Feed Production

Solid waste is generated at every stage of the chicken production process, including housing, feeding, and watering. Poultry waste consists of feces, wasted feed, bedding material, litter material, feathers, soil, urine, process water, and condemned corpses (Bist et al., 2024). Numerous factors, such as the breed of poultry, the feed content, the length of time the animals are housed in the poultry house, the density of the animals, and seasonal variations, all affect the chemical composition of poultry dung and litter.

A fair amount of nitrogen, phosphorus, and other expelled materials, including antibiotics, pathogens, and heavy metals, are present in poultry feces (Neeteson-van et al., 2013). These compounds' leaching and runoff could inevitably contaminate local groundwater and surface water supplies (Himu & Raihan, 2023). Water contaminated with these pollutants might result in waterborne illnesses including diarrhea. The World Health Organization estimates that 1.8 million people die from diarrheal illness each year (Kumar & Patyal, 2020).
Excreta from poultry contain uric acid, which is converted to volatile ammonia under certain conditions. Emissions of ammonia from poultry buildings contribute to the acidification of soils and water, and can have a negative impact on populations of acid-sensitive flora (Bist & Chai, 2022).

The spread of feed crop production into natural ecosystems has indirect repercussions such as ecosystem degradation and a biodiversity catastrophe (Rodić et al., 2011). Landscape Changes in land use, cropping intensity, and crop production technologies (for example, large-scale mechanisation) can alter the kind of landscape and the mosaic of land use, vegetation types, and habitats found in the environment. Such changes have an impact on biodiversity because they alter and destroy habitats (forests, grasslands, hedgerows, wetlands) and affect the numbers and compositions of biological species present. These changes can also have an impact on the landscape's aesthetic and amenity value, which may be culturally and historically significant. Such effects are becoming more recognized in prosperous advanced nations, and they are increasingly being considered in land-use planning and environmental legislation (Gerber et al., 2006).

The next sections of this article will explore how sustainable feed ingredients can address these challenges and pave the way for a greener future in poultry production.

3. Sustainable Feed Ingredients

Sustainability is a concept that refers to meeting the needs of the present without compromising the ability of future generations to meet their own needs. It encompasses the responsible use of resources, the protection of ecosystems, and the promotion of social and economic well-being (Vaarst et al., 2015). According to the Brundtland Commission, sustainability is a broad and aspirational policy goal which includes equally significant environmental, economic, social, and institutional factors (Valentin et al., 2000).

Sustainable feed ingredients are alternative feed supplies that are grown and used in methods that reduce environmental impact, conserve natural resources, and promote long-term ecological equilibrium. These ingredients are frequently generated from renewable resources, byproducts, or innovative production methods that lessen reliance on conventional, resource-intensive crops (Bist et al., 2024). Algae and microalgae, like spirulina and chlorella, are nutrient-rich and can be cultivated using CO_2 emissions, promoting carbon recycling. Single-cell proteins (SCP), derived from yeast, bacteria, and fungi, offer efficient and scalable protein sources (Leinonen & Kyriazakis, 2016). By providing innovative and environmentally responsible substitutes for conventional chicken feeds, sustainable feed ingredients lessen the negative effects of poultry farming on the environment.

3.1. Insect-Based Proteins:

Considering their nutritional value and possible environmental benefits, utilizing insects to feed poultry birds is a viable alternative when evaluating the sustainability of this type of farming (Leinonen & Kyriazakis, 2016).One innovative method and excellent example of a sustainable circular economy is the use of insects in the bioconversion of waste materials. While there is less competitiveness between feed and food, less land is needed to produce 1 kg of protein, and organic waste can be converted into high-value protein products (Sogari et al., 2019).

Insects have recently attracted a lot of interest as a vital supply of sustainable raw materials for animal feed, particularly for pigs, poultry, and fish. According to Sajid et al. (2023), the common house fly (Musca domestica, MD), the yellow mealworm (Tenebrio molitor, TM), and the black soldier fly (Hermetia illucens, HI) are the most promising species.

Insect meal has been shown to be a rich source of protein, amino acids (lysine, methionine), and minerals (calcium, phosphorus, zinc), with a high digestibility rate, making it a valuable feed ingredient for poultry production. Mealworms and black army fly larvae are examples of insects that are high in digestibility and high in protein (35–53%), vital amino acids, and minerals (Belhadj Slimen et al., 2023**)**.

For example, Sun et al. (2013) observed that male broilers grown on grassland with a high population of grasshoppers scored much higher on chewiness, flavor, scent, and overall enjoyment for the meat of the breast and thighs than a control sample raised on a maize–soybean diet.. However, there were no appreciable variations in color or juiciness between the two treatments. As the authors noted, it was challenging to determine whether the greater sensory qualities in their trial were brought about by the grasshopper meal or by the greater dietary variety and mobility provided in a free-range setting.

Image of Insects used in poultry nutrition, (Belhadj Slimen et al., 2023).

Insect farming is resource efficient, requiring less water and land than conventional feed production, resulting in a much lower ecological imprint (Khalifah et al., 2023). The use of insect protein sources in quail diets, such as the mopane worm (Gonimbrasia belina), has demonstrated possibilities in reducing dependency on conventional protein sources, especially fish and soybean meals, while meeting the growing demand for animal protein. With an average protein content of 55% and an appropriate amino acid composition, mopane worms are a very nutrient-dense feed item. (Sajid et al., 2023).

According to research, house fly larval meal can enhance broiler performance and substitute other protein sources without negatively affecting the carcass's qualities (Khalifah et al., 2023). Countries worldwide have houseflies (HF), which can be raised on food scraps and animal dung. Significant quantities of CP and CF, ranging from 40 to 64% and 2.5 to 28%, respectively, are present in HF meal (Table 1). As HF larvae age, their CP content falls but their CF content rises (51, 52). The two amino acids that restrict poultry nutrition the most are lysine and methionine. HF meal contains substantial levels of both of these amino acids (Belhadj Slimen et al., 2023). Allowing poultry to eat insects could reduce the amount of antibiotics used in the poultry industry, given the well-established harm that antibiotics cause to both humans and the environment (the emergence of drug-resistant bacterial species) (Bist et al., 2024).

4.0 Conclusion

The adoption of sustainable feed ingredients can address critical environmental issues, while ensuring food security for a growing global population. By integrating these innovative solutions, the poultry industry can transition toward more eco-friendly responsible practices, aligning with global sustainability goals. From an economic perspective, sustainable feed ingredients not only mitigate input costs in the long run but also open avenues for value-added market differentiation, catering to consumers increasingly demanding ethically produced and environmentally friendly animal products. Additionally, regulatory frameworks and industry incentives supporting sustainability in animal agriculture reinforce the need for proactive adoption of such practices.
Ultimately, the findings of this paper underscore the imperative role of sustainable feed strategies in shaping a resilient and environmentally conscious poultry sector. Rather than being an optional innovation, sustainable feed ingredients emerge as a fundamental necessity, paving the way for a more secure, efficient, and ecologically balanced food system.

The Role of Genomics in Improving Egg and Meat Production

Yusuf Shafiu Yusuf[1], Sibel CANOĞULLARI DOĞAN[1]

[1] Department of Animal Production and Technologies, Faculty of Agricultural Science and Technologies, Niğde Ömer Halisdemir University, Niğde/Türkiye

Abstract

Poultry breeding programs have been augmented with technologies such as genome-wide association (GWAS), marker-assisted selection, genomic prediction models, and genome editing (CRISPR/Cas9), creating significant advancement in productivity, resistance to diseases, and quality of products. The aim of this review is to discuss how genomics positively impacts various aspects of egg-and-meat production in poultry. The paper discusses genetic factors that influence traits of major importance, that is, growth rate, efficiency in feed conversion, muscle development, and egg-laying performance, emphasizing domestic breeding aided by molecular tools and bioinformatics as a strategy to accelerate genetic gain. Relevant findings on Norfa chickens, Japanese quail, and indigenous African poultry suggest that breeding strategies can be designed addressing both ecological constraints and economic demands. With beneficial changes, the review acknowledges some challenges, including source data complexity, the ethics of the matter, and the integration of genomic technologies into conventional breeding programs. The discoveries emphasize that meeting the increasing global demand for high-quality animal protein with utmost care for sustaining genetic diversity and resilience within poultry may call for a balanced approach combining state-of-the-art genomics with sustainable management practices.

Keywords: *Egg-meat, Genomics, molecular markers, Poultry.*

1.0 Introduction

There has been a steady increase in the global demand for animal proteins, so much so that the demand for milk and meat products is set to be at 1.25 billion tonnes by 2050 (Ritala et al., 2017) . The current increase in the search for better poultry breeding strategies for increased egg and meat production stems in part from this rising global demand (De Olde et al., 2020). As the human population increases, it applies greater pressure on the poultry industry to produce higher yields, while also regarding efficiency, sustainability, and animal welfare (Kleyn and Ciacciariello, 2021). So far, the traditional selective breeding techniques have brought dramatic improvements in genetic improvement among poultry species, pushing for improvements in productivity. However, these methods are based mainly on observable traits recorded on a long breeding cycle, which limits speed and accuracyy in genetic betterment. Proper genomics can revolutionize poultry breeding by precise genetic selection and better productivity and disease resistance.

Genomics is basically defined as the entire characterization of organisms at the level of their entire genetic makeup, and it provides many different aspects of very important insight into gene functions, interactions and its effects on economically relevant traits in poultry production (Xu et al., 2023). In fact, genomic instruments enable breeders to make genetic data-based decisions rather than phenotype driven decisions (Wolc et al., 2016). This marks a shift of superimposing phenotype-based selection toward genotype-based selection which optimizes growth rate, feed conversion efficiency, egg production, and meat quality genotype in rapid genetic gains in poultry, with further emphasis on long term genetic gain (Vanavermaete et al., 2020). With genome editing technologies like CRISPR/Cas9, genome changes can be made in livestock with efficient precision to improve desirable traits: increased milk yield or improved egg composition. A classic example is the knockout of β-lactoglobulin in dairy cattle producing milk that is hypoallergenic, but with a rich nutritional profile. These advancements greatly assist in meeting the soaring demand for food of animal origin while averting adverse environmental consequences (Yadav et al., 2024).

This review delineates research on genomics for improved egg and meat production across genomic selections, nutrigenomics, and genome-editing technologies. Through rigorous analysis and critique of research findings on the concerned subjects, this paper intends to give a clear view of the role and impact of genomics into nutrition quality, productivity, and resilience of egg and meat production against challenges presented by global food security.

2.0 Genomic Innovations in Poultry Breeding

Many modern breeding tools of genomics, such as genome-wide association studies (GWAS) and genomic selection, have opened the field to the identification and selection of better genetic lines on a much more pragmatic basis (Srivastava et al., 2020). GWAS analyses genetic differences across populations to identify genetic variants linked to important production traits. On the other hand, genomic selection applies high-density molecular markers

across the entire genome to predict an animal's breeding value with extremely high accuracy (Wolc et al., 2016; Ren et al., 2024). Compared to selection based on phenotype, genomic selection has massively boosted selection speed and accuracy in breeding programs (Vanavermaete et al., 2020). Consequently, the efficiency of poultry production has also been substantially increased. Enhancements in feed conversion ratio, assessment of skeletal development, and changes in hatchability have been attributed to genomic selection in a commercial context for overall profit in poultry production.

Improving flock health and reducing economic loss is another area where genomics comes in after productivity (Saxena and Kolluri, 2018). Poultry diseases, for example, avian influenza, Newcastle disease, and infectious bronchitis, are some of the most prominent threats to the industry, with mass mortality rates and economic blowbacks (Abdisa and Tagesu, 2017). Advances in genomic research have identified some specific markers for genetic resistance to these diseases so that poultry breeding for resistant strains can be carried out. Incorporating these markers into breeding programs have allowed breeders and poultry producers to boost the natural immunity of these birds (Cheng et al., 2013), minimizing the need for antibiotics and vaccines, which achieves two things; one is that it makes the birds mostly immune to these diseases and secondly by reducing the use of antibiotics it also reduces the cases of antimicrobial resistance, a pressing problem in the world today affecting both humans and animals (Köser et al., 2014).

Genomics influences characteristics such as tenderness, juiciness, and composition of fat on the meat because these are considered by consumers and therefore fall into market value (Leal-Gutiérrez et al., 2020). Transcriptomic analysis and expression profiling have helped researchers pinpoint the key genes involved in muscle development, lipid metabolism, and protein synthesis, for example, identifying the role of myostatin (MSTN) in muscle mass regulation and fatty acid-binding proteins (FABP) in intramuscular fat content that relates to tenderness of the meat (Bennett et al., 2019; Del Pino et al., 2020). Next, precision breeding methodologies are applied to increase the quantity and quality of poultry products while conserving genetic diversity (Huang et al., 2020).

Genomics has also played a role in egg production including laying performance, eggshell quality, and egg size (Li and Tian, 2018). Years of genetic studies have localized and mapped important regions in the genome associated with eggshell strength, yolk composition, and persistence in laying (Goto and Tsudzuki, 2017). New advances in functional genomics have broadened the understanding of genes that control reproduction efficiency, leading to the improvement of layers that have longer and more consistent laying cycles (Bain et al., 2016).

3.0 Genomics Tools and Technologies in Poultry Breeding

3.1 Molecular Genetic Approaches

The identification of candidate genes that determine major traits such as egg production, growth rate, and meat yield and has thus far been one of the most significant achievements in the field of genomics and a well-known molecular genetic approach. Radostina (2024) discussed molecular-genetic approaches in poultry breeding, stating that techniques like GWAS and microsatellite markers have been valuable accessions for establishing the association of genetic variants with traits of economic importance. GWAS, for example, enables the researcher to scan the whole genome for loci that are associated with desirable traits such as body weight or disease resistance (Ren et al., 2024). These findings build a sort of road-map for the breeders to select poultry with certain specific genetic traits relevant with market expectations. Breeders could further combine the genes in fine-tuning their selection programs, speeding up the breeding process and increasing the precision with which desirable traits are incorporated into new poultry lines (Radostina, 2024).

In the molecular genetic toolkit of poultry breeding, molecular markers play an indispensable role. These include microsatellites, single nucleotide polymorphism (SNP), and restriction fragment length polymorphism (RFLP) (Beuzen et al., 2000). Whereas microsatellites are very polymorphic and are good for genetic mapping, SNPs are very ubiquitous within the genome and are good markers of identifying the genetic variation (Miah et al., 2013).

4.0 Genetic Improvement of Egg Production in Poultry

One of the primary studies that has provided compelling evidence of genetic improvement in poultry emerges from research carried out at Menoufia University, where Norfa chickens were studied for over two generations with respect to the heritability and improvement of egg production traits. The experimental design involving the division of the base population into selected and control lines showed that further strategies of breeding aimed at egg production through a selection index method were able to enhance productivity significantly. Key management

practices such as feed adjustment and a lighting program based on "step down-step up" also played considerable roles in the optimization of laying performance in Norfa hens, indicating the equivalency of genetic versus environmental factors involved in poultry production.

In sharp contrast, a long-term study was also performed on Japanese quail (Nandanam quail-3) across six generations to improve egg production traits through a multi-stage selection process (Pandian et al., 2022). Here, the report showed that hen housed egg production had been significantly enhanced with an increase from 202 to 220 eggs over 40 weeks of laying, with a high goodness of fit ($R^2 = 0.97$). Notably, a negative correlation was exhibited between body weight and egg production traits, which, the multi-stage selection strategy successfully addressed, resulting in enhancement of both traits.

4.1 Indigenous Chicken Production and Disease Resistance

Research by Zhou et al. (2024) explored the enhancement of egg production traits in African village chickens, with an emphasis on resilience to Newcastle disease (ND). The Feed the Future Innovation Lab for Genomics to Improve Poultry developed a genetic selection platform designed to improve survival rates, reduce virus shedding, and enhance both growth rates and egg production in these chickens. Unlike the controlled breeding environments of the Norfa and Japanese quail studies, this research highlighted the challenges posed by real-world production systems, where disease resistance and adaptability to environmental stressors are critical. The study's findings suggest that integrating genetic selection for ND resistance with traditional vaccination and biosecurity measures offers a promising avenue for improving egg production in indigenous poultry lines.

4.2 Genome-Wide Association Study in Qingyuan Partridge Chickens

Another level of insight was brought into genetic improvement for egg production by the recent genome-wide association study (GWAS) done on Qingyuan partridge chickens (Kang et al. in 2024). The research identified MTA2 as a potential new candidate gene responsible for the egg laying rate in laying hens. Notably, this is the first time that this gene has been associated with traits for egg production in chickens. Further, one genomic-significant SNP and three chromosomal significant single nucleotide polymorphisms (SNPs) correlated with egg laying rate were found, indicating that whole genome resequencing is an efficient way to identify genetic markers accurately. The genetic enhancement of traits pertaining to egg production can be furthered by molecular genetics techniques.

5.0 Genetic Improvement of Meat Production in Poultry

Growth rate and feed conversion ratio (FCR) are two very economically relevant traits in broiler chickens. Selection programs have seen much progress in the improvement of these traits over the past several decades. Genetic factors concerning growth are associated with key regions of the chicken genome; comparatively, quantitative trait loci (QTL) studies indicate specific markers for faster weight gain and better feed efficiency (Cahyadi et al., 2014). For example, the insulin-like growth factor-I (IGF1) gene is vital for growth and feed utilization. By means of marker-assisted selection (MAS), the favourable alleles of IGF1 and similar genes can be incorporated by the breeder to improve growth performance without compromising health or reproductive traits (Dou et al., 2022).

Genomic selection, in addition to being based on estimated breeding values (EBVs), allows for multiple-trait advancement such as rapid growth with optimal FCR while avoiding adverse effects such as leg disorders or cardiovascular problems (Xu et al., 2020). Thus, the entire concept is about making genetic progress that will sustain the poultry producer and also be good for the bird (Fleming et al., 2007).

5.1 Muscle Development and Meat Quality

A key aspect of genetic enhancement in broiler chickens refer to muscle development and meat quality. Rapid growth is desirable but needs to be combined with the required texture, flavour, and tenderness of meat, according to consumer preferences (Mir et al., 2017). Many candidate myogenic genes and muscle fibre characteristics have been identified through advanced techniques in molecular genetics (Joo et al., 2013). For instance, the myostatin (MSTN) gene is one of the most prominent muscle regulators, and MSTN inhibition or downregulation can result in an increase in muscle mass—an indicator in the meat production feature. Expression of MSTN must be done carefully to eliminate problems such as muscle hypertrophy that adversely affect meat quality or animal welfare.

Additionally, genes regulating postmortem glycolysis in muscle pH, for example, AMP-activated protein kinase (AMPK) pathway genes, also play major roles in the tenderness of meat and water-holding capacity (Scheffler et al., 2011). Breeders can select for favourable variants of these genes to gain benefits from both yield and sensory quality of poultry meat.

5.2 Fat Deposition and Carcass Quality

As we understand it, fat distribution and carcass yield are the most important traits in broiler production, influencing processing efficiency and, hence, consumer satisfaction (Mir et al., 2017). According to Moreira et al. (2018), Genomics research has reported much of the genetic understanding of the mechanisms whereby fat is deposited and lean meat is produced, such that more accurate selection for these traits is now possible. The gene involved in peroxisome proliferator-activated receptor gamma (PPARG) marks the entry point in the regulation of adipogenesis, making mutations here consequential to the regulation of the balance between fat and muscle growth (Fredenrich and Grimaldi, 2004). Thus, breeders could increase the quality of carcasses by excluding alleles caused by excessive fat deposition, which leads to increased feed inefficiency. From GWAS, SNPs have been detected that were significantly associated with abdominal fat percentage and breast muscle yield, two of the major traits considered in the optimization of broiler carcass composition.

6.0 Challenges and Limitations of Genomic Applications

The sheer complexity of genomic data is one of the most remarkable technical barriers. The bulk of information produced by genomic sequencing makes its accurate analysis and interpretation rather tedious and, thus, tends to create delays and even possible misdiagnoses. Moreover, protein stability prediction—an important factor with respect to precision medicine—is still a challenging exercise mostly because of scant thermodynamic data and variability in experimental conditions. This lack of predictively accurate assays precludes the establishment of definitive therapeutic interventions pertaining to proteins for research use (Sanavia et al., 2020).

7.0 Conclusion

The genetic improvement of poultry production, whether for egg or meat yield, represents a remarkable convergence of traditional breeding practices and modern genomic technologies. It enhances productivity, disease resistance, and economic viability in poultry farming. Techniques like selective breeding, molecular genetics, and genome-wide association studies (GWAS) optimize egg and meat production traits, even in the face of environmental and disease-related challenges. However, challenges such as data complexity, ethical considerations, and organizational difficulties present challenges. As genomic technologies continue to evolve, their thoughtful application promises to shape a more efficient and resilient poultry industry, supporting global food security and economic development.

Abstract

Urban agriculture is fundamental to Nigeria's economy, as it addresses the pressing issues of food insecurity, rapid urbanization, and environmental degradation and promotes sustainable livelihoods, hence, this study assessed the utilization of urban agricultural practices in Osogbo metropolis. Specifically, it described the socio-economic characteristics of the respondents, identified the urban farming practices in the study area, as well as the level of utilization of these practices and constraints facing utilization of urban agricultural practices. To accomplish the objectives of the study, data was collected with the aid of a well-structured interview schedule and snowballing was used to generate a sampling frame and, consequently, random sampling to obtain 83 respondents as the sample size. Data collected was analyzed using frequency counts, percentages and mean while Pearson product moment correlation (PPMC) was used to test the hypothesis. Result revealed that Urban livestock is very popular in the study area, while Aquaponics and hydroponics attracted less attention. Women participated more in urban agricultural practices, as 60.2% of the respondents were female, also, respondents earned a substantial amount of money from urban agriculture. Regulatory restriction, Initial investment cost and Limited space were the constraints facing the utilization of urban agricultural practices. There was significant relationship between annual income ($r= 0.247$, $p= 0.024$) and level of utilization of urban agricultural practices. The study concluded that many urban dwellers in Osogbo metropolis practiced urban agriculture, such as urban livestock and culinary gardens, but faced problems of regulatory restrictions, initial investment cost and limited space. The study recommends that, the extension services of Osun State Agricultural Development Programme should be extended to those practicing urban agriculture, this will go a long way in improving and sustaining households' livelihoods.

Keywords: Urban**,** Agriculture**,** Urban Agriculture, Utilization**,** Urban Farming

Introduction

Urban agriculture can be referred to as small areas within cities, such as vacant lots, gardens, verges, balconies and containers, that are used for growing crops and raising small livestock or milk cows for own-consumption or sale in neighborhood markets (Poulsen *et al.,* 2015). However, the global urban population has been expanding rapidly over the last few decades, in early 2010s, half of the world's population was living in cities (The World Bank, 2014). This proportion is expected to reach 70 percent by 2050 mainly driven by the growing urbanization in the developing world, particularly in sub-Saharan Africa (SSA) (FAO, 2012; Poulsen *et al.,* 2015). By the end of the current decade, 24 of the world's 30 fastest growing cities will be African, and within 18 years, the urban population of SSA is projected to reach almost 600 million, twice how much it was in 2010 (FAO, 2012). As a result of this rapid urbanization, ensuring food security of urban residents has become a critical challenge (Poulsen *et al.,* 2015) and the focus of food insecurity has shifted and expanded from rural to urban areas (Davies *et al.,* 2020).

Urban Agriculture has a potential to increase food security in several ways (Poulsen *et al*., 2015). First, it may create easier and stable access to nutritious food for those households producing their own food (Binns *et al*, 2013). Secondly, household may be able to generate additional income by selling their products and hence improve their livelihood (Redwood, 2009). Third, it could help to improve food security of the community by increasing the total production output available in the market (Poulsen *et al*. 2015).

The urban mass exodus which is exacerbated by migrants of able-bodied men and youth leaving the disadvantaged groups (women, children, elderly, retired and people terminally ill) in the rural areas to perform agricultural operations with simple implements which cannot sustain their subsistence production let alone for supply to the cities (Adedayo and Tunde, 2012) had led to hunger and starvation in the land, hence, there is need to increase food production in urban space to meet up urban food requirement. Therefore, this study examined the utilization of Urban Agriculture in Osogbo metropolis, the study describes the socio-economic characteristics of the respondents; examined the level of utilization of urban agricultural practices and investigate the constraints facing utilization of urban agricultural practices in the study area.

Methodology

This study was carried out in Osogbo metropolis, in Osun state, Nigeria. This study makes use of a two-stage sampling technique, the first stage involved the purposive selection of three communities from the two local government areas that made up Osogbo and its environ, and that are well known with urban farming, the selected communities includes Oke-oniti, Oke-Bale and Oke-Ayepe. Snowballing was used to generate sampling frame and consequently random sampling to obtain 83 respondents as sample size.

Results And Discussion

Socio-Economic Characteristics Of The Respondents

Data presented in table 1 revealed the following information, 5% of the respondents fall under the age of 20 years, 38.4% were between the ages of 21-40 years, 36.0% were between the ages of 41-60 years of age, while 20.4% claimed to be above 60 years, as their mean age sum up to be 45.30. This is indicative that people that are full of vigor and strength are more involved in urban agriculture. Olofin (2006) established that farmers between 30 and 70 years of age undertake urban crop production. Also, 39.8% of the respondents were male, while 60.2% were female, this implies that women participated more in urban agricultural practices.

Table 1: Distribution of the respondents according to their socio-economic characteristics n=84

Socio-Economic Characteristics	Frequency	Percentage	Mean
Age (years)			
≤ 20	5	4.8	
21-40	32	38.4	
41-60	30	36.0	45.30
61 & above	17	20.4	
Sex			
Male	34	39.8	
Female	50	60.2	
Marital status			
Single	16	19.3	
Separated	3	2.4	
Divorced	2	2.4	
Widow	7	8.4	
Married	56	67.5	
Religion

No	39	47.0	
Yes	45	53.0	

Source: Field survey, 2024.

This result agreed with the findings of Paola (2003), who reported that women are more dominant in farming due to the fact that they are responsible in feeding the family, also table 1 further revealed that 67.5% of the respondents were married, 19.3% claimed to be single, 8.4% were widow while 3% were separated.
Furthermore, 57.8% of these respondents were Christians, 32.5% Muslims, while very few 8.4% claimed to be traditional worshipers, more than half, 56.6% of the respondents had tertiary education, 34.9% had secondary school education, while very few 8.4% had primary school education, this implies that the respondents in the study area are well learned. Also 35.3% of the respondents claimed farming and artisan as their secondary occupation, 26.5% claimed trading, 6.0% claimed transport services, while very few 2.4% were clergy. Also 43.4% of these respondents had up to 5 individuals in their household, 45.9% had between the 6- 9, while very few 10.8% had up to 9 individuals in their home.
Lastly table 1 revealed the annual income of the respondents from urban agriculture, 56.6% earned up to #300,000, also 31.2% earned between #300001,00 to #600,000, also 4.8% earned between #60001- #800,000, while 7.2% earned up to 800001 and above .Also 53.0% of the respondents claimed to belong to social organization.

Level Of Utilization Of Urban Agricultural Practices

The result presented in Table 2 showed the level of Utilization of Urban Agricultural practices among the respondents, the most utilized practice to the least utilized was rank using Weigh mean score. Urban livestock ranked first as the most utilize practice with a Weighted mean score of 1.80, Culinary gardens in second with a WMS of 1.39, Aquaponics ranked third with a WMS of 1.16, Backyard snail farming with a WMS of 0.69 ranked fourth, Hydroponics ranked fifth with a WMS of 0.36, while Community gardens and Seed libraries ranked least in sixth and seventh with a WMS of 0.25 and 0.22 respectively. This implied that among the selected agricultural practices, Urban livestock and Culinary gardens is the most utilized practices. This is in agreement with the findings of Olumba, *et al.,* (2021) who found poultry as the prominent livestock raised by urban farmers in Southeast Nigeria.

Constraints Facing Utilization Of Urban Agricultural Practices

The result presented in Table 3 showed the constraints facing utilization of Urban agricultural practices, the constraints was ranked from highest to least using Weighted mean score, Regulatory restriction ranked first with a WMS of 1.19, Initial investment cost ranked second with a WMS of 1.04, Limited space ranked third with a WMS of 0.96, Improper sewage disposal, Incomplete information about urban agriculture, Water access, Incomplete information, about urban agriculture, Inadequate equipment to practice, Lack of technical know-how, Limited access to extension services, Water quality were are ranked 4th, 5th, 6th, 7th, 8th, 9th,and 10th with a WMS of 0.88, 0.86, 0.84, 0.83, 0.83, 0.75, 0.53, and 0.14 respectively, while High cost of soil management ranked least in eleventh with a WMS of 0.05. This implies that majority of urban dwellers would have love to participate in urban agriculture, but face problem like Regulatory restriction and Initial investment cost, this may be so, because most of the urban areas in Nigeria are guiding by strict laws that might not permit these practices.

Table 2: Distribution of the respondents according to the Level of Utilization of Urban Agricultural practices

Practices *	Always utilized	Moderately utilized	Occasionally utilized	Not utilized	WMS	Rank
Urban livestock	29 (34.9)	30(36.1)	3(2.4)	22(26.5)	1.80	1st
Culinary gardens	17(20.5)	31(37.3)	3(2.4)	33(39.8)	1.39	2nd
Aquaponics	15(18.1)	23(27.7)	6(6.0)	40(48.2)	1.16	3rd
Backyard snail farming	6(6.0)	20(24.1)	2(2.4)	56(67.5)	0.69	4th
Hydroponics	3(2.4)	9(10.08)	6(7.2)	66(79.5)	0.36	5th
Community gardens	3(2.4)	5(6.0)	5(6.0)	71(85.5)	0.25	6th
Seed libraries	3(3.6)	3(3.6)	3(3.6)	75(89.2)	0.22	7th

Hypothesis Testing

Pearson product moment Correlation analysis of the relationship between the socio-economic characteristics of the respondents and level of utilization of urban agricultural practices.

Data presented in Table 4 shows that, there is a positive and significant relationship between annual income (r= 0.247, p= 0.024) and level of utilization of urban agricultural practices. This implies that the more the respondents realizes from this practices the more they engage in it, also this result means that irrespective of the standard of living of the respondents before engaging in urban agriculture, they considered their standard of living to have been better than others after engaging in urban agriculture. This finding agrees with that of Mupeta *et. al.* (2020), that the income of households that practiced urban agriculture increased from 13.7% to 19.1%. It implies that urban agriculture has the potential to improve household standard of living through enhanced income.

Table 4: PPMC showing the relationship between selected socio-economic characteristics of the respondents and level of utilization of urban agricultural practices

Variables	r- value	p- value	Remark
Age	0.126	0.257	Not significant
Academic qualification	0.042	0.707	Not significant
Annual income	0.247*	0.024	Significant

Source: Computed data, 2024.
*correlation is significant at the 0.05 level (2 tailed)

Conclusion And Recommendation

Based on this research findings, it can be concluded that, many urban dwellers were practicing urban agriculture such as urban livestock and culinary gardens and but faced problem of regulatory restrictions, initial investment cost as well as Limited space.

Form findings made during this research work, it is recommended that extension services of Osun State Agricultural Development Programme should be extended to those practicing urban agriculture. This will go a long way in improving and sustaining households' livelihoods.

Abstract

Surfactants are amphiphilic compounds known as surface-active agents. Due to this property, they accumulate at the interfaces of different phases and reduce the surface tension between these phases, facilitating their mixing and the formation of emulsions. Consequently, surfactants have widespread applications in detergents and cleaning products, the food industry, cosmetics and personal care products, the oil and gas industry, as well as in medicine and pharmaceuticals. However, these synthetic surfactants, which are chemically synthesized, have certain adverse effects on both the environment and human health. Therefore, biosurfactants, which are naturally synthesized by bacteria, fungi, and other microorganisms, have gained significant importance as alternatives to synthetic surfactants. Eco-friendly biosurfactants offer several advantages, including low toxicity, biodegradability, high biocompatibility, sustainable production, and stability under various conditions. Additionally, their diversity makes them a promising group of compounds for a wide range of industrial and biotechnological applications. This study aims to investigate the biosurfactant production potential of the Aeromonas caviae LipT51 strain. Biosurfactants are increasingly attracting interest in biotechnology due to their advantages, such as low toxicity, biodegradability, and environmental compatibility. In this study, *A. caviae* LipT51 was cultured in a medium containing olive oil to induce biosurfactant production. The presence of biosurfactant production was confirmed through various tests, including the Parafilm M test, oil spreading test, emulsification index (E24) measurement, CTAB agar method, hemolytic activity test, foam formation test, and phenol-sulfuric acid method. The results demonstrated that the produced biosurfactant exhibited surface-active properties, possessed emulsification capacity, and showed potential for biotechnological applications, including hydrocarbon bioremediation and antimicrobial activity.

Key Words: *Biosurfactant, Aeromonas caviae, surface active agents, biotechnology*

Aeromonas caviae ile Biyosürfaktan Üretimi

Özet

Sürfaktanlar, yüzey aktif maddeler olarak bilinen amfifilik bileşiklerdir. Bu özellikleriyle farklı fazlar arasındaki yüzeylerde birikir ve bu fazlar arasındaki yüzey gerilimini azaltarak bunların daha kolay karışmasını ve emülsiyon oluşumunu sağlar. Bu sayede sürfaktanlar deterjan ve temizlik ürünleri, gıda endüstrisi, kozmetik ve kişisel bakım ürünleri, petrol ve gaz endüstrisi, tıp ve ilaç endüstrisinde geniş kullanım alanlarına sahiptir. Ancak, kimyasal olarak sentezlenen bu sentetik sürfaktanlar çevresel ve sağlık açısından bazı olumsuz etkilere sahiplerdir. Bu yüzden, sürfaktanlara alternatif olarak genellikle bakteriler, mantarlar ve diğer mikroorganizmalar tarafından doğal olarak sentezlenen biyosürfaktanlar büyük önem kazanmıştır. Çevre dostu biyosürfaktanlar düşük toksisite, biyolojik olarak parçalanabilirlik, yüksek biyouyumluluk, sürdürülebilir üretim, farklı koşullarda kararlılık gibi avantajlara sahiptir. Ayrıca, biyosürfaktanların çeşitliliği, onları geniş bir endüstriyel ve biyoteknolojik uygulama yelpazesinde potansiyel olarak kullanılabilir bir bileşik grubu haline getirir. Bu çalışma ise *Aeromonas caviae* LipT51 suşunun biyosürfaktan üretim potansiyelini araştırmayı amaçlamaktadır. Biyosürfaktanlar, düşük toksisite, biyobozunurluk ve çevresel uyumluluk gibi avantajları nedeniyle biyoteknolojide giderek daha fazla ilgi görmektedir. *A. caviae* LipT51 zeytinyağı içeren besi ortamında kültüre edilerek biyosürfaktan üretimi gerçekleştirilmiştir. Parafilm M testi, yağ yayma testi, E24 emülsifikasyon indeksi ölçümü, CTAB agar yöntemi hemolitik aktivite testi, köpüklenme testi ve fenol sülfirik asit yöntemi ile biyosürfaktan üretimi doğrulanmıştır. Yapılan testler sonucunda, üretilen biyosürfaktanın yüzey aktif özellikler gösterdiği, emülsifikasyon kapasitesine sahip olduğu ve hidrokarbon bioremediasyonu, antimikrobiyal etkisi ile biyoteknolojik uygulamalar için potansiyel taşıdığı belirlenmiştir.

Anahtar Kelimeler: *Biyosürfaktan, Aeromonas caviae, yüzey aktif bileşikler, biyoteknoloji*

Giriş

Sürfaktanlar, yüzey aktif maddeler olarak bilinen bileşiklerdir ve hem hidrofilik (suyu seven) hem de hidrofobik (sudan kaçınan) bileşenlere sahip olmaları sayesinde farklı fazlar arasında yüzey gerilimini azaltma özelliği gösterirler. Moleküler yapılarındaki hidrofilik baş kısmı genellikle şeker, amino asit, fosfat, karboksilik asit veya alkol gibi polar fonksiyonel gruplardan oluşurken, hidrofobik kuyruk kısmı ise genellikle β-hidroksi yağ asitlerinin hidrokarbon zincirlerini içerir (Banat et al., 2010).

Amfifilik özellikleri nedeniyle sürfaktanlar, sıvı/katı, sıvı/gaz ve sıvı/sıvı (yağ/su) gibi farklı fazlar arasındaki yüzeylerde birikir ve bu fazlar arasındaki yüzey gerilimini azaltarak bunların daha kolay karışmasını ve etkileşime girmesini sağlar. Bu yüzey aktif özellikleri, onları evsel kullanımlarından endüstriyel süreçlere ve tarımsal uygulamalara kadar geniş bir kullanım alanına sahip çok yönlü kimyasal bileşikler haline getirmektedir (Pierre et al., 2025).

Kimyasal olarak sentezlenen sürfaktanlara alternatif olan biyosürfaktanlar da büyük önem taşır. Biyosürfaktanlar, bakteriler, mantarlar ve diğer mikroorganizmalar tarafından doğal olarak sentezlenen yüzey aktif biyomoleküllerdir ve düşük toksisite, biyolojik olarak parçalanabilirlik, çevresel uyumluluk gibi avantajlara sahiptir. Ayrıca, yüksek köpürme kapasitesi, seçicilik ve sıcaklık, pH ve tuzluluk gibi çevresel faktörlere karşı direnç gibi özellikleri ile endüstriyel ve çevresel uygulamalarda büyük bir potansiyel taşımaktadırlar (Adetunji, 2022; Kumar and Dubey, 2023; Kugaji et al., 2025).

Biyosürfaktanlar kimyasal sürfaktanlara kıyasla çevre dostu ve biyolojik olarak parçalanabilir olduklarından, özellikle son yıllarda sürdürülebilir alternatifler olarak büyük ilgi görmektedir. Su-yağ ara yüzeylerinde emülsiyonlar oluşturabilme, köpük stabilizasyonu, biyofilm inhibisyonu ve kirleticilerin uzaklaştırılması gibi özellikleri sayesinde çevresel, tıbbi ve endüstriyel birçok alanda yaygın şekilde kullanılmaktadırlar. Glikolipidler, lipopeptitler, fosfolipidler, yağ asitleri, lipidler, polimerik sürfaktanlar ve partikül sürfaktanlar gibi çeşitli alt gruplara ayrılan biyosürfaktanlar, sahip oldukları geniş substrat erişilebilirliği sayesinde ticari uygulamalarda önemli bir potansiyel sunmaktadır (Jahan et al., 2020).

Biyosürfaktanların sunduğu geniş fonksiyonel çeşitlilik, onları farklı endüstrilerde uygulama alanı bulabilen değerli bileşikler haline getirmektedir. Tarım, çevre, tıp, gıda ve petrol sanayisi gibi birçok sektörde kullanılan biyosürfaktanlar, antiviral, antifungal ve antibakteriyel etkileri nedeniyle sağlık ve kozmetik ürünlerinde de değerlendirilmektedir (Gürkök and Özdal, 2021; Ozdal et al., 2023; Kugaji et al., 2025).

Yağ-su emülsiyonlarının stabilitesini artırarak biyosürfaktanlar gıda ürünlerinin raf ömrünü uzatmada, margarin, dondurma, mayonez gibi emülsifiye gıdalarda kullanılabilir. Gıda patojenlerine karşı antimikrobiyal ve antibiyofilm özellikler göstererek doğal koruyucu ajan olarak işlev görebilir ve gıda güvenliğini artırırlar. Bu özellikleriyle ayrıca tarımda bitki hastalıklarına neden olan bazı mantar ve bakterilere karşı zararlı karşı biyolojik mücadelede kullanılabilirler. Emülsifiye edici özellikleriyle topraktaki besin maddelerinin biyoyararlanımını artırarak bitki büyümesini teşvik edebilir ve pestisit ve ağır metal gibi kirleticilerin topraktan uzaklaştırılmasına yardımcı olabilirler (Adetunji, 2022; Sharma et al., 2025).

Aeromonas caviae LipT51 suşu bir kaplıcadan izole edilmiş olup, yüksek sıcaklık ve alkali koşullara dayanıklı bir lipaz enzimi ürettiği bildirilmiştir. Bu çalışmada ise *A. caviae* LipT51'in zeytinyağı içeren besi ortamında biyosürfaktan üretiminin araştırılması amaçlanmıştır.

Materyal ve Yöntem

Bakteri Kültürü ve Besiyeri Koşulları

Aeromonas caviae LipT51 (GenBank ID: MN818567.1) daha önce tamamlanmış bir proje kapsamında Erzurum İli'ndeki bir kaplıcadan izole edilmiştir. *A. caviae* LipT51 suşu, nutrient agar besiyerine ekilerek 30 °C'de inkübe edilerek çoğaltılmıştır. Ön kültür, Nutrient Broth (NB) ortamında bir gece inkübe edilerek hazırlanmıştır. Biyosürfaktan üretimi için %1 zeytinyağı içeren NB besiyeri kullanılmış ve kültürler 30 °C'de, 180 rpm'de çalkalamalı inkübasyona tabi tutulmuştur. Ayrıca, %0,5, 1, 2 ve 5 konsantrasyonlarında zeytinyağı içeren besi ortamlarında geliştirilerek *A. caviae* LipT51'in biyosürfaktan üretimi üzerine yağ miktarının etkisi incelenmiştir.

Biyosürfaktan Üretimi ve Hasat

Kültürler dört gün boyunca inkübe edildikten sonra, biyosürfaktan analizleri başlatılmıştır. Biyosürfaktan varlığının tespiti için bakteri kültürleri 10.000 rpm'de 20 dakika santrifüj edilmiş ve analizlerde hücresiz kültür süpernatantı kullanılmıştır.

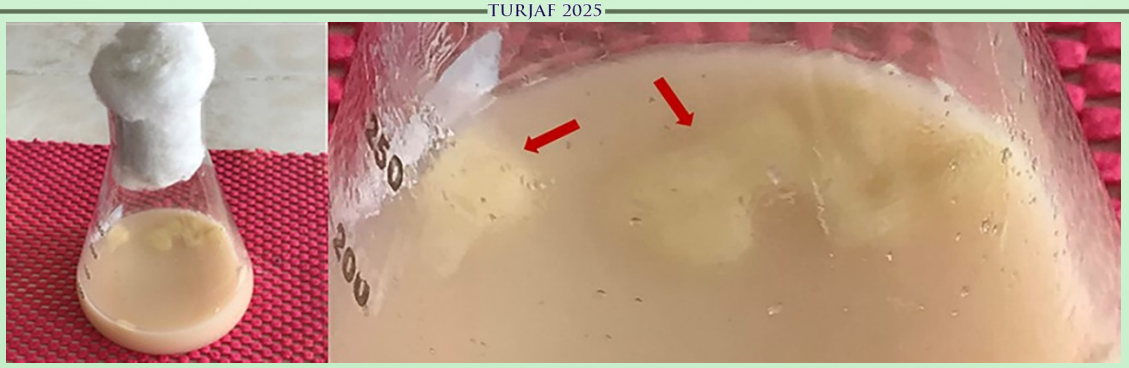
Biyosürfaktan Varlığının Analizi
Üretilen biyosürfaktanın yüzey aktif özelliklerini değerlendirmek için çeşitli testler uygulanmıştır. Bu analizlerde pozitif kontrol (+) olarak %1'lik SDS ve negatif kontrol (+) olarak distile su kullanılmıştır.

Parafilm M Testi
Biyosürfaktan varlığını değerlendirmek için kullanıllan parafilm M testinde kültür süpernatantından 25 µL alınarak parafilm yüzeyine damlatılarak yayılma özellikleri gözlemlenmiştir ve kontrol numuneleri ile karşılaştırılmıştır. Pozitif kontrol olarak %1'lik SDS ve negatif kontrol olarak distile su kullanılmıştır (Gurkok and Ozdal, 2023).

Emülsifikasyon İndeksi (E24)
Yağ-su arayüzünde emülsiyon oluşturma kapasitesini belirlemek için %1 zeytinyağında kültüre edilen A. caviae süpernatantı kullanılmış ve emülsiyon stabilitesi ölçülmüştür. Bir tüp içerisine 2 mL süpernatant ve 2 mL zeytinyağı konularak ve vorteksle 2 dakika boyunca iyice karıştırılmıştır. Ardından 24 saat dinlendirilmiştir. Süre sonunda E24 ölçümleri aşağıdaki denkleme göre hesaplanmıştır (Cooper and Goldenberg, 1987; Gurkok, 2022).
E24 (%)= (Emülsiyon tabakasının yüksekliği/Toplam yükseklik) x 100

Yağ yer değiştirme Testi
Biyosürfaktanın yağ yer değiştirme testi 9 cm çapa sahip petri kaplarında gerçekleştirilmiştir. 20 mL distile su petri kaplarına konuşmuş ve üzerine 500 µL zeytinyağı eklenerek bir tabaka oluşturulmuştur. Yağ tabakasının ortasına 15 µL kültür süpernatanı aktarılmıştır. Yağ tabakasının üzerinde oluşan zon çapı cetvelle ölçülmüştür (Morikawa et al., 2000). Zon çapı 0.5-0.9 cm ise '+', 1-1.5 cm ise '++', 1.5-2.1 cm aralığında ise '+++', 2.1 cm'den büyük ise '++++' olarak değerlendirilmiştir.

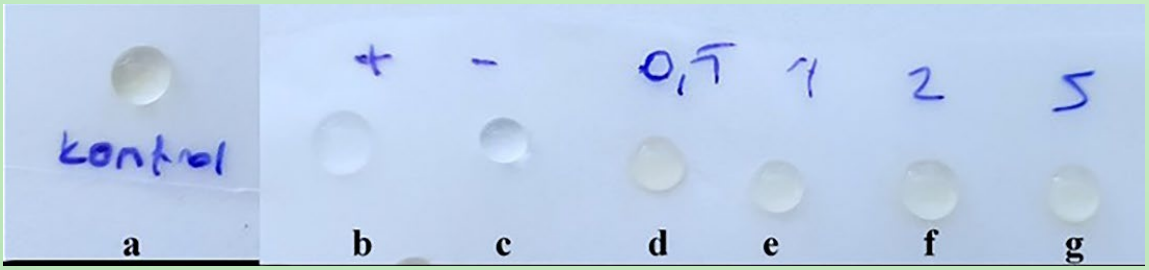
Hemolitik Aktivite Testi
A. caviae bakterisi kanlı agar (%5 koyun kanı içeren) petrilerine ekildi ve 37 °C'de 2-3 gün boyunca inkübe edildi. Sürenin sonunda kan hücrelerinin hemolizine bağlı olarak kolonilerin etrafında zon oluşumu izlendi (Mulligan et al. 1984; Gurkok, 2022).



Köpüklenme Testi
Biyosürfaktanın köpük oluşturma kapasitesini ölçmek için 5 mL kültür süpernatantı 2 dakika boyunca kuvvetli bir şekilde çalkalandı ve köpüklenme aşağıdaki denkleme göre hesaplandı (El-Sheshtawy & Doheim, 2014).
Köpüklenme (%) = Köpük yüksekliği / Toplam yükseklik x 100

Fenol-Sülfürik Asit Yöntemi
Karbonhidrat bazlı biyosürfaktan varlığını belirlemek amacıyla gerçekleştirilmiştir. *A. caviae* LipT51 kültür süpernatantından 400 µL alınarak, 200 µL fenol ve 1000 µL H_2SO_4 ile karıştırılmıştır. Karışım soğutulduktan sonra spektrofotometrede 480 nm'de optik yoğunlukları (OD) ölçülmüştür. Karbonhidrat miktarı 0-150 mg/L konsantrasyon aralığında hazırlanan ramnoz standart eğrisi kullanılarak hesaplanmıştır (Ozdal et al., 2017).

Atık Ayçiçek yağı ile Biyosürfaktan Üretimi
Hem daha ekonomik biyosürfaktan üretimi elde etmek hem de atık maddelerin değerlendirilmesi amacıyla farklı miktarlarda (%0,5, 1, 2, ve 5) atık ayçiçek yağı içeren kültürlerdeki biyosürfaktan üretimleri araştırılmıştır. Fenol sülfrik asit yöntemiyle miktar tayini gerçekleştirlmiştir.



Bulgular ve Tartışma

***A. caviae* LipT51 ile biyosürfaktan üretimi**
A. caviae LipT51'in %1 zeytinyağı içeren NB besiyerinde inkübasyonu sonucunda Şekil 1'de görüldüğü gibi kültür yüzeyinde bazı metabolik ürünlerin biriktiği, santrifüj edildiğinde kolaylıkla çökmediği ve SDS gibi kimyasal sürfaktantlara benzer yüzey aktivitesi gösterdiği görülmüştür.

Şekil 1. %1 zeytinyağı içeren NB besiyerinde gelişen *A. caviae* Lip51 kültür yüzeyinde gözlemlenen yüzey aktif madde

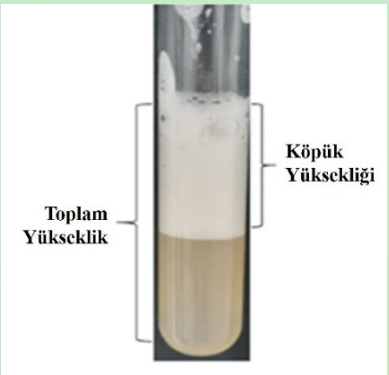
A. caviae LipT51 ile biyosürfaktan üretimi öncelikle parafilm-M testi kullanılarak incelenmiştir. Şekil 2'de görüldüğü gibi, %0,5, 1, 2 ve 5 oranlarındaki zeytinyağlı besi ortamlarında büyütülen *A. caviae* LipT51 kültüründen elde edilen süpernatantların parafilm yüzeyinde yayılma gösterdiği tespit edilmiştir. Buna karşın, negatif kontrol grubunda ve yağ içermeyen (%0) kontrol kültüründe herhangi bir yayılma gözlenmemiştir.

Şekil 2. Parafilm M testi. Kontrol besiyeri (a), pozitif kontrol SDS (b), negatif kontrol H_2O (c) ile %0,5 (d), %1 (e), %2 (f), ve %5 (g) zeytinyağı içeren besiyerinde gelişen *A. caviae* LipT51 süpernatantı

A. caviae LipT51 süpernatantı kullanılarak gerçekleştirilen yağ yayma testi sonucunda Şekil 3'de gösterildiği üzere, kültür süpernatantı hem petri yüzeyine yerleştirilen zeytinyağı hem de motor yağı üzerinde yayılma sağlamıştır. Buna ek olarak, farklı yağ konsantrasyonlarının etkisini değerlendirmek amacıyla %0,5, 1, 2 ve 5 zeytinyağı içeren besi ortamlarında geliştirilen *A. caviae* LipT51 kültürüne ait süpernatantlarla yağ yayma testi gerçekleştirilmiştir. Test sonucunda, biyosürfaktan varlığına bağlı olarak oluşan şeffaf zon çapları ölçülerek Tablo 6'da sunulmuştur. Kontrol grubunda herhangi bir yağ yayılması gözlemlenmezken, en yüksek yağ yayma aktivitesi %2 ve %5 oranında zeytinyağı içeren ortamlarda tespit edilmiştir.

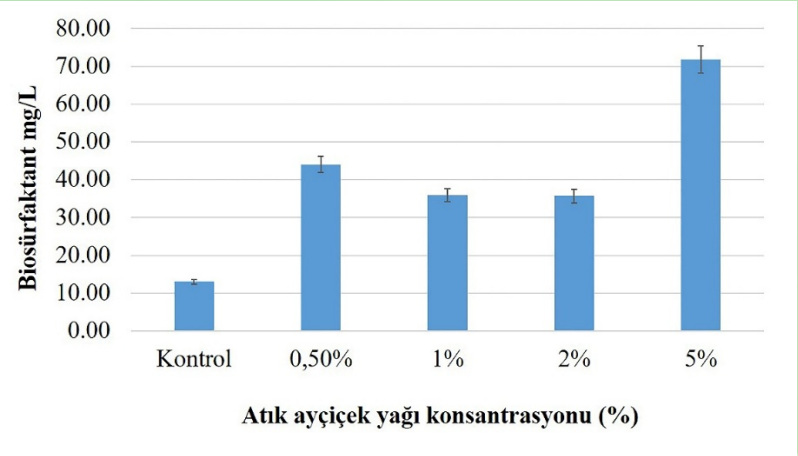
Tablo 1. Farklı zeytinyağı içeren besiortamlarında gelişen *A. caviae* LipT51 kültür süpernatantlarının yağ yayma aktivitesinin ve zon çaplarının belirlenmesi

Numune	Zon Çapı (cm)	Yağ Yayma Aktivitesi
Kontrol	0	-
%0.5 Zeytinyağı	1.2	++
%1 Zeytinyağı	1.7	+++
%2 Zeytinyağı	2.3	++++
%5 Zeytinyağı	2.8	++++



Kanlı agar petrisi üzerinde gelişen *A. caviae* LipT51'in kolonileri etrafında oluşturduğu şeffaf zon Şekil 3'de gösterilmiştir. *A. caviae* LipT51'in hemolitik aktiviteye sahip olması eritrositlerin hemolizine neden olan biyosürfaktan maddenin üretiminin bir göstergesi olarak değerlendirilmiştir.

Şekil 3'de kanlı agar petrisinde gelişen *A. caviae* LipT51 kolonilerinin çevresinde oluşan şeffaf zon gösterilmiştir. Bu şeffaf alan, bakterinin hemolitik aktiviteye sahip olduğunu ve eritrositlerin hemolizine neden olan biyosürfaktan üretiminin bir göstergesi olarak değerlendirilmektedir.



Şekil 3. Kanlı (%5 koyun kanı) agar üzerinde *A. caviae* LipT51'in hemolitik aktivitesi

Köpük testi sonuçlarına göre, Şekil 4'te gösterildiği gibi, zeytinyağı içeren numunelerde %56 oranında belirgin bir köpük oluşumu gözlemlenmiştir. Buna karşın, kontrol grubunda herhangi bir köpüklenme meydana gelmemiştir, bu da biyosürfaktan üretiminin varlığını destekleyen önemli bir bulgu olarak değerlendirilmiştir.

Şekil 4. %1'lik zeytinyağı içeren ortamda geliştirilen A. caviae süpernatatının köpük yüksekliği ölçümü

Biyosürfaktan miktarının belirlenmesinde kullanılan fenol-sülfürik asit yöntemi kapsamında, öncelikle standart bir L-ramnoz kalibrasyon eğrisi oluşturulmuştur. Daha sonra farklı miktarlarda (%0,5, 1, 2, ve 5) atık ayçiçek yağı içeren kültürlerdeki biyosürfaktan üretimleri karşılaştırılmıştır. Elde edilen standart eğriye göre yapılan hesaplamalara göre en yüksek biyosürfaktan üretimi Şekil 5'te görüldüğü üzere %5 atık ayçiçek yağı içeren kültürde elde edilmiştir.

Şekil 5. Farklı atık ayçiçek yağı konsantrasyonlarının biyosürfaktan üretimine etkisi

Gerçekleştiren analizler sonucunda *A. caviae* LipT51 suşunun biyosürfaktan ürettiği belirlenmiş ve yapılan testlerde yüzey aktif özellikler sergilediği görülmüştür. Parafilm M testi ve yağ yayma testi sonuçları biyosürfaktan varlığını doğrulamıştır. E24 emülsifikasyon indeksi, biyosürfaktanın emülsiyon oluşturma yeteneğini gösterirken, CTAB agar yöntemi ile glikolipid yapısındaki biyosürfaktanların varlığı tespit edilmiştir. Ayrıca, hemolitik aktivite testi pozitif sonuç vermiş ve biyosürfaktanın biyolojik aktivite gösterdiği belirlenmiştir. Köpüklenme testi sonuçları, biyosürfaktanın stabil köpük oluşturma kapasitesine sahip olduğunu ortaya koymuştur.

Bu bulgular, *A. caviae*'nin biyosürfaktan üretiminde etkili bir mikroorganizma olabileceğini ve biyoteknolojik uygulamalarda değerlendirilebileceğini göstermektedir. Özellikle çevresel biyoremediasyon, petrol kirliliğinin giderilmesi, tarım, gıda ve farmasötik endüstrilerinde biyolojik ajan olarak *A. caviae* kaynaklı biyosürfaktanın önemli bir potansiyel taşıdığı görülmektedir. Gelecekte yapılacak çalışmalarda, biyosürfaktan üretim verimliliğini artırmak, biyosürfaktanın kimyasal yapısını analiz etmek ve antimikrobiyal özelliklerini araştırmak üzerine olacaktır.

Teşekkür
Bu makale, Sümeyra Gürkök tarafından yönetilen "*Aeromonas caviae* ile Biyosürfaktan Üretimi ve Biyosürfaktanın Biyoteknolojik Kullanım Alanlarının Araştırılması" başlıklı yüksek lisans tezinden üretilmiştir. (Yüksek Lisans Tezi, Atatürk Üniversitesi, Erzurum/Türkiye, 2025). Bu araştırma Atatürk Üniversitesi Bilimsel Araştırma Projeleri Koordinasyon Birimi tarafından [FYL-2024-13379] numaralı proje kapsamında desteklenmiştir.

Effect of stocking density on crablets nursing performance and assessment of growth comparison between wild-sourced and hatchery-sourced juvenile crabs

Md. Masudul Haque, Anirban Sarker, Shilpi Saha, Akond Mohammad Rafiqul Islam, Mohammad Abdul Baki*

*Correspondence: Mohammad Abdul Baki, Professor, Department of Zoology, Jagannath University, 9-10 Chittaranjan Ave, Dhaka-1100, Bangladesh; Email: mabaki@gmail.com

Mud crab (*Scylla olivacea*) farming has gained popularity in Bangladesh but most farmers depend on wild juveniles for stock establishment. This dependency on wild sources for juvenile crabs is the key challenge for sustainable crab aquaculture. Hence, this study aims to assess the effect of stocking densities on the growth and survivability of crablets in the nursing pond and the growth comparison of wild and hatchery-sourced juvenile crabs in farming ponds. Thus, two separate experimental trials were conducted in a Randomized Complete Block design to determine the effective stocking density for crablets nursing and to compare the performance of wild and hatchery-sourced juveniles for aquaculture practices. Three different stocking densities (T1=1000 ind/decimal, T2=1500 ind/decimal, and T3= 2000 ind/decimal) were treated for seven weeks for the first experiment to compare the result of growth variables (body weight, carapace width, carapace length, and abdominal width) and survivability percentages. The study results showed that growth variables and survivability rate varied significantly ($p < 0.05$) in different weeks. However, at harvest, the highest body weight (27.33 ± 1.53 g), carapace width (55.17 ± 1.04 mm), carapace length (41.67 ± 0.58 mm) abdominal width (25.50 ± 0.50 mm), and survivability rate (58.10%) was observed at T1 stocking density. However, the highest survivability 60.67% was observed with hatchery-sourced juvenile crabs. The study explored that stocking density T1(1000 ind/decimal) is the most suitable density for crablets nursing in ponds, and the hatchery-sourced juvenile was better than that of wild-sourced juvenile for crab aquaculture practices.

Tabe 1. Effects of stocking densities on growth and survivability performance of crablets at harvest

Stocking Density	Body Weight (g)	Carapace Width (mm)	Carapace Length (mm)	Abdominal Width (mm)	Survivability (%)
T1	27.33 ± 1.53a	55.17 ± 1.04a	41.67 ± 0.58a	25.50 ± 0.50a	58.10 ± 3.35a
T2	24.63 ± 0.55b	51.67 ± 1.15b	38.67 ± 1.53b	24.67 ± 0.29b	49.24 ± 3.18b
T3	22.73 ± 0.23c	50.16 ± 2.02b	37.50 ± 0.50b	23.50 ± 0.87c	42.30 ± 3.13c

Spatiotemporal Charactheristics in Climatic Extremes over Agricultural Lands in Türkiye

Serhan Yeşilköy[1,2,3]

[1] USDA-ARS, Adaptive Cropping Systems Laboratory, Beltsville/MD, USA
[2] Oak Ridge Institute for Education and Science, Oak Ridge/TN, USA

Abstract

In recent years, heatwaves have developed into a phenomena that is growing more prevalent and severe on a worldwide scale. The issues of public health, agriculture, water supplies, and other environmental concerns are all significantly impacted by these heatwaves. The frequency, duration, and intensity of heatwaves have all been shown to have significantly increased, according to statistical data, both worldwide and regionally. Heat stress poses a threat to lives and livelihoods all across the world, particularly in the agricultural sector. By causing decreasing yields and a reduction in food quality, it exacerbates the water scarcity that already exists. Greater strain is being placed on water supplies as heatwaves exacerbate drought conditions, decrease the amount of water that is accessible, and raise the danger of wildfires. There are disruptions that occur in ecosystems, such as the loss of biodiversity and the deterioration of habitat systems. The frequency and duration of heatwaves in Mediterranean Basin are increasing. Across the country, there has been a notable increase in the number of heatwaves, and air temperatures have exceeded records in a number of different places. In a warming climate, it is projected that heatwaves would grow more frequent, stay longer, and extend across greater geographical regions. This is a cause for concern since it indicates that heatwaves will become more commonly occurring. In this study, using the most recent climate projections, the number of heatwave episodes that occurred across agricultural lands in Turkey as well as their length will be provided.

Effect on Germination of Mung Beans (*Vigna radiata* W.) Using Different Methods of Seed Priming

Anita Bhandari, Tirth Narayan Yadav, Ajita Pokhrel, Abhisek Shrestha

College of Natural Resource Management, Bardibas
Corresponding author: aneetaxettri02@gmail.com

Abstract

The productivity of mung beans (*Vigna radiata W.*) is harshly affected by patchy plant stand due to uneven seed germination. Seed priming can improve crop emergence and establishment, which are thought to be the primary causes of crop success. Thus,the study was to investigate the effect of priming agents on mung beans. The experiment was conducted under laboratory conditions at College of Natural Resource Management, Bardibas, Mahottari, Nepal. This research consisted of 6 treatments (T1; control, T2; 5% cow urine solution, T3; tap water, T4; 5% Moringa leaf extract solution, T5; 5% Neem leaf extract solution, and T6; 5% Aloe Vera sap solution) with 3 replication and laid out in complete randomized design (CRD). The seeds were soaked for 24 hours in priming solution and dried for 2 hours at room temperature before sowing. The germination diversity parameters (i.e. speed of germination, germination %, root length, shoot length, dry weight, seed vigour index 1, seed vigour index 2) were recorded and analyzed using Gen-Stat Ver.2015. The data revealed that all germination parameters of mung beans were highly affected by seed priming. The highest germination % (85.55%), dry weight (0.2180 gm), seed vigor index 1 (1942 cm) and seed vigor index 2 (1.865 gm) were observed in 5% Aloe Vera sap solution. Highest speed of germination (22.75 seeds/day) was observed in 5% cow urine solution followed by 5% Aloe Vera sap solution i.e. (22.43 seeds/day). The highest root length (5.04 cm) was recorded in 5% Neem leaf extract solution and shoot length (19 cm) in 5% Moringa leaf extract solution. Seed priming using aloe vera sap solution was found effective in mung beans to increase germination, crop establishment, seed and seedling vigor. In conclusion, this priming should be conducted in farmer's field condition for validation of the results.

The Impact of Carbon Emissions on the Agricultural Sector: A Comparative Analysis of Turkey and the European Union

Sema Ezgi YÜCEER[1], Sibel TAN[2]

[1]Department of Agricultural Economics, Faculty of Agriculture, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye
[2]Department of Agricultural Economics, Faculty of Agriculture, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye

Abstract

This study examines the effects of agricultural value added, producer price index, fertilizer and energy consumption, and land surface temperature change on carbon emissions from the agricultural sector in Turkiye and the European Union (EU) countries. Using regression analysis, the determinants of agricultural carbon emissions were identified, and the differences between Turkiye and the EU were highlighted. The dataset covers the period from 2000 to 2022. The results reveal that in Turkiye, the agricultural producer price index, fertilizer use, and land surface temperature change have statistically significant positive effects on agricultural carbon emissions. In contrast, in the EU, the producer price index reduces emissions, while fertilizer use contributes to an increase. In both models, the positive impact of input use on emissions underscores the necessity of adopting sustainable production practices. The findings suggest that Turkiye should promote low-carbon agricultural approaches in alignment with the objectives of the European Green Deal.

Key Words: *Carbon emissions, Agricultural sector, EU–Turkiye comparison*

Karbon Emisyonlarının Tarım Sektörü Üzerine Etkileri: Türkiye-AB Karşılaştırması

Özet

Araştırmada, Türkiye ve Avrupa Birliği (AB) ülkelerinde tarımsal katma değer, üretici fiyat endeksi, gübre ve enerji kullanımı ile kara üzerindeki sıcaklık değişiminin; tarım sektöründen kaynaklanan karbon emisyonları üzerindeki etkileri incelenmiştir. Regresyon analizi ile karbon emisyonlarının belirleyicileri incelenerek, Türkiye ve AB arasındaki farklılıklar ortaya konulmuştur. Çalışmada değişkenlere ait veriler 2000-2022 dönemini kapsamaktadır. Türkiye'de tarımsal üretici fiyat endeksi, gübre kullanımı ve kara üzerindeki sıcaklık değişiminin tarımsal karbon emisyonlarını istatistiksel olarak anlamlı şekilde artırdığı tespit edilmiştir. Avrupa Birliği'nde ise tarımsal üretici fiyat endeksi karbon emisyonlarını azaltıcı yönde etkilerken, gübre kullanımı emisyonları artırıcı etki göstermiştir. Her iki modelde de tarımsal girdi kullanımının emisyonlar üzerindeki artırıcı etkisi, sürdürülebilir üretim tekniklerinin benimsenmesinin gerekliliğini ortaya koymaktadır. Elde edilen bulgular, Türkiye'nin Avrupa Yeşil Mutabakatı hedefleri doğrultusunda düşük karbonlu tarım uygulamalarını yaygınlaştırması gerektiğine işaret etmektedir.

Anahtar Kelimeler: *Karbon emisyonu, Tarım sektörü, AB-Türkiye karşılaştırması*

Giriş

İklim değişikliği ve çevresel bozulma, sadece Avrupa'nın değil, küresel ölçekte tüm dünyanın karşı karşıya olduğu en büyük tehditlerden biri haline gelmiştir (European Union EUR-Lex, 2025). Bu bağlamda, tarım sektöründe sera gazı emisyonlarının azaltılması, küresel ısınmayı 1,5 °C ile sınırlama hedefine ulaşmak açısından kritik öneme sahiptir (Van Hoof, 2023). Avrupa Birliği (AB), tarım sektörünün iklim değişikliğine etkisini azaltmak amacıyla uzun yıllardır Ortak Tarım Politikası (OTP) kapsamında çeşitli reformlar uygulamaktadır. Avrupa bütünleşmesinin ilk yıllarında tarımsal üretimi artırma ve tarımı yeniden yapılandırma amacıyla başlatılan OTP, günümüzde AB'nin en uzun soluklu politikası haline gelmiş; çiftçilere, kırsal alanlara ve tarım-gıda sistemine ekonomik, sosyal ve çevresel açılardan destek sağlamaya devam etmiştir. 2021–2027 döneminde AB bütçesinin %31'i OTP'ye ayrılmıştır (European Union EUR-Lex, 2025). 2023 yılı itibarıyla yürürlüğe giren OTP'nin altıncı büyük reformu, sürdürülebilir tarımı desteklemeyi, küçük ölçekli çiftliklere hedefli destek sunmayı ve üye devletlere yerel koşullara uygun esneklik tanımayı amaçlamaktadır. Bu reformla birlikte, AB vatandaşları için istikrarlı, güvenli ve sağlıklı bir gıda arzı sağlanması hedeflenmiş; daha adil, daha yeşil ve performansa dayalı bir OTP oluşturulmuştur. Tarım ve kırsal alanlar, Avrupa Yeşil Mutabakatı'nın temel bileşenleri arasında yer almakta; OTP, çiftlikten çatala ve biyolojik çeşitlilik stratejilerinin hedeflerine ulaşmada anahtar bir araç niteliği

taşımaktadır (European Union EUR-Lex, 2025). Benzer şekilde, Türkiye'de iklim değişikliğiyle mücadelede iddialı hedefler belirlemiştir. 2012 yılını baz alarak güncellediği Birinci Ulusal Katkı Beyanı'nda Türkiye, 2030 yılına kadar sera gazı emisyonlarını %41 oranında azaltmayı taahhüt etmiştir. Bu hedef, 2030 yılı itibarıyla emisyonların 695 Mt CO2 eşdeğeri seviyesinde olmasını öngörmektedir. Türkiye'nin beyanı, azaltım ve uyum eylemlerini içeren kapsamlı bir planı ortaya koymakta; emisyonların en geç 2038 yılında zirve yapması ve 2053 itibarıyla net sıfır seviyesine ulaşılması hedeflenmektedir (Türkiye Cumhuriyeti Güncellenmiş Birinci Ulusal Katkı Beyanı, 2023).

Tarım sektöründe Türkiye, 2030 yılına kadar karbon emisyonlarını azaltmak için çeşitli stratejiler benimsemiştir. Bu kapsamda, hayvan yemi rasyonlarının düzenlenmesi, biyogaz tesislerinin etkin kullanımı ve gübre yönetiminin iyileştirilmesiyle metan emisyonlarının azaltılması; bitkisel üretimde ise azotlu gübre kullanımının azaltılması, baklagil ekiminin teşvik edilmesi ve optimum gübre kullanımının sağlanması hedeflenmektedir. Ayrıca, pirinç üretiminde yüzey altı sulama sistemlerinin geliştirilmesi, tarımsal biyokütleden enerji üretiminin artırılması ve toprak koruma uygulamalarının yaygınlaştırılması planlanmaktadır. Bu önlemlerin yanı sıra çiftçilere sürdürülebilir tarım uygulamaları konusunda eğitim verilmesi ve su yönetimi ile tahsis planlarının geliştirilmesi yoluyla tarım sektörünün iklim değişikliğine uyumu desteklenecektir (Türkiye Cumhuriyeti Güncellenmiş Birinci Ulusal Katkı Beyanı, 2023).

AB'nin 2023–2027 OTP dönemi hedefleri arasında, sera gazı emisyonlarının azaltılması, karbon tutulmasının artırılması ve sürdürülebilir enerjinin teşvik edilmesi yer almakta; bu hedefler aracılığıyla hem iklim değişikliğinin hafifletilmesine hem de uyum sağlanmasına katkı sunulması amaçlanmaktadır (European Commission, 2025). Benzer şekilde Türkiye de tarım sektörüne yönelik sera gazı azaltımını, kapsamlı politikalarıyla desteklemektedir. Ancak, AB OTP aracılığıyla daha yapısal ve merkezi finansman mekanizmaları yürütürken, Türkiye'nin uygulamaları daha çok sektörel projeler etrafında şekillenmektedir.

Türkiye ve Avrupa Birliği (AB) ülkelerinde tarım sektörüne ilişkin ekonomik göstergeler ile çevresel değişkenlerin tarımsal karbon emisyonları üzerindeki etkilerini ortaya koymak çalışmanın amacıdır.

Materyal ve Yöntem

Çalışmanın ana materyalini ikincil veriler oluşturmaktadır. Araştırmada kullanılan Türkiye Avrupa Birliği (27 ülke) ülkelerine ait 2000-2022 yılları arasında Birleşmiş Milletler Gıda ve Tarım Örgütü (FAO) tarafından sağlanan veriler kullanılmıştır. Çoklu regresyon analizinde kapsamında kullanılan değişkenler şu şekildedir:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \varepsilon$$

Y : Tarımsal karbon emisyonu (CO2-eq, kt)
β_0: Sabit terim
X_1: Tarımsal katma değer (milyon USD)
X_2: Tarımsal üretici fiyat endeksi (2014-2016=100)
X_3: Tarımsal girdi kullanımı (NPK gübre tüketimi, ton)
X_4: Tarımsal enerji kullanımı (TJ)
X_5: Kara üzerindeki sıcaklık değişimi (°C)
ε: Hata terimi.

Karbon yoğunluğu (kg CO_2-eq / milyon USD), tarımsal katma değer başına düşen sera gazı emisyonlarını hesaplamak için kullanılmıştır. Karbon yoğunluğu şu formülle hesaplanmıştır:

$$\text{KY} = \frac{E}{TKD}$$

KY = Karbon yoğunluğu (kg CO_2-eq / milyon USD),
E = Toplam tarımsal karbon emisyonları (kiloton CO_2-eq),
TKD = Tarımsal Katma Değer (milyon USD, sabit fiyatlarla).

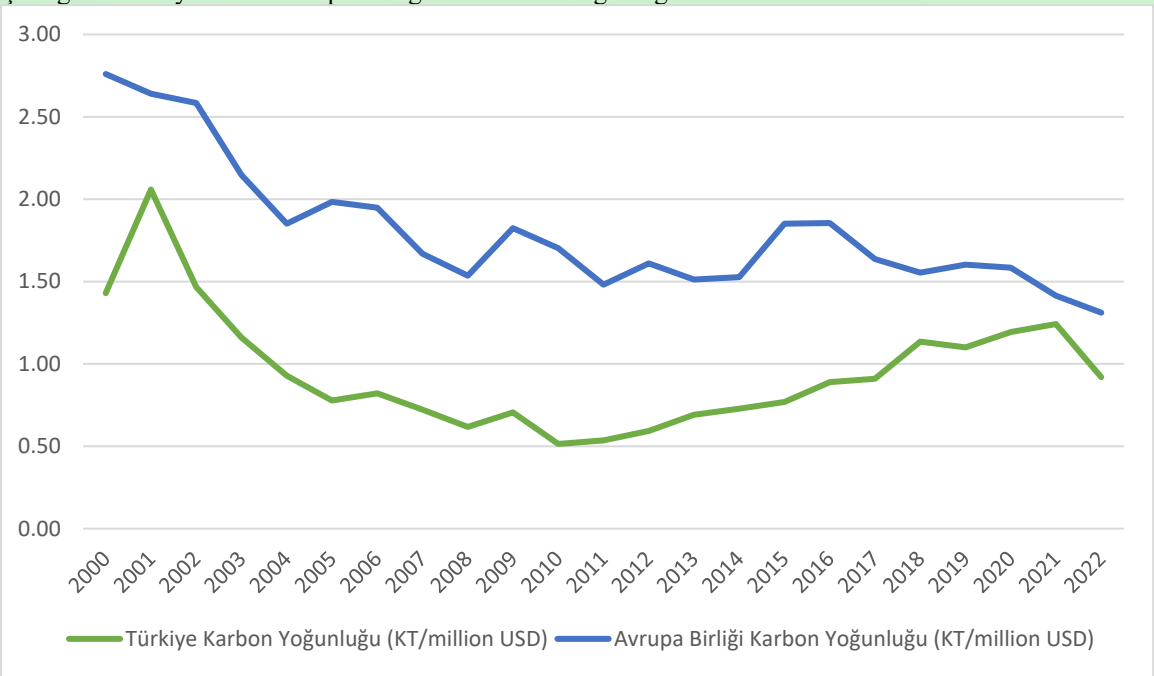
Bu yöntemle hesaplanan karbon yoğunluğu, tarım sektörünün ekonomik çıktısı başına ürettiği sera gazı miktarını göstererek Türkiye ve Avrupa Birliği (AB) arasındaki çevresel etkinliği karşılaştırmaya olanak tanımaktadır.

Bulgular ve Tartışma

Araştırma verileri ile tarımsal karbon emisyonlarını etkileyen faktörler regresyon analizi ile açıklanmaya çalışılmıştır. Modelde bağımlı değişken olarak tarımsal karbon emisyonu Y ($CO_{2\text{-eq}}$, kt); bağımsız değişkenler olarak ise tarımsal katma değer X_1 (milyon USD), Tarımsal üretici fiyat endeksi X_2 (2014-2016=100), tarımsal girdi kullanımı X_3 (NPK gübre tüketimi, ton), Tarımsal enerji kullanımı X_4 (TJ), kara üzerindeki sıcaklık değişimi X_5 (°C) alınmıştır. Regresyon analizi sonucunda hesaplanan modeller şu şekildedir:

Türkiye için;

$$Y = 16233{,}938 - 0{,}044X_1 + 29{,}766X_2 + 0{,}011X_3 - 0{,}017X_4 + 3160{,}380X_5 + \varepsilon$$



Avrupa Birliği için;

$$Y = 380207{,}455 - 0{,}095X_1 - 313{,}416X_2 + 0{,}002X_3 + 0{,}970X_4 + 963{,}935X_5 + \varepsilon$$

Türkiye'de ve Avrupa Birliğinde karbon yoğunluğu Çizelge 1'de verilmiştir. Türkiye'de tarımsal karbon emisyonlarının yıllık ortalaması 42.596,6 kt, AB'de ise 410.847 kt olarak hesaplanmıştır. Türkiye'nin tarımsal

karbon yoğunluğu 2000 yılında 1,43 kt/milyon USD iken 2022'de 0,91 kt/milyon USD'ye gerilemiştir. AB'de ise bu değer 2,76 kt/milyon USD'den 1,31 kt/milyon USD'ye düşmüştür (Çizelge 1).

Çizelge 1. Türkiye'de ve Avrupa Birliğinde Karbon Yoğunluğu

Türkiye için hesaplanan regresyon analiz sonuçları Tablo 1'de sunulmuştur. Modelin açıklayıcılığı oldukça yüksektir ($R^2 = 0,843$), bu da bağımsız değişkenlerin karbon emisyonlarındaki değişimi büyük ölçüde açıkladığını göstermektedir. Modelin genel olarak anlamlılığını gösteren F-testi anlamlıdır ($p<0,001$) ve denklemde otokorelasyon problemi yoktur (Durbin-Watson=1,755). Tarımsal üretici fiyat endeksi ($p<0,001$), tarımsal girdi kullanımı ($p<0,001$) ve kara üzerindeki sıcaklık ($p<0,05$) arttıkça tarımdan kaynaklanan karbon emisyonlarında artış olduğu tespit edilmiştir. Modelden elde edilen esneklik katsayıları tarımsal girdilerin ve sıcaklık değişimlerinin karbon emisyonlarına duyarlılığını ortaya koymakta; özellikle tarımsal girdi kullanımındaki %1'lik artışın emisyonları %0,51 oranında artırması, sürdürülebilir üretim tekniklerinin önemini vurgulamaktadır. Benzer şekilde, sıcaklık artışına duyarlılık, iklim değişikliğinin etkisini gözler önüne sermekte, tarım sektörünün iklim kırılganlığını pekiştirmektedir. Bu nedenle, düşük karbonlu tarım uygulamalarının yaygınlaştırılması ve iklim dostu üretim yöntemlerinin teşvik edilmesi gereklidir. (Tablo 1).

Avrupa Yeşil Mutabakatının Türkiye'deki tarımsal karbon emisyonları üzerinde önemli bir etkisinin olduğu sonucuna varılmıştır (Taneja ve Özen, 2023). Türkiye'de tarımda %1'lik bir artış CO_2 emisyonlarını %1,516 oranına artırdığı tespit edilmiştir. Bu bulgu, sektördeki fosil yakıt kullanımının emisyonlar üzeridenki belirleyici etkisi olduğu anlamına gelmektedir (Yurtkuran, 2021). Avrupa ülkelerinde yapılan bir çalışmada özellikle Hollanda, Belçika ve Lüksemburg gibi ülkelerde azotlu gübre kullanımının artmasının, emisyon yoğunluğunu üzerinde %100'ü aşan etkiler yarattığı vurgulanmıştır (Robaina-Alves ve Mountinho, 2014). Avrupa OECD ülkelerinde yapılan bir çalışmada yine benzer bir sonuç ile gübre kullanımının karbon ayak izi üzerinde arttırıcı etkileri olduğu belirlenmiştir (Haller, 2022). Bu bulgular, Türkiye'de gübre kullanımının CO_2 emisyonlarını artırıcı etkisine ilişkin bu çalışmanın sonuçlarıyla örtüşmektedir. E7 ülkelerinde yapılan bir çalışmada, tarımsal katma değerdeki artışın uzun vadede CO_2 emisyonlarını arttırdığı tespit edilmiştir (Aydoğan ve Vardar, 2020). Ancak Türkiye'de CO_2 emisyonunda yaşanacak değişikler, tarımsal GSYİH üzerinde anlamlı ve negatif bir etkide bulunarak, uzun dönemde tarım verimi ve tarımsal ürünlerin kalitesini düşürmektedir (Bayraç ve Doğan, 2016). Bu bulgular, tarım ve çevre ilişkisini çift yönlü değerlendiren bütüncül politikalara olan ihtiyacı göstermektedir. Yine Türkiye'de tarımsal ihracatın uzun vadede çevresel bozulmayı önemli ölçüde azalttığı tespit edilmiştir (Turan, 2025). Türkiye'nin Avrupa Birliğine ihracatından kaynaklanan emisyonların, Avrupa Birliğinin Türkiye'ye ihracatından kaynaklanan sera gazı emisyonlarından fazla olduğu tespit edilmiştir (Tunç vd., 2022). Türkiye'de tarım sektörü iklimsel etkilerden yüksek düzeyde etkilenmektedir. Bu durumda tarım sektörünün iklim değişikliğine karşı kırılgan olduğunu göstermektedir (Kılıç, 2022). Türkiye'de tarımsal verimlilikte meydana gelecek %1'lik artış karbondioksit emisyonlarında %0,12 oranında azalmaya neden olacağı tespit edilmiştir (Raihan ve Tuspekova, 2022). Cortignani ve Coderoni (2022) tarafından İtalya tarım sektörü üzerine yapılan çalışmada, çevresel hedeflerin uygulanmasının çiftliklerin ekonomik performansını olumsuz etkileyebileceği; ancak sera gazı emisyonlarının önemli ölçüde azaltılabileceği tespit edilmiştir. Türkiye'de de gübre kullanımı ve sıcaklık artışının emisyonları artırıcı etkisi, benzer politika senaryolarının ekonomik ve çevresel etkiler

bakımından değerlendirilmesini gerekli kılmaktadır. Bu bağlamda, Türkiye'nin Avrupa Birliğine uyum sağlayabilmesi ve tarım sektöründe karbon emisyonlarını azaltabilmesi için bütüncül önlemler alması ve stratejik politikalar geliştirmesi gerekmektedir. Özellikle gübre kullanımı ve tarımsal girdi verimliliği, öncelikli müdahale alanları olmalıdır. Ayrıca fiyat mekanizmalarının, çevre dostu üretim yöntemlerini teşvik edecek şekilde yeniden yapılandırılması büyük önem taşımaktadır.

Tablo 1. Türkiye için Regresyon analiz sonuçları

Değişkenler	Katsayı	Standart hata	p	t-değerleri	Esneklik
Sabit	16233,938	9604,437	0,109	1,690	-
X_1	-0,044	0,066	0,511	-0,671	-0,082
X_2	29,766	7,800	0,001***	3,816	0,427
X_3	0,011	0,003	0,001***	3,990	0,510
X_4	-0,017	0,041	0,681	-0,418	-0,053

F testi	18,257		0,000***		
R^2	0,843				
Durbin-Watson	1,755				

*, ** ve *** ilgili değişkenlerin bağımlı değişken üzerinde etkisinin sırasıyla %10, %5, %1 ihtimal düzeyinde istatistiki açıdan önemli olduğunu ifade etmektedir.

Avrupa Birliği için hesaplanan regresyon analiz sonuçları Tablo 2'de verilmiştir. Modelin açıklayıcılığı Türkiye'den daha yüksektir (R^2 = 0,901). Bağımsız değişkenler, tarımsal karbon emisyonlarındaki değişimin %90,1'ini açıklıyor. Modelin genel olarak anlamlılığını gösteren F-testi anlamlıdır ($p<0,001$) ve denklemde otokorelasyon problemi yoktur (Durbin-Watson=1,755). Tarımsal üretici fiyat endeksi ($p<0,05$) arttıkça karbon emisyonlarını azaltırken, tarımsal girdi kullanımı ($p<0,05$) arttıkça tarımdan kaynaklanan karbon emisyonlarında artış olduğu tespit edilmiştir. Modelde elde edilen esneklik katsayıları, Avrupa tarımının emisyonlara olan tepkisini ortaya koymaktadır. Tarımsal üretici fiyat endeksindeki %1'lik artışın karbon emisyonlarını %0,42 oranında azaltması, piyasa fiyatlarının çevresel etkileri şekillendirmede önemli bir rol oynayabileceğini göstermektedir. Buna karşılık, tarımsal girdi kullanımındaki %1'lik artışın emisyonları %0,23 oranında artırması, Avrupa tarımında da sürdürülebilir girdi kullanımının gerekliliğini ortaya koymaktadır (Tablo 2). AB'nin tarımda uyguladığı karbon ayak izi temelli destek sistemleri ve düşük emisyonlu üretim tekniklerine sağladığı finansal teşvikler, çevresel hedeflere ulaşmada önemli bir araç olarak öne çıkmaktadır. Türkiye'nin de yenilenebilir enerji kaynaklarının tarımsal üretime entegrasyonunu hızlandırması ve çiftlik bazlı enerji dönüşümünü desteklemesi gerekmektedir.

Avrupa ülkelerinde tarımsal gayrisafi katma değerin karbon emisyonları üzerinde farklı yönlerde etkiler oluşturduğu gösterilmiştir. Avrupa ülkelerinde özellikle Almanya, Fransa ve Birleşik Krallık gibi ülkelerde 1990-2016 döneminde tarımsal karbon emisyonlarında anlamlı azalmalar gözlemlenmiştir (Mohammed vd., 2020). Kuzey Avrupa ülkelerinde tarımın emisyonları artırdığı, Güney Avrupa ülkelerinde ise azaltıcı yönde etkide bulunduğu tespit edilmiştir (Sibgh ve Dhiman, 2022). Bu çalışmadan elde dilen AB bulguları, özellikle Güney Avrupa'daki negatif ilişkiyle örtüşmektedir. Bu durum, daha sürdürülebilir tarım uygulamalarının yaygın olduğu bölgelerde, tarımsal üretimin çevre için daha zararlı olabileceğini göstermektedir. Avrupa Birliği 2030 yılına kadar, yalnızca tarımdan kaynaklanan sera gazı emisyonlarını azaltmakla kalmayıp aynı zamanda karbon sekastarsyonunu arttıran, tarımsal üretimin dayanıklılığını arttıran, kırsal alandaki biyolojik çeşitliliği iyileştiren ve büyüyen dünya nüfusuna besleyici ve sağlıklı gıda sağlamaya katkıda bulunan düzenleyici araçlara sahip olmaldır (Verschuuren, 2022). CO_2 emisyonlarında bazı dalgalanmalara rağmen, Avrupa Birliği genelinde tarım sektöründe karbon nötrlüğüne ulaşma stratejileri izlenmelidir (Harsányi vd., 2021). Bu stratejiler arasında emisyon yoğunluğunu iyileştirmede tarımsal üretimi desteklemeye devam etmelidir (Bajan vd., 2022). Bu bağlamda, hem çevresel hedeflere ulaşmak hem de üretim kapasitesini korumak amacıyla, düşük emisyonlu üretim yöntemleri teşvik edilmekte, üretici gelirleri ise çeşitli destek mekanizmaları ile güvence altına alınmaktadır.

Okul Çağı Çocuklarında Ambalajlı Gıda Tüketim Alışkanlıklarının Belirlenmesi Obezite İle İlişkisinin İncelenmesi

Feride ÖZER[1], Kübra ERGAN[1], Hilal DEMİRKESEN BIÇAK[1]

[1] Beslenme ve Diyetetik, Sağlık Bilimleri Fakültesi, İstanbul Yeni Yüzyıl Üniversitesi, Istanbul, Türkiye

Özet

Amaç: Hızla değişen modern dünyada, tüketiminin hızlı, taşınmasının kolay olması ve daha ekonomik olması sebebiyle bireylerin paketlenmiş gıda ve fast food ürün tüketimleri artmıştır. Bu gruptaki besinlerin enerji ve yağ içeriği geleneksel gıdalara oranla oldukça yüksektir. Sağlıklı beslenme alışkanlıklarının değişmesiyle beraber yetersiz fiziksel aktivite nedeniyle dünya genelinde obezite oranları hızla artmaktadır. Çocukluk döneminde kazanılan beslenme alışkanlıkları obezite ve beraberinde getirebileceği hastalıkları önleme noktasında kritik öneme sahiptir. Bu çalışma kapsamında, öğrencilerin beslenme davranışları ve paketlenmiş gıda tüketim sıklığının kilo kontrolü ve obezite üzerindeki etkisinin incelenmesi amaçlanmıştır.
Yöntem: İstanbul ili Güngören ilçesinde yer alan ilkokul ve ortaokullarda eğitim gören 7-14 yaş arasındaki gönüllü katılımcılar çalışmaya dahil edilmiştir. Araştırmacılar tarafından hazırlanan ve sosyo-demografik özellikleri ve beslenme alışkanlıklarını değerlendiren anket formu, tüm katılımcılara uygulanmıştır. Çalışmada 98 çocukla yapılan anket ile sağlık durumu, yeme alışkanlıkları, besin tüketimi verileri toplanmış ve antropometrik ölçümler yapılmıştır.
Bulgular: Araştırma bulgularına göre, çocukların Vücut Kitle İndeksi (VKİ) değerlerine göre beslenme alışkanlıkları arasında anlamlı ilişkiler bulunmuştur. Evde yemek yiyen çocuklar ile okul kantininde yemek yiyen çocuklar arasındaki ilişki dikkate alındığında, evde yemek yiyen çocukların VKİ değerleri anlamlı olarak daha düşük bulunmuştur ($p<0,05$). Paketlenmiş gıda tüketimi ile BMI arasındaki ilişki de anlamlı bulunmuştur. Haftada bir veya daha fazla paketlenmiş gıda tüketen çocukların VKİ değerlerinde, daha az tüketenlere göre istatistiksel olarak farklılıklar gözlemlenmiştir ($p<0,05$). Ayrıca, annenin eğitim düzeyi ile çocuğun paketlenmiş gıda tüketimi arasında da anlamlı bir ilişki bulunmuştur ($p<0,05$).
Sonuçlar: Okul çağı dönemi tüm hayat boyu sürecek ve sağlığı etkileyen davranışların kazanıldığı bir dönemdir. Bu yaşlardaki çocuklar günün büyük bir kısmını okulda geçirmekte ve okulda kantin/yemekhane hizmetinden yararlanmaktadırlar. Toplum sağlığı açısından okul çağı çocuklarının sağlıklı besinlere ulaşımının sağlanması ve sağlıklı beslenme alışkanlıklarının kazandırılması başta çocukluk çağı obezitesinin önlenmesi olmak üzere birçok olumlu etkilere sahiptir. Bu gruptaki çocuklara verilecek olan beslenme eğitimleri ve okul diyetisyenliği çalışmaları ile okul çağı çocuklarına büyük faydalar sağlanabilir.

Determination Of Packaged Food Consumption Habits In School Age Children And Examination Of Their Relationship With Obesity

Abstract

Purpose: In the rapidly changing modern world, individuals have increased their consumption of packaged and fast food products due to their convenience, ease of transportation, and relatively economical nature. The energy and fat content of foods in this group are considerably higher than those of traditional foods. Along with the shift in eating habits, obesity rates are rising rapidly worldwide due to insufficient physical activity. Eating habits acquired during childhood are critical in preventing obesity and the associated diseases. The aim of this study is to examine the effects of students' eating behaviors and the frequency of packaged food consumption on weight control and obesity.
Method: Volunteer participants between the ages of 7 and 14, studying in primary and secondary schools in the Güngören district of Istanbul, were included in the study. A questionnaire prepared by the researchers, which assessed socio-demographic characteristics and eating habits, was administered to all participants. In the study, health status, eating habits, and food consumption data were collected through a questionnaire administered to 98 children, and anthropometric measurements were taken.
Findings: The research findings revealed significant relationships between children's eating habits and their Body Mass Index (BMI) values. The BMI values of children who ate at home were significantly lower than those who ate in the school cafeteria ($p<0.05$). Additionally, a significant relationship was found between packaged food consumption and BMI. Statistical differences were observed in the BMI values of children who consumed packaged food once or more per week compared to those who consumed it less frequently ($p<0.05$). Moreover, a significant relationship was found between the mother's education level and the child's packaged food consumption ($p<0.05$).
Results: The school-age period is crucial for the development of lifelong behaviors that affect health. Children in this age group spend most of their day at school and utilize school canteen/cafeteria services. In terms of public health, ensuring that school-age children have access to healthy foods and promoting healthy eating habits can have numerous positive effects, most notably in preventing childhood obesity. Nutrition education and school dietitian interventions for children in this age group can provide significant benefits for their health.

Abstract

Düzce is one of the significant provinces for beekeeping in the Western Black Sea region of Türkiye due to its geographical location, climate, and floral diversity. The province has gained prominence in the apiculture sector through the registration of the Yığılca honey bee ecotype and the patenting of its chestnut honey. The Yığılca ecotype, which is endemic to the Yığılca district, is a highly specialized subspecies in terms of morphological, genetic, and physiological traits, and is known for its high productivity. Following the official registration of the Düzce-Yığılca ecotype by the Breed Registration Commission of the Ministry of Agriculture and Forestry, nine queen bee production enterprises were established in the district.

Currently, there are 713 registered beekeeping enterprises and 59,911 hives listed in the Beekeeping Registration System in Düzce. The province produces monofloral chestnut honey, Rhododendron honey, and polyfloral flower honey. However, beekeepers in Düzce primarily focus on monofloral chestnut (*Castanea*) and Rhododendron honey production. Based on a ten-year average, Düzce ranks 54th in Türkiye with an annual production of 551 tons of honey. The average annual production of beeswax is 22.117 tons, ranking 46th nationally. In recent years, increased attention has been paid to the production of high value-added bee products such as royal jelly and propolis, although these products are not yet reflected in official statistics.

Although Düzce does not rank among the top provinces in Türkiye in terms of total honey production, its unique flora and fauna, patented chestnut honey, and the Yığılca ecotype render it strategically important for the future of beekeeping in the country. The aim of this study is to examine the most recent data on beekeeping in Düzce including the production volumes of various bee products and colony management practices in order to develop a strategic roadmap and plan for the sustainable development of beekeeping in the province.

Keywords: *Beekeeping, Apis mellifera, raw material production, Düzce Province*

Düzce'de Arıcılığın Mevcut Durumu ve Geleceği

Özet

Düzce, Türkiye'nin Batı Karadeniz bölgesinde yer alan coğrafik konumu, iklimi ve floral yapısı bakımından arıcılık açısından önemli illerimizden biridir. Düzce arıcılık sektöründe tescilli Yığılca bal arısı ve patentli kestane balıyla ön plana çıkmıştır. Düzce'nin Yığılca ilçesine endemik olan Yığılca ekotipi morfolojik, genetik ve fizyolojik bakımlardan özelleşmiş, davranış ve performans bakımından yüksek verimli bir ekotiptir. Düzce Yığılca ekotipi Tarım Orman Bakanlığı ırk tescil komisyonu tarafından tescillendikten sonra İlçede 9 adet ana arı üretim işletmesi kurulmuştur. Düzce genelinde arıcılık kayıt sistemine kayıtlı 713 adet arıcılık işletmesi ve 59.911 adet arılı kovan bulunmaktadır. İlde monofloral kestane balı, ormangülü ve polifloral çiçek balı üretilmektedir. Ancak Düzce ilinde arıcılar monofloral kestane (*Castane*) ve orman gülü (*Rhododendron*) balı üretimi üzerinde yoğunlaşmıştır. Düzce'de on yıllık ortalamaya göre 551 ton/yıl bal üretimi yapılmakta olup Türkiye genelinde 54. Sırada yer almaktadır. Balmumu üretimi ise ortalama 22.117 ton olup 46. Sırada bulunmaktadır. Son dönemlerde arı sütü ve propolis gibi bal dışındaki katma değeri yüksek ürünlerin üretimine de ağırlık verilmiştir. Ancak bu üretim tipleri istatistiklere yansıtılmamıştır. Düzce ili arıcılık faaliyeti bakımından Türkiye'de üst sıralarda olmasada, yerel flora ve fauna kaynakları, patentli kestane balı ve eşsiz Yığılca ekotipi nedeniyle Düzce ili arıcılık faaliyetleri nedeniyle Türkiye için son derece önemlidir.

Bu çalışmanın amacı Düzce'de son yıllık süreçte arıcılığın durumu, arı ürünleri üretimi ve üretim miktarı, koloni bakım yönetiminde yapılan uygulamalara ilişkin verileri inceleyerek Düzce arıcılığı için gelecek planlamaları yapmak ve yol haritası oluşturmaktır.

Anahtar Kelimeler: Arıcılık, Apis mellifera, ham madde üretimi, Düzce

Introduction

Honey bees (*Apis mellifera*) hold significant importance due to their production of various substances with high pharmacological and nutritional value. These substances include eight different bee products: honey, pollen, beeswax, propolis, royal jelly, apilarnil, bee bread (perga), and bee venom. In addition to being used as nutritional supplements, these products also have widespread applications in the pharmaceutical and cosmetic industries. However, the role of honey bees in pollination which enhances both the quantitative and qualitative aspects of crop yields is considered even more vital than the products themselves (Free, 1993). Honey bees are responsible for approximately 85% of all insect-mediated pollination, positioning them as key contributors to ecological balance. Therefore, their role as primary pollinators is essential for environmental sustainability.

In contemporary agricultural practices, the intensive use of chemicals particularly pesticides has led to a significant decline in the populations of wild pollinators. As a result, honey bees have emerged as the sole effective pollinators capable of filling this ecological gap. One-third of the human diet is derived, either directly or indirectly, from plants that require bee pollination. For this reason, honey bee colonies are critical during vegetation periods to ensure sufficient pollination (Delaplane and Mayer, 2000).

Although wild bees and other insects also play a role in natural pollination, honey bees are considered the most effective due to their large colony sizes, ease of transportation, and manageability. Most of pollination activities in nature is carried out by honey bees, and the economic value of this service is estimated to be approximately 15 times greater than the value of honey. A mutually beneficial relationship exists between forests and bees: As the world's most important pollinating insects, bees also contribute to the propagation of herbaceous and woody plants that protect the soil, thereby helping to prevent erosion particularly critical in a country like Türkiye (Özbek, 2002). Beekeeping is a sector that must be supported and sustained due to its contributions to biodiversity conservation, sustainable food security, and the Turkish economy (Kekeçoğlu et al., 2014). Approximately 40,000 families in Türkiye rely on beekeeping for their livelihoods. There are 72,000 registered beekeepers, and it is estimated that 300,000 individuals are financially dependent on this sector (Table 1). Both local and national surveys indicate that the average age of beekeepers is around 49 years (Kekeçoğlu et al., 2007; Kekeçoğlu et al., 2013).

According to 2020 data from the Food and Agriculture Organization (FAO), the global number of bee colonies has reached 90.1 million. India ranks first with 13 million colonies and a 13.6% share, followed by China with 9 million colonies (10.1%), and Türkiye ranks third with 8 million colonies, corresponding to a 9.0% share. In terms of total honey production, China is the global leader with 446,900 tons, producing 49.39 kg per colony. Türkiye ranks second with 114,113 tons but falls far behind in colony productivity, with a yield of 14.36 kg per hive.

Table 1. Beekeeping data for 2023 by some country (FAO, 2023)

Rank	Country	Number of Colonies (units)	Total Honey Production (tons)	Honey Yield (kg/hive)
1	China	9,492,353	472,221.14	49.39
2	Türkiye	9,224,881	114,886.43	14.36
3	Ethiopia	6,794,876	84,591.00	8.31
4	Iran	7,358,044	80,389.00	11.75
5	Argentina	3,013,042	73,395.30	26.31
6	India	12,663,817	70,850.20	5.17
7	Russia	2,743,100	64,511.00	20.43
8	Brazil	1,026,934	64,189.00	41.62
9	United States	2,509,000	62,855.00	24.65
10	Mexico	2,201,329	58,033.20	29.58
11	Tanzania	3,080,237	31,613.10	10.13
12	South Korea	2,128,266	29,467.80	12.34
13	Angola	1,192,639	23,458.90	20.29
14	Kenya	1,676,583	17,151.00	13.38
15	Central African Republic	1,675,246	16,714.00	9.64
16	Serbia	1,103,300	11,346.00	12.50

When the average figures of the past four years in Türkiye are examined, the average number of beehives is 7,343,182; the number of beekeeping enterprises is 82,139; annual honey production is approximately 103,018 tons; and annual beeswax production is around 4,372 tons. In addition to honey, beeswax production on a global scale totals 66,099 tons. India ranks first with 25,691 tons of beeswax production, while Türkiye ranks fifth with 4,737 tons (TÜİK, 2021). Furthermore, although not officially recorded in national statistics, it is estimated that Türkiye produces approximately 100 tons of propolis, 3 tons of royal jelly, 150 tons of pollen, 10 tons of bee bread (perga), and 100 kilograms of bee venom annually.

As a branch of agricultural production, beekeeping contributes approximately 160 trillion Turkish Liras directly to the national economy through the production of honey and beeswax. When the contribution of pollination is

considered which is estimated to be at least 10 to 15 times greater than that of honey and beeswax production the total economic contribution of beekeeping to the Turkish economy rises to approximately 1.6 to 2.4 quadrillion Turkish Liras. In addition, beekeeping serves as a source of employment for nearly 150,000 individuals, the majority of whom live in rural areas and lack access to sufficient farmland. This further underscores the significance of beekeeping for the national economy.

Beekeeping in Düzce

When considering honey production at the provincial level in Türkiye, Ordu ranks first with 17,057 tons, followed by Muğla (14,688 tons) and Adana (11,077 tons) (FAO, 2020). Düzce ranks 54th in terms of total honey production. According to research, the active beekeeping season in Düzce spans June, July, and August (Albayrak and Bayır, 2019). The high number of rainy days and short beekeeping season constitute disadvantages for beekeeping in the province. On the other hand, the extensive forested areas, the abundance of chestnut and *Rhododendron* plants, and rich plant biodiversity provide significant advantages. Approximately 700 plant species, 10% of which are endemic, are found within Düzce's borders (Aksoy et al., 2010). One-third of the province is covered by forests. According to the General Directorate of Forestry, Türkiye has 262,045 hectares of chestnut forests, with approximately 15,767 hectares located in Düzce.

Two harvests take place annually in Düzce: *Rhododendron* honey is harvested in June, followed by chestnut honey in July. Both are classified as monofloral honeys. Chestnut and *Rhododendron* honeys, which are sold at higher prices and are valued for their apitherapeutic properties, form the primary production profile of Düzce. Scientific studies have confirmed the therapeutic properties of chestnut and wildflower honeys produced in the region, increasing the added value of local honey and propolis. Research indicates that the chestnut honey and propolis from Yığılca district exhibit antibacterial activity comparable to various antibiotics (Kekeçoğlu et al., 2021; 2022).

More importantly, the most significant factor elevating Düzce's beekeeping profile and increasing its international visibility is the presence of the Yığılca honey bee ecotype (Kekeçoğlu, 2010; Gültekin, 2019; Kekeçoğlu, 2021). Unique to Yığılca district, this ecotype produces up to three times more honey than other native bee subspecies in Türkiye and shows superior spring development and overwintering abilities compared to Anatolian and Caucasian races. As a result of research conducted by the Beekeeping Research, Development and Application Center (DAGEM) at Düzce University, established in 2009, the Yığılca bee was granted legal protection by the Ministry of Agriculture and Forestry on September 14, 2017 (official letter no: 73291108-12502.04-E 2223544). On May 22, 2022, the ecotype was officially registered by the National Commission for the Registration of Native Animal Breeds. Scientific data generated by DAGEM played a pivotal role in this registration process (Kekeçoğlu, 2010; 2018; Kekeçoğlu et al., 2021; Bir and Kekeçoğlu, 2021).

DAGEM's work has not only contributed to the recognition of the Yığılca bee but has also increased the value of local bee products. The center has been instrumental in transforming bee products into high value-added goods, facilitating their commercialization and branding. Products like propolis and bee venom, which had not been previously produced in Düzce, have now entered production. The project titled *Beekeeping, Honey Forests and Sustainable Development*, implemented by DAGEM, won the 2011 European Enterprise Award, significantly enhancing international awareness of the Yığılca bee (Kekeçoğlu, 2021). As a result, national and international demand for Yığılca queen bees has been steadily increasing.

To support the development of beekeeping in Düzce, a comprehensive study was conducted to examine the structure of the sector and its challenges. Key issues identified include insufficient technical knowledge, inadequate colony management and feeding practices, failure to use ecotypes suited to local conditions, errors in overwintering preparation, and incorrect practices in combating bee diseases and pests. Based on these findings, a strategic roadmap was developed for the future of beekeeping in Düzce (Kekeçoğlu et al., 2013; 2014).

Kekeçoğlu et al. (2013), conducted face-to-face interviews with 412 beekeepers from 245 villages in Düzce and its districts to identify colony losses and challenges related to bee health. According to the findings, 81.2% of beekeepers experienced winter losses, while 18.8% did not. The causes of colony loss included queen loss (39.8%), Varroa infestation (23.8%), starvation (21.9%), and robbing behavior (3.9%). Additionally, 89.8% of beekeeping operations reported *Varroa* infestation, 51.6% reported wax moths, 18.2% reported *Nosema*, and 13.11% had American foulbrood disease (Kekeçoğlu et al., 2013).

The study concluded that there were significant shortcomings in overwintering preparation, colony management, and disease diagnosis and treatment. In response, several projects were launched to address these issues. The average age of beekeepers in Düzce was found to be 50; 73.1% were primary school graduates, 14.1% had completed high school, and 20.9% relied on beekeeping as their primary source of income. Although these figures have not changed dramatically, the average age has decreased slightly, and more young people and women are now entering the profession.

In 2013, 620 individuals were members of beekeeping associations—59.2% of them belonged to the Beekeepers' Union and 24.5% to the Honey Producers' Union. Today, that number has risen to 1,020 registered members. Regarding bee races, a 2013 study found that 61.5% of beekeepers preferred local ecotypes and 34.7% used Caucasian queens. However, problems related to access to high-quality breeding queens persist.

Approximately 46.8% of Düzce's beekeepers practice migratory beekeeping. The preferred nectar sources for honey production are sunflower (62.96%), chestnut (54.32%), wildflowers (22.22%), canola (11.73%), and Rhododendron (11.73%). According to the study, 79.1% of respondents considered beekeeping a secondary income source, 10.7% practiced it as a hobby, and only 11.4% relied on it as their primary livelihood (Kekeçoğlu et al., 2013; 2014).

In terms of honey production, Düzce ranks 54th in Türkiye with 551 tons and 46th in beeswax production with 22.117 tons. The province hosts 713 beekeeping enterprises and 59,911 Langstroth-type hives, making it one of the few provinces that no longer use traditional hives. Apart from honey and beeswax production, there are three queen bee production facilities in the districts of Yığılca, Çilimli, and Kaynaşlı, each with a capacity of 3,000 queens, totaling 9,000 queens annually (Anonim, 2020).

Since 2012, the number of beekeeping enterprises and hives in Düzce has steadily increased each year. Honey yield per hive has also shown improvement in the last three years compared to earlier periods. The highest honey production to date in Düzce was recorded in 2019 at 552 tons. For beeswax, the highest figure was 47 tons in 2015, and the lowest was 15 tons in 2017. As beekeeping is a nature-dependent activity, production volumes fluctuate annually. In years with heavy rainfall during nectar flow, honey yields tend to decline (Albayrak and Bayır, 2019). (Table 2).

Table 2. Annual honey and beeswax production, number of enterprises and hives in Düzce province (Anonym, 2020; TÜİK, 2023; TEPGE 2021, 2022, 2023, 2024)

Years	Honey(Tons)	Beeswax (Tons)	Number of Enterprises	Number of Hives	Honey Yield (kg/hive)
2012	470	-	442	36.164	12.99
2013	518	26	491	43.611	11.88
2014	470	19	530	48.222	9.75
2015	421	47	578	52.051	8.08
2016	450	23	610	53.266	8.45
2017	481	15	637	54.971	8.75
2018	540	22	674	60.356	8.95
2019	552	22,1	711	59.911	9.21
2020	518	21	713	58.473	8.85
2021	693	21	713	63.943	10.8
2022	531	16	744	65.903	8.1
2023	412	14	793	52.314	7.9

An examination of production data related to apicultural products in Düzce reveals that, in addition to honey and beeswax, other bee products such as pollen, propolis, and royal jelly are also produced (Kekeçoğlu et al., 2014). However, the limited production of these high-value-added products is primarily due to beekeepers concerns about market access (Kekeçoğlu et al., 2014). It has been noted that as the demand for bee products such as royal jelly, bee venom, honey, and pollen in the pharmaceutical and cosmetic sectors increases, their production is also expected to rise (Kekeçoğlu et al., 2014). Therefore, beekeeping in Düzce holds strong potential to be transformed into a high-value economic sector. Based on the numerical data presented in Table 2 and field research findings, the following annual revenues are estimated for Düzce: 100 million TL from honey, 3 million TL from beeswax, 700,000 TL from raw propolis, 1.5 million TL from processed propolis, 600,000 TL from pollen, approximately 700,000 TL from royal jelly, and approximately 2 million TL from queen bee production. The total economic contribution of beekeeping to Düzce's local economy exceeds 120 million Turkish Liras. This figure could be significantly increased through the production and value-added processing of next generation bee products such as bee venom, bee bread (perga), and apilarnil.Beekeeping is closely associated with forest ecosystems. Approximately 50% of Düzce's land area consists of forested terrain. This provides a valuable opportunity for beekeeping activities, which are best conducted away from areas subjected to chemical spraying and do not require flat or fertile agricultural land. The large extent of forest cover, along with the presence of high-nectar-yield plant species such as chestnut, linden, and *Rhododendron*, and the unique Yığılca honey bee ecotype, give Düzce significant potential to become a leading region in the beekeeping industry. Furthermore, due to the abundance of wood resources in these forest areas, the production of beehives could also be developed as a complementary local industry in Düzce.

Abstract

Agriculture is a main source of economic and food security in low- and middle-income countries and there is a growing trend of migration from rural to urban areas and towards developed countries. Migration causes a loss of agricultural productivity due to many factors in which the main is shortage of agricultural workers in rural areas. Other factors including improper usage of fertilizers for better growth and production of crops, Households with more migrants have difficulties in dealing with harsh weather to get more agricultural yield. Those regions which have higher rate of male migration have problem to hire manpower for agricultural work. Then women are playing these roles properly, but they receive discrimination because many people believe that these works are specified for men. This discriminate behaviour leads to the potential for less agriculture production. Migration also causes diseases to spread in crops, humans and animals. Crop and animal diseases led to reduction in agricultural production and human disease cause reduction in farm workers. This labor shortage causes difficulty in crop management like planting, weeding and harvesting. It also causes a rise in salaries of agricultural workers which increases the cost of growing crops and less profit from agricultural production.

Key Words: *Agriculture production, Migration, Manpower, Crop management, Fertilizer*

Introductıon

Agriculture plays a significant role in promoting economic growth, reducing poverty, and enhancing food security in many developing nations. Agricultural productivity is decreasing because of rural-urban migration, even while emerging nations are working to end poverty, hunger, and malnutrition. Due to the rapid pace of urbanization in emerging nations and the fact that people are moving from rural to urban regions more quickly than in the past, there is a risk of future shortage of food and other agricultural products if nothing is done (UK AID, 2016).

Agriculture output can be significantly impacted by migration, both at the movement's origin and destination. The number of individuals traveling worldwide is rising annually. Most migrants are moving inside their own countries, from rural to urban areas, despite the common misconception that they mostly leave their place of origin, according to recent statistics. About 281 million individuals moved in 2020 according to the report of United Nations department of economics and social affairs (UNDESA, 2020).

This extends to about 4 percent of the world's population that will be living abroad in 2020. High remittances that migrants send to their family back home, scholars contend that migration is now an essential component of rural livelihoods in many low- and middle-income countries (LMICs) (Mathew, 2014; Obi et al., 2020; Tuladhar et al., 2014). In several LMICs, remittances have played a key role in rural development (Mohapatra and Ratha, 2010). According to a recent World Bank analysis, around US$ 626 billion entered LMICs in 2022, and this amount is anticipated to rise in the years to come (World Bank, 2022). Remittances are becoming a significant source of off-farm income and a significant addition to the national gross domestic product in many developing nations where agriculture is a significant industry (ADB, 2017; Koczan et al., 2021).

Migration affects the nations of origin and destination in both good and bad ways. As a result, migration has emerged as a significant issue in public discussions of the global economic, social, and political spheres (Castles and Miller, 2014). A significant factor contributing to the labor shortage in LMICs is migration. Numerous studies have evaluated the benefits of labor migration for the rural welfare of the countries of origin, including reducing poverty (Adams and Page, 2005; Lokshin et al., 2010; Wagle and Devkota, 2018; Zhu and Luo, 2010; Nguyen et al., 2015), food security (Isoto and Kraybill, 2017; Mora-Rivera and van Gameren, 2021; Nguyen et al., 2017), improving health (Berloffa and Giunti, 2019; Gustafsson, 2018), reducing inequality (Agwu et al., 2018), consuming calories (Karasoy, 2017), managing natural resources (Bierkamp et al., 2021; López-feldman and Chávez, 2016), improving nutritional intake (Isoto and Kraybill, 2017), and improving education (Amuedo-Dorantes and Pozo, 2010; Edwards and Ureta, 2003). However, the detrimental impacts of household labor migration in LMICs have only been the subject of a small number of research.

Negative consequences, such as the loss of productive labor, can also occur in a family with labor migrants (Paudel et al., 2019a). These consequences can eventually impact labor dynamics at the household and community levels as well as the availability of labor in agriculture. Crop production and farm earnings are decreased when workers

leave the home and community, raising rural salaries and crop cultivation costs (Duda et al., 2018; Yamauchi, 2016; Zhang et al., 2014). However, many households in developing nations depend on agriculture as their primary source of income and subsistence, even when there are migrants living there. A household may concurrently experience both good and negative consequences under such circumstances.

The loss of productive labor and a drop in agricultural production and profitability might have a negative impact, while an increase in off-farm income through remittances could have a positive one. However, migration's overall effects are complicated. In terms of rural development, nutrition, food security, agricultural capacity, and the larger rural economy, it can have long-lasting impacts on both the origin and destination areas (Zezza et al., 2011; FAO, 2017; State of Food and Agriculture, 2018).

The broader effects of migration on both origin and destination are examined here.

Gender-based prejudice in the agriculture area

In regions where there is gender-based migration imbalance, with frequently more males departing than women, the agriculture industry may be indirectly impacted, eventually affecting productivity. Research indicates that regions with a greater male migration rate also have difficulties hiring males for agricultural management roles. More women are effectively establishing themselves in farm management jobs since fewer males are available to fill these posts, which are typically held by men in these areas. However, women are experiencing prejudice and unjust treatment since many in the sector believe that a male should fill this function. In addition to having a negative effect on the health of the women who hold these jobs, prejudice can also make it more difficult for the company to succeed. One of the numerous detrimental effects of institutional gender discrimination is the potential for a decline in agricultural production. There is no shortcut to this problem. Addressing gender disparities at their source requires a variety of integrated approaches over an extended period (Zezza et al., 2011; FAO, 2017; State of Food and Agriculture, 2018).

Disease Spread

Research has shown that cross-border migration may contribute to the spread of disease, which might have a detrimental effect on agricultural output and industry overall. Migration can affect the spread of illnesses in humans, animals, and crops which may have a negative effect on agricultural output. Agricultural diseases have the potential to directly reduce agricultural output, and their effects can linger for years. Human and animal diseases can also affect agricultural output; for instance, if a workforce is affected, a farm might not have enough workers to harvest its crops. Alternatively, the framework may suffer if a crucial animal species is affected, which may also have a similar result (Zezza et al., 2011; FAO, 2017).

Impact of migration on fertilizer use efficiency

Increasing fertilizer application is a crucial step in raising agricultural output, however overuse of fertilizers has led to major environmental issues (Wu et al., 2018). Due to a shortage of workers for on-farm work, migration may lead farmers to apply all their fertilizer at once rather than gradually, depending on the demands of plant development (Ma et al., 2017). Migration mostly reduces labor, which impacts the efficiency of technological and fertilizer usage. This is because households with a higher number of migrants have a harder time adapting to weather, plant development, and natural calamities (Sauer et al., 2015). Migration can therefore, on the one hand, reduce the amount of manpower available for agricultural output, which in turn can reduce farm technical efficiency. However, because migrant households have limited agricultural labor, they choose one-time fertilization, which will result in losses of fertilizer and worse fertilizer usage efficiency than spreading fertilizer over time.

Impact of migration on agricultural productivity

Several household and farm-level factors can influence the choice to migrate (Maharjan et al., 2013). Since agriculture is the primary source of income for many households in developing nations (FAO, 2014), a few other factors, such as farm size, household size, land typologies, land productivity, farm management techniques, and climate, influence their decision to move. This makes it possible for us to connect household labor migration to factors including agricultural productivity, labor shortages, crop cultivation costs, farm profitability, and off-farm income.

Communities are experiencing a labor shortage, and rural salaries are rising because of households losing productive workers (Wang et al., 2016; Wiggins and Keats, 2014; Zhang et al., 2014). Even though smallholders often have a lower land-to-labor ratio, their inclination to recruit laborers is impacted by labor shortages and rises in rural wages (Paudel et al., 2019b). There are two ways in which this affects agricultural productivity and output. First, high salaries raise labor prices and crop-growing expenses for farmers, which lowers farm profitability, particularly if remittances aren't utilized to buy better agricultural technology. But for certain households that depend entirely on agricultural labor for their income, raising rural wages may improve their welfare.

Second, farmers might not be able to engage enough workers because of shortages, which would make it more difficult to complete necessary crop management tasks including timely weeding, planting, harvesting, and threshing (Paudel et al., 2019a). Due to labor shortages, timely crop management is inefficient, which lowers agricultural production and profitability and has a detrimental effect on the agricultural economy. Thus, it is empirical to investigate possible trade-offs and synergies between family labor migration and agricultural productivity, production costs, farm profitability, and off-farm income.

According to 30% of all respondents, the primary reason for the drop in agricultural output is migration from rural to urban areas. They said loss of agricultural labor is the primary effect of rural-urban migration, according to people in the examined regions, including the leaders. Since many fields in rural regions are excavated by adults, most people think that if nothing is done to address this issue, agricultural productivity will decline, and poverty will develop. Rural migration also contributes to the rise in agricultural output prices. People claim that because of the high level of market demand, prices rise when agricultural production declines. They claim that if rural-urban migration keeps up, agricultural output will rise significantly (Niyonzima, 2023).

Potential direction

The agricultural sector should get ready to gain from migration by utilizing its potential to boost production and improve the region's overall economic well-being. Additionally, the sector should be conscious of the possible harm that migration may do to farming and put plans in place to anticipate and address these issues.

Abstract

Food has been evolved in recent years as consumer demand for as they think food is not just to satisfy hunger but its directly impact their health. Scientists are trying to formulate novel food products by blending foods or by adding some additives to natural foods or byy using some technological methods. Some scientific methods like biotechnology and animal and plant breeding also can produce novel food products. There are some innovative methods which can be used to increase the shelflife of food products including edible packaging, coating and microencapsulation. Processing of agricultural raw material for food production makes the food industry one of the most important industry in European Union. Thus food industry has to adopt innovations in raw material and production methods to compete with other industries and fulfill the consumer demand. Food Innovations include scientific and technological procedures for food processing to make it more appealing for customers. Functional foods include probiotics and vegan products are examples of food innovations and now are trending in european union.

Key Words: *Food industry, Innovation, Functional food, Packaging, Vegan products*

Introduction

The food industry is one of the most important sectors in the European Union due to its high economic importance. In most countries, food consumption has peaked, and the European food market appears to be extremely saturated (Gracia and Albisu, 2001). In the European food system, this type of competitive climate leads to a constant search for new goods, procedures, and services (Gracia and Albisu, 2001), which enables industries to differentiate themselves from rivals and satisfy customer demands (Menrad, 2004). Institutional research and development operations, which are often thought to produce innovations, universities and research institutions are widely recognized to play a dominant role (Fearne et al., 2013; Acosta et al., 2011, 2015; Garcia-Alvarez-Coque et al., 2015). Transferring scientific and technical information to industries has therefore been the primary goal of innovation programs (Coenen and Moodysson, 2009; Arias-Aranda and Romerosa-Martinez, 2010; Acosta et al., 2011; Muscio and Nardone, 2012; Moodysson and Zukauskaite, 2014).

The processing of agricultural raw materials and the provision of food make the food industry one of the most significant sectors of the national economies of Italy and the European Union as a whole. As a result, several writers emphasized its importance in relation to employment and economic production (Menrad, 2004). The food business has historically been viewed as a field with low research intensity on innovation in literature (Christensen et al., 1996; Garcia Martinez and Briz, 2000). Nevertheless, innovations defined as new goods, procedures, or services are acknowledged as a crucial tool for businesses in the food sector to differentiate themselves from rivals and meet customer demands (Menrad, 2004).

Consumer demand in the food production sector has evolved significantly over the past ten years; in fact, consumers now more strongly think that food directly affects their health (Mollet and Rowland, 2002; Young, 2000). So now meals are designed to avoid nutrition-related disorders and to promote physical and mental well-being, rather than only to satisfy hunger and supply the required nutrients (Menrad, 2003; Robertfroid, 2000b).

Innovation in the food industry

Introduction of innovative foods and new scientific & technological methods in food processing are the two key examples of food business innovations in recent years. Innovations in the food sector are frequently focused on creating significant substitutes, adhering to dietary guidelines, or meeting laws governing food additives. They can concentrate on aspects of food technology, such as process engineering, product formulation, food attributes, or customer demands, and are often new consumer goods and services. Furthermore, to create food that meets the dietary, individual, and social demands of every community, they must integrate technical innovation with social and cultural innovation. Researchers consider functional food to be one of the most intriguing areas of study and invention among all the advancements offered in this business (Annunziata and Vecchio, 2011; Jones and Jew,

2007; Siro et al., 2008). The rising expense of healthcare, the constant rise in life expectancy, and older people's desire for a higher quality of life in their later years all contribute to their importance (Kotilainen et al., 2006; Robertfroid, 2000a, 2000b).

Functional foods

Fortified food products with unique constituents have beneficial physiological effects, a study on the connections between nutrition, sensory satisfaction, fortification, and physiological system modulation led to the first use of the term "functional food" in Japan in 1984 (Hardy, 2000; Kwak and Jukes, 2001). Functional meals have cholesterol-lowering products which reduce the risk of certain diseases, enhance the body's overall condition, and may even be used to treat certain illnesses (Mark-Herbert, 2004; Menrad, 2003; Side, 2006). Probiotics have recently taken the lead in the functional food industry in both Europe and Japan, with over 370 products introduced globally in 2005 (Ouwehand, 2007). The most researched and often utilized probiotics are bifidobacteria and lactic acid bacteria (LAB) (Kociubinski and Salminen, 2006). Probiotics are mostly sold in Scandinavia, the Netherlands, Switzerland, Croatia, and Estonia, with growing markets like Greece, France, and Spain, as recently noted by Makinen-Aakula (2006).

Technological process

Food processing has always made use of technology. Its use in the development of new functional foods has a long history of successfully controlling deficiencies in vitamins A and D, several B vitamins (thiamine, riboflavin, and niacin), iodine, and iron. Formulation and blending constitute a straightforward, affordable, and adaptable technology (Betoret et al., 2011). The scientific community, consumers, and food manufacturers have paid more attention to this category of food products in recent years due to the growing significance of dietary compounds and the associated health benefits, which presented an excellent opportunity to improve public health (Karaaslan et al., 2011; Kim et al., 2010). Additional options include biotechnology and animal breeding, which offer the potential to produce better food products (Laible, 2009; Matsushita et al., 2007; Zhu et al., 2008), as well as agriculture and livestock, which serve as the main source of the nutrients needed by humans (Zhao and Shewry, 2011).

Technologies are made to stop physiologically active substances from degrading. The two that are most passionately contested in scientific literature are edible films and coatings, which refer to any kind of material used to encase different foods in order to prolong the shelf life of the product that may be consumed with food (Pavlath and Orts, 2009); and microencapsulation, which involves enveloping small solid particles, liquid droplets, or gases in a coating based on the embedding effects of a polymeric matrix (Betoret et al., 2011). Vacuum impregnation is thought to be a practical method of introducing desired solutes into the porous structure of foods, changing their original composition. This has the high potential to carry active ingredients that can lower the risk of pathogen growth on the food surface and provide specific nutrients (Watanabe et al., 2011).

The goal of recent technology was to create customized functional meals. Given that dietary recommendations that are suitable for one person may not be suitable for another, nutrigenomics considers the relationship between food and a person's genome and the ensuing downstream impact on their phenotype (Ferguson et al., 2010). Although this cutting-edge technology is still in its infancy and many elements are still unclear, it has the potential to open a wide range of options in the field of functional foods (Penders et al., 2007; Ronteltap et al., 2007). Furthermore, there are currently only a few instances of clinical trials employing these technologies, so many problems need to be resolved before the genomic approach is accepted as a means of directing food development or nutritional advice (Betoret et al., 2011; Kaput and Dawson, 2007).

Vegan trend in Europe

Food companies embark on plant-based food-related sustainable innovation journeys that how these foods might eventually result in a socio-technical regime of sustainable food production and consumption (Geels et al., 2008). As evidenced by the gradually rising number of vegans and plant-based diet adherents, veganism is a modern and developing social movement that has recently expanded in Western industrialized countries (Strecker, 2015). A plant-based diet is being aggressively promoted by national health research agencies in several European nations to improve public health and slow down climate change (Appleby et al., 2011; Dyett et al., 2013). The output of animal feed has increase rapidly in recent decades, as seen by Italy, where the Mediterranean plant-based diet has long been the most popular diet. According to 2017 research by the Italian Society of Human Nutrition, government institutions and health groups ought to encourage Italians to adopt a vegetarian diet (Agnoli et al., 2017). In the meantime, Environmental policies are considered necessary to help Norwegian consumers make climate-friendly food choices because, in Norway, researchers have found that informing consumers about the health or climate benefits of eating less meat has had little effect (Austgulen et al., 2018).

According to a Danish survey consumers are clearly divided into those who have a good attitude and those who have a negative attitude toward plant-based diets. To boost the consumption of plant-based meals, researchers suggested that future consumer campaigns address concerns expressed by regular meat eaters such as the

preparation, taste, and skepticism regarding the low protein content of plant-based diets (Reipurth et al., 2019). In addition to having an influence on sustainable consumption practices (Büchs et al., 2015), the food business is also taking notice of the rising popularity of veganism and plant-based diets (Pojic et al., 2018).

Food industries have needed to be ready to swiftly provide new items in response to shifting consumer expectations (Traill and Meulenberg, 2002). As a result, businesses in the food industry have had to develop marketing skills in addition to scientific and R&D capabilities, and produce novel goods based on market research. Several policies within the European Union, such as the Common Agricultural Policy, impact food production and consumption. Furthermore, the entire food production system depends on farmers, merchants, consumers, and municipal governments (Westhoek et al., 2011). Now, neither the decrease of meat consumption nor the promotion of sustainable eating habits is the goal of such programs (Dagevos and Voordouw, 2013; Hansson et al., 2018; Westhoek et al., 2011). Without strong incentives, manufacturers who launch new vegan products appear to be responding to customer demand and the expanding vegan movement, reducing manufacturing costs, or addressing environmental issues on their own initiative.

Due to their observable efforts in creating and introducing new plant-based items, major corporations have viewed the vegan trend as a growing and sustained phenomenon. By developing cutting-edge goods and production technology, businesses may also be seen as playing a pioneering role in introducing new, inventive vegan products to mainstream customers in their local and national marketplaces. Rogers (2003) indicates two significant factors of the adoption rate of innovations are compatibility and added value. Conversely, the suitability of vegan products depends on how well these innovations fit with consumers' preexisting preferences and expectations (Dedehayir et al., 2017).

Innovation in Traditional Food Products

In a competitive global food market, manufacturers must innovate to preserve and grow their market share (Guerrero et al., 2009). Researchers find a common criterion that improvements in traditional food items must guarantee maintaining the original "taste" and "flavour" to determine whether innovations may be effective (Guerrero et al., 2012; Stolzenbach et al., 2013). In fact, several market research have revealed that customers have unfavorable emotional reactions to processes that alter conventional items (Stolzenbach et al., 2013). According to Guerrero et al. (2009), the modifications must effectively preserve the notion of traditional products, which are predicated on the idea of a basic, natural, simple, and pure product, particularly in the sense that little to no alteration has taken place after the first manufacture. Otherwise, according to other academics, the "new haute cuisine" is seen as a special setting where conventional food preparation and ingredient changes might take place (Guerrero et al., 2009; 2012). Accordingly, innovative techniques used at the restaurants of famous haute cuisine chefs have been examined in the most recent management studies (Messeni Petruzzelli and Savino, 2014, 2015).

Researchers in Nordic and Southern European nations are equally interested in investigating technologies that might impact conventional food items. The connection between a region's history and its traditional cuisine is a key feature that is recommended for growth in Southern nations (Guerrero et al., 2009). Studies of Nordic settings, where chefs, authors, and specialists emphasize the necessity "to continue using local, regional, and national raw goods," also revealed the connection between traditional food items and certain geographic regions (Amilien and Hegnes, 2013). In the context of the Noma restaurant, where studies determined that successful new dishes are mostly based on the exploitation of traditional Nordic ingredients, this method serves as inspiration for the new dishes created there (Messeni Petruzzelli and Savino, 2014).

Remarkably, a recent study on Italian haute cuisine discovered the rise of a new tactic: new products are created by combining traditional ingredients with other ingredients and by utilizing methods from other, far-off cultures (Messeni Petruzzelli and Savino, 2015). The cultural backdrop of Southern European nations, where ethnicity is seen as an acceptable source of invention, may help to explain this final innovation method (Guerrero et al., 2009). Furthermore, studies conducted on Southern European nations have demonstrated that any prospective improvements pertaining to traditional food items must be health-oriented, such as enhanced or functional foods and the decrease of salt, fat, and sugar (Guerrero et al., 2009, 2010, 2012). Conversely, Nordic nations seem to have a more critical stance toward innovation in traditional food items, as they are already regarded as healthy (Guerrero et al., 2009, 2010, 2012).

Remarkably, research in Nordic European countries paid more attention to the "Innovation in traditional food products" than Southern European countries. Furthermore, the results of this stream also appear unexpected. Southern European consumers appear to be more receptive to changes in traditional food goods if those changes improve nutritional value by lowering the amount of salt, saturated fat, or sugar while maintaining the original flavor. Conversely, in Nordic food markets, where traditional food products are already regarded as healthy, introducing novelty seems to be quite challenging.

Comparative Analysis of Water Quality in Dam Lakes of Edirne Province, Türkiye

Said Muhammed[1], Cem Tokatlı[2]

[1]University of Peshawar, National Centre of Excellence in Geology, Peshawar / Pakistan
[2]Trakya University, Evrenos Gazi Campus, Edirne / Türkiye

e-mail: saidmuhammad1@gmail.com

Abstract

Edirne Province is located in the northwestern part of Türkiye's Marmara Region. This area is classified as "Agricultural Land" because of its abundant freshwater resources and fertile soils. In the current research, the water qualities of Sultanköy and Altınyazı dam lakes were assessed and compared. Water samples were taken from the reservoir outlets in the autumn of 2024. A total of 12 physicochemical parameters were measured, including dissolved oxygen (DO), electrical conductivity (EC), pH, total dissolved solids (TDS), turbidity (Tur), salinity (Sal), suspended solids (SS), nitrite-nitrogen (NO_2-N), phosphate-phosphorus (PO_4-P), nitrate-nitrogen (NO_3-N), sulphate (SO_4), and ammonium-nitrogen (NH_4-N) using a multi-parameter meter and a spectrophotometer. The results of the study indicated that the water quality in both dam lakes was comparable, with both reservoirs demonstrating first-class water quality for DO, pH, NO_3-N, and NH_4-N parameters, second-class water quality for EC and NO_2-N parameters, and third-class water quality for PO_4-P.

Keywords: Sultanköy Dam Lake, Altınyazı Dam Lake, Water quality comparisson

Introduction

Freshwater pollution is one of the most critical environmental challenges of the 21st century, posing significant threats to aquatic ecosystems, biodiversity, and human health (Helvacıoğlu et al., 2025; Haq et al., 2023; Din et al., 2023; Muhammad et al., 2024; 2025; Tokatlı et al., 2025). Among freshwater bodies, dam lakes play a crucial role in water supply, irrigation and flood control. However, increasing anthropogenic activities, including agricultural runoff, industrial discharges, and domestic wastewater inputs, have led to the deterioration of water quality in these reservoirs (Çiçek et al., 2014; Köse et al., 2020; Varol et al., 2022; Ustaoğlu et al., 2022; Yüksel et al., 2024)

Sultanköy and Altınyazı Dam Lakes are among the most significant reservoirs in Edirne Province, Türkiye, playing a crucial role in regional water supply for both irrigation and drinking purposes. Constructed by the General Directorate of State Hydraulic Works (DSİ) to support agricultural productivity and meet the water demands of local communities, these reservoirs have become vital resources for sustaining both economic and ecological balance (http://www2.dsi.gov.tr/). However, like many freshwater ecosystems, they are increasingly subjected to anthropogenic pressures, particularly from agricultural runoff and domestic wastewater discharge, which introduce excessive nutrients, pesticides, suspended solids, and organic pollutants into the water bodies (Tokatlı et al., 2017; Tokatlı, 2019; 2020a; 2020b).

In response to these environmental challenges, this study aims to evaluate and compare the water quality of Sultanköy and Altınyazı Dam Lakes by analysing key physicochemical parameters. Through a detailed evaluation of these indicators, the research seeks to provide valuable insights into the current state of these reservoirs and contribute to the development of sustainable water management strategies to ensure the long-term protection and usability of these essential freshwater ecosystems.

Materials and Methods

Research area and sample collection

Sultanköy and Altınyazı Dam Lakes, along with the selected sampling stations on these reservoirs, are presented in Figure 1, providing a visual representation of the study area. To evaluate the current water quality status, water samples were systematically collected from the designated stations during the autumn season of 2024, ensuring that potential pollutant influxes were accurately represented in the analysis.

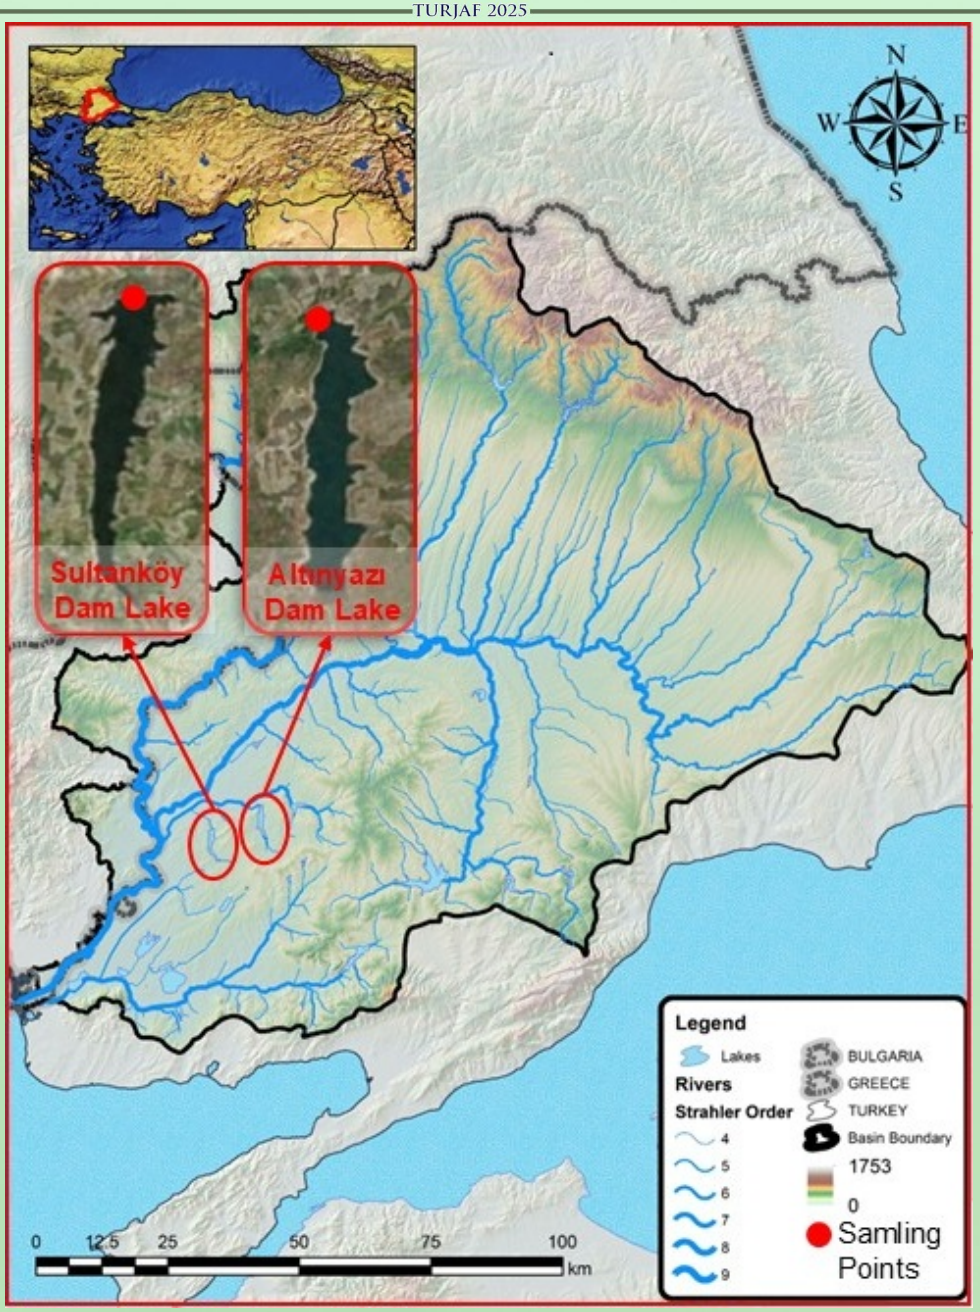

Figure 1. Meriç – Ergene Basin, investigated reservoirs and selected sampling stations

Physicochemical analysis

Dissolved oxygen, electrical conductivity, pH, total dissolved solids, salinity, and turbidity were measured on-site in the field following APHA standards (1998, 2017) using a Hach portable multi-parameter meter and a Hach turbidimeter. The concentrations of suspended solids, phosphate-phosphorus, nitrite-nitrogen, nitrate-nitrogen, ammonium-nitrogen and sulphate were analysed in the laboratory following APHA protocols (1998) using a Hach spectrophotometer and a Hach colorimeter.

Results and Discussion

The detected variables are given in Figure 2. Significant spatial differences in levels of investigated parameters were not recorded and the water qualities of both investigated reservoirs were quite similar. The data of the measured variables in waters of Sultanköy and Altınyazı Dam lakes as follows respectively: 9.62 – 9.40 mg/L for DO; 8.04 – 8.18 for pH; 359 – 313 mg/L for TDS; 734 – 643 µS/cm for EC; 0.36 – 0.31 ‰ for salinity; 47 – 286 NTU for turbidity; 32 – 188 mg/L for SS; 0.021 – 0.023 mg/L for NO_2-N; 0.80 – 0.05 mg/L for NO_3-N; 0.85 – 0.44 mg/L for NH_4-N; 0.30 – 0.21 mg/L for PO_4-P; and 83 – 95 mg/L for SO_4. It was also determined that both reservoirs exhibited first-class water quality in terms of DO (> 8 mg/L), pH (6 – 9), NO_3-N (< 3 mg/L) and NH_4-N (< 0.2 mg/L) parameters, second-class water quality in terms of EC (400 – 1000 µS/cm) and NO_2-N (0.01 – 0.06 mg/L) parameters, and third-class water quality in terms of PO_4-P (> 0.16 mg/L) parameter (TSWQR, 2021). Elevated phosphate levels can lead to eutrophication, a process where excessive nutrients stimulate algal blooms, depleting oxygen levels and disrupting the aquatic food web. In reservoirs, high phosphate concentrations may arise from agricultural runoff containing phosphate fertilizers, wastewater discharge, and soil erosion. Agricultural activities, particularly the use of phosphate-rich fertilizers, contribute significantly to phosphate influx, while wastewater and industrial discharges further augment nutrient loading (Mutlu et al., 2021a; 2021b; Tokatlı et al., 2023; 2024). It is thought that the quite high phosphate values detected in the waters of both investigated dams, which are quite close to residential areas, are caused by agricultural activities and domestic waste.

Conclusions

In conclusion, the water quality data collected from Sultanköy and Altınyazı Dam lakes reveal generally similar characteristics across both reservoirs, with some variations in specific parameters. Both reservoirs exhibit first-class water quality for several critical parameters, including dissolved oxygen (DO), pH, and nitrate-nitrogen (NO_3-N)while they exhibit second-class water quality for electrical condictivity (EC) and nitrite-nitrogen (NO_2-N). However, elevated phosphate levels observed in both lakes suggest a potential risk for eutrophication, which may result from agricultural runoff and domestic waste, given the proximity of these reservoirs to residential areas. Despite their overall good water quality, the higher concentrations of phosphate in both dams indicate that agricultural activities and domestic effluents may contribute significantly to nutrient loading, potentially threatening the long-term ecological balance of these aquatic ecosystems.

Abstract
The study aimed to investigate the effect of different levels of soya flour and soya oil on the sensory attributes and nutritional qualities of smoked-cooked chicken sausages. The sausages were manufactured by replacing part of the chicken meat in four treatments with soya flour (T1 =0.0g; T2=94g; T3 =75g and T4 = 52g) and soya oil (T1=0.0ml; T2=56ml; T3=75ml; and T4= 98ml). The products were smoked, cooked and served to forty consumer panelists for sensory evaluation. Consumer panelists evaluated the appearance, texture, juiciness, flavor, taste and overall acceptability of the sausages using a 9-point hedonic scale. Other parameters determined were proximate composition, cooking yield and water holding capacity. The results from proximate composition showed no significant differences ($p>0.01$) in ash and moisture contents of all treatments. There were significant differences ($p<0.01$) in the protein contents, with T2 having the highest protein content and T4 having the lowest. It was observed that fat contents significantly increased ($p<0.01$) as the levels of inclusion of soy oil increased in sausage formulations, and T4 had the highest fat content. There were also significant differences ($p<0.01$) in water holding capacity, with T4 having the highest. No significant differences ($p>0.01$) were observed in the cooking yield and all the sensory attributes evaluated. It was concluded that using higher quantities of flour and lower oil levels resulted in higher protein contents of sausages. While incorporating lower quantities of flour and higher oil levels resulted in higher fat contents. But the levels of soya flour and soya oil used did not affect the sensory attributes of sausage. The best chicken sausage was obtained with 5.35% soya flour and 3.18% soya oil in product formulations.
Keywords: Chicken sausage, sensory attributes, nutritional quality, soya flour, smoked-cooked sausage.

Introduction

The consumption of meat and meat products have long been regarded as an essential part of human diets since they are important sources of a wide range of nutrients that are essential for optimal growth and development. According to You *et al*. (2020) global developments and industrialization have induced a worldwide increase in meat-based diets, including differently processed meat. Such meat-based diets including sausages contain several nutrients in high quantities and quality, however, the contents of protein (amino acids), vitamins, minerals and fatty acids may vary depending on the animal species and processing methods.

A sausage is a meat product obtained from the formulation of different meat ingredients and spices in different proportions to satisfy consumer demands in different regions. According to Carballo (2021) there are varieties of sausages produced worldwide each with outstanding socio-cultural and economic significance, and each local variety is a reflection of the availability and type of raw materials, the climatic influences of the geographical environment, cultural and religious conditions, as well as the knowledge of manufacture passed on from one generation to another. Among the various types of meat, chicken is a popular source of protein due to its low fat, high protein, and balanced amino acid contents. It is therefore recognized by modern consumers as an ideal protein source for healthy eating (Kawecki *et al*., 2021; Hwang *et al*., 2020). According to Barbut (2001) chicken sausages are considered one of the popular foodstuffs among food products and it is consumed across the world. However, during storage, quality attributes of products deteriorate due to lipid oxidation, microbial growth, and also due to chemical reactions (Moawad *et al.,* 2020). Their perishable nature is due to high moisture content, minerals, fat and proteins, which may favour microbial activity leading to a loss in sensory attributes. As a result, the incorporation of some ingredients may maintain the product quality and shelf life (Pagthinathan and Gunasekara, 2021). Thus, food industry experts are continuing to explore innovative means to obtain foods that can meet consumer acceptance for nutritional and sensory characteristics with better storage life based on careful selection and formulation of ingredients available.

According to Zhang *et al*. (2021) soy flour helps to reduce cooking loss, prevent fat separation, and increase yield in meat products. Aside from its use in sausage making, soy protein in particular could have health benefits since it contains essential amino acids that the body needs to function properly. The use of soy flour can also increase the protein contents of other products, which can be beneficial for consumers who require more protein in their diets (Zhang *et al*., 2021).

Thus, many research reports are available on the effects of the addition of soy flour or protein concentrate in sausage making, but there is paucity of work done specifically on effects of using both soy flour and oil on the quality of chicken sausages.

The main objective of this study was to evaluate the quality of chicken sausage through the incorporation of both soy flour and soy oil. The specific objectives included assessments of the impact of soy flour and oil on the physicochemical, nutritional, and sensory attributes of smoked-cooked chicken sausages.

Materials and methods

Study location

This study was conducted at the Meat Science and Processing Unit, Department of Animal Science Kwame Nkrumah University of Science and Technology (KNUST), Kumasi.

Source of experimental materials

10kg of frozen chicken drumsticks were obtained from a local meat shop and spices and seasonings used were obtained from the Kumasi Central Market. Soy oil was purchased from Vester Oil Mills Limited while the soy flour was from ABI'S Special, both located in Kumasi. The chicken drumsticks were thawed overnight at 2°C and deboned, after which the boneless obtained was minced using a table-top mincer with 5mm sieve diameter (MADO Super wolf, Germany).

Sausage production

The total of 6.5kg minced chicken obtained was divided into four portions of 1.754kg, 1.604kg, 1.604 and 1.604kg, each labelled as T1, T2, T3 and T4 respectively (Table 1). The same quantities of spices (20g curing salt, 5g black pepper, 4g garlic powder, 6g nutmeg powder,10g phosphate, 500g ice, 8g chili pepper in each of the minced meat) were added to each treatment. Soy oil and soy flour were added at different levels for T2, T3, and T4 except T1 (control).

Table 1 Ingredients used in product formulations

Ingredients (g)	Treatments			
	Control T1	T2	T3	T4
Meat Sample	1754	1604	1604	1604
Soy flour	0.0	94	75	52
Soy oil (ml)	0.0	56	75	98
Cure Salt	20	20	20	20
Black pepper	5	5	5	5
Garlic powder	4	4	4	4
Phosphate	10	10	10	10
Nutmeg powder	6	6	6	6
Ice and Water	500	500	500	500
Chili pepper	8	8	8	8

The minced meat with all the ingredient was placed in an electric meat mixer and chopped into a consistent paste (meat batter), which was filled into edible cellulose casings and liked to 6cm lengths for hot smoking in a traditional smoke oven. Smoked sausages were cooked in hot water at 80°C to obtain internal temperature of 65°C. The cooked sausages were cooled in ice water, packaged in labelled transparent bags for storage at -18°C for further studies.

Parameters measured

Sensory properties

Sensory evaluation of the sausages was carried out the following day and repeated after 7 days by 35 consumer panellists. The panelists comprised of members and research fellows of the Department of Animal Science. Each sausage treatment sample evaluated was cut into equal sizes of 2cm, after which it was warmed and served to the panel members. Each sample was coded with 3-digit random numbers for the evaluation of sensory attributes for appearance, flavor, texture, juiciness and overall acceptability using 9-point hedonic scale (where 1 is dislike extremely and 9 means like extremely). Drinking water was provided to all panel members to rinse their mouth before and between tasting each sausage sample to avoid carry-on effects.

Proximate analyses and pH of sausages

The crude protein, crude fat, moisture, and ash contents of the products were determined according to AOAC (2023) methods. The pH of sausage samples which were homogenized in deionised distilled water was determined using a digital pH meter (Precisa pH 900-9050, Switzerland).

Thiobarbituric acid reactive substances value (TBRS)

Lipid oxidation in the chicken sausages was measured as TBARS value, according to the procedures described by Alina *et al*. (2012) and Xiong *et al.* (2015). Briefly, 5g of sausage sample without casing was mixed thoroughly with 25 mL of aqueous solution containing 5 mL ≥99.0% trichloroacetic acid, then with 20 mL of deionised water.

The resulting mixture was placed in a 100 mL beaker for 1 h at room temperature, after which it was filtered through a Whatman No.1 filter paper. The filtrate obtained was diluted to 50 mL with deionized water. A mixture of 5 mL of 0.02 M aqueous solution of 2-thiobarbituric acid (TBA) and 5 mL of diluted filtrate was heated in a water bath at 95 °C for 20 min for the formation of a pink colour. The sample absorbance was recorded at 532 nm on a UV/Vis 3200 spectrophotometer and expressed as mg malondialdehyde (MDA) equivalent/ kg sample.

Statistical Analysis

All data generated from the study were analyzed using SPSS version 20.0 using one-way analysis of variance (ANOVA) and significant differences between treatment means were determined using Duncan's test of homogeneity at 1%.

Results and discussion

Sensory characteristics of smoked-cooked chicken sausages

Sensory scores of sausages incorporated with or without soy flour and soy oil are presented in Table 2. The sensory evaluation results showed no significant differences among the samples in terms of appearance ($p = 0.619$), flavor ($p = 0.809$), taste ($p = 0.222$), juiciness ($p = 0.619$), texture ($p = 0.136$), and overall acceptance ($p = 0.897$). These results suggest that all the samples were similar, no matter the type treatment formulation used. Appearance scores ranged from 5.85(T1) to 6.35(T2), flavour was between 6.15(T2) and 6.50(T4), taste ranged from 6.025(T2) to 6.775(T3), juiciness was scored between 5.77(T3) and 6.300(T2), texture ranged from 5.575(T1) to 6.275(T4), and Overall acceptance was scored between 6.425(T1) and 6.700(T2).

Table 2 Sensory characteristics of chicken sausages with or without soy flour and soy oil

Parameters	Type of sausage				Sem	p-value
	T1	T2	T3	T4		
Appearance	5.850	6.350	6.250	6.300	0.147	0.619
Flavor	6.200	6.150	6.250	6.500	0.135	0.135
Taste	6.625	6.025	6.775	6.450	0.133	0.222
Juiciness	6.275	6.300	5.770	6.150	0.156	0.619
Texture	5.575	6.250	6.225	6.275	0.124	0.136
Overall Acceptance	6.425	6.475	6.700	6.550	0.133	0.897

Sensory scale: 1=Dislike extremely; 2=dislike slightly; 3=dislike moderately; 4= dislike; 5=neither like nor dislike; 6=like; 7=like slightly; 8=like moderately; 9=like extremely; Sem=standard error of means

The panel evaluation in this study suggested that all the sensory properties of chicken sausages were not influenced by the addition of soy flour or soy oil at the different levels studied. However, Choi *et al.* (2014) reported that the addition of brewer's spent grain fibre decreased the sensory scores for appearance, flavour, tenderness, juiciness as well as overall liking of chicken sausages. Malav *et al.* (2015) also reported decreased sensory properties for mutton patties produced with cabbage powder. But Fang *et al.* (2019) observed no significant differences in the sensory properties of chicken sausages produced with 3% sugar fibre.

Proximate composition of chicken sausages

The results for the proximate composition of the chicken sausages are presented in Table. 3. All the proximate components considered were significantly different ($p<0.01$) among the various formulations except for the crude ash and moisture contents. The fat content was highest in T4 (23.252%) and lowest in T1 (14.052%), while the protein content was highest in T2 (23.765%) and lowest in T3 (18.289%). Sausages with or without soy flour and oil were similar in moisture contents but significantly higher ($p<0.01$) fat and lower protein contents ($p<0.01$) were observed in soy-treated chicken sausages. These differences are related to the different composition of soy flour and oil ingredients used. Soy flour has higher protein content but lower fat content than soy oil. Chicken sausages with higher oil levels showed differences ($p<0.01$) in fat content compared to the control: the higher the added level, the higher the fat content. Also, the lower the flour added, the lower the protein contents observed. These trends regarding the changing fat and protein levels in meat products depending on the percentages of added ingredients agree with the reports of other authors for several meat products (Trout *et al.,* 1992; Biswat *et al.,* 2007; Peña-Saldarriaga *et al*., 2020).

Moisture contents ranged from 66.395%(T3) to 69.230%(T2) while percentage ash was between 1.480%(T4) and 1.855%(T3), and these were not statistically different ($p<0.01$) among treatments. These observations were similar to results reported by Peña-Saldarriaga et al. (2020) for chicken sausages produced with different chicken by-products as replacement for chicken fat.

Table 3 Proximate composition of the Smoked-cooked sausage

Parameter (%)	Type of sausage				Sem	p-value
	T1	T2	T3	T4		
Moisture	69.079	69.230	66.395	67.690	0.446	0.056
Ash	1.569	1.827	1.855	1.480	0.097	0.527
Fat	14.052[a]	17.745[a]	21.790[b]	23.252[b]	1.386	<0.001
Protein	21.692[b]	23.765[c]	18.289[a]	19.464[a]	0.803	<0.001

[abc]Means in the same row with different superscript are significantly different (p<0.01); soy flour (T1 =0.0g; T2=94g; T3 =75g and T4 = 52g); soy oil (T1=0.0ml; T2=56ml; T3=75ml; and T4= 98ml); Sem=standard error of means

Cooking yield, water holding capacity, and pH

No significant differences (p>0.01) were found among the cooking yield of the four sausage types studied. The mean cooking yields were 82.745% (T1), 86.605% (T2), 78.565% (T3), and 85.145% (T4). These results suggest that the different treatments of soy flour and oil did not potentially have any significant impact the yields of chicken sausages. However, Fang et *al.* (2019) reported significant differences in the cooking yield of chicken sausages. The observed differences in cooking yields reported by Fang *et al.* (2019) could be attributed to the different ingredients used in the different treatments. Where as Fang *et al.* (2019) used different levels of sugarcane fibre and water, the current study utilized soy flour and oil in the manufacture of the sausages.

Table 4 Percentage Cooking Yield, Water Holding Capacity, and pH

Parameters	Type of sausage				Sem	p-value
	T1	T2	T3	T4		
Cooking Yield	82.745	86.605	78.565	85.145	2.016	0.627
Water Holding Capacity	21.200[a]	23.700[b]	34.100[c]	37.100[d]	2.547	<0.001
pH	6.015[c]	5.695[a]	5.890[b]	6.210[d]	0.071	<0.001

[abcd]Means in the same row with different superscript are significantly different. (p<0.01); soy flour (T1 =0.0g; T2=94g; T3 =75g and T4 = 52g); soy oil (T1=0.0ml; T2=56ml; T3=75ml; and T4= 98ml); Sem=standard error of means

There were significant differences (p<0.01) in both pH and water holding capacity among the four chicken sausage types produced. The mean water holding capacities were 34.100% (T1), 37.100% (T2), 23.700 %(T3), and 21.200% (T4). It was observed that higher pH levels in T1(6.105) reduced significantly to 5.89(T3) in the soy-treated sausages. Both pH and water holding capacity have important functions in meat and meat products. Whereas water holding capacity influences juiciness, pH has significant effects of microbial activity and food texture development. The results in this study suggest that the significantly higher water holding capacity in soy-treated sausages could result in more juicier sausages, while their lower pH values may limit microbial activity to cause spoilage in the sausages during storage.

Effects of soy flour and oil usage on lipid oxidation in chicken sausages during storage Thiobarbituric acid-reacting substances (TBARs) value is commonly used to indicate the extent of lipid oxidation in food products. A higher TBAR value suggests a higher level of oxidative spoilage during storage. The observed TBARS values in both control and soy-treated chicken sausages were not significantly different during the entire 3 weeks of refrigerated storage though the levels seem to increase in absolute terms (Table 5). The recorded values during the first, second and third weeks of storage ranged from 0.585(T1) to 0.635(T3), 0.615(T2) to 0.620(T1) and 0.612(T3) to 0.641(T4) respectively.

Table 5 TBARs values in chicken sausages with or without soy flour and oil

Storage Duration	Treatments TBARs				SEM	p-value
	T1	T2	T3	T4		
Week 1	0.585	0.635	0.625	0.630	0.147	0.564
Week 2	0.620	0.615	0.625	0.650	0.135	<0.021
Week 3	0.630	0.613	0.612	0.641	0.137	0.072

Sem=standard error of means; TBARS=thiobarbituric acid reactive substance value in mg malonaldehyde equivalent/kg sample

There were reported reduced TBARS values in sausages (mortadella) with citrus fibre incorporated (Viuda-Martos *et al.,* 2010), goat meat nuggets with incorporation of broccoli powder extracts (Banerjee *et al.,* 2012), and mutton patties with the addition of cabbage powder (Malav *et al.,* 2015). These reductions in TBAR values earlier reported could be due to differences in phenolic contents of soy flour and oil as used in the production of chicken sausages in this study compared to citrus fibre, broccoli powder or cabbage powder used in the production of mortadella, goat meat nuggets and mutton patties respectively. Color of chicken sausages with or without soy oil

The results obtained for colour profile analysis of sausages are shown in Table 6. According to Kamani *et al.* (2017) colour is regarded, first, as a qualitative criterion in meat products and it plays a significant role in consumer's perception and overall product acceptability. There were no significant differences ($p>0.01$) for all the colour coordinates analysed. L* (Lightness) coordinate ranged from 57.453(T1) to 58.001(T4), a* (redness) value was between 17.256(T2) and 18.916(T1) while b* (yellowness) was from ranged from 7.400(T1) to 7.980(T3). Different findings were reported for L*, a* b* values by Peña-Saldarriaga *et al*. (2020) when chicken sausages were formulated with and without chicken fatty-byproducts. Overall, the L* a* b* analysis in this current study suggests that the incorporation of soy flour and soy oil in chicken sausage did not potentially affect the colour of sausages and thus, the consumers were not able to detect any differences in the appearance and acceptability scores during sensory evaluation (Table 2).

Table 6 Color profile of chicken sausages with or without soy flour and oil

Parameters	Treatments				Sem	p-value
	T1	T2	T3	T4		
L*	57.453	57.933	58.000	58.001	0.525	0.012
a*	18.916	17.636	17.256	17.330	0.330	0.031
b*	7.400	7.516	7.980	7.433	0.243	0.021

Means in the same row are not significantly different ($p>0.01$). Sem=standard error of means

Conclusions and recommendation

The use of soy flour and soy oil as ingredients did not affect the sensory characteristics, cooking yield, TBARs and colour of the smoked-cooked chicken sausages. But using higher flour levels resulted in higher protein contents while the incorporating higher oil levels gave higher fat contents in the sausages. The best chicken sausage was obtained with 5.35% soy flour and 3.18% soy oil in the formulation of smoked-cooked chicken sausages. Further study is recommended using soy flour and oil in the formulation of other types of sausage.

Comparison of Bioactive Properties and Phenolic Compounds of Turkish Coffee, Filter Coffee and Espresso Coffee

Sevde Nur Çataltepe, Nurhan Uslu , Mehmet Musa Özcan

Department of Food Engineering, Faculty of Agriculture, Selcuk University, Konya

Abstract

In this study, total phenolic content, total flavonoid content, antioxidant activity and phenolic compound contents of Turkish coffee, espresso and filter coffees taken from a local business were compared. Coffee is a popular beverage consumed in social life and has important effects on human health due to its rich bioactive compounds. Phenolic compounds such as caffeic acid and its derivatives, chlorogenic acids and flavonoids make significant contributions to the antioxidant activity of coffee.
When the obtained results were examined, the highest total phenolic and flavonoid amounts were found in espresso coffee as 6185.71 mg GAE/100 g and 4886.90 mg QE/100 g, respectively. The coffee with the highest antioxidant activity was determined as filter coffee (70.25 mmol TE/kg). The dominant phenolic compounds of coffee were determined as caffeic acid (113.73 mg/100 g) and chlorogenic acid (85.47 mg /100 g) in Turkish coffee, and protocatechuic acid (118.27 mg /100 g) in espresso coffee at the maximum level. When the flavonoid contents of coffees were compared, espresso coffee (2709.53 mg/100 g) ranked first in terms of catechin amount , followed by Turkish coffee (1270.80 mg/100 g). It has been observed that coffees prepared with three different methods, namely decoction (Turkish coffee), pressure (espresso) and infusion (filter coffee), contain significant amounts of phenolic compounds and have high antioxidant activity.

Key Words: *Antioxidant activity, Phenolic compound, Espresso, Turkish coffee, Filter coffee*

Introduction

Coffee, the fruit of evergreen sapling-sized trees, is a member of the Rubiaceae family (Kaur et al., 2018). The origin of coffee is Abyssinia/Ethiopia. Coffee, which is said similarly in most parts of the world, took its name from the " Kaffa" region in Abyssinia where coffee is grown (Topalakçı, 2011). Although there are many stories about the emergence of coffee, the most well-known is that it was discovered by goat shepherds. Observing that goats did not sleep at night and were constantly moving after consuming coffee berries, shepherds boiled and drank this fruit, and the coffee adventure that has continued until today began (Kaplan, 2011).
Among the Rubiaceae family, the ones with commercial importance *are Coffea arabica* (Arabica) and *Coffee canephora* (Robusta) (Olechno et al., 2021). *Coffee arabica* (Arabica) and *Coffee canephora* (Robusta), which account for 70% and 30% of global production, respectively (Neves et al., 2019). The chemical composition of coffee beans varies depending on the region where they are grown, the type of soil there, cultivation methods, species, climatic conditions, as well as the processing of the beans, i.e. cleaning and roasting (Zukiewicz-Sobczak et al., 2012). More than 1500 different compounds of coffee beans have been identified, of which 30-40% constitute carbohydrates, 13% fats, and 4% proteins, including free amino acids (Uslu, 2022).
Coffee beans contain aroma compounds, vitamins and minerals. In addition, coffee contains essential oils and phenolic compounds. Among the polyphenols contained in them, chlorogenic (CLA) and caffeic acid are distinguished (Olechno et al., 2020). It is also an important source of compounds with antioxidant potential such as (Çelik & Gökmen, 2018). However, most coffee globally is roasted and the antioxidant profile of coffee changes during roasting due to the degradation of natural antioxidants, the formation of new ones such as melanoidins and the formation of other Maillard reaction products (MRPs) (Nunes & Coimbra, 2007). The taste, quality and phytochemical properties of coffee, the interaction of water and coffee, and the brewing times and techniques are of great importance due to the fact that coffee contains many soluble and insoluble compounds during extraction (Cordoba et al., 2020)There are many techniques used to brew coffee such as (Komes & Belščak-Cvitanović, 2014). In this study, the total phenolic content, total flavonoid content, antioxidant activity and phenolic components of Turkish coffee, espresso and filter coffees purchased from a local business were compared

Materials and Methods

Material

Turkish coffee, espresso and filter coffee purchased from a local business in Konya were analysed after cooling at room temperature.

Methods

Coffee samples were diluted 10-fold to prepare the extracts and made ready for analyses.

Total Phenolic Content

Total phenolic contents of coffee extracts were detected using Folin Ciocalteu (FC) reagent (Yoo et al., 2004). Extracts (0.5 ml) were mixed with 2.5 ml FC reagent and 1.5 ml sodium carbonate solution. For absorbance values, samples stored in the dark at room temperature for 2 h, were measured in a spectrophotometer at a wavelength of 725 nm. The results were recorded as mg gallic acid equivalent (GAE)/100 g.

Total Flavonoid Content

Total flavonoid contents of coffee extracts were determined according to the method described by Hogan et al. (2009) The extracts (1 ml) were mixed with 0.3 ml $NaNO_2$, 0.3 ml $AlCl_3$ and 2 ml NaOH. The absorbance of the mixture was recorded at 510 nm with a spectrophotometer. The results were expressed as mg quercetin equivalents (QE)/100 g.

Antioxidant Activity Determination

Antioxidant activity of coffee extracts was determined using 2,2-diphenyl-1-picrazyl (DPPH) as suggested Lee et al. (1998). After the extracts (0.1 ml) were mixed with 2 ml of DPPH solution, the absorbance values of the samples, kept in the dark for 30 min at room temperature, recorded at 517 nm in a spectrophotometer. The results are given as mmol trolox equivalent (TE)/kg.

Determination of Phenolic Compounds

The phenolic compounds of coffee extracts were detected by HPLC (Shimadzu) equipped with a PDA detector and an Inertsil ODS-3 (5 µm; 4.6×250 mm) column. A mixture of 0.05% acetic acid in water (A) and acetonitrile (B) with a flow rate of 1 ml/min at 30 °C was used as the mobile phase. The injection volume was 20 µL. Peaks were taken at 280 °C using a PDA detector. The elution program was used: 0–0.10 min 8% B; 0.10–2 min 10% B; 2–27 min 30% B; 27–37 min 56% B; 37–37.10 min 8% B; 37.10–45 min 8% B. Total run time per sample was 60 minutes.

Results and Discussion

Total phenolic contents, total flavonoid contents and antioxidant activities of coffees prepared with three different methods, namely decoction (Turkish coffee), pressure (espresso) and infusion (filter coffee), are shown in Table 1. When the results obtained were examined, the highest total phenolic content was found in espresso coffee as 6185.71 mg GAE/100 g, while this value was recorded as 3787.76 mg GAE/100 g and 2212.93 mg GAE/100 g in Turkish coffee and filter coffee, respectively. In a study, the highest total phenolic content in coffees prepared in a coffee (Olechno et al., 2020). In another study, the highest total phenolic content was found in espresso coffee as 9.87 mg GAE mL^{-1}, while the same value was found as 5.05 mg GAE mL(Derossi et al., 2018). In a study conducted Kaur et al. (2018), it was reported that coffee made with the decoction method had higher total phenolic content than coffee made with the infusion method. Considering the literature data, the highest total phenolic content was found in espresso, followed by Turkish coffee and filter coffee.

The highest total flavonoid content was found in espresso as 4886.90 mg/100 g, these values were 1632.14 mg/100g and 875.48 mg/100 g in Turkish coffee and filter coffee, respectively. Uslu (2022)8671.77 mg/100 g) was found to be higher than that of coffee made with the infusion method (8518.71 mg/100 g). According to another study, the total flavonoid content in espresso was detected as 554.78 µg QE/ mL (Jung et al., 2021). In another study, it was determined that coffee prepared with the decoction method (69.24 mg/g) had higher total flavonoid content than the hard infusion method (35.76 mg/g) (Kaur et al., 2018). Among the pressure (espresso), decoction (Turkish coffee) and infusion (filter coffee) methods, espresso had the highest total flavonoid content, followed by Turkish coffee and filter coffee.

The antioxidant activities using the DPPH method were equal to 70.25 mmol TE/kg in filter coffee, 66.64 mmol TE/kg in Turkish coffee and 51.63 mmol TE/kg in espresso coffee. In a study, the antioxidant activity of espresso with the DPPH method (1587.7 mmol TE/L) was found to be higher than that of filter coffee (628.9 mmol TE/L) (Chavez et al., 2022). In another study, the antioxidant activity value was higher in the infusion method (8.51 mmol TE/kg) than in the decoction method (7.38 mmol TE/kg) (Uslu, 2022).

The phenolic compounds of coffees are given in Table 2. Caffeic acid (113.73 mg/100 g) and chlorogenic acid (85.47 mg/100 g) in Turkish coffee, protocatechuic acid (118.27 mg/100 g) in espresso coffee and caffeic acid (55.73 mg/100 g) in filter coffee were determined as the main phenolic acids.

The flavonoid contents of coffees are shown in Table 3. Espresso coffee (2709.53 mg/100 g) ranked first in terms of catechin content, followed by Turkish coffee (1270.80 mg/100 g) and filter coffee (597.33 mg/100 g). In a study recorded by Górecki and Hallmann (2020), caffeic acid (28.37 mg/g) was found in 3-minute brewing, while caffeic acid (27.74 mg/g) was found in 6-minute brewing. In another study, epigallocatechin (0.64 mg/g) was found in a coffee brewed at a medium level (Król et al., 2020).

Table 1. Total phenolic, total flavonoid contents and antioxidant activities of coffee samples

Coffee Samples	Total Phenol Content (mg GAE/100 g)	Total Flavonoid Content (mg QE/100 g)	Antioxidant Activity (mmol TE/kg)
Espresso coffee	6185.71 ± 194.68	4886.90 ± 50.68	51.63 ± 1.43
Filter coffee	2212.93 ± 32.80	875.48 ± 8.25	70.25 ± 0.00
Turkish coffee	3787.76 ± 110.37	1632.14 ± 14.29	66.64 ± 0.08

Table 2. Phenolic acid contents of coffee samples

Phenolic acids (mg /100g)	Espresso coffee	Filter coffee	Turkish coffee
Gallic acid	40.80 ± 0.69	32.33 ± 1.00	2.60 ± 0.04
Protocatechuic acid	118.27 ± 4.23	46.20 ± 2.75	4.87 ± 0.07
Chlorogenic acid	39.27 ± 1.38	52.60 ± 1.78	85.47 ± 3.01
Caffeic acid	32.73 ± 0.27	55.73 ± 2.84	113.73 ± 5.94
Coumaric acid	17.80 ± 1.20	1.33 ± 0.04	1.53 ± 0.03
Ferulic acid	1.67 ± 0.05	4.53 ± 0.12	5.13 ± 0.23
Cinnamic acid	0.67 ± 0.02	0.67 ± 0.02	7.73 ± 0.32

Table 3. Flavonoid contents of coffee samples

Flavonoids (mg /100 g)	Espresso coffee	Filter coffee	Turkish coffee
Catechin	2709.53 ± 18.25	597.33 ± 3.23	1270.80 ± 3.89
Routine	7.73 ± 0.19	6.47 ± 0.20	55.40 ± 1.61
Hesperid	7.00 ± 0.35	0.80 ± 0.03	1.60 ± 0.06
Quercetin	9.73 ± 0.19	4.47 ± 0.05	2.67 ± 0.06
Kaempferol	36.13 ± 0.29	30.60 ± 0.43	29.67 ± 0.53

In this study, bioactive properties of espresso, filter and Turkish coffees, which were obtained a local coffee shop, were analyzed and compared. The highest total phenolic and flavonoid contents were found in espresso coffee, followed by Turkish coffee and filter coffee. Antioxidant activity results were recorded as the opposite of the others, the highest in filter coffee, followed by Turkish coffee and espresso coffee. The main phenolic acids were found to be caffeic acid, chlorogenic acid and protocatechuic acid. The dominant flavonoid was determined as catechin.

Conclusion

In this study, bioactive properties of espresso, filter and Turkish coffees, which were obtained a local coffee shop, were analyzed and compared. The highest total phenolic and flavonoid contents were found in espresso coffee, followed by Turkish coffee and filter coffee. Antioxidant activity results were recorded as the opposite of the others, the highest in filter coffee, followed by Turkish coffee and espresso coffee. The main phenolic acids were found to be caffeic acid, chlorogenic acid and protocatechuic acid. The dominant flavonoid was determined as catechin.

Abstract

As a result of the parboiling procedure, where the starch in the grains is gelatinized and solidified when cooled, the husk may be removed from the grain during shelling with minimal harm. Nutrient loss while cooking the grain is also prevented as a result of gelatinization. Water was absorbed by the grain's empty spaces during the gelatinization and retrogradation processes. Hence, the absorbed water and nutrient molecules can't leave after the starch has swelled up and cooled. In this study, the Selam rice variety was subjected to three factors: soaking temperatures of 40, 60, and 80°C; soaking times of 6, 12, and 24 hours; and steaming times of 15, 25, and 35 minutes. The control group, non-parboiled rice, was also subjected to the full factorial design, which had a Completely Randomized Design (CRD) arrangement. The samples exposed to the highest time-temperature combinations showed variations in cooking time, swelling ratio, water uptake ratio, and percentage of chalkiness that were statistically significant ($P<0.05$). The cooking duration varied between 8.13 to 12.37 minutes, whereas the control took 9.28 minutes. The swelling ratio varied from 1.04 to 1.57, while the control was 1.26. The water uptake ratio values weren't statistically different, though. The color value difference varied from 8.95 to 19.57. When the soaking and steaming periods were extended to 24 hours and 35 minutes, respectively, for the 80°C soaking temperature, the amount of chalkiness in the grains drastically dropped from 99.48% of the non-parboiled rice to just 0.33%. The highest soaking temperature (80°C), soaking time (24 hours), and steaming time (35 minutes) were generally the best combinations for achieving the best cooking quality of parboiled rice.

Keywords: *chalkiness, cooking loss, cooking time, gelatinization, parboiling*

INTRODUCTION

Rice (*Oryza sativa*) belongs to cereal grain of the family *Poaceae*. For the vast majority of people on the planet, it is regarded as the main food crop (Vijay and Roy, 2018). According to IRRI, it is clear that rice cultivation has an impact on youth employment, food security, and poverty reduction. Rice is a staple food for people in many countries and is one of the most widely grown cereal crops worldwide (Rohman *et al.,* 2014). It is a grain with a diverse genetic makeup that is cultivated in hundreds of different kinds all over the world. One of the most significant food grains for humans has historically been rice due to its vast spread. Two-thirds of the world's population is fed this rice grain (Dhankhar, 2014). About 27% of the energy in low- and middle-income nations comes from rice. In all regions of the world, including Sub-Saharan Africa (SSA), it is one of the food commodities with the fastest rate of growth (Dawit and Tompson, 2020). The most significant crop in West Africa and the third-most significant crop in all of Africa is rice. It is consumed by more than 750 million people in sub-Saharan Africa (SSA) (EIAR, 2019). As opposed to other food crops, rice is ingested as a whole grain, making grain quality factors far more important. Around 618 million tons of rice were produced worldwide each year, of which 50% were converted into parboiled products (Rahimi-Ajdadi *et al.*, 2018).

Rice cultivation in Ethiopia most likely began when wild rice (*Oryza longistaminata*) was discovered in the wet, marshy areas of the Fogera (Amhara) and Gambella plains. In several regions of Ethiopia, rice output has grown consistently (EIAR, 2019). The entire land area has grown since the early 1970s, going from roughly 10,000 hectares in 2006 to about 50,000 ha in 2018. Before rice was introduced, the farmers in the Fogera Plain subsisted on pastoral farming and a modest amount of crop output (Tilahun *et al*., 2018). Gambella from 1973 to 1982, Pawe from 1985 to 1988, and the Fogera plain in the early 1980s were the first places where rice was introduced. The Fogera plain, however, has remained one of the top rice-producing regions among them, having shown a significant number of agricultural modifications related to rice production and its marketing.

According to Takele, (2017) and Dawit *et al*., (2018), Ethiopia is regarded as a significant rice-growing nation in Africa. More than 39 million hectares of Ethiopian land are ideal for growing rice. A little under 30 million hectares are upland, 3.7 million are irrigated, and the remaining area is used for lowland rice. From being the poorest farmers in the area to becoming the richest, the Fogera Plain's rice farmers have improved their quality of life. In the rice processing and marketing industry, private company owners have arisen and prospered (Dawit *et al*., 2018).

Even though rice is growing rapidly by area coverage and demand, the local rice varieties in Ethiopia have low physical and cooking quality attributes. Rice passes multiple steps of processing to be eaten during which it could

be lost quantitatively and qualitatively due to milling at low moisture content, mal-operation of the polishing machine, and impurities with rice grain (EIAR, 2019). According to the study by Da, (2021), there is a very high loss of rice during de-hulling and polishing, when using poor-performance machines and unskilled operators. Parboiling emerged to improve the cooking and milling qualities of rice, where the process involves soaking, steaming, and drying (Ayenew *et al*., 2020). Thus, to solve this problem, parboiling technology has been introduced to Ethiopia recently to gelatinize the starch and harden the kernel.

Ethiopian rice varieties are not yet treated by the parboiling process. Rice consumers are asking the rice research and training center for technologies that could improve the cooking quality of rice. Rice processors in the South Gondar zone are adapting the parboiling process using the Africa Rice GEM parboiling technology. The processors were using firewood or electricity as a source of energy before the introduction of the Africa Rice GEM soaking and steaming apparatus. However, the GEM parboiling technology is easier and uses rice husk burning in a gasifier as a source of power. This study aimed to improve the rice cooking quality and reduce the percentage of chalkiness. The research was expected to enhance the livelihood of farmers and contribute to the betterment of the marketing system. Thus, the objectives of this study were to:

a) study the effect of soaking and steaming time-temperature interaction on the cooking time of parboiled rice,
b) study the effect of the time-temperature combination of soaking and steaming on the water uptake ratio of parboiled rice,
c) investigate the impact of the rice parboiling process on the swelling ratio of rice, and
d) study the effects of parboiling on the percentage of chalkiness and color of the parboiled rice

MATERIALS AND METHODS

Experimental Materials

Domestic lowland rice (*Selam*) variety of 81 kg was collected from Fogera National Rice Research and Training Center (FNRRTC), Ethiopian Agricultural Research Institute.

Experimental Plan

The experiment of parboiling was conducted with a full factorial design of having a completely randomized arrangement. It consisted of three factors with three levels. These are soaking temperatures of 40, 60, and 80°C; soaking time of 6, 12, and 24 hours and steaming time of 15, 25, and 35 minutes. Each treatment was carried out with three replications. The non-parboiled milled rice was the control that passed through the same processes except the parboiling. A control sample of 20-kg paddy was sun-dried (without parboiling) to 14% moisture content and was milled (Hasbullah *et al.,* 2017; EIAR, 2019).

Sample Preparation

Cleaning

According to Ndindeng *et al*. (2015) and Nambi *et al*. (2017), the cleaning of paddy was done based on the different physical properties such as size, density, weight, and properties of impurities. Both the experimental and control groups of collected rice grains were first cleaned very well using a hand-operated winnower. Impurities that were lighter than the paddy were removed by aspiration whereas those that could not be removed by the winnower were cleaned by handpicking.

Washing

The immature grains of the experimental groups were separated by floating in the water Ndindeng *et al*. (2015). The floated grains were removed and only the submerged ones were taken for the next process. Water-soluble dirt in the paddy was removed by washing it in water to prevent the entry of pollutants into the embryo during soaking and steaming. Then, the cleaned paddy was sun-dried and weighed.

Parboiling Process

Soaking

The soaking temperature was 40°C, the first 9 kg of paddy was soaked for 6 hours, the second 9 kg for 12 hours, and the third for 24 hours and left in ambient conditions till the time was up. The same procedures were followed for 60 and 80°C soaking temperatures. Each division of the sample was added into a soaking tank (which was made up of stainless steel, Inox 304), with plenty of water at the water-to-paddy rice ratio of 2:1 (Ndindeng *et al*. 2015; Hasbullah *et al*. 2017). The soaking temperatures and soaking time values used for this study were the medium values that scholars used (Ayamdoo *et al*., 2013; Bello *et al*., 2015; Ndindeng *et al*., 2015; Hasbullah *et al.,* 2017).

Steaming

Each of the samples was soaked for 6, 12, and 24 hours at a temperature of 40, 60, and 80°C divided into three equal parts having 3 kg each (Ndindeng *et al*., 2015). Each of the 3-kg samples was added to a perforated steaming apparatus made of stainless steel (Inox 304) one by one. The amount of water that was added to the steaming apparatus was a 1:2 ratio with the paddy. The paddy did not contact the water directly. It was steam-heated by the vapor released from the steaming tank. Samples from each soaking time were steamed for 15, 25, and 35 minutes of duration without removing the heat source. The steaming time values selected for this study were the medium values used by most scholars (Ndindeng *et al.*, 2015; Hasbullah *et al.*, 2017; Yerragopu and Palanimuthu, 2019).

Drying

The parboiled paddy was dried in the open sun by spreading it on a plastic sheet. It was continuously stirred to avoid over-drying on one side and to protect against the formation of internal cracks. The paddy dried up to 18% moisture content and was placed in the shade until it was slowly reduced to 14% (Ndindeng *et al.*, 2015; Hasan *et al.*, 2019). The moisture content level was checked every 15 minutes, using a rice grain moisture meter KETT J301, Japan (Ayenew *et al*. 2020).

Husking

The dried paddy was husked with a machine, SATAKE SB 2000, SATAKE Corporation, Hiroshima, Japan that was properly adjusted according to the technical manual, and brown rice was obtained (Nambi *et al*. (2017) and Ayenew *et al*. (2020).

Polishing

The brown rice was transferred into the polishing machine SATAKE SB 2000, Satake Corporation, Hiroshima, Japan to remove the bran from the endosperm. The properly adjusted rubber roll machine produced the polished white rice (Ayenew *et al*., 2020).

Determination of Physical Characteristics of Parboiled Rice

Moisture Content

The moisture content of the paddy was measured randomly using a digital rice moisture meter J301, Japan (Ayenew *et al.,* 2020; Paul *et al*., 2020; Bagchi *et al*., 2016) by taking a few grains from the sample. Measurements were taken after soaking, after steaming, during drying at different time intervals, and before husking or polishing to be sure of the 14%. Additionally, the moisture content of each sample was analyzed by the FOSS NIR Systems-6500 machine when the proximate composition was examined.

Percentage of chalkiness

Chalkiness is a level of low transparency of light through the grain. The number of chalky grains in the milled/polished rice was determined by a grain viewer magnifying lens (QUG/A2-SL, U.K.) with fluorescent light. Rice grain is said to be perfectly translucent when it allows light transmission through it. Otherwise, it's considered opaque or chalky. The percentage of chalkiness was determined by taking 10 g of parboiled milled rice from the samples. It was estimated by the following formula (Equation 1) (Ayenew *et al*., 2020; Jittanit and Angkaew, 2020; Sethy *et al.*, 2018).

$$\text{Chalkiness (\%)} = \left[\frac{\text{Weight of chalky grains}}{\text{Weight of sample grains}}\right] \times 100 \qquad (1)$$

Color

Color is an important criterion for the marketing value of parboiled rice. The whiteness color value of parboiled rice decreases to slightly darker (Taghinezhad *et al*., 2015). The overall color of the parboiled rice could be estimated using the formula given below (Equation 2); using Konica Minolta CM-5, Tokyo, Japan (Jittanit and Angkaew, 2020).

$$\Delta E = \sqrt{(L_2 - L_1)^2 + (a_2 - a_1)^2 + (b_2 - b_1)^2} \qquad (2)$$

Where: L_2 stands for the brightness of parboiled rice, while L_1 represents the brightness of non-parboiled rice, a_2 is the red-green color component of parboiled rice, a_1 refers to the red-green component of non-parboiled rice color, b_2 refers to the yellow-blue color component of treated rice, and b_1 stands for the yellow-blue color component of non-parboiled rice (Nawaz *et al*., 2018). According to Taghinezhad *et al*. (2015), soaking at 65°C and steaming time of 4 min gives the highest values of desirable quality of parboiled rice, such as lightness.

Determination of Cooking Quality

Cooking time

According to Ndindeng *et al*. (2015) and Hasan *et al*. (2019), ten grams of milled rice from each sample were poured into 135 ml of vigorously boiled water in a 400 mL beaker and covered by a glass. After about 10 minutes of boiling, 10 grains were taken out one by one every minute with a perforated ladle. The removed grains were immediately pressed between 2 Petri dishes to know whether it was well cooked or not. The cooking continued until a minimum of the 10 grains had no opaque centers. The time taken for that to happen was recorded and considered the sample's optimum cooking time.

Water uptake ratio

The water uptake ratio is the capacity of the rice kernel to suck water when cooked. According to Thomas *et al*. (2013), Chavan *et al*. (2018), and Yerragopu and Palanimuthu (2019), the water uptake ratio (WUR) was estimated by taking 20 g of head rice and cooking in 200 mL of distilled water at 90°C until there was no white core left in the grain. Then water uptake ratio was calculated mathematically by subtracting the weight of the uncooked kernel from the weight of the cooked kernel and dividing by the uncooked kernel using Equation 3.

$$\text{WUR} = \frac{\text{Weight of cooked} - \text{Weight of uncooked}}{\text{Weight of uncooked}} \qquad (3)$$

Swelling ratio

The swelling ratio (elongation ratio) is the extension of rice kernel length due to cooking and water uptake. It was estimated by randomly selecting 10 cooked rice kernels, measuring their lengths by digital Vernier Calliper, and

dividing their mean value by the average length of 10 randomly selected raw rice grains measured by the same instrument (Thomas *et al*., 2013; Yerragopu and Palanimuthu, 2019) using Equation 4.

$$\text{Swelling ratio} = \frac{\text{Length of cooked kernel}}{\text{Length of raw kernels}} \quad (4)$$

Data Analysis

The collected data were statistically analyzed using Statistix-10 software. They were subjected to analysis of variance (ANOVA) to see the statistically significant differences due to the different parboiling treatments and the control (non-parboiled rice). The parameters considered were the percentage of broken rice, head rice yield, milling recovery, physicochemical properties, cooking quality, and nutritional qualities of rice. The statistically significant differences between sample means were analyzed by following a full factorial design arranged in CRD at a 5% level of significance.

Results And Discussions

Interaction Effects of Soaking Time, Soaking Temperature, and Steaming Time on the Quality Parameters of Parboiled Rice

Effects of pre-treatment temperature and soaking time on cooking quality

Table 1 presents data showing the interaction effects of soaking temperature and time on the cooking quality of parboiled rice. The interaction has a significant ($P<0.05$) effect on the cooking quality parameters except for the water uptake ratio. The cooking time ranged from 9.17 to 11.84 minutes, the longest being of samples soaked at 60°C for 24 hours. On the other hand, the shortest cooking times (9.17 and 9.33 minutes) belonged to two samples soaked at 40 and 60°C for 12 hr each. The interaction of the two factors appeared to have a balanced effect on the cooking time of parboiled rice and the values increased for most samples as compared to the control. This finding was corroborated by the report of Chavan *et al*. (2018) who showed that soaking at 85°C for three hours prolonged the cooking time of parboiled rice as compared to non-parboiled rice.

The swelling ratio data of parboiled rice showed significant ($P<0.05$) differences due to the interaction of the two factors. However, the data didn't show any trend with increasing soaking temperature and time. The swelling ratio values ranged from 1.16 to 1.38, the highest being of samples subjected to 40°C for 6 hours. On the other hand the lowest values, 1.16, 1.17, and 1.22 mm/mm, with no statistical difference among them, were recorded for the combination of a soaking temperature of 60°C and all three soaking times.

Chalkiness values were highest (14.78 and 12.56%) for samples subjected to the lowest soaking temperature (40°C) and shorter soaking times of 6 and 12 hours, respectively. On the contrary, the four lowest chalkiness values (0.90, 1.11, 2.01, and 3.56) were of samples subjected to the longest soaking times regardless of soaking temperature. The data showed that the interaction effect of the two factors on chalkiness values was dominated by soaking time, i.e. short soaking time led to high values while long soaking times resulted in low values at each soaking temperature considered in the study. This indicated that the parboiling process conducted for longer soaking times resulted in a higher starch gelatinization rate and formed a translucent grain while short soaking time resulted in minimal gelatinization of the starch in the kernels thus some white spots remained inside the kernels.

The color values of the parboiled rice ranged from 11.57 for samples treated with a combination of 40°C soaking temperature and 6 hours of soaking time to 18.26 for samples soaked at the highest temperature (80°C) for the longest time (24 hours). The data showed increment due to increased soaking time for each soaking temperature with a similar increasing trend among the group of data of the different soaking temperatures exhibiting a balanced influence of the two factors on the color values in their interaction. The trend in the color data is inversely related to that of chalkiness data because the higher the chalkiness in the grains the lower the color difference between the parboiled and the non-parboiled rice grains. This is related to the level of starch gelatinization in the parboiled grain: higher gelatinization leads to lower chalkiness hence higher color difference from that of the non-parboiled grain.

Table 1: Effect of soaking temperature and soaking time on cooking qualities of rice

SkTp (°C)	SkTm (hrs)	CT (min)	SR (mm/mm)	Chalkiness (%)	Color (ΔE)
40	6	$9.42^{f}\pm0.70$	$1.38^{a}\pm0.17$	$14.78^{a}\pm9.67$	$11.57^{g}\pm3.06$

Effects of steaming time and soaking temperature on cooking quality

Table 2 presents the interaction effect of soaking temperature and steaming time on cooking qualities. Cooking quality parameters were significantly (P<0.05) affected by the interaction of the factors. Generally, the cooking time increased as both the soaking temperature and steaming times increased. The minimum cooking times (9.52 and 9.31 minutes) were recorded at the combinations of the lowest (40°C) soaking temperature and shortest (15 and 25 minutes) steaming times. These values were statistically the same as the 9.28 minutes of the control sample. As the soaking temperature and steaming time rose, the cooking time of parboiled rice was extended. The interaction effect appeared to be balanced both factors exerting their influence on the cooking time. Ayenew *et al*. (2020) reported that the minimum cooking times of Ethiopian rice varieties were identified as 16-23 minutes for both *Ediget* and *Gumara* varieties when soaked at 40-80°C for 10-50 minutes.

The interaction of soaking temperature and steaming time significantly (P<0.05) affected the water uptake ratio of parboiled rice. The highest values (1.46 and 1.62) were of samples subjected to the combination of the lowest (40°C) soaking temperature and the two lower soaking times (15 and 25 minutes). At combinations of the higher soaking temperatures (60 and 80°C) and the three steaming times the values significantly dropped in some cases with no significant difference from the 0.98 of the non-parboiled rice. These findings are supported by the work of Chavan *et al*., l (2018) who showed that soaking at 85°C and steaming for 40 minutes significantly (P<0.05) improved the water uptake ratio to 2.96%.

The swelling ratio of parboiled rice was also significantly (P<0.05) affected by the interaction of the two factors. The values ranged between 1.17 and 1.42 varying randomly. The non-parboiled rice exhibited a value of 1.26.

The chalkiness of parboiled rice was significantly affected (P<0.05) by the interaction of soaking temperature and steaming time. The highest value (99.48) was of the control non-parboiled sample. Of the parboiled rice, the highest value (15.22%) was of the combination of the lowest soaking temperature (40°C) and shortest steaming time (15 minutes). The values decreased as the steaming time increased for all soaking temperatures and as the soaking temperature increased the chalkiness values dropped significantly. Thus the lowest value (0.68%) was of the combination of the highest (80°C) soaking temperature and longest (35 min) steaming time.

The parboiling process affected the overall color difference of the rice samples. The highest overall color value (16.79) was determined for samples treated by the lowest soaking temperature (40°C) and longest steaming time (35 minutes). The color difference value of parboiled rice in this study ranged from 10.54 to 16.79. Similar research work also showed that the color value for fresh parboiled rice samples was significantly (P<0.05) reduced to the non-parboiled rice (Nawaz *et al*., 2018).

Table 2: Effects of soaking temperature and steaming time on cooking quality parameters

Effects of soaking and steaming times on Cooking Quality

Table 3 presents the data showing the interaction effects of soaking time and steaming time on the cooking qualities of parboiled rice. All parameters of cooking quality were affected by the interaction of these two factors except the water uptake ratio, which did not exhibit statistically significant differences. The shortest cooking times of the parboiled rice were 9.76, 9.66, and 9.85 minutes for samples with a steaming time of 15 minutes combined with soaking times of 6 and 12 hours, respectively, and for the sample treated with a combination of 12 minutes of soaking and 35 minutes of steaming. On the other hand, the longest cooking times (11.09, 10.96, and 11.00 minutes with no statistical difference among them) were recorded for combinations of 24-hour soaking time with all three (15, 25, and 35 minutes) steaming times, respectively. The control sample (non-parboiled rice) had the shortest (9.28 minutes) cooking time. Thus parboiling process led to prolonged cooking time for the *selam* rice variety.

The interaction of soaking and steaming times significantly (P<0.05) affected the swelling ratio. The values ranged from 1.17-1.32 with the highest values being 1.27, 1.28, 29, and 1.32, the majority belonging to the 6 hours of soaking time combined with all three steaming times. All swelling ratios of the parboiled rice were significantly greater than the 0.98 of the control sample showing that parboiling improves swelling of rice granules.

Table 3: Interaction effects of soaking and steaming time on cooking quality parameters

SkTm	SmTm	CT (min)	SR	Chalkiness (%)	Color (ΔE)
6	15	9.76^{d}± 0.53	1.27^{abc}±0.17	17.67^{b}±3.39	11.45^{h}±2.25

Note: SkTm: soaking time (hour), SmTm: steaming time (min), CT: cooking time in minutes, SR: swelling ratio, (ΔE): overall color, values are in mean±SD

The percentage of chalkiness was also significantly (P<0.05) affected by the interaction of soaking and steaming times. It decreased the values from 17.67 to 0.33% as the combinations of factors were increased from 6 hours and 15 minutes to 24 hours and 35 minutes. The effect of the interaction of the two factors on chalkiness is balanced such that a reduction of the values is observed both within each soaking time and across the three steaming times. Regarding the color difference between the parboiled and non-parboiled rice significant (P<0.05) differences were observed attributed to the interaction of the two factors. The largest difference (18.47) was of the sample subjected to the combination of largest soaking time (24 hr) and longest steaming time (35 minutes). It appeared that the influence of the highest steaming time within the interaction is visible resulting in the highest value at each of the three soaking times. However, the interaction of the two lower steaming times (15 and 25 minutes) and the three soaking times did not show a visible trend in color difference values. The color value of the non-parboiled rice is 72.27.

Interaction Effects of Heat Treatment, Soaking Time, and Steaming Time on Cooking Qualities of Parboiled Rice

Effects of parboiling on cooking time

Table 4 presents the three-factor interaction effects of pre-heating, soaking time, and steaming time on the cooking qualities of rice. At the lowest soaking temperature (40ºC) samples subjected to the highest soaking (24 hr) and steaming (25 and 35 minutes) times showed relatively longest cooking times of 10.14 and 11.29 minutes. A similar trend was observed for a soaking temperature of 60ºC with cooking times of 11.81, 12.29, and 11.43 minutes for 15, 25, and 35 minutes of steaming times whereas at 80ºC soaking, this trend was noted for combinations of 12 hr soaking time and 25 and 35 min steaming times. The rest of the combinations of the three factors did not show any clear trend in the cooking times. Some combinations of the three factors had even resulted in cooking times shorter than that of the non-parboiled rice. For instance, cooking times of 8.13, 8.68, 9.05, 9.10 and 9.17 minutes had been observed.

A similar study that was done by Ayenew *et al*. (2020) reported that the minimum cooking time of *Gumara* and *Ediget*, domestic rice varieties, was found to be 16 minutes, which were recorded at 40°C and 10 minutes, respectively.

Effects of parboiling on swelling ratio

The interaction of these three factors also significantly affected (P<0.05) the swelling ratio. The records did not show any clear trend with some of the values being lower than the 2.26 of non-parboiled rice used as control while others exhibited higher values even up to 1.41 and 1.54. A similar study showed that the value of the swelling ratio of the *Gumara* variety ranged from 2.46 at a temperature of 40°C and steaming time of 10 minutes to 3.00 recorded at a soaking temperature of 80°C and 50 minutes of steaming time (Ayenew *et al*., 2020).

It was also mentioned that the swelling ratio of parboiled rice varied depending on the parboiling conditions and varieties (Nawaz *et al*., 2018).

Effects of Parboiling on Chalkiness of Rice

The data showing the degree of chalkiness of rice are given in Table 8. The result indicated that the chalkiness value significantly (P<0.05) decreased with an increase in soaking temperature, soaking time, and steaming time. For a given soaking temperature as the soaking time increased, chalkiness values decreased, and for each soaking time the chalkiness values decreased as the steaming time increased. Thus all three factors have a strong and balanced influence on the chalkiness of the rice grains. Samples subjected to a combination of the lowest soaking

temperature (40°C), short soaking times of 6 and 12 minutes) and short steaming time (15 and 25 minutes) resulted in statistically the highest (20.33, 22.00, and 22.67%) chalkiness value. This is because the level of gelatinization of the starches in the grain under this treatment combination is low. Rice starch gelatinization temperature is between 55 and 79°C. On the other hand, samples subjected to the highest soaking temperature (80°C), longest soaking time, and longest steaming time resulted in the lowest chalkiness value of 0.33%. The steaming times, 15, 25, and 35 minutes have played a significant role in reducing the chalkiness values since thermal treatment is responsible for gelatinizing the starch inside the rice kernels in the presence of water. Gelatinized starch allows more light through it changing the rice grain into more translucent and thus less chalky. Combinations of different intermediate values of the soaking temperature, soaking time, and steaming time resulted in intermediate chalkiness values (Saha, et al., 2021).

Generally, parboiling decreased the percentage of chalkiness from 99.48% of the control non-parboiled sample to 0.33% of the parboiled one. A similar study on the *Narica-4* rice variety showed that the percentage of chalkiness was decreased from 100% (control) to 0.13% when soaked at 70°C heating temperature 50 minutes of steaming time, and 80°C soaking temperature and 50 minutes of steaming time (Ayenew *et al*., 2020). Another study also argued that the opaque white appearance seen on the rice grain of milled rice was highly reduced by the parboiling process (Oli *et al*., 2014).

Effects of parboiling on a color value

The overall color value (ΔE) of parboiled ranged from 8.95 to 19.54. The highest color difference was found at the lowest temperature (40°C), highest soaking (24 hours), and highest steaming times (35 minutes). The least color difference (8.95) was recorded at a soaking temperature of 40°C, soaking time of 6 hours, and steaming time of 25 minutes (Table 8). A similar study conducted in this regard stated that the color of parboiled rice was found to be 25.8, which was recorded at the soaking temperature and time, and steaming time combination of 67.7°C, 13 hours, and 18 minutes, respectively (Ogunbiyi *et al*., 2018). According to the study by Srisang and Chungcharoen (2019), the percentages of whiteness for the parboiled rice showed a decreasing trend compared to the non-parboiled rice.

Table 4: Effects of three-way interaction of parboiling factors on cooking quality

SkTp	SkTm	SmTm	Cooking time(min)	Swelling Ratio	Chalkiness (%)	Color (ΔE)

Conclusions

Rice is becoming one of the most valuable crop commodi-ties in Ethiopia. Rice can be consumed directly by cooking brown or white processed rice. But the domestic rice lacks the desired milling and cooking qualities. This study was launched to enhance the quality of rice kernels by examining treatment combinations during the parboiling process. The parboiling method enhanced the rice's physical characteristics. The length of parboiled milled rice increased to 5.33-6.84 mm compared to 4.57 mm for non-parboiled. Cooking factors included cooking duration, absorption of water ratio, and swelling ratio. The cooking time for par-boiled milled rice varied from 8.13 to 12.35 minutes. The swelling ratio was highest (1.54) at a soaking temperature of 40°C, a soaking period of six hours, and a steaming time of 25 minutes. The chalkiness of parboiled rice was signifi-cantly decreased to 0.33%. The color distinction between parboiled grains and non-treated rice grew with the duration and before treatment temperature of soaking and steaming.

Acknowledgments

Fogera National Rice Research and Training Center, Ethiopian Institute of Agricultural Research (EIAR) is highly acknowledged for the study sponsorship, research fund, rice variety provision, and parboiling equipment. Haramaya University is also highly acknowledged for its technical support of research work.

Funding

The work was supported by the Fogera National Rice Research and Training Center, Ethiopian Institute of Agricultural Research (EIAR).

Authors contribution

Melese Ageze contributed to proposal writing, conducting the experiment, data collection, data analysis, and final paper writing. Getachew Neme contributed to proposal writing, revising, and interpretation. Solomon Abera contributed to methodology and design setup, final paper writing, and interpretation and approval.

Abstract

Agricultural production in the Turkish economy is strongly influenced by macroeconomic variables. Macroeconomic indicators such as inflation, interest rates, exchange rates and credit policies are among the basic elements that determine the production volume in the agricultural sector. The aim of this study is to examine the effects of macroeconomic factors on agricultural production in Turkey. In the study, the effects of the identified macroeconomic variables on agricultural production were evaluated using time series analysis. The data were obtained and analysed from the Turkish Statistical Institute (TURKSTAT), the Central Bank and other official institutions. The results show that exchange rate fluctuations have an impact on production, that changes in interest rates affect agricultural investments and that public support has a significant impact on production levels in the sector. This study aims to contribute to the development of policies that support sustainable growth in the agricultural sector by proposing solutions to better understand the impact of macroeconomic policies on agricultural production.

Key Words: *Agricultural Production, Macroeconomics, Inflation, Interest Rates, Exchange Rates, Agricultural Policies*

Türkiye'de Makro Ekonomik Değişkenlerin Tarımsal Üretim Üzerine Etkisi

Özet

Türkiye ekonomisinde tarımsal üretim, makro ekonomik değişkenlerden yoğun bir şekilde etkilenmektedir. Enflasyon, faiz oranları, döviz kuru ve kredi politikaları gibi makroekonomik göstergeler, tarım sektöründe üretim hacmini belirleyen temel unsurlar arasında yer almaktadır. Bu çalışma, Türkiye'de makro ekonomik faktörlerin tarımsal üretim üzerindeki etkisini incelemeyi amaçlamaktadır. Araştırmada, zaman serisi analizleri kullanılarak, belirlenen makro ekonomik değişkenlerin tarımsal üretim üzerindeki etkileri değerlendirilmiştir. Veriler, Türkiye İstatistik Kurumu (TÜİK), Merkez Bankası ve diğer resmî kurumlardan temin edilerek analiz edilmiştir. Elde edilen bulgular, döviz kurlarındaki dalgalanmaların üretim üzerinde etkili olduğu, faiz oranlarındaki değişikliğin tarımsal yatırımları etkilediğini ve kamu desteklerinin sektörde üretim seviyesini önemli ölçüde şekillendirdiğini ortaya koymaktadır. Bu çalışma, makro ekonomik politikaların tarımsal üretime olan etkilerini daha iyi anlamaya yönelik çözüm önerileri sunarak, tarım sektöründe sürdürülebilir büyümeyi destekleyici politikaların geliştirilmesine katkı sağlamayı hedeflemektedir.

Anahtar Kelimeler: *Tarımsal Üretim, Makro Ekonomi, Enflasyon, Faiz Oranları, Döviz Kuru, Tarım Politikaları*

Giriş

Türkiye'de tarım sektörü, gayri safi milli hasılayı (GSYİH), istihdam yapılarını, gıda güvenliğini ve ihracat performansını etkileyerek ulusal ekonomide çok yönlü bir rol üstlenmektedir. Türkiye'de tarım sektörü, GSYİH'ye katkısı açısından, genel ekonomik yapı için kritik önemini korumasına rağmen, göreli çıktıda düşüş yaşamıştır. Son yirmi yılda uygulanan yapısal uyum programları, ulusal ekonomik öncelikleri tarımdan imalat ve hizmetlere doğru yeniden yönlendirmiş ve böylece ülkenin katma değerindeki tarımın payını azaltmıştır (Günçavdı vd., 2013). Ek olarak, büyüyen ekonomilerdeki yapısal dönüşümü inceleyen araştırmalar, genel tarımsal GSYİH ve istihdam payları azalırken, tarımsal emtialar ulusal ihracattaki göreli varlığının önemli kalabileceğini vurgulamaktadır (Anderson & Ponnusamy, 2022). Bu bulgular, tarımın GSYİH'ye doğrudan katkısının azalmasına rağmen, performansının hala daha geniş ekonomik göstergelerle, özellikle ihracatla iç içe olduğunu ve kırsal ekonomik kalkınma için bir temel oluşturmaya devam ettiğini göstermektedir (Günçavdı vd., 2013; , Anderson & Ponnusamy, 2022).

Tarım sektöründeki istihdam, değişen dinamiklere rağmen Türkiye işgücü piyasasının temel taşlarından biri olmaya devam etmektedir. Yapılan çalışmalar, tarımın ülke işgücünün yaklaşık %20'sini istihdam ettiğini, bu değişimin farklı ölçüm yaklaşımlarına ve gayri resmi işgücünün dahil edilmesine atfedildiğini bildirmektedir (Günçavdı vd., 2013; Aksüt ve Eren, 2024). Sektör, nüfusun önemli bir bölümüne istihdam sağlamakla kalmayıp aynı zamanda önemli miktarda kayıt dışı işgücünü de içermektedir (Bulut vd., 2023).

Türkiye'de gıda güvenliği, iç tarımsal üretimle karmaşık bir şekilde bağlantılıdır. Tarımın istikrarlı bir gıda tedariki sağlamadaki rolü, istihdam, gelir yaratma ve yerelleştirilmiş üretim ağları aracılığıyla bağlantılar kurarak kritik bir güvenlik ağı görevi görür (Diaz-Bonilla, 2015). Politika analizleri, tarımsal üretimin yarattığı büyüme çarpanlarının, özellikle işgücünün yüksek oranlarının tarımsal faaliyetlere bağımlı olduğu bağlamlarda, yoksulluğun azaltılmasına ve gıda güvenliğinin teşvik edilmesine önemli ölçüde katkıda bulunduğunu göstermiştir. İhracat açısından, Türk tarımı küresel piyasa baskıları ışığında hem zorluklarla hem de fırsatlarla karşı karşıya kalmıştır. Ampirik kanıtlar, tarımsal destek politikalarının yıllar içinde azaldığını ve tarımsal emtia fiyatlarının uluslararası seviyelere doğru eğilim göstermesine yol açtığını göstermektedir (Dağdemir, 2014). Aynı zamanda, tarımın GSYİH ve istihdamdaki payının azalmasıyla karakterize edilen tarımdan uzaklaşma olgusu, tarımsal ürünlerin ihracat potansiyelinde mutlaka bir düşüş anlamına gelmez (Anderson & Ponnusamy, 2022). Yapısal dönüşümün dinamiklerine odaklanan çalışmalar, tarım sektörü küresel piyasa standartlarına etkili bir şekilde uyum sağladığında ulusal ihracatta önemli bir paya sahip olduğunu ve ekonomik dayanıklılık ve döviz kazançlarındaki rolünü güçlendirdiğini vurgulamaktadır (Anderson & Ponnusamy, 2022).

Bu kapsamda, tarımsal üretimin makroekonomik faktörlerden etkilenme durumu önemli bir çalışma konusu haline gelmektedir. Döviz kuru, gösterge faiz oranı, üretici fiyat endeksi ve tarımsal kredi hacmi gibi değişkenlerin tarımsal üretim üzerindeki etkisini incelemenin politika yapıcılar açısından stratejik karar almayı kolaylaştıracaktır.

Kavramsal Çerçeve

Tarımsal Kredilerin Üretime Etkisi

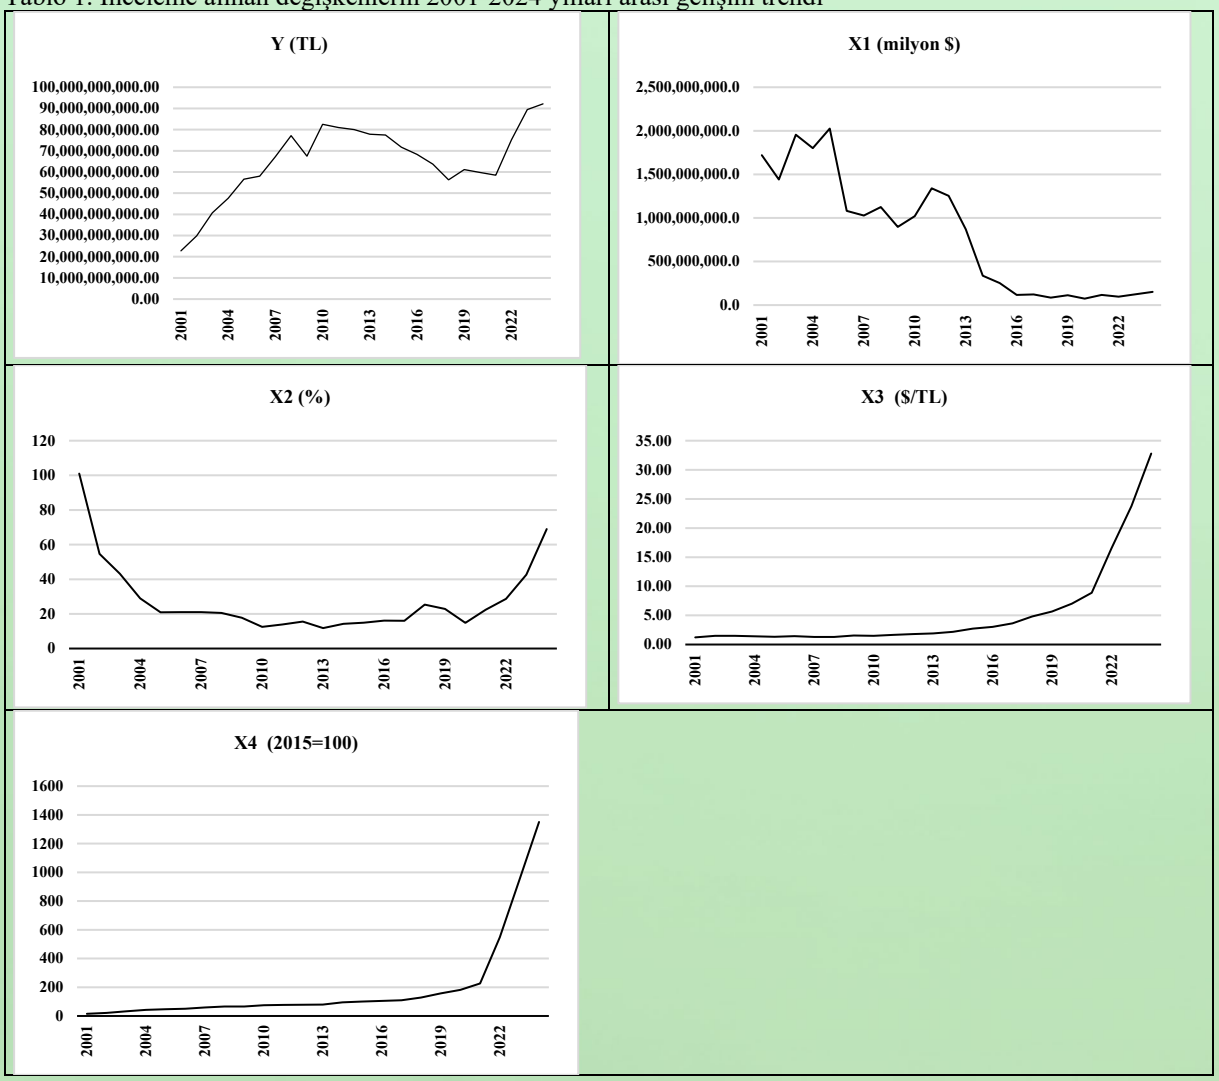
Tarımsal krediler, üretimi modernize etmenin, girdi erişimini geliştirmenin ve likidite kısıtlamalarını hafifletmenin temel belirleyicisidir. Yapılan çalışmalar, tarımsal kredinin mevcudiyetinin girdilere, teknolojiye ve verimli kaynak tahsisine yatırımı kolaylaştırdığını göstermektedir (Kaya & Kadanalı, 2021; Akdemir vd., 2021)

Tarımsal krediler, üreticilerin girdi temini ve teknolojilerin benimsemesini engelleyen finansal kısıtları hafifleterek teknik verimliliği ve genel üretim seviyelerini artırmaktadır (Sekyi vd., 2020; Sial vd., 2011; Bahşi ve Çetin, 2020). Birçok durumda, kredi enjeksiyonu, fazla üretimin sektöre yeniden yatırılabilmesi ve inovasyonu ve pazar katılımını daha da teşvik edebilmesi nedeniyle tarımın daha fazla ticarileşmesiyle ilişkilendirilmiştir (Sekyi vd., 2020; Misra vd., 2016; Magazzino vd., 2021). Teknolojik ve girdi yönlerinin ötesinde, tarımsal kredi, tarım sektöründe daha iyi risk yönetimi ve daha verimli kaynak tahsisini teşvik ederek daha geniş ekonomik çevreyi etkiler. Tarım sektörünün ulusal GSYİH ve istihdamın önemli bir oranını temsil ettiği birçok gelişmekte olan ekonomide, kredi müdahaleleri çiftçilerin üretim ve piyasa talepleri arasındaki boşluğu kapatmasını sağlamada temel olmuştur (Sekyi vd., 2020; Ammani, 2012; Magazzino vd., 2021).

Faiz Oranı - Tarımsal Üretim ilişkisi

Faiz oranlarının tarımsal yatırımlardaki rolü çok yönlüdür ve hem sermayenin doğrudan maliyeti hem de yatırım planlamasında bulunan daha geniş belirsizlik yoluyla kararları etkiler. Optimum bir faiz oranı ortamı, yalnızca tarımsal girdilerin modernizasyonu için giriş engelini düşürmekle kalmaz, aynı zamanda belirsizliği de azaltır ve böylece tarıma sürdürülebilir yatırım yapılmasını teşvik eder. Bu da, sektör içinde artan üretkenliği ve uzun vadeli büyümeyi teşvik eder (Koželský vd., 2024; Dias & Shackleton, 2009; Abdulah & Latif, 2023; Hmzah, 2017).

Döviz Kuru – Tarımsal Üretim İlişkisi



Döviz kurları, ithal girdilerin (örneğin gübre, yakıt, makine, böcek ilacı) satın alındığı fiyatı etkilemenin yanı sıra yerli girdilerin rekabet gücünü etkileyerek tarımsal girdi maliyetlerinin şekillenmesinde merkezi bir rol oynar. Yapılan çalışmalar, döviz kuru dinamiklerinin tarımsal girdi maliyetlerinin önemli bir belirleyicisi olduğu görüşünü desteklemektedir. İthal girdilerin fiyatları üzerindeki doğrudan etkiler ve küresel enerji fiyatları ve daha geniş makroekonomik oynaklığın aracılık ettiği dolaylı etkiler yoluyla döviz kuru dalgalanmaları, tarımsal üreticilerin karşı karşıya kaldığı maliyet baskılarına önemli ölçüde katkıda bulunmaktadır. Bu nedenle, etkili döviz kuru yönetimi ve para politikası, girdi maliyeti oynaklığını azaltmak ve tarımsal üretimin rekabet gücünü ve sürdürülebilirliğini artırmak için değerli araçlar olarak hizmet edebilir (Johnson vd., 2011; Kim, 2015; Harri vd., 2009; Adejumo, 2020; Javadi vd., 2024; Damba vd., 2019) .

Üretici Fiyatları Endeksi – Tarımsal Üretim ilişkisi

Üretici fiyat endeksi, yalnızca fiyat istatistiklerini değil aynı zamanda piyasa talebi, girdi maliyeti dinamikleri ve dış ekonomik şoklardan etkilenen daha geniş bir üretim ekosistemini temsil etmektedir. İstikrarlı veya iyileşen girdi maliyeti koşullarıyla uyumlu olduğunda artan bir ÜFE, gelişen bir tarımsal üretim ortamını gösterebilir. Buna karşılık, artan ÜFE ile artan girdi maliyetleri arasındaki tutarsızlıklar, üreticilerin karlılığı için potansiyel zorluklara işaret ediyor olabilir. ÜFE'lerin üretim sonuçlarını tahmin etmek ve tarımsal politika ayarlamalarına

rehberlik etmek için stratejik araçlar olarak nasıl işlev görebileceğine dair önemli öngörüler sunabilmektedir (Nwaubani vd., 2020; Vargas vd., 2023; Dhakal, 2020). Bu araştırma kapsamında incelemeye alınan değişkenlere ilişkin 2001-2024 yılları arası gelişim trendleri Tablo 1' de verilmiştir.

Tablo 1. İnceleme alınan değişkenlerin 2001-2024 yılları arası gelişim trendi

Tablo 1 incelendiğinde, tarımsal GSUD genel olarak uzun vadede pozitif trend göstermiştir, fakat ekonomik krizler ve pandemi gibi dönemlerde şoklardan etkilenmiş olarak değerlendirilebilir. Tarımsal kredi hacmi ekonomik şoklara duyarlı bir değişken olarak değerlendirilebileceğinden kriz ve pandemi dönemlerinde dalgalanma göstermiş, fakat toparlanma dönemlerinde hızlı şekilde artış yönlü hareket etmiştir. Gösterge faiz zaman içinde yavaş ama istikrarlı bir şekilde büyümüş, ani dalgalanmalardan fazla etkilenmemiştir. Bu trend gösterge faiz için temel bir değişken olabileceğine işaret etmektedir. Dolar kuru kriz ve pandemi gibi şoklara duyarlı bir değişkendir ancak toparlanma dönemlerinde çok güçlü bir büyüme potansiyeli göstermektedir. Üretici fiyat endeksi ise genel olarak stabil ve orta vadede büyüme göstermiştir.

Materyal Yöntem

Söz konusu değişkenler kullanılarak yapısal kırılmalı birim kök testi ve sonrasında kantil regresyon analiziyle değişkenlerin tarımsal GSUD üzerindeki etkisi açıklanmıştır.

Zaman serisinin durağan olup olmadığını ve seride yapısal kırılmaların varlığını test etmek amacıyla ADF Breakpoint Unit Root Testi kullanılmıştır. Klasik Augmented Dickey-Fuller (ADF) testi, serinin tüm dönem boyunca aynı yapıyı koruduğunu varsaymakta ve olası yapısal kırılmaları dikkate almamaktadır. Ancak ekonomik ve finansal zaman serilerinde çeşitli şoklar nedeniyle yapısal değişiklikler meydana gelebilmektedir. Bu nedenle, seride bir kırılma noktasına izin veren ADF Breakpoint testi tercih edilmiştir. Test sürecinde kırılma noktası içsel olarak (endogenous) belirlenmektedir. Yani, veri setindeki en uygun kırılma noktası veri tarafından belirlenir, önceden dışsal bir şekilde seçilmez. Kırılma zamanlaması, genellikle test istatistiğini en küçük yapan tarih olarak tespit edilir.

Tablo 2. Değişkenler ve veri kaynakları

Değişken açıklaması	Sembol	Veri kaynağı
Tarımsal GSUD	Y	FAOSTAT
Tarımsal Kredi Hacmi	X_1	FAOSTAT
Gösterge Faiz	X_2	TC Merkez Bankası
Yıl ortası Dolar/TL kuru	X_3	TC Merkez Bankası
Üretici fiyat endeksi (2015=100)	X_4	TUIK

Veriler 2001-2024 yılları arası yıllık seri biçiminde kullanılmıştır. Tablo incelendiğinde, Y, X1, X2, X3, X4 sembolleri sırasıyla Tarımsal GSUD, Tarımsal Kredi Hacmi, Gösterge Faiz, Dolar/TL kuru ve Üretici fiyat endeksi (2015=100) ni temsil etmektedir. Veri seti 2001-2024 yılları arasını kapsamakta ve yıllık seri olarak incelenmeye alınmıştır.

Birim kök testi sonuçları değerlendirildikten sonra durağan serilerle kantil regresyon analizi yapılmıştır. Bağımlı değişkenin koşullu dağılımının farklı noktalarında (kantillerinde) açıklayıcı değişkenlerin etkisini analiz etmek amacıyla kantil regresyon yöntemi kullanılmaktadır. Klasik doğrusal regresyon yöntemleri (OLS) yalnızca ortalamaya odaklanırken, kantil regresyon modeli bağımlı değişkenin çeşitli dağılım noktalarında (örneğin medyan, alt veya üst çeyrekler) ilişkilerin farklılık gösterip göstermediğini incelemeye olanak tanımaktadır (Koenker ve Bassett, 1978).

Kantil regresyon modeli, aşağıdaki genel formda ifade edilir:
$Qy(\tau|X) = X\beta(\tau)$
Burada:
-$Qy(\tau|X)$, bağımlı değişkenin τ kantili koşullu tahminini temsil eder.
-X, açıklayıcı değişkenler matrisini,
-$\beta(\tau)$, τ kantiline özgü regresyon katsayılarını göstermektedir.

Kantil regresyon analizi hata terimlerinin pozitif ve negatif yönlerde farklı ağırlıklandırılmasını sağlar, böylece model değişkenliğin farklı bölümlerinde daha esnek bir şekilde tahmin yapabilir. Çalışmada, farklı kantil düzeylerinde (τ = 0.25, 0.50, 0.75) regresyon tahminleri gerçekleştirilmiş ve katsayıların değişimi incelenmiştir. Böylece, değişkenler arasındaki ilişkinin sadece ortalamada değil, dağılımın farklı bölümlerinde nasıl farklılaştığı ortaya konmuştur. Model doğrulama sürecinde pseudo R-kare değerleri ve Wald testi sonuçları dikkate alınmıştır.

Araştırma Bulguları

Araştırmada incelemeye alınan değişkenler için yapılan yapısal kırılmalı ADF birim kök testi Tablo 3' de verilmiştir. Tüm değişkenler I(1) yani birinci farkta durağan. Bu, serilerin seviye değerlerinde durağan olmadığını, ancak farkları alındığında durağanlaştığını göstermektedir. Serilerde yapısal kırılmalar özellikle 2020–2021 dönemlerinde yoğunlaşmaktadır. Bu COVID-19, kur şokları gibi olaylarla ilişkilendirilebilir.

Tablo 3. Birim kök testi sonuçları (ADF Breakpoint Unit Root Test)

Değişkenler	I(0)	I(1)	Breakpoint date
Y	-3,3865	-4,7177***	2021
X_1	-3,2256	-7,5920*	2013
X_2	-3,0311	-7,1764*	2020
X_3	-0,3108	-8,5046*	2021
X_4	-2,9481	-7,2545*	2021

Tablo 4. Kantil Regresyon Analizi Sonuçları

Bağımlı değişken: Y	0,25Q	0,50Q	0,75Q
X_1	0,0362 (0,0410)	0,0348 (0,0342)	0,0356 (0,0320)
X_2	-0,0957 (0,0672)	-0,1166*** (0,0606)	-0,1138** (0,0563)
X_3	-0,5755* (0,1302)	-0,5733* (0,1440)	-0,6582* (0,1904)
X_4	0,7652* (0,0874)	0,7209* (0,0194)	0,7506* (0,1188)
Diagnostik Tests	Pseudo-R^2:0,68 Prob:0,0000 Wald: 2,0976 Ramsey Reset: 1,05	Pseudo-R^2:0,75 Prob:0,0000 Wald: 2,0976 Ramsey Reset: 1,55	Pseudo-R^2:0,79 Prob:0,0000 Wald: 2,0976 Ramsey Reset: 2,62

Modelin genel geçerliliği, yüksek düzeydeki Pseudo R^2 değerleri ile desteklenmektedir. Ayrıca, Ramsey RESET testi değerlerinin düşük çıkması, modelde anlamlı bir spesifikasyon hatasına işaret etmediğini göstermektedir. Wald testi sonuçlarına göre, değişkenlerin kantiller arasında istatistiksel olarak anlamlı farklılık göstermediği belirlenmiştir. Bu da modelin genel yapısının kantil düzeylerinde tutarlı olduğunu ortaya koymaktadır. Birim kök testleri ve regresyon uyum kriterleri çerçevesinde, modelin yapısal sorunlara sahip olmadığı ve güvenilir sonuçlar sunduğu anlaşılmaktadır.

Kantil regresyon analizi sonuçları, tarımsal kredi hacminin tüm kantillerde pozitif bir ilişki gösterdiğini fakat bu ilişkinin istatistiksel olarak anlamlı olmadığını ortaya koymaktadır. Bu sonuç, kredi kullanımın tarımsal üretimi artırıcı yönde eğilim taşısa da söz konusu etkinin güçlü ve güvenilir düzeyde istatistiki anlamlılık bulmadığını göstermektedir. Faiz oranı, tüm kantil düzeylerinde tarımsal üretim ile negatif yönlü ve orta yüksek düzeyde anlamlı bir ilişki içerisindedir. Özellikle medyan (Q0.50) ve üst orta (Q0.75) kantillerde bu ilişkinin istatistiksel olarak anlamlı bulunması, faiz oranlarındaki artışın özellikle orta ve yüksek üretim düzeyine sahip gruplarda tarımsal üretimi olumsuz etkilediğini ortaya koymaktadır. Döviz kuru, üç kantilin tamamında tarımsal üretim ile yüksek düzeyde negatif bir ilişki olduğunu ve bu ilişkinin istatistiki olarak anlamlı olduğu tespit edilmiştir. Bu sonuç, kur artışlarının özellikle ithal girdilere olan bağımlılık nedeniyle üretim maliyetlerini artırarak tarımsal üretimi olumsuz yönde etkilediğini göstermektedir. Üretici fiyat endeksi (ÜFE) tüm kantil düzeylerinde pozitif ve anlamlı ilişki sunmuştur. ÜFE'nin pozitif etkisi, tarımsal üretimin aynı zamanda fiyatlara da yansımasıyla ilgili olabilir.

Sonuç ve Öneriler

Bu çalışma Türkiye'de tarımsal üretimin başlıca makroekonomik göstergeler ile olan ilişkisini incelemeyi amaçlamıştır. Çalışma sonuçları, tarımsal üretimin döviz kuru ve faiz oranlarındaki değişimlere karşı oldukça hassas olduğunu ortaya koymaktadır. Bu sonuç literatürle ile paralellik göstermektedir. Ochalibe vd, (2019) ve Eniekezimene vd. (2023) çalışmalarında, döviz kurundaki olumlu bir değişimin tarımsal üretim üzerinde olumlu bir etkiye sahip olduğunu, faiz oranlarındaki artışların ise daha yüksek borçlanma maliyetleri yoluyla üretimi baskılama eğiliminde olduğunu bildirmektedir. Döviz kuru artışının tüm kantillerde negatif ve istatistiki olarak anlamlı olması, tarımsal üretimin ithal girdilere bağımlılık düzeyinin yüksek olduğunu göstermektedir. Benzer şekilde faiz oranlarındaki artışın orta ve yüksek düzeylerinde üretimi anlamlı bir şekilde baskılaması, finansman maliyetlerinin bu gruplarda üretim kararlarını etkilediğini ortaya koymaktadır. Ogbuabor vd.(2020), faiz oranlarını etkileyen parasal politikanın, sermaye maliyetini değiştirerek tarım üzerinde yaygın bir etki uyguladığını ve böylece hem kısa hem de uzun vadeli üretim kararlarını etkilediğini ifade etmişlerdir.

Tarımsal kredi hacminin pozitif ilişkisine karşın istatistiki olarak zayıf etkisi, kredilerin üreticilerin ihtiyaçlarına etkin bir şekilde yanıt vermediğini ortaya koymaktadır. Benzer sonuçlar, Narayanan (2016) ve Alabi vd., (2023) araştırmalarında da mevcuttur. Bu sonuç, kredi sistemlerinde reformist yaklaşımlara ihtiyaç olduğunu göstermektedir. Bununla birlikte ÜFE ile tarımsal üretim arasında pozitif ve istatistiki olarak anlamlı ilişkisi bulunmuştur. Ancak teorik olarak üretici fiyatlarındaki artışın üretim maliyetlerini yükselterek, üretimi azaltması beklenmektedir. Bu durum, ÜFE artışlarının üreticiler tarafından gelecek dönem gelir beklentilerine olumlu yönde şekillenmesiyle açıklanabilir. Ayrıca devlet destekleri ve ürün fiyatlarındaki artışın girdi maliyetlerini telafi edici düzeyde olması da üretim kararlarının pozitif yönde etkilenmesine neden olmuş olabilir. Teoriğe ters olarak elde edilen sonucu destekleyen birçok çalışma da bulunmaktadır (Xie & Wang, 2017; Dhakal, 2020)

Elde edilen bulgular ışığında Türkiye tarımsal üretiminde üretim değerine yönelik gelişmelerin istikrarlı bir şekilde devam etmesi için bazı öneriler ortaya koyulabilir. İthal girdilere (gübre, mazot, tohum, ilaç) bağımlılığı azaltmak için yerli üretimi teşvik eden politikalar geliştirilebilir. Son yıllarda kamuoyuna da yansıyan benzer uygulamalar görülse de henüz serbest piyasa koşullarında etkisinin görülmediği ifade edilebilir. Diğer taraftan mevcut destekleme sistemi içerisinde tarım için kur bazlı sübvansiyonlar uygulanabilir. Örneğin, doğru, etkili ve dengeli bir planlamayla kurdaki ani artışlara karşı çiftçiye fiyat farkı ödemesi yapılabilir. Tarımsal girdi piyasalarında dövizle yapılan sözleşmelerin TL'ye çevrilmesi teşvik edilmesi de kur şoklarına karşı alınabilecek diğer bir önlem olarak düşünülebilir. Tarıma yönelik özel döviz kuru sigortası ürünleri de diğer bir alternatif olarak geliştirilebilir. Tarım sektörüne özel düşük faizli kredi uygulamaları daha da yaygınlaştırılabilir. Faiz destekli tarım kredileri (örneğin Ziraat Bankası kanalıyla) üreticilerin erişimine daha açık hale getirilerek yıllık değil mevsimlik ödeme planlarına uygun faiz sistemleri oluşturulup (hasat dönemine göre uyarlanmış krediler) hedef, üretim ve yerindelik esasları dikkatli bir şekilde izlenebilir. Bu süreçte yatırımların (sera, teknoloji, sulama sistemleri gibi) yönlendirilmesi kamu erki eliyle kontrol altında sıkı önlemlerle takip edilebilir. Ek olarak, üreticinin finansal okuryazarlık eğitimi ve bilgi düzeyine yönelik yayım çalışmaları kredi kullanım verimliliği sürecine olumlu katkı sağlayabilir. Bunun sağlanabilmesi adına teknik danışmanlık sisteminin geliştirilmesi önemli görülmektedir. Üretici fiyat endeksindeki artış ise, maliyetleri temsil etmesi bakımından üretici fiyatlarına doğrudan yansımaktadır. Enflasyon sorununun ilk aşaması olarak değerlendirilen ÜFE artışları ekonomik büyüklük olarak piyasaya yansıdığından tarımsal GSÜD arttırıcı bir etkiye sahip olabilir. Ancak, oluşan yüksek fiyatlar üreticinin üretim kararları ve üretim motivasyonu üzerinde olumlu etki oluşturmakla birlikte enflasyonla mücadele kapsamında dikkatle izlenmesi önerilmektedir.

Abstract

The Russia-Ukraine war is having a profound effects on global food and agricultural markets and represents a significant risk factor for countries like Turkey that are dependent on sunflower oil imports. Turkey meets a large part of its sunflower oil needs from Ukraine and Russia, and there have been serious disruptions in this supply chain due to the war. The aim of this study is to assess the effects of the Russian-Ukrainian war on sunflower production, import dependency and vulnerability of the sector in Turkey. In this context, pre- and post-war import data, price fluctuations and changes in domestic production capacities in Turkey were analyzed and policy recommendations to reduce the sector's foreign dependency were discussed. The results show that the supply of sunflower oil in Turkey fluctuated significantly due to the war, prices increased and domestic production was insufficient. Therefore, it is recommended to support domestic production, develop strategies to increase supply diversity and make long-term planning in agricultural policies to reduce external dependence on sunflower oil imports.

Key Words: *Sunflower Production, Foreign Dependency, Russia-Ukraine War, Agricultural Policies, Food Security*

Rusya-Ukrayna Savaşının Türkiye'de Ayçiçeği Üretiminde Dışa Bağımlılık ve Kırılganlık Üzerine Etkileri

Özet

Rusya-Ukrayna savaşı, küresel gıda ve tarım piyasaları üzerinde derin etkiler yaratmış olup, Türkiye gibi ayçiçeği yağı ithalatına bağımlı ülkeler için önemli bir risk faktörü oluşturmaktadır. Türkiye, ayçiçeği yağı ihtiyacının büyük bir kısmını Ukrayna ve Rusya'dan karşılamakta olup, savaş nedeniyle bu tedarik zincirinde ciddi aksaklıklar yaşanmıştır. Bu çalışma, Rusya-Ukrayna savaşının Türkiye'deki ayçiçeği üretimi, ithalat bağımlılığı ve sektördeki kırılganlıklar üzerindeki etkilerini değerlendirmeyi amaçlamaktadır. Bu kapsamda, savaş öncesi ve savaş sonrası ithalat verileri, fiyat dalgalanmaları ve Türkiye'nin yerli üretim kapasitesindeki değişimler analiz edilmiş, sektördeki dışa bağımlılığın azaltılmasına yönelik politika önerileri tartışılmıştır. Bulgular, savaş nedeniyle Türkiye'de ayçiçeği yağı arzında ciddi bir dalgalanma yaşandığını, fiyatların arttığını ve yerli üretimin yetersiz kaldığını göstermektedir. Sonuç olarak, ayçiçeği yağı ithalatındaki dışa bağımlılığın azaltılması için yerli üretimin desteklenmesi, tedarik çeşitliliğini artıracak stratejiler geliştirilmesi ve tarım politikalarında uzun vadeli planlamalar yapılması önerilmektedir.

Anahtar Kelimeler: *Ayçiçeği Üretimi, Dışa Bağımlılık, Rusya-Ukrayna Savaşı, Tarım Politikaları, Gıda Güvenliği*

Giriş

Gıda güvenliği, 'tüm insanların her zaman, aktif ve sağlıklı bir yaşam için beslenme ihtiyaçlarını ve gıda tercihlerini karşılamak üzere yeterli, güvenli ve besleyici gıdaya fiziksel ve ekonomik erişime sahip olması' durumu olarak tanımlanmaktadır (FAO,1996). Birleşmiş Milletler Gıda ve Tarım Örgütü (FAO) tarafından ana hatları çizilen gıda güvenliğinin dört ana bileşeni bulunmaktadır. Bunlar, bulunabilirlik, erişim, kullanım ve istikrardır (Ericksen, 2008). Dört ana bileşen temel olarak kabul edilirken, eylem ve sürdürülebilirlik gibi belirli niteliklerden yoksundurlar. Bunlar, Sürdürülebilir Kalkınma Hedeflerine ulaşmak için gıda sistemlerinde gerekli değişiklikleri yapmak için kritik olarak kabul edilir (HLPE, 2020). Yapılan çalışmalar, silahlı çatışmaların ve savaşların küresel gıda güvensizliğinin en önemli itici güçlerini temsil ettiğini göstermektedir (FAO, 2017).

Ukrayna ve Rusya, küresel gıda tedarik zincirinde kritik bir konuma sahip olup, dünya buğday ihracatının yaklaşık %30'unu ve ayçiçeği yağı ile mısır gibi diğer stratejik tarım ürünlerinin önemli bir kısmını karşılamaktadır (Jagtap et al., 2022; Skydan et al., 2023; Chen et al., 2024). Savaş öncesinde Ukrayna'nın, dünya tahıl pazarına önemli miktarda ihracat gerçekleştirmesi beklenirken, askeri operasyonlar ve Karadeniz limanlarına uygulanan abluka nedeniyle bu faaliyetler ciddi şekilde sekteye uğramıştır (Liefert, 2023; Chepeliev et al., 2023). Ukrayna'nın

tarımsal üretiminde meydana gelen bu aksamalar derin bir nitelik taşımakta; mevcut raporlar, tarımsal üretimde önemli düşüşler yaşandığını ve bu durumun bölgede onlarca yıllık üretkenlik kazanımlarını tersine çevirebileceğini ortaya koymaktadır (Chen et al., 2024; Deininger et al., 2023).

Ukrayna'nın tarımsal ihracatına erişimin kısıtlanması, özellikle ithalata bağımlı ülkeler ve savunmasız nüfuslar üzerinde olmak üzere, küresel emtia fiyatlarının artmasına ve gıda güvensizliğinin derinleşmesine yol açmıştır (Deng et al., 2022; Benton et al., 2022). Küresel piyasalardaki yüksek derecedeki karşılıklı bağımlılık, çatışmanın etkilerinin Ukrayna ve Rusya sınırlarının ötesine yayılarak çok daha geniş bir coğrafyada ekonomik ve sosyal sonuçlar doğurmasına neden olmuştur.

Bu bağlamda, Rusya-Ukrayna Savaşı, özellikle ayçiçeği yağı ve türev ürünlerin önemli bir tedarikçisi olan Ukrayna'dan yapılan tarımsal ihracatın kesintiye uğramasıyla Türkiye'nin ithalat dinamiklerini doğrudan etkilemiştir. Ukrayna'nın, ayçiçeği yağı ihracatında önde gelen ülkelerden biri olması nedeniyle, savaşın üretim ve ihracat kapasitesinde yarattığı aksamalar, Türkiye'yi bu emtiadaki arz kıtlıkları ve fiyat dalgalanmalarına karşı daha kırılgan bir konuma getirmiştir (Fedulova, 2022). Ayrıca çatışmanın neden olduğu lojistik aksaklıklar ve ticaret yollarındaki belirsizlikler, Türkiye'nin gıda işleme sanayisi için kritik öneme sahip olan ayçiçeği ürünlerinin düzenli teminini riske atmıştır (Sezgin, 2022).

Bununla birlikte, savaş süreci Türkiye'yi, Ukrayna tarımsal ürünlerine olan ithalat bağımlılığı nedeniyle daha geniş ölçekli risklere de açık hale getirmiştir. Türkiye, önemli miktarda ayçiçeği ürününü Ukrayna'dan ithal etmektedir. Ancak, Rusya ve Ukrayna döviz piyasalarında yaptırımlar ve ticaret kesintileri sebebiyle yaşanan aksaklıklar, Türkiye'nin bu ürünlerde istikrarlı fiyat ve tedarik hacmi sağlamasını giderek güçleştirmiştir (Sezgin, 2022). Çatışmanın tetiklediği küresel gıda fiyatlarındaki artışlar ve tedarik zincirlerindeki kırılmalar, hem üreticiler hem de tüketiciler için maliyetlerin yükselmesine neden olmuştur. Bu gelişmeler, Türk tüccarları ve politika yapıcılarını, ayçiçeği ithalatındaki oynaklıkla ilişkili orta vadeli ekonomik etkileri azaltmak amacıyla ticaret stratejilerini yeniden değerlendirmeye ve tedarik kaynaklarını çeşitlendirmeye yöneltmiştir.

Türkiye'nin ayçiçeği ithalatına olan bağımlılığı, devam eden Rusya-Ukrayna çatışmasıyla birlikte daha görünür hale gelmiştir. Ukrayna'dan yapılan ihracattaki aksamalar, dalgalı uluslararası ticaret koşullarıyla birleşerek arz sıkıntılarına ve belirgin fiyat oynaklıklarına yol açmış; bu durum, Türk politika yapıcılarını acil stratejik adımlar atmaya zorlamıştır. Ortaya çıkan bu kırılganlığın giderilebilmesi, kısa vadede tedarik zincirinin istikrarını sağlamaya yönelik önlemler alınmasını, uzun vadede ise belirsizleşen küresel pazarlarda ulusal gıda güvenliğini güçlendirmek için ithalat kaynaklarının çeşitlendirilmesini gerekli kılmaktadır.

Bu çalışmanın amacı, Rusya-Ukrayna savaşının Türkiye'deki ayçiçeği üretimi, ithalat bağımlılığı ve sektördeki kırılganlıklar üzerindeki etkilerini değerlendirmeyi amaçlamaktadır. Bu kapsamda, savaş öncesi ve savaş sonrası ithalat verileri, fiyat dalgalanmaları ve Türkiye'nin yerli üretim kapasitesindeki değişimler analiz edilmiştir. Çalışma, ulusal gıda güvenliğini güçlendirmek amacıyla alternatif tedarik stratejilerinin geliştirilmesine yönelik politika önerileri sunmayı hedeflemektedir.

Materyal ve Yöntem

Bu çalışma, Rusya-Ukrayna Savaşı'nın Türkiye'deki ayçiçeği üretimi, ithalat bağımlılığı ve sektördeki kırılganlıklar üzerindeki etkilerini değerlendirmek amacıyla gerçekleştirilmiştir. Çalışmada, Türkiye'nin 2001-2024 yılları arasındaki ayçiçeği ithalat verileri, fiyat dalgalanmaları ve yerli üretim kapasitesindeki değişimler analiz edilmiştir. Veri kaynakları olarak Türkiye İstatistik Kurumu (TÜİK) ve FAO gibi ulusal ve uluslararası veri tabanlarından elde edilen istatistikler kullanılmıştır. İthalat verileri, ayçiçeği ithalatının yapıldığı ülkeler ve ithalat oranlarını içerirken, fiyat verileri yurt içi ayçiçeği fiyatlarındaki yıllık değişimleri kapsamaktadır. Yerli üretim kapasitesindeki değişimler ise yıllık üretim miktarları ve değişim oranları üzerinden analiz edilmiştir. Araştırmada kullanılan değişkenler ve sembolleri şu şekildedir. X1: UFE, X2: dolar/TL kuru, X3: ithalat miktarı (ton), X4: üretim (ton), X5: ihracat (ton), X6: ithalat oranı (%), X7: yerli üretim oranı (%), X8: yurt içi fiyat (TL, kg), X9: kırılganlık endeksi dir. Ayçiçeği ithalatını etkileyen faktörlere ilişkin normalizasyon değerleri hesaplanmış ve sektördeki kırılganlığın ölçülmesinde ise Min-Max Normalizasyonu ile Kırılganlık Endeksi hesaplanmıştır. Endeks değeri 1' e yaklaştıkça kırılganlığın arttığı, 0' a yaklaştıkça kırılganlığın azaldığı ifade edilebilir. Bu endeks, ithalatı etkileyen çeşitli ekonomik göstergelerin (ÜFE, döviz kuru, ithalat miktarı, üretim, ihracat, fiyat vb.) normalizasyonu ile elde edilmiş ve sektörün dış şoklara karşı ne kadar hassas olduğunu göstermek amacıyla kullanılmaktadır. Çalışma sonucunda elde edilen bulgular, Türkiye'nin ayçiçeği sektöründeki dışa bağımlılık ve kırılganlık durumunu ortaya koyarak, bu bağımlılığı azaltmaya yönelik politika önerileri geliştirilmesine katkı sağlamayı amaçlamaktadır

Araştırma Bulguları

Türkiye'nin ayçiçeği ithalatında en büyük pay Ukrayna, Bulgaristan, Romanya ve Moldova arasında paylaşılmıştır. 2010 sonrası Rusya önemli bir aktör olmuş; fakat siyasi gerilimler etkisiyle 2022 sonrası Ukrayna ve Romanya yeniden öne çıkmıştır. Avrupa ülkeleriyle yakınlık ve lojistik avantajları bu ülkeleri öncelikli hale

getirmiştir. 2022–2023'teki değişimler, savaş ve küresel gıda krizi gibi dışsal faktörlerin etkisini açıkça göstermektedir. Ukrayna, 2001'de %35,95 oranla ithalatta en büyük paya sahip ülke konumundaydı. 2010'ların ortasında payı düşse de 2022'de %68 ile yeniden zirve yapmıştır. Dikkat çeken dönem ise 2022 yılı olmuştur. 2022 yılında ithalatın %68'i Ukrayna'dan yapılmıştır. Bu artış, Rusya-Ukrayna Savaşı'na rağmen Türkiye' nin bölgedeki etkin konumundan kaynaklı oluşturulan Karadeniz Tahıl Koridoru anlaşmasının etkisiyle açıklanabilir. Ukrayna Türkiye'nin ayçiçeği ithalatında en istikrarlı ve baskın aktörlerden biri olmaya devam etmektedir. Bulgaristan Ayçiçeği ithalatında 2001–2010 arasında Türkiye'nin en büyük tedarikçisi olmuştur. 2005'te %80,29 ile tarihi bir zirve yapmıştır. 2015 sonrası payı ciddi oranda azalmış ve 2022'de ancak %3,58 oranından gerçekleşmiştir. Bu durum, AB üyeliği ve iç pazar değişimleriyle Türkiye pazarındaki rolünün zayıflamasıyla açıklanabilir. Her ne kadar 2023'te bir toparlanma görülse de Türkiye üzerinde ayçiçeği ihracatı bakımından eski gücünden uzak olarak değerlendirilebilir. Değişken bir grafik izledi. 2015'te %64,12 ile önemli bir zirve yaptı. Türkiye'nin ayçiçeği ithalatında Moldovya'nın durumu incelendiğinde, 2001–2023 arası en fazla dalgalanan ülkelerden biri olarak görülmektedir. 2023 yılına gelindiğinde Türkiye'nin ithalatındaki payı %4,39'a kadar gerilemiştir. Coğrafi yakınlık ve lojistik avantajına rağmen tedarik sürekliliği konusunda istikrarsız bir süreç izlediği ifade edilebilir. Romanya, Türkiye için Orta düzeyde bir tedarikçi olarak tanımlanabilir. 2006 ve 2014 yıllarında Türkiye ayçiçeği tedarik payının %27–30 seviyelerine ulaştığı görülmektedir. Uluslararası dengelerden kaynaklı olarak 2014'ten sonra Türkiye üzerindeki etkinliğini yavaş yavaş kaybetse de 2023'te tekrar %28,01'e çıkarak önemli bir tedarikçi rolü misyonunu üstlenmiştir. Romanya, Türkiye'ye coğrafi yakınlık ve AB üyesi olması nedeniyle güvenli ve artan tedarikçi etkinliğine sahip bir konumunda düşünülebilir. Rusya ise, 2012 ve 2020 yıllarında Türkiye'ye ayçiçeği ihracatı bakımından önemli sıçramalar yapmıştır. 2020'de %58,10'luk oranla zirve yapmış ancak 2021 sonrası payı ciddi şekilde düşmüştür (2021:%1,36 -2022:%0,01). Politik riskler ve savaş sonrası Türkiye ithalatını yeniden Ukrayna ve Romanya'ya kaydırmıştır.

Tablo 2 incelendiğinde ÜFE, genel ekonomik eğilimleri ve tarım sektöründeki maliyetleri yansıttığı düşünüldüğünde, 2001'de 15,18 olan ÜFE, 2024'te 1.350,54'e yükselmiştir. Yaklaşık 90 katlık artış, enflasyonist baskıların yoğunluğunu ve tarımsal girdi fiyatlarındaki ciddi yükselişi göstermektedir. Özellikle 2021–2022 arasında ÜFE'deki artış %141,4'tür. Bu, küresel gıda ve enerji krizlerinin etkisinden kaynaklı artışları işaret etmektedir. Çünkü hem döviz kuru hem ithalat hem de ihracat maliyetlerini doğrudan etkiler. 2001'de 1,23 TL olan dolar kuru, 2024'te 32,79 TL'ye yükselmiştir. Bu süreçte TL'nin ciddi şekilde değer kaybettiği anlaşılmaktadır. 2021–2022 döneminde %86,3'lük artış, ithalat maliyetlerini artırıcı bir etkiye sahiptir. Ayçiçeği ithalatı değerlendirildiğinde, 2001 yılında 552 bin ton olan ithalat, 2023 yılında 5,8 milyon tonla zirve yapmış, 2024'te 4,59 milyon tona gerilemiştir. Bu durum, yerli üretimin yetersizliğini ve ayçiçeğinde dışa bağımlılığın artışını gösterir. 2002'de ithalat %49 artarken, 2012'de bir önceki yıla göre %45,6 oranında artmıştır.

*ÜFE (2015=100 endeks değerinden hareketle değişim oranları hesaplanmıştır). Kaynak: TUIK, 2025 ve yazar hesaplamaları.

2020 sonrası ithalat hızla artmış, bu da yerli üretimle arzın karşılanamadığını ifade etmektedir. Tablo 2'den ayçiçeği üretimi incelendiğinde 2002 yılında %18,75'lik ciddi bir düşüş dikkat çekmektedir. Bu düşüş Türkiye' deki 1999 ve 2001 krizlerinin etkisiyle ortaya çıkan gerilimden kaynaklı olabileceği gibi iklimsel faktörler ve dönemin koşullarında kamu destekleme politikalarındaki yönlendirici etkinin zayıflığından ortaya çıktığı düşünülebilir. 2003 yılında görülen %30,77'lik artış ise, üreticinin yeniden üretime yönelmesini ve toparlanmayı göstermektedir. 2008 yılında %23,5 oranında bir azalış görülmekte olup ilgili yıldaki küresel krizin etkileri ve kuraklık kaynaklı bir azalışın sonucu olarak değerlendirilebilir. 2011–2015 yılları arasında üretim istikrarlı bir şekilde artmış, bu dönem devlet desteklerinin artması ve tarımsal verimliliğin yükselmesiyle ilişkilendirilebilir. 2022 ve 2023'teki artışlar, ithalat oranlarının yükselmesine rağmen yerli üretimin artırıldığını göstermektedir. 2024'teki %13,8 oranındaki düşüş, maliyet artışları, iklimsel sorunlar veya çiftçinin ayçiçeğinden uzaklaşması gibi nedenlerle açıklanabilir. Stok seviyeleri incelendiğinde, dalgalı bir seyir izlemektedir. Negatif stok değişimleri (örneğin 2002, 2005, 2006) arz-talep dengesizliğini yansıtırken, yüksek stok artışları (örneğin 2013, 2015) ithalat fazlası veya talep düşüşü anlamına gelmektedir. 2013'te stoklar %2453 artmış, bu da beklenmedik dış ticaret hareketleriyle açıklanabilir. İhracat oranları genel olarak düşük seviyededir. 2001'de 196 bin ton olan ihracat, 2024'te 3,67 milyon tona çıkmıştır. Ancak bu rakam, ithalatın oldukça gerisindedir. Özellikle 2010–2012 arası ihracatta %270'lik bir artış görülmektedir. Ancak bu artışlar da ithalatı dengeleyecek düzeyde değildir. Arz miktarı üretim + ithalat – ihracat ± stoklarla belirlenir. Süreç içinde artış göstermekle birlikte 2001'de 1,17 milyon ton olan yurtiçi arz, 2023'te 5 milyon tonu aşmıştır. 2004 yılında arzda %61'lik bir sıçrama görülmüştür. İthalat oranı değerlendirildiğinde bu oran toplam arz içindeki ithalat payını gösterir. 2001'de %40,34 olan oran, 2023'te %69,39'a ulaşmıştır. 2024'te %66,96'ya gerilese de hâlâ çok yüksektir. Bu artış, yerli üretimin arzı karşılamada yetersiz kaldığını ve dışa bağımlılığın arttığını göstermektedir. Yerli üretim oranı ise toplam arz içindeki yerli üretimin payıdır. 2001'de %59,66 olan oran, 2023'te %30,61'e kadar düşmüştür. 2024'te %33,04'e küçük bir toparlanma yaşanmıştır. Bu azalma, yerli üretimin görece gerilediğini ve arz içinde ithalatın payının giderek arttığını kanıtlar niteliktedir. Ayçiçeğinde yurt içi fiyat seyri incelendiğinde, 2001'de 0,27 TL olan fiyat, 2024'te 20,00 TL'ye ulaşmıştır. Bu 74 katlık artış hem maliyet artışları hem de arz-talep dengesizliklerinden kaynaklanmaktadır. En çarpıcı artış 2021–2022 arasında yaşanmış olup %92'lik bir fiyat sıçraması görülmektedir. 2023'te fiyat %9 oranında artarken, 2024'te %48,3'lük dev bir artış kaydedilmiştir. Bu, ithalatın ilgili yılda azalması ve maliyet artışlarından kaynaklı olabileceği düşünülen üretimin azalmasının sonucu olarak değerlendirilebilir.

Tablo 3. Türkiye'nin 2001-2024 yılları arası Ayçiçeği İthalatını Etkileyen Faktörlerin Min-Max Normalizasyonu ile Hesaplanmış Kırılganlık Endeksleri

Yıl	X1 ufe	X2 dolarkuru	X3 ithalat/ton	X4 üretim	X5 ihracat	X6 ithoran	X7 yerlioran	X8 fiyat	X9 kırılganlık	X9'daki değişim

İthalat üzerinde etkili olan faktörlere ilişkin kırılganlık endeksleri yıllar itibariyle incelendiğinde, 2001–2010 döneminde, kırılganlık endeksi 0,09 ile 0,23 arasında değişmiştir. Türkiye'nin yerli ekonomik anlamda istikrarlı yapısı, düşük döviz ve girdi fiyatları sayesinde arz güvenliğinin bu dönemde yüksek olduğu ifade edilebilir. 2011–2019 döneminde, endeks değerleri 0,28 ile 0,42 arasında seyretmiş, kırılganlık orta düzeye ulaşmıştır. Bu dönemde ithalat oranı artmış, döviz kuru dalgalanmış, yerli üretimin artış hızı ithalat oranı artış hızının gerisinde kalmaya başlamıştır. 2020–2021 döneminde, pandemi sonrası yaşanan tedarik zincirindeki kopmalar, ülkelerin korumacı yönlü üretim ve Pazar davranışları fiyat artışları ve girdi maliyetlerindeki yükseliş olarak boyutlanmış ve kırılganlık endeksi 0,50 seviyelerine çıkmıştır. 2021 yılında endeks 0,71 olarak hesaplanmıştır. 2022–2024 döneminde ise, Rusya-Ukrayna savaşının etkisiyle kırılganlık zirve yapmıştır. 2022'de endeks 0,88, 2023'te 0,93 ve 2024'te 1,00 olarak ölçülmüştür. Bu dönemde hem ithalat oranı hem de fiyatlar maksimum seviyeye ulaşmış, yerli üretimin payı ise minimum olarak görülmüştür. Elde edilen sonuçlara göre, Türkiye'nin ayçiçeği arzındaki dışa bağımlılığı ve yapısal kırılganlığı 2020 sonrası dönemde ciddi ölçüde artmıştır. Özellikle 2022 sonrası yaşanan jeopolitik gelişmeler ve döviz bazlı maliyet artışları bu kırılganlığı daha da derinleştirmiştir.

Sonuç ve Öneriler

2001–2024 dönemi incelendiğinde, Türkiye'nin ayçiçeği sektöründe üretimin artmasına rağmen ithalatın daha hızlı bir ivmeyle yükseldiği, dolayısıyla yerli üretimin toplam arz içerisindeki payının gerilediği görülmektedir. Bu süreçte döviz kuru ve üretici fiyat endeksindeki (ÜFE) hızlı artışlar, üretim maliyetlerini ve nihai ürün fiyatlarını önemli ölçüde yukarı çekmiştir. İthalat oranının %70 seviyelerine ulaşması, tarımsal dışa bağımlılığın belirgin şekilde arttığını göstermektedir. Aynı dönemde fiyatlardaki dalgalanmalar, hem üreticilerin üretim kararlarını hem de tüketicilerin alım gücünü ciddi şekilde etkilemiştir. Türkiye'nin ayçiçeği ithalatında başlıca tedarikçiler arasında Bulgaristan ve Ukrayna öne çıkmaktadır; Bulgaristan 2005 yılında %80,29 ile tarihsel olarak en yüksek ithalat payına ulaşmıştır. Ukrayna ise özellikle son yıllarda önemli bir tedarikçi konumuna gelmiştir. 2011–2019 döneminde ithalatın ülkesel çeşitliliği artmış; Romanya, Moldova ve Rusya gibi ülkelerin payı belirgin şekilde yükselmiştir. Bu durum, Türkiye'nin ithalat politikasında kaynak çeşitlendirmeye yönelik bir strateji izlediğine işaret etmektedir. 2020–2023 döneminde ise, jeopolitik gelişmeler ithalat dinamiklerini yeniden şekillendirmiştir. 2020 yılında Rusya %58'lik payla en yüksek seviyeye ulaşırken, 2022 yılında Ukrayna %68'lik rekor bir oranla Türkiye'nin en büyük tedarikçisi olmuştur. Gelinen noktada, Türkiye'nin ayçiçeği ithalatında aşırı bağımlılığı (örneğin Ukrayna'ya %68 oranında bağımlılık), bölgesel krizler (Rusya-Ukrayna Savaşı) ve

lojistik/tedarik zinciri aksamaları gibi önemli riskler barındırmaktadır. Hassan ve Bilali (2022) yaptıkları çalışmada, Türkiye'nin, Rusya-Ukrayna savaşı sırasında tedarik zincirinde zorluklar yaşadığını belirtmiştir. Ayrıca Han vd. (2023), savaşın küresel gıda fiyat enflasyonunu artırdığını belirtmiştir. Bu durum, özellikle ithalata bağımlı ülkeler için gıda arz güvenliğini ve fiyat istikrarını daha kırılgan hale getirmiştir. Türkiye ise, yakın coğrafyadaki alternatif tedarikçilere erişim imkânı, bölgesel diplomatik ilişkilerdeki gücü ve yerli üretim kapasitesini artırma potansiyeli gibi önemli fırsat alanlarına sahiptir.

Bu veriler ışığında, Türkiye'nin tarımsal sürdürülebilirliği ve gıda güvenliği açısından yerli üretimi artırıcı politikalar geliştirmesi, ithalata olan bağımlılığı azaltacak stratejiler uygulaması, kriz dönemleri için kamu ve özel rezerv/muhafaza/depo sistemlerinin aktif olması ve jeopolitik olarak riskleri öngörebilecek şekilde aksiyoner olması önemli görülmektedir.

Evaluation of *Bacillus* Strains for Protease Production

Fikriye Alev Akçay, Ayşe Avcı

Food Engineering Department, Faculty of Engineering, Sakarya University, Sakarya, Türkiye

Abstract

Proteases have diverse industrial applications, particularly in laundry detergents and the leather industry, as well as in the food, textile, and pharmaceutical sectors. While plant- and animal-derived proteases are traditionally used, their production is limited by environmental and agricultural constraints. Microorganisms, especially *Bacillus* species and lactic acid bacteria, have emerged as key sources due to their high yield and ease of biotechnological manipulation, accounting for nearly 60% of global commercial enzyme sales. This study aimed to evaluate protease production in *Bacillus* isolates obtained from food and soil samples. Eight isolates were screened on milk powder-containing agar, and six demonstrated significant protease activity. The isolates ZGT9, EBTA7, and ZBP10 showed the largest clear zones (20.0, 18.8, and 18.5 mm, respectively) and were selected for further investigation. Crude enzymes were obtained from 48-hour nutrient broth cultures, and protease activity was assessed using 1% casein solution at pH 8 and 60°C for 15 minutes. Protein concentrations were determined using Bradford assay, with BSA as the standard. Total protein content ranged from 112.6 to 182.6 µg BSA eq./mL, while protease activity varied between 360.8 and 2530.8 U/mL. Specific activities ranged from 3221 to 13,862 U/mg. The isolate with the highest activity (EBTA7) was further analyzed to determine its optimal operating conditions. Enzyme activity was evaluated at various pH (7–11) and temperature (50–80°C) values. The enzyme showed maximal activity at 60°C and pH 9, with high relative activity at 50°C (76%) but a sharp decline above 60°C (35% at 70°C, 29% at 80°C). These results indicate that the enzyme is moderately thermophilic and functions best under alkaline conditions. Biochemical characterization and 16S rDNA gene sequence analysis confirmed that the strain belongs to the *Bacillus* genus.

Key Words: *Microbial proteases, Bacillus, protease activity*

Tracking *Salmonella* in Sesame Foods: Genomic Diversity and Resistance Patterns

Mustafa Guzel

Hitit Universitesi, Çorum, Türkiye

Abstract

Sesame-based products such as tahini and halva have gained international popularity due to their nutritional benefits and cultural significance. However, their association with recent *Salmonella* outbreaks and recalls has raised global concerns regarding their microbiological safety. Despite low water activity traditionally limiting microbial growth, these products have demonstrated the ability to harbor *Salmonella* for extended periods, leading to recalls and international trade disruptions.

This study aimed to investigate the molecular epidemiology of *Salmonella* strains isolated from sesame, tahini, and halva. Genome assemblies were obtained from the NCBI database and filtered based on product metadata. Quality control assessments were performed using CheckM and QUAST to ensure high-quality genomes. Serotyping and core genome multilocus sequence typing (cgMLST) were conducted using SISTR, while resistance genes, virulence factors, and plasmid content were identified using Abricate and Bakcharak. Pangenome analysis was performed with Roary, and phylogenetic relationships were inferred using IQ-TREE with 1,000 bootstrap replicates.

The analysis revealed notable genomic diversity among the *Salmonella* isolates, with multiple serovars and cgMLST types identified across the three commodity groups. Several isolates carried clinically relevant antimicrobial resistance genes and virulence factors, including those linked to enhanced environmental persistence. Phylogenomic analysis showed both commodity-specific clustering and instances of inter-commodity genetic similarity, indicating potential shared contamination sources or cross-contamination events.

These findings underscore the importance of genomic surveillance in tracking the emergence and dissemination of foodborne pathogens in low-moisture foods. By applying molecular epidemiology approaches, this study contributes to the understanding of *Salmonella* diversity, resistance, and distribution in sesame-based products and highlights the need for proactive food safety strategies in international supply chains.

Abstract

This study investigated the effects of *Moringa oleifera* (*M. oleifera*) supplementation on fetal growth in Nubian goats within the Butana region, utilizing real-time ultrasonography. The research aimed to explore the relationship between gestational age and key fetal measurements, including crown rump length (CRL), biparietal diameter (BPD), and femur length (FL). A total of 200 Nubian female goats, aged 24.00 ± 0.75 months and weighing 46.42 ± 2.96 kg, were randomly selected from a large herd and assigned to four groups (n=50 each) based on their dietary supplementation of *M. oleifera*: Group A (0%, control), Group B (20%), Group C (40%), and Group D (60%). Pregnancy was confirmed through management practices and transabdominal ultrasound. Fetal measurements were taken at three distinct stages of gestation to assess CRL, BPD, and FL. Results indicated significant differences in CRL measurements at day 45 of gestation ($p < 0.05$), with Group C exhibiting the highest mean measurement and Group D the lowest. At day 80, significant differences were observed in FL and BPD measurements among the groups ($p < 0.05$). The study also found significant correlations between CRL, BPD, and FL with gestational age ($p < 0.05$), with FL demonstrating the strongest positive correlation (R = 0.957), followed by BPD (R = 0.614) and CRL (R = 0.501). In conclusion, *M. oleifera* supplementation significantly influenced fetal growth parameters, particularly CRL, FL, and BPD. These findings suggest that dietary supplementation of *M. oleifera* may enhance fetal development in Nubian goats, highlighting its potential benefits in goat husbandry.

Key Words: *Moringa oleifera,* Nubian goats, Fetal growth, Reproductive characteristics, Dietary supplementation.

Introduction

Goats significantly contribute to the livelihoods of many countries and communities in Africa, offering vital resources such as milk and meat, especially to those in rural areas (Alfadul et al., 2024; Saleh et al., 2021; Saleh et al., 2023). This agricultural relevance becomes even more pronounced with the Nubian goat, one of the world's oldest and most renowned dairy breeds. Native to the Nubian desert region extending to parts of northern Sudan and Southern Egypt, Nubian goats are lauded for their adaptability to harsh climates and their dual-purpose utility in milk and meat production (Brewer et al., 2024; Trimingham, 1960).

Despite advancements in agricultural practices, goats remain vital to subsistence and smallholder systems, as evidenced by ongoing efforts to enhance the productivity of the Nubian breed through crossbreeding with other high-yielding varieties like the Saanen (Agossou and Koluman, 2017; Strahsburger and Scopinich-Cisternas, 2021). This breed is pivotal to Sudan's goat population, representing nearly half of the total (Ali, 2010; Ibrahim et al., 2022). Nonetheless, fully optimizing their production potential requires a profound understanding of their nutritional and reproductive needs (Saleh and Hassanine, 2019).

The reproductive and productive potential of goats can be significantly improved with adequate supplemental feeding, especially in arid areas where feed resources become scarce and costly (Ali, 2010; Mellado et al., 2022; Urrutia-Morales et al., 2012; Zewdie and Welday, 2015). This reality has driven a search for alternative, cost-effective feed solutions enriched in protein and minerals to enhance livestock productivity (Boudalia et al., 2024; Makkar et al., 2022; Misra and Kumawat, 2021; Salem and Smith, 2008; Singh and Chauhan, 2017). Among the alternative feed sources, the leaves of *Moringa oleifera* (*M. oleifera*) have emerged as a promising candidate.

Known for its high protein content and essential nutrients, *M. oleifera* potential as a livestock feed supplement is gradually gaining recognition, although its utility remains underexplored (Dantas et al., 2024; Kekana et al., 2021; Matic et al., 2018; Moustafa and Assem, 2024; Patir, 2022; Parkunan et al., 2024).

M. *oleifera*, often cultivated in various parts of Africa, is renowned for its nutritional value. It is high in crude protein, vitamins, and essential minerals, which suggests it could fulfill the dietary needs of livestock, improve their nutritional status, and subsequently, enhance their productive and reproductive performance (Divya et al., 2024; Farrag, 2024; Mashamaite et al., 2024b; Worku et al., 2024).

Moreover, the benefits of *M. oleifera* extend beyond nutritional enhancements (Divya et al., 2024; Mohamed Husien et al., 2022). Its incorporation into the diets of ruminants has shown promising results in improving reproductive parameters due to the presence of bioactive compounds such as flavonoids and antioxidants, which can positively influence reproductive efficiency and outcomes (Divya et al., 2024; Xu et al., 2024). The antioxidants present in *M. oleifera* may help enhance productive and reproductive health by mitigating oxidative stress, which is crucial for maintaining high fertility rates and improving the overall breeding success of goats (El Bilali et al., 2024; Shea, 2024). By exploring alternative feed resources like *M. oleifera*, there is a dual benefit of improving livestock performance and ensuring sustainability in farming practices, which is especially pertinent in regions that face environmental and economic challenges (Delfín-Portela et al., 2024; El Bilali et al., 2024; Kumssa et al., 2017; Mashamaite et al., 2024a; Rahman et al., 2024).

The integration of *M. oleifera* as a sustainable feed resource aligns with global efforts to enhance animal nutrition while reducing costs (Akintan et al., 2024; Husien et al., 2024; Lungu et al., 2024; Makkar, 2016). The tree's leaves, pods, and seeds have been noted for their high crude protein content and an array of essential vitamins and minerals that contribute to improved animal health and productivity (Divya et al., 2024; Farrag, 2024; Mashamaite et al., 2024b; Worku et al., 2024). *M. oleifera* adaptability to semi-arid climates and its resistance to drought make it a viable option for regions such as the Sudanese Butana area, where conventional feed resources are often scarce or prohibitively expensive. This adaptability, coupled with its high nutritional profile, positions *M. oleifera* as a potential game-changer in livestock feeding strategies, allowing for improved body condition and milk production without the high costs associated with traditional feed (Kholif et al., 2015).

This study seeks to examine the impacts of feeding varying levels of *M. oleifera* leaves on the reproductive and productive traits of Nubian goats in Sudan, Butana area. Specifically, it aims to assess the influence of *M. oleifera* supplementation on; **a**) blood serum parameters such as total protein and mineral composition, **b**) evaluate the reproductive performance indicators including oestrus response and pregnancy rates, and **c**) determine the effects on body weight, milk yield and composition. Through this research, the study provided further insights into how *M. oleifera* supplementation can be practically applied to optimize the productivity of Nubian goats, enhancing both economic and nutritional outcomes for the farming communities.

Materials and Methods

Study Area

This research was carried out at the farm of the College of Agricultural Sciences, University of Gezira, Wad Medani, Gezira State, Sudan (GPS: 14o 23' 9.51" N, 33o 31' 46.85" E), which is situated in the eastern region of Gezira State. The area's climate features a rainy season from July to October and a dry season from February to May, with average daily temperatures ranging from 37°C to 39°C. The study was conducted over the period from April 2023 to April 2024.

Experimental design

A total of 200 goats were randomly selected from a flock of 500. Non-pregnancy was confirmed using ultrasonography. The goats were approximately 24.00±0.75 months old and 46.42±2.96 kg. Each goat underwent a comprehensive physical and vaginal examination and was determined to be in good health. The goats were housed in separate pens, ear-tagged, and allowed a 10-day acclimation period. They were given oral deworming treatments with 10 ml (10 mg/ml) of Albendazole in two doses over fifteen days and subcutaneous injections of 1 ml Ivomec (Ivermectin 10 mg/ml), as well as Cypermethrine (Cypermethrine 10% EC) washes. Additionally, they received intramuscular injections of Oxytetracycline 20%, 3 ml per doe/48h. The animals were then randomly divided into four groups, each containing five goats, housed separately from males.

Feeding

During the study, goats were provided daily with 500 g of a balanced concentrate diet consisting of 30% sorghum, 50% wheat bran, and 20% molasses. Mineral salt and water were available *ad libitum*. The goats were organized into four groups based on the proportion of *M. oleifera* leaves in their roughage: group A (control) received 100% groundnut hulls with no *M. oleifera*, group B received 20% *M. oleifera* and 80% groundnut hulls, group C received 40% *M. oleifera* and 60% groundnut hulls and group D received 60% *M. oleifera* and 40% groundnut hulls **Table 1**.

Table 1. Proximate analysis of the experimental feed

Sample type	D.M%	Ash%	C.P%	E.E%	C.F%
A (0%) *M. oleifera*	93.20	16.528	10.979	0.8	**25.50**
B (20%) *M. oleifera*	93.40	12.419	12.457	2.4	**35.00**
C (40%) *M. oleifera*	93.60	14.743	15.202	2.6	**22.00**
D (60%) *M. oleifera*	93.60	13.887	11.824	3.2	**33.00**

Blood serum analysis

Blood serum albumin (ALB) and total protein (TP)

Blood samples were taken biweekly from the external jugular vein over a three-month period at the beginning of the experiment. Samples were left to stand overnight at room temperature in 10 ml vacutainers without anticoagulant to prepare for serum analysis. Serum was then pipetted into 10 ml test tubes, centrifuged, and the supernatant was stored at -25°C for biochemical analysis. For total protein (TP) determination, reagent A (containing Copper (II) acetate, potassium iodide, sodium hydroxide, detergent) and protein standard S (Bovine albumin, traceable to Standard Reference Material 927) were used. Albumin (ALB) determination utilized reagent A (acetate buffer, bromocresol green, detergent, pH 4.1) and albumin standard S.

Macro mineral blood serum levels

Phosphorus (P) was measured using reagent RGT (Ammoniumheptamolibdate and Sulphuric acid) and a phosphorus standard. Magnesium (Mg) levels were determined using buffer R1, chromagen R2, and a magnesium standard, following methods by (Fick 1979). Calcium (Ca) was analyzed using OCC indicator R1, OCC buffer R2, and a calcium standard. Sodium (Na) and Potassium (K) levels were assessed using a spectrophotometer with a visible UV setup.

Micro mineral blood serum levels

Iron (Fe) levels were measured with reagents A and B, and an iron standard. Zinc (Zn) and Copper (Cu) levels were assessed with a stock standard solution as outlined by (Harris et al., 1954).

Milk composition

Basic composition

The proximate composition of goat milk, including moisture, fat, ash, crude fibre, crude protein, and carbohydrates, was assessed using methods from the Horwitz and Association of Official Analytical 2000.

Determination of milk pH and titratable acidity

Milk pH was determined using a pH meter as per the procedure by O'Connor 1995. While, the milk sample's titratable acidity was measured according to Horwitz and Association of Official Analytical 2000 protocols, with the formula:

$$\text{Titratable Acidity (\%)} = \frac{\text{N/10NaOH (ml)x 0.009}}{\text{Weight of milk sample}} \text{x } 100$$

Milk yield and body weight

Goats were weighed biweekly using an unequal-arm balance, and their milk yield and composition were recorded during the first three months postpartum, according to Landi et al., 2021 and Saleh et al., 2022, for body weight and milk yield/ composition, respectively.

Fertility trait measurements

Oestrus synchronization and detection

Each doe received two intramuscular injections of prostaglandin 150 µg PGF2α, with vitamin A.D.E. supplementation. Sexually experienced Nubian bucks were introduced for natural service, and behavioral signs of oestrus were observed after the second PGF2α injection. Oestrus response percentage and pregnancy were determined according to Ogunbiyi et al. 1980.

Pregnancy diagnosis

Pregnancy was diagnosed using managemental and ultrasonographic methods. Post-insemination, goats were observed for non-return rates and later confirmed via abdominal ultrasonography. Pregnancy rate, kidding rate, litter size and gestation period were recorded following parturition according to Saleh et al., 2020.

Ultrasonographic fetal measurements

Goats underwent fasting before scanning, with sufficient ultrasonic gel applied to the shaved ventral abdomen. A real-time ultrasound scanner (Canon Medical Systems, Aplio i-series ultrasonographic device, Japan) with various transducers was employed to record fetal measurements including crown-rump length (CRL), biparietal diameter (BPD) and femur length (FL).

Crown-rump length (CRL)

CRL was measured at 45 days of gestation. Measurements were taken from the most dorsal part of the fetus to the end of the sacrum.

Bi parietal diameter (BPD) and femur length (FL)

BPD was assessed at 80 days of gestation, in a specific coronal section. While, FL was measured at 80 days of gestation, identifying calcification zones.

The effect of different levels of M. oleifera leaves on birth weight (Kg)

The goats were housed in similar conditions to minimize confounding variables and were monitored throughout their gestation period. Birth weight was recorded for each kid born from the respective groups.

Statistical analysis

To ensure robust results, we conducted a comprehensive statistical analysis of the collected data. Initially, means and standard deviations were calculated to summarize the dataset. For a deeper analysis, we employed the Analysis of Variance (ANOVA) using the general linear model approach to identify significant differences among groups. In cases where significant effects were detected, Duncan's multiple range test was used to determine which specific groups differed from each other. These statistical procedures were carried out using SPSS software, version 24.0 (IBM Corp., Armonk, NY, USA), and adhered to standards established since its introduction in 1998.

Results and Discussion

Blood serum ALB and TP

Table 2 presents data on blood serum ALB and TP in Nubian goats fed varying levels of *M. oleifera*. Despite significant differences among the groups ($p < 0.05$), the highest ALB values were observed in groups C (26.27±5.49 g/dL) and B ((26.17±8.94 g/dL), whereas the lowest values appeared in groups A (23.27±12.2 g/dL) and D (22.97±11.0 g/dL). Similarly, TP levels were highest in group C (62.55±14.9 g/dL), with the lowest in group C (51.65±24.9 g/dL), and moderate levels in groups B (59.92±15.09 g/dL) and A (54.01±23.77). These findings align with previous studies, such as Meel et al., 2018 on Sirohi goat, Kholif et al., 2016 and Babeker and Abdalbagi, 2015 on Nubian goat, Leitanthem et al., 2022 on goat kids and Selim et al., 2021 on Rabbits, indicating that the levels of blood serum TP and ALB observed here are consistent with established norms in similar ruminant studies. The consistency in these data across different studies suggests that *M. oleifera* supplementation did not significantly alter protein metabolism, maintaining a baseline established by historic norms in livestock nutrition.

Table 2. Mean blood serum ALB and TP of Nubian goats fed on different levels of *M. oleifera* leaves

Parameter	Mean ± SD				Overall mean
	Group A	Group B	Group C	Group D	
ALB (g/dL)	23.27±12.2^{b}	26.17±8.94^{a}	26.27±5.49^{a}	22.97±11.0^{c}	24.66±10.03
TP (g/dL)	54.01±23.77^{b}	59.92±15.09^{ab}	62.55±14.9^{a}	51.65±24.9^{c}	57.03±20.45
No. of Samples	55	55	59	51	220

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Macro mineral blood serum levels

The average macro mineral blood serum values of the goats, outlined in **Table 3**, showed significant differences across groups ($p < 0.05$). Ca levels peaked in group C (8.47±3.11 mg/dL), while lower levels were noted in groups A (7.89±3.21 mg/dL), B (7.53±4.26 mg/dL) and D (7.12±3.97 mg/dL). Significant trends were seen in P concentrations, with group C showing the highest concentration (4.62±1.98 mg/dL). K and Mg levels also showed significant variation, with notable higher concentrations in group C. However, Na levels varied significantly ($p < 0.05$), with groups C and B displaying the highest values (248.19 mg/dL and 240.83 mg/dL, respectively). Aligning with prior reports for ruminants (Al Mufarji et al., 2023; Kekana et al., 2019; Singh, 2021; Wankhede et al., 2022). The slightly lower Ca levels (7.12 to 8.47 mg/dL) compared to previous studies suggest potential dietary influences, perhaps from the *M. oleifera* supplementation or other factors. Meanwhile, Mg levels were similar to recommended values (Council, 2007), supporting their consistency across different dietary conditions. Na levels were lower than reported norms (Council, 2007), potentially reflecting variations in dietary salt provision. These macromineral observations underscore the importance of tailoring diets to meet specific nutrient requirements for optimal health and productivity, emphasizing the role of *M. oleifera* as a supplementary feed component.

Table 3. Mean values of macro mineral blood serum levels of Nubian goats fed on different levels of *M. oleifera* leaves

Parameter	Mean ± SD			
	Group A	Group B	Group C	Group D
Ca (mg/dl)	7.89±3.21^{b}	7.53±4.26^{b}	8.47±3.11^{a}	7.12±3.97^{b}
P (mg/dl)	3.93±2.198^{c}	3.88±2.56^{c}	4.62±1.98^{a}	4.099±1.76^{b}
K (mq/dl)	9.83±2.89^{c}	10.18±3.45^{b}	12.13±2.90^{a}	11.66±3.77^{ab}
Mg (mg/dl)	1.95±1.27^{b}	1.99± 1.32^{b}	2.33±0.95^{a}	2.29±1.39^{a}
Na (mg/dl)	207.67±38.23^{bc}	240.83±41.05^{ab}	248.19±39.56^{a}	199.18±29.40^{c}
No. of samples	35	35	39	35

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Micro mineral blood serum levels

The micro-mineral content, summarized in **Table 4**, revealed significant differences across zinc and Fe concentrations between groups ($p < 0.05$), though group C exhibited the highest Zn levels. Cu concentrations showed significant variance with higher values in groups C and B (approximately 0.122 meq/L; 0.121 meq/L) compared to group A (0.108 meq/L). in line with previous findings in goats (Liu and Shen, 2024; Solaiman et al., 2024), reinforcing the observation that Cu levels remain within acceptable ranges across diverse environments and diets. Zn concentrations observed (0.099 to 0.114 mg/dL) correspond with earlier studies (Hayuningtyas et al., 2024), while Fe levels (2.22 mg/dL) were higher than some past research but still within a normal range (Khan, 2003). These micro-mineral profiles suggest that *M. oleifera* does not significantly alter the balance of essential minerals, despite its rich micronutrient content, indicating its compatibility as a dietary supplement in livestock without negatively impacting essential mineral homeostasis.

Table 4. Mean values of micro-mineral blood serum levels of Nubian goats fed on different levels of *M. oleifera* leaves.

Parameter	Mean ± SD				Overall mean
	Group A	Group B	Group C	Group D	
Zn (meq/L)	0.11±0.01^{a}	0.10±0.02^{ab}	0.11±0.01^{a}	0.09±0.04^{b}	0.11±0.02
Fe (meq/L)	2.31±0.80^{ab}	2.22±1.01^{b}	2.32±0.70^{a}	2.04±0.89^{c}	2.22±1.00
Cu (meq/L)	0.108±0.09^{c}	0.121±0.07^{ab}	0.122±0.09^{a}	0.120±0.09^{b}	0.118±0.08
No. of samples	35	35	39	35	144

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Basic composition of goat milk

Table 5 illustrates the basic composition of Nubian goat milk. PH, acidity, moisture content, and ash levels showed significantly ($p < 0.05$) across groups, with variations in fat values being highest in group C and lowest in group D. Protein content remained uniform among the groups, as did the carbohydrate content, with group C recording the highest carbohydrate value. consistent with findings by Park et al., 2000. Protein content (3.94% to 4.21%) was slightly higher than reported by Jenness, 1980, possibly indicating enhanced nutritional quality. Ash, carbohydrate, and moisture content were largely consistent with previous reports (Kholif et al., 2015). These outcomes suggest that while *M. oleifera* drastically change milk composition, it maintains or potentially enhances certain nutritional criteria, affirming its role as a sustainable feed option that could promote dairy productivity without adverse impacts on milk quality.

Table 5. Mean values of basic composition of goat milk (%) of Nubian goats fed on different levels of *M. oleifera* leaves.

Parameters	Mean ± SD			
	Group A	Group B	Group C	Group D
PH	6.55± 0.17^{c}	6.60±0.079^{b}	6.65±0.11^{a}	**6.55±0.13^{c}**
Acidity	2.68±0.15^{ab}	2.43±0.12^{ab}	2.93±0.397^{a}	**2.18±0.38^{c}**
Moisture (%)	88.11±0.52^{b}	88.24±0.23^{ab}	88.41±0.34^{a}	**87.23±0.199^{c}**
Ash (%)	0.39±0.018^{b}	0.40±0.12^{ab}	0.41±0.03^{a}	**0.38±0.096^{c}**
Fat (%)	2.31±0. 59^{b}	2.68±0.34^{ab}	2.71±0.49^{a}	**2.28±0. 24^{c}**
Protein (%)	4.00±0.52^{b}	4.15±0.084^{b}	4.21±0.45^{a}	**3.94±0.37^{c}**
Carbohydrate (%)	4.64±0.38^{c}	4.95±0.61^{b}	5.01±0.56^{a}	**4.63±0.45^{c}**

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Milk yield and body weight

Data in **Table 6** demonstrates milk yield and body weight, highlighting significant differences in milk yield ($p < 0.05$). Groups C achieved the highest yields, with groups D showing comparatively lower yields. Body weight a slight increase ($p < 0.05$) was noted in group C across other groups, corroborating findings by Kholif et al., 2015; Mataveia et al., 2019; Kholif et al., 2019 and Afzal et al., 2022 which noted *M. oleifera* potential to enhance rumen function and microbial output. Body weight exhibited significant changes ($p < 0.05$), corroborating findings from Sultana et al., 2015 as well as other research focusing on the growth performance enhanced by *M. oleifera*. These results indicate that the advantages of *M. oleifera* supplementation may be more pronounced in lactational performance rather than in general growth metrics. This observation underscores the potential of *M. oleifera* as a strategic tool in dairy goat management, suggesting that its incorporation into feeding regimens could optimize milk production and overall herd productivity. By prioritizing lactation improvements, farmers can enhance the efficiency of their operations, ensuring better health and productivity for dairy goats, while also potentially increasing profitability.

Table 6. Mean values of milk yield (L/day) and Body weight (Kg) of Nubian goats fed on different levels of *M. oleifera* leaves.

Parameter	Mean ± SD			
	Group A	Group B	Group C	Group D
Milk yield (L/day)	0.77±0.32^{b}	0.99±0.39^{ab}	1.01±0.35^{a}	**0.74±0.34^{c}**
Body weight (kg)	21.17±10.109^{b}	22.64±4.85^{ab}	23.23±3.75^{a}	**20.39±10.81^{c}**

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Fertility traits

Presented in **Table 7**, fertility outcomes exhibited significant differences in oestrus response ($p < 0.05$), with groups B and C achieving a 100% response rate. Conception rates (100%) and litter sizes were higher ($p < 0.05$) in groups B and C. These results align with studies by Romano, 1998 and Kusina et al., 2000, proving effective synchronization and enhanced reproductive readiness with *M. oleifera* supplementation. Conception rates remained constant at 100%, while litter sizes were similar to previous findings, indicating robust fertility outcomes regardless of dietary variations. The insight into oestrus synchronization strategies could inform improved breeding practices in goats, particularly integrating natural feed supplements like *M. oleifera* to bolster reproductive efficiencies.

Table 7. Mean values of fertility traits of Nubian goats fed on different levels of *M. oleifera* leaves.

Parameter	Mean ± SD			
	Group A	Group B	Group C	Group D
Oestrus response (%)	80^{ab}	100^{a}	100^{a}	**60^{b}**
Conception rate (%)	100^{a}	100^{a}	100^{a}	**100^{a}**
Litter size	1.30±0.55^{b}	1.40±0.55^{ab}	1.50±0.58^{a}	**1.00±0.00^{c}**
Birth weight/Kg	2.38±0.32^{b}	2.40±0.91^{ab}	2.75±0.25^{a}	**1.95±0.65^{c}**
Gestation/day	152.50±2.89^{b}	153.60±3.36^{ab}	155.33±0.58^{a}	**151.20±5.45^{c}**

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Ultrasonographic fetal measurements

The fetal measurements, as shown in **Table 8**, illustrate FL, BPD, and CRL at various gestation days. Group C displayed the highest mean FL measurements at 80 days, while CRL were longest in group B at 45 days of gestation, these differences were statistically significant ($p < 0.05$), they provide insight into fetal development under the diet regimen, closely mirroring the results of Abdelghafar et al., 2010; Yadav, 2021 and Gouda et al., 2021. These metrics suggest that *M. oleifera* supplementation impact fetal development, thus providing a valuable baseline for concluding that *M. oleifera* enhanced diets can support normal gestational progress in goats. The integration of such nutritional strategies could refine prenatal care, ensuring optimal developmental outputs while maintaining economic and environmental sustainability in goat husbandry.

Table 8. Mean values of foetal femur length (FL), Biparietal diameter (BPD) and Crown rump length (CRL) of Nubian goats fed on different levels of *M. oleifera* leaves

Parameters	Mean ± SD			
	Group A	Group B	Group C	Group D
FL (cm)	2.08±0.17^{b}	2.19±0.41^{ab}	2.72±0.59^{a}	**2.06±0.35^{c}**
BPD (cm)	2.52±1.14^{b}	2.47±0.52^{ab}	2.73±0.32^{a}	**2.42±0.22^{c}**
CRL (cm)	2.46±2.25^{b}	2.78±2.01^{a}	2.70±2.34^{ab}	**2.16±2.58^{c}**

Values within different superscripts in the same row are differ significantly ($p < 0.05$).

The effect of different levels of M. oleifera on birth weight (Kg)

The results of the study examining the effect of different levels of *M. oleifera* leaves on the birth weights of Nubian goats are presented in **Table 9**. For single males, the mean birth weights across the groups varied, with group A having a mean of 3.02±0.30 kg, group B at 3.38±0.40 kg, group D at 3.00±0.25 kg, and group C showing the highest mean of 3.50±0.35 kg. The comparable birth weights of single males in groups A and D, along with the elevated weights in groups B and C, indicate a possible dose-response correlation suggesting that higher *M. oleifera* supplementation may lead to increased birth weights in single males. Specifically, Group A had a mean birth weight of 3.02±0.30 g, while Group D weighed 3.00±0.25 g, in contrast to the higher weights found in Groups B and C, which were 3.38±0.40 g and 3.50±0.35 g, respectively. In single females, the mean birth weights were

relatively uniform across the groups, with group A and C both at 2.63±0.18 kg, suggesting no significant effect of *M. oleifera* supplementation within the studied range on female singletons. However, for twins, significant variation was observed with groups B and C showing the highest mean of 2.50±0.35 kg, group C at 1.67±0.53 kg, group B at 1.25±0.00 kg, and group A at 1.63±0.88 kg, indicating potential differential effects based on the varying levels of *Moringa* supplementation.

Table 9. Mean Values of Birth Weight (Kg) of Nubian Goats Fed on Different Levels of *M. oleifera* leaves

Parameter	Mean ± SD			
	Group A	Group B	Group C	Group D
Birth weight of single males	3.02±0.30^{b}	3.38±0.40^{ab}	3.50±0.35^{a}	3.00±0.25^{c}
Birth weight of single females	2.62±0.18	2.62±0.14	2.62±0.18	2.63±0.35
Birth weight of twins	1.63±0.88^{b}	2.50±0.35^{a}	2.51±0.71^{a}	1.52±0.00^{c}

Values within different superscripts in the same row are differ significantly ($P < 0.05$).

Conclusions

Feeding Nubian goats *M. oleifera* leaves at varying inclusion levels demonstrated a significant impact on a range of physiological parameters, including blood serum albumin, total protein, and both macro and micro minerals. Notably, there were increases in copper and sodium levels at medium inclusion rates of *M. oleifera*. Moreover, milk yield was positively correlated with the amount of *M. oleifera* provided, suggesting that higher supplementation can enhance milk production. In terms of reproductive performance, various fertility traits were influenced by the dietary *M. oleifera*; however, improvements in oestrus response were particularly notable at inclusion rates of 20% and 40%. This finding suggests that certain levels of *M. oleifera* can optimize reproductive health and efficiency in Nubian goats. Additionally, differences in fetal measurements observed via ultrasound further underscore the potential benefits of *M. oleifera* on reproductive outcomes. Overall, *M. oleifera* emerges as a promising dietary supplement for goat nutrition, effectively enhancing milk yield while maintaining reproductive health. Given these positive results, further studies should investigate the effects of *M. oleifera* on male fertility, expanding our understanding of its potential benefits across different aspects of goat husbandry. This research could pave the way for implementing *M. oleifera* as a strategic supplement to boost overall productivity in goat farming systems.

Sensory and Texture Profile Analyze of Bulgur Samples

Buket Cetiner[1]

[1]Department of Quality and Technology, Field Crops Central Research Institute, Ankara, Türkiye

Abstract

Sensory and textural characteristics have a great influence on consumers' purchasing and consumption decisions and the food product should have a certain level of sensoral and textural profile to be preferred by the consumers. The main aim of this study was to compare the sensory and texture profile of the bulgur samples produced by two pea cultivars and commercial bulgur as a control sample. The hardness, adhesiveness, springiness, cohesiveness, gumminess, chewiness, and resilience characteristics were determined to assess the texture profile of the bulgur samples. There were statistically significant differences between samples in terms of hardness ($p<0.05$). Hardness values of bulgur samples produced using cv. Deren and Irmak-01 were 2132 and 1801 g, respectively, while the value of the control bulgur sample was 682 g. In terms of adhesiveness and springiness, the differences between samples were not statistically significant ($p>0.05$).In terms of cohesiveness, gumminess, chewiness and resilience values, cv. Deren had the highest values ($p<0.05$). Sensory analyses of bulgur samples were conducted by fifteen panelists. Panelists were asked to score the cooked bulgur samples in terms of appearance, color, smell, texture, taste and overall acceptability. They were evaluated with the 9-point hedonic scale ranging from 1 = Dislike extremely and 9 = Like extremely. The sensory profile of pea bulgur samples produced with cv. Deren and Irmak-01 had lower scores as compared to the control bulgur (7.47) in all characteristics with an overall acceptability value of 4.47 and 4.43, respectively. The color, smell and taste values of the bulgur produced with cv. Irmak-01 had slightly higher scores rather than those of cv. Deren (4.67), however, the differences were not statistically significant ($p>0.05$). It can be concluded that the sensory profile of pea cultivars had almost similar sensory profiles. Hovewer, textural profiles of bulgur samples varied depending on the variety.

Responses of Some Almond (*Prunus dulcis*) Varieties to Drought Stress

Melih Aydınlı[1]

[1]Islah ve Genetik Bölümü, Meyvecilik Araştırma Enstitüsü, Isparta, Türkiye

Abstract

Drought stress, which has become more pronounced due to global climate change, is a significant factor limiting agricultural sustainability. One of the necessary steps to address this issue is the use of drought-tolerant plants. In this study, the drought tolerance of some newly developed almond varieties, such as Makako, Marinada, and Vairo, was determined with the help of morphological and physiological markers. The plants, grafted onto Garnem rootstocks and grown in 18-liter pots, were subjected to deficit irrigation treatments (T1: 100% irrigation (control); T2: 50% irrigation; T3: 25% irrigation) for two years to induce drought stress. At the end of the study, it was found that fresh and dry plant weights, membrane stability index (MSI), leaf water potential (LWP), CO_2 assimilation rate, and stomatal conductance were significantly affected by drought stress. The Marinada variety exhibited the highest fresh and dry plant weights. However, in terms of MSI, LWP, CO_2 assimilation, and stomatal conductance, the Vairo variety showed greater drought tolerance. As a result, the drought tolerance and sensitivity of the grafted varieties on Garnem rootstock were evaluated. However, it is believed that detailed biochemical analyses and field studies are necessary to reach a definitive conclusion.

Kuraklık ve Sıcaklık Stresinin Patates Bitkisi Üzerine Etkileri

Tuğba Özkan

Patates Araştırma Enstitüsü Müdürlüğü

Özet

Küresel iklim değişikliği, tarım sektörünü önemli ölçüde etkileyen bir faktördür. İklim değişikliği ile birlikte kuraklık olaylarının sıklığı ve şiddeti artmaktadır, bu da tarımsal üretimi ve gıda güvenliğini tehdit etmektedir. İklim değişikliği nedeniyle artan kuraklık şiddeti ve sıklığı, patates üretimini olumsuz etkilemektedir. Bunun yanı sıra küresel iklim değişikliği; sıcaklık ve CO_2 seviyeleri, zararlılar ve hastalıklar, toprak ve su kaynakları ve bölgesel farklılıklar gibi faktörlerde patates verimini ciddi anlamda azaltır. Artan sıcaklıklar, değişen yağış zamanları ve miktarları tarımsal üretimi ve gıda güvenliğini tehdit etmektedir. Bitkiler abiyotik streslere karşı farklı mekanizmalar geliştirebilirler. Bu streslerle mücadelede fotosentez, biyokimyasal yollar ve stres toleransı gibi çeşitli mekanizmaları kullanırlar. Patates suya duyarlı bir bitki olduğundan kuraklık stresinde verim ve kalite olumsuz etkilenir. Bu çalışmada iklim değişikliğinin tarıma etkisi, kuraklık ve sıcaklık streslerinin patatese etkileri değerlendirilmiştir.

Anahtar kelimeler: *İklim Değişikliği, Kuraklık-Sıcaklık Stresi, Verim, Kuraklığa Tolerans*

Determination of Yield and Quality Characteristics of Immortal Flower (*Helichyrsum italicum* (Roth) G. Don fil.) Plant Conditions at Different Growth Periods in Çukurova Conditions

Dilek Savaşlı Yıldırım[1], Elif Ferahoğlu[2], Saliha Kırıcı[2]

[1]Faculty of Pharmacy, Çukurova Universty, Adana, Türkiye
[2]Field Crops,Faculty of Agriculture, Çukurova Universty, Adana, Türkiye

Abstract

This study, which was conducted to determine the yield and quality characteristics of Immortelle ((Helichyrsum italicum (Roth) G. Don fil.)) plant in different development periods under Çukurova conditions, was conducted at the research area of Çukurova University, Faculty of Agriculture, Department of Field Crops in 2021-2022. Three different development periods were selected as the harvesting time of the immortelle plant: beginning of flowering, full flowering and post-flowering. As a result of the research, according to the harvesting time, the average plant height was 37.43-47.80 cm, fresh herb yield was 534.37-784.83 kg/da, dry herb yield was 139.50-361.32 kg/da, fresh flower yield was 65.24-203.80 kg/da, dry flower yield was 25.66-111.64 kg/da, essential oil ratio in flower (0.30-0.88%), flower essential oil yield was 0.22-0.4 l/da. It was found that the main components of the essential oil were α-pinene, γ-curcumene, italidion I, neryl acetate, italidion II, caryophyllene, β-selinene and the ratios of these components changed according to the harvest time of the plant. As a result of the research, it was found that the most suitable harvest time for H. italicum was the beginning of flowering and full flowering. However, further research is needed to determine the appropriate time for the beginning of flowering.Key Words*: Helichyrsum italicum,* Immortal Flower, development period, essential oil, yield and quality

Çukurova Koşullarında Ölmez Çiçek (*Helichyrsum italicum*) Bitkisinin Farklı Gelişme Dönemlerinde Verim ve Kalite Özelliklerinin Belirlenmesi

Özet

Çukurova koşullarında ölmez çiçek (*Helichyrsum italicum* (Roth) G. Don fil.) bitkisinin farklı gelişme dönemlerinde verim ve kalite özelliklerinin belirlenmesi amacıyla yapılan bu çalışma 2021-2022 yıllarında Çukurova Üniversitesi Ziraat Fakültesi, Tarla Bitkileri Bölümü araştırma alanına kurulmuştur. Ölmez çiçek bitkisinde hasat zamanı olarak çiçeklenme başlangıcı, tam çiçeklenme ve çiçeklenme sonrası olmak üzere üç farklı gelişme dönemi seçilmiştir. Araştırma sonucunda hasat zamanlarına göre bitki boyu ortalamaları 37.43-47.80 cm, taze herba verimleri 534.37-784.83 kg/da, kuru herba verimleri 139.50-361.32 kg/da, taze çiçek verimleri 65.24-203.80 kg/da, kuru çiçek verimleri 25.66-111.64 kg/da, çiçekte uçucu yağ oranı (% 0.30-0.88), çiçek uçucu yağ verimleri 0.22-0.4 l/da arasında değişmiştir. Uçucu yağın ana bileşenleri α-Pinene, γ-Curcumene, italidion I, Neryl acetate, italidion II, Caryophyllene , β-Selinene olduğu ve bu bileşenlerin oranlarının bitkinin hasat zamanına göre değişim gösterdiği belirlenmiştir. Araştırma sonucunda *H.italicum*'da en uygun hasat zamanının çiçeklenme başlangıcı ve tam çiçeklenme dönemleri olduğu belirlenmiştir. Bununla birlikte, çiçeklenme başlangıcında da uygun zamanı belirlemek için daha fazla araştırma yapılması gerekmektedir.

Anahtar Kelimeler: *Helichyrsum italicum, Ölmez Çiçek, gelişme dönemi, uçucu yağ, verim ve kalite*

Giriş

Bitkiler, insanların yaşamında her zaman çok önemli bir yere sahip olmuştur ve insanoğlunun varoluşundan bu yana bitkileri ihtiyaç duydukları her alanda (beslenme, hastalıkların tedavi edilmesi, barınma, yakacak) kullanmışlardır. Tıbbi ve aromatik bitkiler insanların daha sağlıklı ve kaliteli bir yaşam sürmeleri açısından önemli olan sekonder metabolit (alkaloitler, terpenoitler ve fenolikler) olarak adlandırılan biyoaktif etken maddeler içerirler (Kırıcı ve ark., 2020). Sekonder metabolitler başta ilaç, gıda katkı maddeleri, aroma verici, kozmetik ve endüstriyel açıdan benzersiz kaynaklardır (Ramakrishna ve Ravishankar, 2011). Dünyadaki 20.000 bitki türünden elde edilen 4000 kadar bitkisel drogunun tıbbî amaçlarla kullanıldığı, Türkiye'de yetişen 12.000'e yakın bitki taksonundan 500 tanesinin tıbbi bitki olduğu bilinmektedir (Nohutçu ve ark., 2019). Ekonomik değeri yüksek tıbbi ve aromatik bitkilerden özellikle uçucu yağ içerenler gün geçtikçe daha fazla önem kazanmaktadır. Uçucu yağlara olan talep her geçen yıl artmakta ve ekonomik boyutta da önemli bir sektör olarak gelişmektedir. Uçucu yağlar ve rezinoitler, parfümeri, kozmetik vd. dünya ihracat değerleri 2001 yılında 34.1 milyar dolar iken 2019 yılına gelindiğinde beş kat artarak 150.7 milyar dolara ulaşmış, 2021 yılında ise 157,6 milyar dolar ile tıbbi ve aromatik bitkiler ihracatında en fazla artışa sahip olan ürün grubu olmuştur (Boztas ve ark., 2021; Kırıcı, 2022). Bu bitkilerden biri de ilaç, kozmetik ve parfüm endüstrisinde popülaritesi her geçen gün artan *Helichrysum italicum*

(Roth) G. Don fil.'dir. Ülkemizde *Helichrysum* cinsine "alay çiçeği, altınbaşak, altın çiçeği, altın otu, arı çiçeği, bozoğlan, herdemtaze, kovan otu, kudama, mantı çiçeği, yayla çiçeği, yayla gülü" gibi pek çok isim verilmiştir, bununla beraber, genel olarak ölmez çiçek adıyla anılır, Adana ve Kadirli (Osmaniye)'de yöre halkı '' Mantuvar '' ismini kullanmaktadır (Baytop, 1997; Eroğlu, 2018). *H. italicum* çiçekleri gıda sektöründe, unlu mamuller ve alkolsüz içeceklere çeşni ve tat vermek için kullanılmakta, ayrıca cildi yenileme özelliği ile kozmetik sektörünün gözde bitkileri arasında yer almaktadır (Baytop, 1999, Antunes Viegas ve ark., 2014). Geleneksel olarak halk hekimliğinde idrar yolu enfeksiyonları, böbrek hastalıkları ve böbrek taşı, öksürük, bronşit, ishal, dezenfektan madde olarak, yara iyileştirici, baş ağrısı, gribal enfeksiyonlar, safra kesesi, mide, karaciğer ve bağırsak hastalıklarında, sarılık, diyabet, kalp, diş ve göz hastalıkları, bağırsak parazitleri için kullanılmaktadır (Akaberi ve ark., 2021). Yapılan çalışmalar ölmez çiçeğin içerdiği fitokimyasalların antimikrobiyal, antiinflamatuar, antioksidan, antiviral, antikanser , böcek öldürücü ve kovucu aktiviteler de dahil olmak üzere çeşitli biyolojik özelliklere sahip olduğunu göstermiştir (Arbeiter ve ark.,2021). *H.italicum* bitkisinin çiçekleri ve toprak üstü kısımları uçucu yağ ve fenolik bileşikler açısından zengindir. Ölmez çiçek uçucu yağı bileşimi çok fazla farklılık göstermekle birlikte içerdiği başlıca biyoaktif bileşikler monoterpenlerden α-pinen, nerol, neryl asetat ve neryl propianoat, seskiterpenlerden α–selinen, β-selinen, γ-curcumen, nerolidol 'dur (Furlan ve Bren, 2023). Korsika, Sardunya ve Toskana Adalarından hasat edilen *H. italicum* bitkisinin uçucu yağının ana bileşeni neryl asetatdır ve bundan dolayı Akdeniz bölgesinde özellikle Korsika Adası için ekonomik bir öneme sahiptir (Bianchini ve ark., 2009; Bianchini ve ark., 2001; Guinoiseau ve ark., 2013; Leonardi ve ark., 2013).

Ölmez çiçekte verim bitkilerin yaşına ve bölgenin ekolojik koşullarına bağlı olarak değişir, üçüncü ve sekizinci yıllar arası en verimli dönemidir, bu yıllarda 7 ila 8 t/ha taze çiçek ve 3.5 ila 4 ton/ha kuru çiçek elde edilip, uçucu yağ verimi 0.8-1.2 kg/da arasında değişir (Mucalo, 2015). Batı Akdeniz Kalkınma Ajansı (BAKA) tarafından hazırlanan 'Ölmez çiçek (*H. italicum*) tarımı ve endüstrisi' adlı fizibilite raporuna göre taze çiçek veriminin ikinci yıl (350 kg/da), üçüncü yıl (550 kg/da) olduğunu ve en yüksek taze çiçek veriminin beş, altı ve yedinci yıllarda (1000 kg/da) elde edildiğini bildirmişlerdir. Ölmez çiçeğin uçucu yağ oranının çok düşük olduğunu (%0.12-0.35) ve yaklaşık 700-1000 kg çiçekten bir kilogram uçucu yağ elde edildiğini, uçucu yağ veriminin ise (0.8-1.2 kg/ da) arasında değiştiğini belirtmişlerdir (BAKA, 2021). Sırbistan'da yetiştirilen *H.italicum* bitkilerinin ikinci yılında yapılan ilk hasatında bitkilerin boylarının tomurcuklanma aşamasında 35.2 cm-37.2 cm, çiçeklenme döneminde 39.4 cm - 42.2 cm olarak belirtmişlerdir. Biyomas verimini 564 kg/da-538 kg/da olarak açıklamışlardır. Uçucu yağ oranını % 0,148-%0.143 ve uçucu yağ veriminin 0.8 kg/da-0.7 kg/da olduğunu açıklamışlardır (Miloradović, 2018).

Bu araştırmada ekonomik öneme sahip olan Ölmez Çiçek (*Helichyrsum italicum*) bitkisinin Çukurova Koşullarında farklı gelişme dönemlerinde verim ve kalite özelliklerinin belirlenmesi amaçlanmıştır.

Materyal ve Yöntem

Materyal olarak kullanılan ölmez Çiçek (*H. italicum*) fideleri ticari bir firmadan temin edilmiştir. Araştırma Ç.Ü. Ziraat Fakültesi Tarla Bitkileri Bölümü Araştırma ve Uygulama Alanında (Rakım 34 m) 2021-2022 yıllarında iki yıl süreyle yürütülmüştür. Hasat zamanları olarak üç gelişme dönemi (çiçeklenme başlangıcı, tam çiçeklenme ve çiçeklenme sonu/solgun çiçek) seçilerek, tesadüf blokları deneme desenine göre 3 tekrarlamalı olarak kurulmuştur. Toplam deneme alanı 260 m^2 olup, her bir tekerrür 6 m×13 m (78 m^2), sıra arası 100 cm (1 m), sıra üzeri 40 cm (0,4 m) olup, 13 sıra, her bir sırada 15 bitkiden oluşmuştur. Her bir tekerrürde 195 bitki, tüm deneme alanında ise 585 bitkiden oluşmuştur. Fideler 06.04.2021 tarihinde deneme alanına şaşırtılmış, dikildikten sonra can suyu verilmiş, daha sonra toprak nemine bağlı olarak sulanmıştır. Bitkilere iki defa dekara 2 kg olmak üzere %46 üre gübresi uygulanmıştır. Deneme alanında görülen yabancı otlar el çapası ile uzaklaştırılmıştır. İlk biçim 3 Eylül 2021 tarihinde 5 cm yükseklikten yapılmıştır. Ancak birinci yıl tesis yılı olarak kabul edildiğinden ilk biçim değerleri kullanılmayıp ikinci yıl verileri değerlendirilmiştir. İkinci yıl kenar tesiri çıkartılarak gerekli ölçümler yapıldıktan sonra; çiçeklenme başlangıcı 10 Mayıs 2022, tam çiçeklenme dönemi 09 Haziran 2022, çiçeklenme sonrası 26 Haziran 2022 tarihlerinde elle hasat makası kullanarak yapılmıştır. Her bir hasat zamanında bitki boyu değerleri alınmış, daha sonra bitkiler toprak yüzeyinden 10 cm yukarıdan biçilmiştir. Hasat edilen bitkiler gerekli tartım işlemlerinden sonra herba ve çiçek verimleri için gerekli örnekler alınarak oda sıcaklığında gölgede kurutulmuştur.

Su buharı distilasyonu yöntemi ile elde edilen uçucu yağların bileşenleri Çukurova Üniversitesi Merkez Araştırma Laboratuvarında GC/MS yöntemi ile saptanmıştır. Analiz Agilent Marka 7890B GC, 7010B MS sistemi ile belirlenmiştir. Hazırlanan örnekler DB-Wax (60 m x 0.25mmi.dx 0.25 µm, J&W Scientific-Folsom, USA) kapiler kolonuna 1uL enjekte edilmiştir. Enjeksiyon sıcaklığı 250 °C, kolon sıcaklığı 40 °C'de başlatılmış dakikada 3 °C artırılarak 240 °C'ye ayarlanmıştır. Taşıyıcı gaz olarak He kullanılmıştır. Elektron enerjisi 70 eV ve kütle aralığı ise 30-600 m/z'dir. Split oranı 1:20 dir. Ayrılan bileşenler NIST14L kütüphanesinde karşılaştırma yapılarak belirlenmiştir.

Elde edilen verilere JMP istatistik paket programı kullanılarak tesadüf blokları deneme desenine göre varyans analizi uygulanmıştır. Elde edilen ortalamalar %5 ve %1 önem düzeyine göre ANOVA analizi yapılarak EGF testine göre belirlenmiştir.

Bulgular ve Tartışma

Bitki Boyu

Çukurova Koşullarında yetiştirilen *H. italicum* bitkisinin farklı gelişme dönemlerinde hasat edilmesiyle elde edilen bitki boyuna ait veriler istatistiksel yönden önemli bir fark bulunmamıştır. *H. italicum* bitki boyu değerleri ortalama 37.43-47.80 cm arasında değişmiştir. En düşük bitki boyu çiçeklenme başlangıcında yapılan hasatta 37.43 cm olarak elde edilirken, en yüksek değer 47.80 cm ile çiçeklenme sonrası yapılan hasattan alınmıştır. Araştırma sonuçları Miloradović, (2018) 35,2-42,2 cm ve Tomičić ve ark., (2022) 'ın 23,4-49,5 cm elde ettiği değerlerle benzerdir.

Taze ve Kuru Herba Verimleri

Farklı hasat zamanlarında elede edilen taze herba verim değerleri arasında %1 düzeyinde önemli farklılık bulunmuştur (Çizelge 1). Taze herba verimi 534.37-784.83 kg/da arasında değişmiştir. En yüksek taze herba verimi 784.83 kg/da ile çiçeklenme sonrası dönemde yapılan hasattan elde edilirken, tam çiçeklenme döneminde 639.67 kg/da verim elde edilmiş, en düşük verim ise 534.37 kg/da ile çiçeklenme başlangıcı döneminde yapılan hasattan elde edilmiştir. Araştırma sonuçlarımız Baniček (2019) 700-800 kg/da ve Čagalj ve ark. (2019)'555,5 kg/da nın sonuçları ile uyumlu olurken Ivankovic ve ark (2016) 243,1-361,6 kg/da sonucunda yüksek çıkmıştır.

Kuru herba verimi üzerine hasat dönemlerinin etkisi varyans analizi sonucunda %5 düzeyinde önemli bulunmuştur (Çizelge 1). Kuru herba verimi 139.5-361.32 kg/da arasında değişmiş, en yüksek kuru herba verimi yaş herba verimine paralel olarak 361.32 kg/da ile çiçeklenme sonrası dönemde, en düşük 139.50 kg/da ile çiçeklenme başlangıcı döneminde yapılan hasattan elde edilmiştir. Taze herba veriminde olduğu gibi kuru herba veriminde de bitkinin gelişim dönemi ilerledikçe verim değerleri artmıştır. Miloradović (2018), yaş herba kütlesinin kurutulmayla yaklaşık %65 azalarak kuru herba verim değerini verdiğini belirtmişlerdir. Benzer şekilde taze herba verimlerinin çiçeklenme başlangıcında %26,10, tam çiçeklenme %46,08 ve çiçeklenme sonrası %53,94 oranında azaldığı saptanmıştır. Herba verimlerinde elde edilen farklılıkların nedeni bitkinin yaşı, yetiştiği bölgenini iklim koşulları, bitki dikim sıklığı gibi birçok faktörden kaynaklanabilmektedir (Ivanković ve ark., 2016; Matin ve ark., 2021; Miloradović, 2018; Mucalo, 2015).

Taze ve Kuru Çiçek Verimi

Farklı gelişme dönemlerinde elde edilen taze çiçek verimi değerleri arasında varyans analizi sonucunda %5 düzeyinde önemli farklılık bulunmuştur. Araştırma da taze çiçek verimi 65.24-203.80 kg/da arasında değişmiştir. En yüksek taze çiçek verimleri çiçeklenme sonrası (203.80 kg/da) ve tam çiçeklenme döneminde yapılan hasattan (203.14 kg/da) elde edilmiş, en düşük verim ise çiçeklenme başlangıcı döneminde yapılan hasattan (65.24 kg/da) elde edilmiştir. İstatistiksel olarak tam çiçeklenme ve çiçeklenme sonrası hasatlardan alınan değerler arasındaki farklılık önemli olmamıştır. Batı Akdeniz Kalkınma Ajansı' nın ölmez çiçek tarım ve endüstrisi fizibilite raporuna göre bitkiden ikinci yıl 550 kg/da taze çiçek alınabildiğini, çiçek veriminin 0.5-1500 kg/da arasında değiştiğini belirtmişlerdir (BAKA, 2021). Tam çiçeklenme döneminde elde edilen 203.14 kg/da olan kuru herba verimi BAKA 'nın açıkladığı verim değerlerinin aksine düşük çıkmıştır. Mucalo (2015) verimin bitkilerin yaşına ve bölgenin ekolojik koşullarına bağlı olarak değiştiğini, üçüncü ve sekizinci yıllar arasında en fazla verimin alındığını, bu yıllarda 700-800 kg/da taze çiçek elde edilebileceğini açıklamışlardır. Bazı araştırıcılar bitki başına çiçek veriminin 16.60 g -141.3 g arasında değiştiğini belirtmektedirler (Göre ve Avcı (2022; Weglarz ve ark., 2022).

Çizelge 1. *H. italicum* bitkisinin farklı gelişme dönemlerinde elde edilen bitki boyu(cm), taze ve kuru herba verimleri (kg/da), taze ve kuru çiçek verimleri (kg/da),uçucu yağ oranı (%) ve uçucu yağ verim (l/da) değerleri

Hasat Zamanları	Bitki boyu cm	Taze herba verimi kg/da	Kuru herba verimi kg/da	Taze çiçek verimi kg/da	Kuru çiçek verimi kg/da
Çiçeklenme Başlangıcı	37.43B	534.37 C	139.50 B	65.24 B	25.66 C
Tam Çiçeklenme	43.70A	639.67 B	345.08 A	203.14 A	91.90 B
Çiçeklenme Sonrası	47.80A	784.83 A	361.32 A	203.80 A	111.64 A
EGF (%5)	5.09	29.52	67.20	59.25	16.09
C.V(%)	5.2	5.1	3.6	6.5	1.6

Kuru çiçek verimi üzerine hasat dönemlerinin etkisi varyans analizi sonucunda %1 düzeyinde önemli farklılık bulunmuştur (Çizelge 1). En yüksek kuru çiçek verimi çiçeklenme sonrası (111.64 kg/da), daha sonra tam çiçeklenme (91.90 kg/da) ve en düşük çiçeklenme başlangıcı hasatında (25.66 kg/da) olarak elde edilmiştir. Mucalo (2015), en fazla verimin alındığını üçüncü ve sekizinci yıllar arasında (350-400 kg/da) kuru çiçek elde edilebildiğini açıklamışlardır.İkinci yılda alınan kuru çiçek verimleri 25.66-111.64 kg/da arasında olup, Mucalo (2015) üçüncü yıl elde ettiği 350-400 kg/da verim değerlerinden düşük çıkmıştır. Kuru çiçek verimi taze çiçeklerin kurutulmasıyla elde edilen bir değer olduğu için sonuçlar taze çiçek verimiyle paralel olmuştur. Demirbaş ve Ateş

(2021) ölmez çiçek bitkilerinin yetiştirileceği alanın bol güneş alıyor olmasının çiçek açma performansını arttırdığını, BAKA (2021) aşırı nemli yaz sıcaklarının çiçek verimliliği ve kalitesini olumsuz yönde etkilediğini belirtmişlerdir. Burada elde edilen taze çiçek veriminin literatür değerlerinden düşük olması ekolojik faktörlerden ve bitki yaşından kaynaklandığı düşünülmektedir.

Çiçekte Uçucu Yağ Oranı

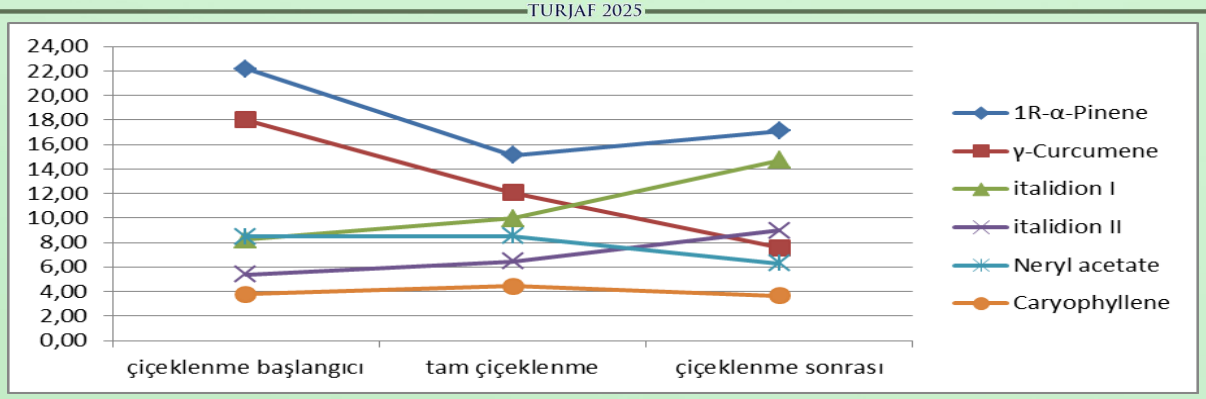
Ölmez çiçek bitkinin ticari öneme sahip kısmı olan uçucu yağı berrak, altın sarısı renk ve belirgin yoğun bir kokuya sahiptir (Peršić ve ark., 2019). *H.italicum* bitkisi çiçek başlarında, genç saplarında ve yapraklarında uçucu yağ salgılayan glandüler trikomlara sahiptir (Morone-Fortunato ve ark., 2010). *H. italicum* bitkisinin farklı gelişme dönemlerinde elde edilen uçucu yağa ait varyans analizi sonucunda hasatlar arasında %1 düzeyinde önemli farklılık bulunmuştur. En yüksek uçucu yağ oranı çiçeklenme başlangıcı %0.88, tam çiçeklenme %0.44 ve en düşük %0.30 çiçeklenme sonrası hasatında elde edilmiştir (Çizelge 2). Ölmez çiçek bitkisinde uçucu yağ oranı hasat dönemlerine göre (ontogenetik varyabilite) ve bitki kısımlarına göre (morfogenetik varyabilite) değişiklik göstermektedir (Bianchini ve ark., 2001; Paolini ve ark., 2006; Satta ve ark., 1999). Benzer şekilde bitkinin gelişme dönemlerine göre yapılan hasatlardan elde edilen uçucu yağ oranları da değişmiş olup, en yüksek değer çiçeklenme başlangıcı dönemden alınmıştır. Araştırma sonuçları bazı araştırıcıların bulduğu değerlerden (Blažeković ve ark., 1995; Kılıçarslan, 2020; Satta ve ark., 1999) yüksek, bazı araştırıcıların değerleriyle (Bilandžija ve ark., 2022; Göre ve Avcı, 2022; Talić ve ark., 2019) uyumlu, bazı araştırıcıların değerlerinden düşük (Judzentiene ve ark., 2022) çıkmıştır. Melito ve ark. (2016), özellikle tıbbi ve aromatik bitkilerin uçucu yağ bileşimi ve veriminin agroteknik uygulamalardan, ekolojik ve iklim faktörlerinden etkilendiğini bildirmişlerdir.

Çiçek Uçucu Yağ Verimi

H. italicum bitkisinin farklı gelişme dönemlerinde elde edilen uçucu yağ verimine ait varyans analizi sonucunda hasatlar arasında %1 düzeyinde önemli farklılık bulunmuştur. Çiçek uçucu yağ verimleri 0.22-0.4 l/da arasında değişmiştir. (Çizelge 2). En yüksek verim 0.4 l/da tam çiçeklenme döneminde, en düşük verim 0.22 l/da çiçeklenme başlangıcı döneminde elde edilmiştir. Elde ettiğimiz bulgular bazı araştırıcıların bulduğu değerlerden (Čagalj ve ark., 2019; Miloradović, 2018) düşük çıkmıştır. *H.italicum*'da uçucu yağ verimi, kuru çiçek miktarına ve bitkinin içerdiği uçucu yağ oranına bağlı olarak değişiklik göstermektedir. (Pohajda ve ark., 2015).

Çizelge 2. *H. italicum* bitkisinin farklı gelişme dönemlerinde elde edilen uçucu yağ oranı (%) verim (l/da) değerleri

Hasat Zamanları	Çiçek uçucu yağ oranı (%)	Çiçek uçucu yağ verimi (l/da)
Çiçeklenme Başlangıcı	0.88 A	0,22 C
Tam Çiçeklenme	0.44 B	0,40 A
Çiçeklenme Sonrası	0.30 C	0,33 B
EGF (%5)	0.11	0.055
C.V(%)	2.01	7.54



Uçucu Yağ Bileşenleri

H. italicum bitkisinin uçucu yağı fitoterapinin yanı sıra kozmetik, ilaç, tarım, gıda sanayi gibi farklı alanlarda da kullanımına olanak sağlar (Morone-Fortunato ve ark., 2010). *H.italicum* uçucu yağı Avrupa Farmakopesinde yer almamakta ve belirli standartı bulunmamaktadır (Bilandžija ve ark., 2023). Kullanım amacı bitkinin kemotiplerine göre değişiklik göstermektedir, bu yüzden uçucu yağın içeriği büyük önem taşımaktadır. Araştırma sonucunda uçucu yağda 38 bileşen tanımlanmış olup ana bileşenleri, α-pinene (%15.11-22.16), γ-curcumene (%7.57-18.20), italidion I (%8.25-14.72), Neryl acetate (%6.31-8.53), italidion II (%5.38-8.98), caryophyllene (%3.66-4.43) ve β-Selinene (%4.27-5.36) olup, bu bileşenlerin oranlarının bitkinin hasat zamanlarına göre değişiklik göstermiştir (Çizelge 3). Furlan ve Bren, (2023) ölmez çiçek uçucu yağında bulunan bazı bileşenleri benzer şekilde α-pinen, limonen, nerol, neryl asetat ve neril propanoat, α-selinen, β-selinen, γ-curcumen ve eudesm-5-en-11-ol olarak belirlemiştir. Djihane ve ark. (2016), Cezayir'de yaptıkları araştırmada bitkinin uçucu yağının baskın bileşenleri α-cedren %13.61, α-curcumen % 11.41, geranil asetat % 10.05, limonen % 6.07, nerol % 5.04, neryl asetat % 4.91 ve α –pinen % 3.78 olarak belirlemişlerdir.

Uçucu yağ içeriğinin değişimi, damıtılacak bitki kısmına, genotipine, bitki yaşına, coğrafi kökene, toprak tipine, toprak asitliğine, güneşlenme süresine, sıcaklık, nem, iklim, rakım, hasat zamanı ve kurutma yöntemine, yağ çıkarma yöntemi gibi birçok etkene bağlıdır (Ninčević Runjic ve ark.,2025; Bahadırlı ve ark., 2024; Aćimović ve ark., 2022; Furlan ve Bren, 2023; Kunc ve ark., 2022; Melito ve ark., 2016; Ninčević ve ark., 2019; Peršić ve ark., 2019). Çevresel faktörler arasında, toprak tipi ve coğrafi konum, ölmez çiçeğin uçucu yağ bileşimindeki farklılığın ana sebebi olarak görülmektedir (Bianchini ve ark., 2003).

Şekil 1. *H.italicum* uçucu yağında bulunan ana bileşenlerin hasat zamanlarına göre değişimi

Çalışmamızda *H.italicum*'da farklı gelişme dönemlerinde yapılan hasatlarda uçucu yağın kimyasal profililinin değiştiği, ana bileşenler olan , α-Pinene, γ-Curcumene, italidion I, Neryl acetate, italidion II, Caryophyllene ve β-Selinene oranlarının bitkinin gelişme dönemlerine göre değişim (ontogenetik varyabilite) grafiği (Şekil 1)'de gösterilmiştir. İtalidion I ve II en düşük çiçeklenme başlangıcında yapılan hasatta elde edilirken tam çiçeklenme döneminde artarak çiçeklenme sonrası dönemde en yüksek seviyeye ulaşmıştır. γ Curcumene çiçeklenme başlangıcında yapılan hasatta en yüksek seviyede iken çiçeklenme döneminden itibaren düşerek çiçeklenme sonrası dönemde en düşük seviyede olmuştur. Neryl acetate çiçeklenme başlangıcı ve tam çiçeklenme dönemlerinde benzer oranlarda bulunurken çiçeklenme sonrasında düşüş göstermiştir. α-Pinene çiçeklenmeye başlangıç hasatında en yüksek seviyede bulunurken tam çiçeklenme haşatında düşüş göstermiş fakat çiçeklenme sonrası dönemde tekrar artmıştır.

Verim ve Kalite Bileşenlerinin Korelasyon Analizi

H.italicum bitkisinin verim ve kalite bileşenlerinin korelasyon analizi sonuçları (Şekil 2.) incelendiğinde bitki boyu, taze herba (+0.98), kuru herba (+0.94), taze (+0.92) ve kuru çiçek (+0,98) verimleri arasında pozitif bir korelasyon bulunduğu görülmüştür. Uçucu yağ verimi ile kuru herba ve taze ve kuru çiçek verimi arasında sırasıyla yüksek pozitif korelasyon (+0.90, +0.92, +0.82) bulunmaktadır. Uçucu yağ bileşenleri incelendiğinde ise α-pinen ve γ-curcumene ile çiçek uçucu yağ oranı arasında yüksek pozitif (+0.88, +0.98) korelasyon kuru çiçek verimi arasında yüksek negatif korelasyon (-0.88,-0.98) bulunmuştur. Γ-curcumene ve italidion I arasında yüksek negatif korelasyon (-0,94), neryl acetate ile arasında yüksek pozitif korelasyon (+0,81) bulunmaktadır. Neryl acetate ile italidion I arasında yüksek negatif (-0,96) korelasyon bulunmuştur. Ayrıca uçucu yağ bileşeni italidion I ile bitki boyu, taze herba verimi, kuru herba vermi taze ve kuru çiçek verimleri arasında pozitif bir korelasyon bulunduğu görülmüştür (Şekil 2). Korelasyon analizi sonucu elde dilen veriler araştırma sonuçlarıyla uyum içerindedir.

Sonuçlar ve Tartışma

Çukurova Koşullarında Ölmez Çiçek (Helichyrsum italicum) bitkisinin farklı gelişme dönemlerinde (çiçeklenme başlangıcı, tam çiçeklenme ve çiçeklenme sonrası) verim ve kalite özellikleri (bitki boyu, taze ve kuru herba verimleri, taze ve kuru çiçek verimleri) yanı sıra uçucu yağ oranı ve bileşenlerinin belirlendiği bu çalışmada, kullanılacak amaca göre uçucu yağ içeriği önemli olmakla birlikte, uçucu yağ verim ve kalite özellikleri bakımından H .italicum'da en uygun hasat zamanının çiçeklenme başlangıcı ve tam çiçeklenme dönemi olduğu belirlenmiştir. Bununla birlikte, çiçeklenme başlangıcında da uygun zamanı belirlemek için daha fazla araştırma yapılması gerekmektedir. Çalışma sonucunda ekonomik olarak yüksek değere sahip olan *H.italicum* bitkisinin Akdeniz ikliminin yaşandığı Çukurova bölgesinde yetiştirmeye elverişli olduğu, bununla beraber neryl acetate oranının düşük olması nedeniyle bu değerin artırılmasına yönelik araştırmaların yapılması gerekmektedir.

Teşekkür

Yazarlar, araştırmaya finansal destek veren Çukurova Üniversitesi Bilimsel Araştırma Projeleri Koordinatörlüğü (BAP) birimine teşekkür eder (Proje No: FYL-2022-14608).

Feather-Plucking in Blue-Breasted Quails (*Synoicus chinensis*): An Abnormal Behavior Associated with Courtship Feeding?

Arzu Üçtepe[1]

[1]Department of Animal Science, Faculty of Agriculture, Isparta University of Applied Science, Isparta, Turkey

Abstract

Twenty pairs of blue-breasted quail were utilized in this study. Lettuce was provided daily to the quails beginning at 70 days of age. Observations of feather plucking, feather eating behavior, and feather condition scores were made at 65 and 100 days of age. Furthermore, the number of fertile eggs from the first ten eggs was recorded during the periods of 52-70 days and 95-115 days of age.
This study examines the relationship between feather plucking and courtship feeding in blue-breasted quail. It was hypothesised that the plucking behaviour observed in both males and females may be linked to courtship feeding, with males offering plucked feathers to females. However, statistical analysis revealed no significant correlation between feather condition scores and the number of fertilized eggs at both 52-70 days and 95-115 days ($P > 0.05$). The results suggest that while feather plucking, followed by its consumption by females, may be linked to courtship feeding, it remains unclear whether this behavior directly influences reproductive success in this species, as no significant correlation was found in this study.

Key Words: *blue-breasted quail, feather plucking, courtship feeding, abnormal behavior*

Mavi Göğüslü Bıldırcınlarda (*Synoicus chinensis*) Tüy Yolma: Kur Beslenmesiyle İlişkili Anormal Bir Davranış mı?

Özet

Bu çalışmada yirmi çift mavi göğüslü bıldırcın kullanılmıştır. Bıldırcınlara 70 günlük yaştan itibaren her gün marul verilmiştir. Tüy yolma, tüy yeme davranışı ve tüy kondisyon skorları 65 ve 100 günlük yaşlarda gözlemlenmiştir. Ayrıca, ilk on yumurtadan elde edilen döllü yumurta sayısı 52-70 günlük ve 95-115 günlük yaş dönemlerinde kaydedilmiştir.
Bu çalışma, mavi göğüslü bıldırcınlarda tüy yolma ile kur beslenmesi arasındaki ilişkiyi incelemektedir. Hem erkeklerde hem de dişilerde gözlenen tüy yolma davranışının, erkeklerin dişilere yolunan tüyleri sunmasıyla kur beslenmesiyle bağlantılı olabileceği varsayılmıştır. Bununla birlikte, istatistiksel analiz, tüy kondisyon skorları ile hem 52-70 gün hem de 95-115 gündeki döllenmiş yumurta sayısı arasında anlamlı bir korelasyon olmadığını ortaya koymuştur ($P > 0.05$). Sonuçlar, tüy yolmanın ve ardından dişiler tarafından tüketilmesinin kur beslenmesiyle bağlantılı olabileceğini düşündürse de, bu çalışmada anlamlı bir korelasyon bulunmadığından, bu davranışın bu türde üreme başarısını doğrudan etkileyip etkilemediği belirsizliğini korumaktadır.

Anahtar Kelimeler: *mavi göğüslü bıldırcın, tüy yolma, kur beslenmesi, anormal davranış*

Introduction

Courtship feeding in birds occurs during the breeding season, with males providing food to females over an extended period, starting before egg-laying and continuing through incubation until the eggs reach an optimal temperature for development (Roughgarden, 2013). This behavior is often viewed as a form of paternal investment, where males supply females with nutritional resources that may enhance reproductive success by increasing fecundity. Through courtship feeding, males may also influence the timing of copulation, thereby promoting the production of larger ejaculates, inducing female refractory periods, accelerating oviposition, and ultimately maximizing reproductive success (Albo and Costa, 2010; Albo et al., 2013). On the other hand, while males may attract females by offering food, thereby improving their chances of mating, the production of these gifts is resource- and time-intensive, which can negatively impact male fitness. Females, in turn, can increase their fitness by receiving nutritionally valuable gifts; however, rejecting males without foods may result in missed mating opportunities. Given that the nutritional value of these resources is not fully understood, certain courtship feeding behaviors may enhance male reproductive success without directly benefiting females nutritionally. Consequently, the reproductive interests of both sexes may not always align, leading to sexual conflict where the fitness goals of each sex are in opposition, preventing either from achieving an optimal outcome (Parker, 2006).

The pecking behavior, which consists of targeting the feathers of other birds and sometimes pulling out and consuming them (Blokhuis, 1989), is believed to facilitate digestion, although birds are unable to digest keratin, rendering feathers nutritionally insignificant (McKeegan and Savory, 1999; Mens et al., 2020). Five types of pecking are identified: aggressive pecking, gentle feather pecking without removal of feathers, severe feather pecking leading to feather loss, tissue pecking in denuded areas, and vent pecking (Savory, 1995). Gentle feather pecking and severe feather pecking are abnormal and destructive behaviors, typically seen only in captive birds (Mens et al., 2020). Severe feather pecking, tissue pecking, and vent pecking are considered injurious pecking and can lead to cannibalism. Aggressive pecking, however, is a natural behavior with a clear purpose and is not comparable to the other types. Directed at the head and neck of conspecifics, aggressive pecking is used by birds to establish a stable dominance hierarchy, known as the pecking order (Savory, 1995). Two primary hypotheses have been proposed to explain the occurrence of feather pecking: the lack of ground pecking for foraging behavior (Blokhuis, 1986) and the lack of pecking during dustbathing behavior (Vestergaard and Lisborg, 1993). Both hypotheses suggest that the lack of adequate foraging or dustbathing substrates in the environment may create an obstruction, or that the bird's strong motivation to engage in ground pecking behavior remains unfulfilled. This frustration, resulting from the inability to express motivated behavior, can lead to the redirection of pecking towards alternative targets such as feathers and/or conspecifics. As a direct consequence, frustration may contribute to feather pecking, or indirectly exacerbate stress, which further promotes the behavior (Mens et al., 2020). The currently more widely accepted directed foraging hypothesis posits that feather pecking is not an act of aggression, but rather a form of directed foraging behavior. This may occur when birds misperceive feathers as an appropriate foraging substrate (Riber et al., 2007).

In the ethogram of blue-breasted quail, courtship feeding behavior is identified as tidbitting, a behavior exhibited exclusively by males (Schleidt et al., 1998). Feather plucking in blue-breasted quail is a problem typically observed in overcrowded flocks, whereas it occurs rarely in smaller groups (Landry, 2015).

This study aims to investigate the relationship between feather pecking and courtship feeding in male and female blue-breasted quail in captivity. It hypothesizes that feather pecking in males, followed by courtship feeding (tidbitting), may result from redirected foraging behavior, where males offer food after engaging in feather pecking. The study seeks to provide insights into how feather pecking and courtship feeding behaviors are interconnected and how these interactions may influence reproductive behaviors and maladaptive behaviors in captive conditions.

Materials and Methods

Bird Management and Husbandry

The study was conducted at the Animal Breeding Laboratory of the Faculty of Agriculture, Isparta University of Applied Sciences, in Isparta, Turkey. Fertilized blue-breasted quail (*Synoicus chinensis*) eggs were incubated at 37.5°C with approximately 50% relative humidity for the first fourteen days, followed by incubation at 37.1°C with approximately 60% relative humidity for the final three days. The chicks hatched after 17 days of incubation. The chicks were initially housed in brooders. The brooder temperature was maintained at 41±1 °C, while areas not directly exposed to heat radiation remained at approximately 35 °C during the first two weeks. Thereafter, the temperature was gradually reduced by 2 °C every two days until it reached 20 °C. Chicks were exposed to continuous 24-hour lighting for the first five weeks.

At the end of five weeks of age, the quails were separated by sex and housed in cages (33×40 cm) with six quails per cage. As the laying period began, one male and one female were randomly paired and housed together in the same cages. A total of 20 pairs (20 males and 20 females) of blue-breasted quail were used in this study. The breeding room maintained an ambient temperature ranging from 20 to 25 °C, with a relative humidity of 60–70% and a natural photoperiod of 14 hours of light and 10 hours of darkness (14L:10D) for the remainder of the experiment.

The feed for blu-breasted quails contained 20% crude protein and 2800 kcal of metabolizable energy per kg until four weeks of age, after which it was adjusted to 17% CP and 2750 kcal of ME/kg for the remainder of the study. The cages were equipped with improvised feeders and drinkers, ensuring ad libitum access to water and feed.

Study design and traits

The first 10 eggs laid by the female quails, housed in pairs, between days 52 and 70 were checked for fertility. In addition, feather plucking and feather eating behaviors of both male and female quail pairs were observed between 15:00 and 17:00 at 65 days of age. Furthermore, feather condition scores at the same age were assessed using a scale adapted from Khalil et al. (2015), ranging from 1 (completely feathered) to 5 (featherless), based on observations of the condition of the feathers on the head, neck, and back. Total values for each bird could range from a minimum of 3 (fully feathered) to a maximum of 15 (featherless), calculated by summing the values of the three areas.

After 70 days of age, lettuce was given daily to reduce feather plucking and feather eating behaviors. Similar observations and measurements were repeated for quails at 100 days of age. In addition, fertility checks were performed separately for the first 10 eggs laid at 95 and 115 days of age. A total of 400 eggs were used to determine fertility.

Statistical analysis

The correlation between feather condition scores of male and female and fertile egg number was analysed using Kendall's tau-b, two-tailed test. Statistical analyses were conducted using the SPSS software (version 27.0; IBM Corporation, Armonk, USA).

Results and Discussion

Figure 1 presents the number of quails exhibiting feather plucking and eating behaviour within the twenty pairs, along with the corresponding pair numbers. As depicted in Figure 1, feather plucking behaviour was exhibited by two male individuals at 65 days of age, while at 100 days of age, this behaviour was no longer observed. Similarly, at 65 days of age, two female individuals demonstrated feather plucking behaviour, whereas at 100 days of age, males in the pairs were noted to engage in feather plucking. Feather eating behaviour was exclusively observed in female individuals and occurred after feathers were presented by males. In addition, a 65-day-old female and a 100-day-old female were observed consuming feathers plucked from their mates. In one instance, a female at 65 days of age plucked a large area of feathers from the male's back without consuming them. The feather plucking behaviour observed among females during the early age period may potentially be attributed to stress associated with mate formation and the necessity of feed presentation during mating. At 100 days of age, plucking occurred in one female and one male in separate pairs, and in these pairs the feathers were consumed by the females.

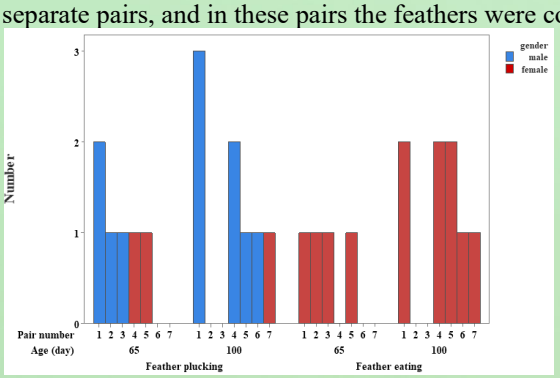

Figure 1. Feather plucking and eating in blue-breasted quail

The results suggest that feather-plucking behavior can develop immediately after pairing. Although this behavior was observed in both males and females, it was noted that the males presented the feathers they plucked to the females as courtship food, which the females subsequently consumed. In other words, the male quail offers the feathers plucked from its mate back to the mate, while the female quail may consume the feathers plucked from the male. On the other hand, Odén et al. (1999) reported that no a male towards a female feather pecking was observed in laying hens. In this study, outside of observation hours, when the female was not interested in the feather offered, the male quail was able to consume the plucked feather.

Hereditary influences, dietary composition, environmental conditions, and husbandry strategies are key determinants in the multifactorial etiology of feather plucking (Schreiter et al., 2020). However in this study, in blue-breasted quail, feather plucking was observed in certain individuals, while absent in others.

The correlation analysis between the feather condition scores of male and female and fertile egg number at 52-70 and 95-115 days is presented in Table 1 and 2, respectively.

Table 1. Correlation coefficients between feather condition scores and fertile egg number at 52-70 days

	Fertile egg number	Male feather score
Male feather score	0.053 (0.792)	
Female feather score	0.185 (0.360)	0.127 (0.522)

The *P*-values are presented in parentheses.

It has long been suggested that hens with increased feather loss on their backs tend to have higher reproductive success compared to those with greater feather coverage (Shi et. al., 2019). Nonetheless, in this research, the Kendall's Tau correlation coefficients, based on data from 20 individuals at 52-70 day, non-significant correlations between the variables: fertile egg number and male feather score ($\tau = 0.053$, $P = 0.792$), fertile egg number and female feather score ($\tau = 0.185$, $P = 0.360$), and male feather score and female feather score ($\tau = 0.127$, $P = 0.522$), suggesting no significant relationships.

Table 2. Correlation coefficients between feather condition scores and fertile egg number at 95-115 days

	Fertile egg number	Male feather score
Male feather score	0.233 (0.250)	
Female feather score	0.168 (0.383)	0.308 (0.110)

The *P*-values are presented in parentheses.

In the previous analysis of individuals aged 52-70 years, no significant correlations were found between the variables (Table 1). Similarly, in the current analysis of individuals aged 95-115 days, there were no significant positive relationships, as indicated by the Kendall's Tau correlation coefficients: fertile egg number and male feather score ($\tau = 0.233$, $P = 0.250$), fertile egg number and female feather score ($\tau = 0.168$, $P = 0.383$), and male and female feather scores ($\tau = 0.308$, $P = 0.110$). Overall, these results suggest that there are no statistically significant associations between the variables.

Feather plucking and/or eating in cage-reared blue-breasted quail may have been motivated by courtship feeding as well as misperception of feathers as a suitable foraging ground. On the other hand, the correlations between the feather condition score and the number of fertilised eggs were not statistically significant. However, it is particularly noteworthy in this species that some male quail present plucked feathers to females in a manner resembling courtship feeding.

Abstract

Agricultural finance is an important and complex structure involving actors such as suppliers, farmers, food processors, logistics, wholesalers, retailers and governments in the agricultural food supply chain. Efforts to increase the unit area yield and quality of field crops that have strategic importance in human life are a matter of curiosity for the scientific community. At this point, food safety and food security emerge as the most important issues in addition to the field crops as well. Agri-food supply chain management is a philosophy that envisages supply chain members working as a single business in order to increase efficiency and added value in the journey of food products from farm to fork. In order to combat all these challenges and ensure that people have access to quality food at adequate and reasonable prices, the proper management of the agricultural-food supply chain with the participation and contribution of all actors, from farmers to consumers, from businesses to states, will be among the most important issues in the future, as it is today. Although the subject of the agri-food supply chain is plant and animal products, only the field crops aspect is discussed in this study because the subjects are very broad. This study was prepared in the light of science to address the problems in this regard, to reveal the developments, and to examine the situation of the sector over the world.

Key Words: *Agricultural economy, Agricultural policy, Business administration, Strategic crops*

Introduction

The survival of human beings and the continuity of healthy generations depend on meeting nutritional needs under the right conditions. At this point, food safety and food security are the most important issues. Nutrition directly affects daily activities by taking and using the nutrients required for human beings to be productive and productive in order to continue their lives. The agricultural-food supply chain must be managed in a way that is appropriate for the purpose in order for people to have access to quality and sufficient food. Economic growth, the factors that trigger growth, the components of growth and the limits of growth are the oldest and most important topics in economic literature. The agricultural sector shows itself at multiple points in almost every field related to humans on earth. At the same time, it has a semantic integrity that develops a relational network within extremely complex, different socio-economic activities and application areas.

Recent studies have focused on the impact of CO_2 emissions in order to achieve sustainable development, reduce global warming, improve environmental quality and develop necessary measures and policies (Stern, 2011). Developed and developing countries were compared (Tiffin and Irz, 2006) and concluded that agriculture is a driving force for growth in developing countries. When the competitiveness of developed countries is ignored, the impact of the agricultural sector on growth is limited. Since agricultural and food products are perishable products, they require more sensitivity than other products in processing, packaging, wrapping, storing, shipping, offering for sale, in short, delivering them to the consumer (Manzini and Accorsi, 2013). About 58.97% of the total agricultural and food products transported in the world (ton*km) were transported by sea and 40.87% by road. Only 0.16% were transported by air (Poore and Nemeccek, 2018).

The state has expectations from agricultural entrepreneurs such as complying with the rules and paying taxes, and sustainability in transferring a livable world to future generations (Ministry of Development, 2018). Today, the concepts of sustainability of development besides sustainability have gone far beyond for field of natural based resources including forestry management and also have entered to the discourses and practices as well in urban based development, tourism, politics, education, agriculture, manufacturing, logistics and all other areas of trade (Heinrichs et al., 2016). Issues such as food supply fear, pollution, and animal welfare are becoming important in consumer attitudes in order to evaluate past events and predict future behaviors in line with research in food and agricultural marketing (Walley et al., 2016). This study was prepared in the light of science to address the problems in this regard and to reveal the developments.

Economics of Agriculture and Sustainability of Agro-Economy

Agricultural activities and farming of plants is kind of science which focused on plant and animal production, the preservation of these products under appropriate conditions, their processing and evaluation, and their distribution.

Food or food is non-drug substances that living beings must consume in order to continue their lives. Growth in sectors other than the agricultural sector creates an increase in the wages of agricultural sector employees (Estudillo and Otsuka, 1999). An entrepreneur is an innovative person who takes precautions against competition and develops himself and his business and manages the business successfully (Manimala and Thomas, 2017). All stages in the marketing channel of agricultural products create a food value while creating shape, time, place, and property benefits (Norwood et al., 2021).

The increase in net output in the agricultural sector will cause an increase in the amount of product in the country. This increase will primarily affect net total growth, and secondly, an increase in per capita production will be provided (Kuznets, 1961). There is a risk at every stage of the agricultural-food supply chain. This risk is relevant both in terms of food safety and losses. Agricultural marketing activities, which consist of many interrelated activities likewise planning of production, raising and harvest, trashing, classification, packaging, transportation, warehouse-silo-storage, agricultural and food based processing, organizing and allocation, advertisiment and sales, are among the issues that concern agricultural producers in terms of decisions regarding which product will be grown, when it will be harvested, in which markets it will be offered for sale and its storage (Vadivelu and Kiran, 2013). Marketing is the correct identification and meeting of consumers' demands and needs in order for the business to achieve its goals (Ritson, 1986). In a world that is becoming more interconnected, people at every level of marketing systems have to act together to implement marketing strategies and plans (Armstrong et al., 2014). The supply chain is defined as a network of organizations that come together through upstream and downstream connections that create value for the end consumer as a product or service as a result of different processes and activities (Christopher, 1992). When an example is examined on the subject, it is seen that exports exceeded imports in the 2017-2018 period when India's agricultural product imports and exports were examined as a result of the implemented policies. However, it is seen that India experienced fluctuations in the production of agricultural products due to problems in irrigation infrastructure and structural deficiencies (Sheeba and Reena, 2019). Researchers examined the effects of R&D expenditures made through domestic and foreign channels on agricultural productivity in 30 Sub-Saharan African countries between 1981-2011 years. Their studies indicate that knowledge accumulation and investments made in this field are very important (Adetutu and Ajayi, 2020).

For a comprehensive perspective, life cycle analyses have come to the forefront and all stages of production processes from input production to waste generation should be analyzed (Smith, 2008). Production process losses due to adverse climatic conditions, product losses remaining in the field due to inadequate prices, and losses resulting from products not accepted for export are also in question. Economic reforms such as the removal or reduction of regulatory institutions in the agricultural sector, the reduction of the role of the public in issues such as subsidized credit, etc. for agriculture, and the regulation of regional and seasonal product pricing strategies have major impacts on agricultural markets (Kindness and Gordon, 2001). It is also observed that the use of new technologies in the agricultural supply chain is increasing. The Internet of Things, block chain, and big data technologies are seen as potential providers of a sustainable agriculture-food supply chain (Kamble et al., 2019). For example, China, which largely meets its needs on a product basis, is an important country in the world agricultural sector as both a producer and a consumer with its high population (FAO, 2020).

An agricultural entrepreneur is someone who starts a business with an entrepreneurial spirit in small-scale farming or who uses managerial skills to grow their business (Morgan et al., 2010). Sustainability of supply chain and its management has been emerged as a type of growing issue that is progressively gaining attention in its field (Seuring and Müller, 2008). Approximately 1/3 ratio of products in agricultural-food supply chains are wasted throughout the chain. Almost by 40% ratio of the lost by underdeveloped besides developing defined countries formed in logistics based processes (storage, transportation and packaging), while 40% of the losses in developed countries occur in retail and consumption processes (Girotto et al. 2015). It is stated that environmental degradation may increase in the early stages of economic growth in a country, but that economic growth will lead to lower levels of environmental degradation in later stages (Rothman, 1998). Managing sustainability in global supply chains continues to be a challenging task. Because sustainability scandals are still repeated for companies with global supply chains (Koberg and Longoni, 2019). On the other hand, the transition from traditional methods to chemical methods in the fertilization system in the agricultural sector leads to serious environmental damage. On the other hand, green technology and eco-innovation reduce the negative effects of pollution by creating new products/services and business methods (Boleti et al., 2021). The transportation of agri-food products must be carried out from a quality, safety and sustainability perspective (Akkerman et al., 2010). The EKC (Environmental Kuznets Curve) hypothesis concluded that there is a kind of inverted U-shaped relations among the country's economic growing and greenhouse gas emissions (Grossman and Krueger, 1991). On the other hand, Cooperatives are organizations operating in the entire agricultural value chain, from the cultivation of agricultural products to animal husbandry, and the industrial processing of agricultural products and animals (Lerman and Parliament, 1991).

Sustainable development requires the use of natural and human resources for the future and at the lowest possible consumption rate, considering the needs of future generations (Keating, 2003). Concerns about the difficulty of energy supply to meet demand, combined with concerns about global warming and nature, lead to continued

interest in researching the relationship between variables related to energy, economic growth and environmental damage (Chandran and Tang, 2013). In order to ensure the continuity of development and to guarantee human life, the continuity of resources should also be ensured (Harrison, 1993). Since the size of the agricultural sector means that the factors affecting agriculture have great effects, the impact of macroeconomic variables and the concept of agricultural productivity on each other is considered reasonable (Gollin, 2010).

The main objectives of agricultural entrepreneurs are to sustain their existence and grow their agricultural enterprises by producing/marketing agricultural products to make a profit (Dias et al., 2019). The verifiability of traceability, which is seen as an important criterion in food quality and food safety, is increasingly demanded by consumers in different parts of the world (Opara, 2003). Population growth, combined with current unsustainable and wasteful food consumption and production patterns, further exacerbates environmental threats, putting more pressure on climate change, natural resources and the environment (Rohmer et al., 2019). Although the world aims to reduce the impact of climate change, bringing about tangible change requires significant resources and funds in most developing countries (Levinson and Taylor, 2008).

Economic growth is important among policy makers because it is one of the basic macroeconomic indicators. In this context, the EKC hypothesis, the link between economic growth and environmental degradation, is a highly controversial issue. While many studies support the EKC hypothesis (Grossman and Krueger, 1991; Pata, 2018; Malik et al., 2020), some studies did not find the hypothesis valid within the scope of the examined country or country groups (Bartlett, 1994; Apergis, 2016; Adu and Denkyirah, 2019). The raw materials of food products are generally agricultural products, and agricultural products are largely composed of field crops and are also called unprocessed food products. In the production of agricultural products, seeds, seedlings, fertilizers, pesticides, water, agricultural machinery and equipment are required. Inflation in agricultural product prices directly affects food product prices. A decrease in inflation in consumer prices can be achieved with strong cooperatives, effective planning and control, efficient marketing and logistics. We are experiencing a period in which agricultural business management and entrepreneurial spirit come to the fore, according to the knowledge and skills needed to produce according to changing customer demands and new technologies.

Conclusions

The production structure in the global economy is undergoing a rapid transformation. The complexity of agricultural production and financial relations is increasing due to the impact of globalization, and significant challenges are being faced due to factors such as climate change and the Covid-19 pandemic. In order to combat all these challenges and ensure that people have access to quality food at adequate and reasonable prices, the correct management of the agricultural-food supply chain with the participation and contribution of all actors, from farmers to consumers, from businesses to states, will be among the most important issues in the future, as it is today. The increase in consumer prices for agricultural products is far beyond producer prices. In other words, while the producer sells the product cheaply, the consumer continues to consume the same product expensively.

While the contribution of the agricultural sector to the national income of countries is below 10% in most countries, it is of great importance with the healthy nutrition of the population, the place of agriculture in foreign trade, the employment it provides, and other effects (energy, food, supportive medicine, cosmetics). The fact that the agricultural sector provides input for many branches of industry, the gradual decrease of scarce resources, changes in consumer behavior, increasing costs, environmental protection and the increasing importance of human health cause the interest in agricultural marketing practices to increase even more. While the level of customer service increases with technological developments, it is of great importance to ensure operational excellence by carrying out supply chain processes faster, more accurately and efficiently, and to conduct multidisciplinary research based on sustainability.

Abstract

Natural disasters are known as natural events that suddenly occur in a certain region on earth, create social stress, create significant losses on people and human settlements, and disrupt life in society. Sinkholes are considered a natural disaster that can cause serious damage to society and the environment. Such unpredictable geological disasters have the potential to cause irreversible damage, especially to settlements and agricultural areas. There are thousands of sinkholes in regions containing salt, gypsum and carbonate rocks in different parts of the world and the main factor that accelerates them is human activities. Disaster prevention and damage reduction policies can be developed with sinkhole risk assessment studies, and disaster-oriented planning can be made to reduce the damage caused by sinkholes. These natural events that occur beyond human control cause loss of life and property. Within the scope of this study, sinkholes, that are considered as an important component of natural disasters and whose numbers are increasing over the world, and agricultural sustainability are discussed.

Key Words: *Climate Change, Disaster management, Groundwater, Sinkhole susceptibility, Unconscious Agriculture*

Introduction

In general, a sinkhole can be defined as the collapse of underground cavities formed as a result of groundwater interacting with the soil, unable to carry the surface weight. Disasters are events that can occur due to natural or anthropogenic causes, affect people physically, socially or economically, stop or interrupt daily life, and cannot be dealt with by local means (AFAD, 2014). Sinkholes, which are karst landforms, are formed when rocks that can dissolve underground such as limestone (limestone, marl, gypsum, etc.) create cavities over time and the ceilings of these cavities collapse (Tapur and Bozyiğit, 2013). Karstification, unlike the external factors that form the surface (streams, glaciers, volcanoes, wind, coastal geomorphologies), develops similar to a large structure connected to each other both on the surface and underground (Anonymous, 2021). Sinkholes are expressed as "karst collapse areas" in another source (MTA, 2018). The main criteria in the formation of sinkholes are; While natural events such as geological, hydrogeological, tectonic and climatological occur, the main accelerating factor is human activities (Günay et al., 2010; Caló et al., 2017).

There are thousands of sinkholes with similar characteristics in regions containing salt, gypsum and carbonate rocks in different parts of the world. Carbonate rocks cover approximately 13.2% of the world's surface except for Antarctica and Greenland. When evaporitic rocks are included, more than 15% of the world's surface is covered with soluble rocks (Anonymous, 2018). In regions where carbonate rocks such as limestone, clayey limestone, marl, dolomitic limestone, dolomite, and evaporites such as gypsum and anhydrite are widespread in the event of interaction with water, the formation of karstic forms such as caves, dolines, lapias and sinkholes is a common geological and geomorphological event (Erol, 1990; Karadoğan, 2001). Since sinkholes are depressions caused by the dissolution of rocks generally composed from calcium carbonates likewise dolomite and also limestone on the surface, karstic rock areas are even more vulnerable than in other regions (Taheri et al., 2021). The widest mechanisms of crack formation are the unconsolidated alluvial basins, as the groundwater level drops, thinner shaped alluvium that is close to edge of basin experiences less compression and subsidence than the thicker shaped alluvium close to deeper, basin central part, besides stress resulting from discriminatory compression causes cracks to form in the overlying cover (Anderson, 1988).

That is a well known fact that formation of the sinkholes accelerates with the rapid decrease in groundwater as a result of excessive water withdrawal from wells (Subramani et al., 1983; Galloway et al., 1999; Yılmaz, 2010). In order to prevent unsustainable water use, it is important to modernize irrigation systems and correctly assess water system requirements. Minimizing problems such as over-irrigation and water insufficiency by ensuring that water is delivered to plants in the right amount and time by modernizing irrigation systems, and adopting conscious and sustainable practices in soil protection and management are important steps to reduce the formation of sinkholes (Ewaid et al., 2019; FAO, 2019). In this study, literature information on sinkholes was reviewed, cause-effect relationships were examined and recommendations were made.

Sinkholes and Agricultural Sustainability

Sinkholes are shaped owing to effects by natural hydrogeological, geological, structural geological in addition to geomorphologic situations. Sinkholes are defined as natural wells represented in karst lands (Bui et al., 2018). Karst formations refer to a land formed by dissolution of main rock besides the improvement of underground shaped drainage. For this reason, although they are primarily associated with limestone, they can also form on the other soluble rocks and carbonates (Waltham et al., 2005). In his technical study on sinkholes (Gutierrez, 2016), he generally justifies the implementation of preventive or compensatory risk reduction measures against these formations in economic and/or social contexts. By natural types geologic factors which give rise to formation for the sinkholes, lithological characteristics and geologic structure, climatic changes, drought factors, hydro-geologic characteristics cannot be controlled by humans, but one of the most important factors that can be controlled is water use (Göçmez et al., 2022). Sinkholes are quite common in all countries in Europe except Iceland, in the Mediterranean and oceanic countries of Africa, in Turkey, Lebanon, Palestine, Israel, Syria, Iraq and Iran in the Middle East, and in Afghanistan, Pakistan, India and China in Asia (Anonymous, 2024a; b). When the literature on sinkholes is examined, it is seen that the subject is more important at the geological and engineering levels, but the sociological importance of the situation is not evaluated in the context of climate crisis, drought and unconscious agricultural practices (Saa, 2022).

It is important to implement preventive planning and corrective measures in high priority risk areas. Anthropogenic factors such as land use, excessive groundwater use, well density, intensive agricultural activities, etc. increase the frequency of sinkhole formation in many places in the world (Galve et al., 2009; Ke, 2017; Wu, 2018). In this study, the researcher stated three main issues that need to be changed by the laws. The mentioned laws are; re-definition for sinkholes, definition for structure based damages and improvement of quality for the underground research (Zisman, 2013). Sinkhole formations can destroy buildings, roads or railways, causing these structures to collapse and high material losses (Xua et al., 2017). As another result that is revealed by the study (Ciantia, 2023), the disintegration in the ground could trigger collapse over time. It was also stated that following the displacement over time in rocks with this type of disintegration is a method that should be used to calculate the safety life of the structure.

It is expected that sinkholes might be occurred in future welded by same or similar conditions as they occurred in the past, and sinkhole inventory maps are used as a basis in defining the hazard areas and creating hazard maps according to this principle (Orhan et al., 2020). In their research (Sahu et al., 2015), they investigated the collapses that occur in the ground and their causes. They stated that collapses are usually caused by underground mines or sinkholes. They stated the factors affecting the collapse as the working techniques performed in underground mining, adjacent working areas, depth of the work, presence of geological deformations, stresses in the ground, surface topography, decreases in groundwater, precipitation and earthquakes. Since the sinkholes formed in the regions where soluble rocks are located have a continuously collapsing structure, the collapses might be monitored based on the surface. Due to suddenly collapses are not expected by those sinkholes, it is possible to develop monitoring and early warning systems for the people living on them and take precautions against the dangers. The inability to fully detect underground structures such as artificial and natural cavities, groundwater or natural caves causes sudden formation of sinkholes of different sizes and shapes and thus increases the extent of environmental damage (Gutiérrez et al., 2014; 2016). Researchers (Nam and Kim, 2017) stated that they are generally studied from a geological perspective, but engineering solutions for sinkholes are still insufficient, and large collapse sinkholes that may occur in metropolises and cities will pose a very serious threat. Considering the difficulties and dangers related to sinkholes, researchers stated that there is still a lack of geotechnical understanding and methods related to sinkholes and that they are insufficient to measure cost-effective repair methods and technologies for sinkholes.

In the literature, studies on the creation of susceptibility maps for many disasters such as landslides, floods, avalanches, fires have been successfully applied (Malczewski, 2006; Abedi et al., 2021; Iban and A. Sekertekin, 2022; Varol, 2022). Subsurface-based soil erosion throughout a crack trace acts the role for opening, widening besides subsequently development of crack channels (Carpenter and Bradley, 1986). Researchers (Gutiérrez et al., 2009) emphasized that conducting trench-opening examinations in settlements against sinkhole risks is cheaper, more reliable and important in reaching detailed information. In their study (Caudron et al., 2006), they analyzed how the soil and structure interactions will be during of the sinkhole event by quite small-scaled model using a 2-dimensionals ground with the building model. In their study, the researchers stated that considering the ground-structure interactions during the presence of a sinkhole or similar hazard can be very cost-effective. In particular, the effect of human activities on the formation of sinkholes is considerable. The dissolution of calcareous rocks by underground water leads to the formation of sinkholes (Shalev et al., 2006). In their study (Zisman et al., 2009), they investigated the damages in structures caused by sinkholes. They stated that in order to determine the source of the cracks that occur, it is necessary to examine the displacement along the cracks, the geometry and movement of the building.

Financial based costs for deal with conclusions for sinkholes are quite often (Kuniansky et al., 2015). One of the most important points for risk evaluation and management of disasters such as sinkholes is the creation from susceptible maps which predicts besides presenting the spatial probability for the future based disaster (Pradhan et al., 2011; Elmahdy et al., 2020). As reported in a study (Fritz, 1961), disasters provide an opportunity for the restoration of social order, and this reconstruction process can increase community solidarity and mutual assistance. Accurate estimation of crop water requirements is important in agricultural irrigation management to prevent water wastage and to increase agricultural productivity. Accurate estimation of water volumes to be supplied to irrigated areas has the potential to decreasing of risk on water scarcity as well as to guarantee the sustainable usage of the water resources (Todorovic, 2005).

Conclusions

Sinkholes, which are considered as one of the important disaster types, cause seriously security-related affairs in the sites where they appeared. Today, the problems about question are seen on the areas where the basic components likewise a gradual reduce in underground water resource, intensively agriculture based activities carried out devoid of considering climate based features, and the existing geological structures in the regions at risk are risky for the formation of sinkholes. Sinkholes are structures that are considered aspect of nature based disasters and their numbers have been increasing in recent years around the world.

Sinkholes are considered a natural disaster that can cause serious damage to society and the environment. People not using the right methods when using nature and not giving enough importance to sustainability issues can cause natural disasters and have negative social consequences. In addition to human activities, climate and geological events are other factors that affect karst formation. It is of critical importance to educate and raise awareness of people living in places with sinkhole risk and those engaged in agricultural activities, to conduct studies through cooperation, to monitor underground water resources and manage them consciously, and to ensure that natural resources are used in accordance with sustainability principles.

Abstract

This research aims to optimize management and decision-making in commercial banana plantations (*Musa* AAA) in Ecuador through the use of advanced machine learning techniques, with a particular emphasis on identifying and grouping lots affected by Moko, a disease caused by *Ralstonia solanacearum race 2*. The initial component of the study involves analyzing the health status of the plantations using high-resolution images obtained by drones and extracting the Normalized Difference Vegetation Index (NDVI), thereby detecting anomalies associated with Moko outbreaks. This information has been crucial for applying clustering techniques, such as K-means, where specific metrics were used to segment lots according to the intensity of the infection, facilitating the identification of those with the highest concentration of outbreak sites. Additionally, other clustering algorithms, including DBSCAN and hierarchical methods, have been implemented to classify the lots based on post-harvest bunch quality. This segmentation has proven fundamental for decision-making, as it differentiates between high- and low-quality lots, thus optimizing the value chain and logistics in product commercialization. The methodological approach further extends to the analysis of nutritional data, where clustering models have been employed to identify lots with similar nutritional profiles. This information enables the development of highly precise fertilization plans, ensuring greater efficiency in the application of inputs and resource optimization. Furthermore, predictive tools such as linear regression have been explored, driven by the limited number of observations in certain scenarios. At the same time, other predictive algorithms—logistic regression, decision trees, k-nearest neighbors, random forests, and neural networks—are being tested on various datasets from other banana plantations. This comprehensive set of techniques and models significantly contributes to the improvement of agricultural management, enabling early and precise interventions that translate into increased productivity and sustainability in banana cultivation.

Sustainable Agriculture: Soil and Cover Crops

Neslihan Doruk Kahraman[1], Onur Okumus[2], Ali Kahraman[1]*

[1]Department of Field Crops, Faculty of Agriculture, Selcuk University, Konya, Turkiye
[2]Department of Field Crops, Faculty of Agriculture, Erciyes University, Kayseri, Turkiye

Abstract

The products produced in agricultural lands and the production methods used show diversity specific to each region. Many parameters such as social structure, climate, soil structure, water availability in rural areas cause the diversity of products and production methods. It is important to conduct studies on recognizing, protecting and improving soil, which is the most important ecosystem that provides the cycle of life. In order to continue our civilization, we need to switch to more sustainable production methods and give importance to the protection and improvement of species and habitats. In addition to the vegetation in the soil, many different vital activities ensure the continuity of the soil. Additionally, the soil provides sustainability to living life by transforming many substances that may be harmful to the lives of living things. Cover crops are plants grown to increase soil fertility, prevent soil erosion, enrich and protect soil, increase nutrient and water availability and soil quality. Cover crops contribute to sustainability by providing multifaceted benefits to soils used for agricultural production. Evaluation of the condition of the soils, identification of problems in agricultural soils, understanding the importance of protecting the soils, introduction of soil protection and improvement methods used in agriculture, theoretical and practical information on cover crops and soil improvement have been compiled in this study.

Key Words: *Agricultural sustainability, Soil fertility, Soil management, Soil protection*

Sürdürülebilir Tarım: Toprak ve Örtü Bitkileri

Özet

Tarım arazilerinde üretilen ürünler ve kullanılan üretim yöntemleri her bölgeye özgü çeşitlilik göstermektedir. Sosyal yapı, iklim, toprak yapısı, kırsal alanlardaki su bulunabilirliği gibi birçok parametre ürün ve üretim yöntemlerinin çeşitliliğine neden olmaktadır. Yaşam döngüsünü sağlayan en önemli ekosistem olan toprağın tanınması, korunması ve iyileştirilmesi konusunda çalışmalar yapılması önem taşımaktadır. Medeniyetimizi devam ettirebilmek için daha sürdürülebilir üretim yöntemlerine geçilmeli, türlerin ve yaşam alanlarının korunmasına ve iyileştirilmesine önem vermeliyiz. Topraktaki bitki örtüsünün yanı sıra birçok farklı yaşamsal aktivite toprağın devamlılığını sağlamaktadır. Ayrıca toprak, canlıların yaşamına zararlı olabilecek birçok maddeyi dönüştürerek canlı yaşamına sürdürülebilirlik sağlamaktadır. Örtü bitkileri, toprak verimliliğini artırmak, toprak erozyonunu önlemek, toprağı zenginleştirmek ve korumak, besin ve su bulunabilirliğini ve toprak kalitesini artırmak için yetiştirilen bitkilerdir. Örtü bitkileri, tarımsal üretimde kullanılan topraklara çok yönlü faydalar sağlayarak sürdürülebilirliğe katkıda bulunur. Bu çalışmada, toprakların durumunun değerlendirilmesi, tarım topraklarındaki sorunların belirlenmesi, toprakların korunmasının öneminin anlaşılması, tarımda kullanılan toprak koruma ve iyileştirme yöntemlerinin tanıtılması, örtü bitkileri ve toprak iyileştirme konusunda teorik ve pratik bilgiler derlenmiştir.

Anahtar Kelimeler: *Tarımsal sürdürülebilirlik, Toprak verimliliği, Toprak yönetimi, Toprak koruma*

Giriş

Tarımsal faaliyetlerin şekillenmesinde birden fazla faktör rol oynar ve bu faktörler üretim yöntemlerinin verimliliği, sürdürülebilirliği ve çevresel etkilerini belirler. İklim koşulları ve coğrafi faktörler, tarımsal üretim yöntemlerinin çeşitliliğinde büyük bir rol oynar. İklimsel değişkenler (sıcaklık, yağış rejimi ve rüzgar) tarımsal ürün çeşitlerini ve tarımsal üretim yöntemlerinde etkilidir. Toprak özellikleri de tarımsal üretimi etkileyen faktörlerdendir. Toprak yapısı, organik madde gibi unsurlar, üretim sistemlerinin uygulanabilirliğini belirler (Gómez et al., 2018a). Tarım arazilerinin kullanım şeklini topoğrafik yapı, eğim ve rakım gibi unsurlar etkilerken, tarımın yoğunluğu ve üretim teknikleri üzerinde su kaynaklarının varlığı ve sulama olanakları, belirleyici etkiye sahiptir (Schnitkey et al., 2023). Toprak tuzluluğu, asidik ya da bazik yapı gibi faktörler, farklı toprak işleme ve gübreleme yöntemlerinin kullanılmasını gerektirir. Tarımsal üretim yöntemlerini, sosyal ve ekonomik faktörler de biçimlendirir. Çiftçilerin eğitim seviyesi, tarımsal üretim yöntemlerini etkilerken, tarımsal girdi maliyetleri de tarım işletmelerinin üretim kararlarını etkiler. Yerel ve uluslararası pazar talepleri, üretim desenini ve tarımsal

ürün çeşitliliğini etkileyerek, üreticilerin tercih ettiği yöntemlerde farklılıklara yol açabilir (Topçu et al., 2022). Uzaktan algılama teknolojileri, sensörler ve veri analiz sistemleri, hassas tarım tekniklerini teşvik ederek üretim süreçlerini düzenler (Cárceles Rodríguez et al., 2022). Teknolojik yenilikler ve mekanizasyon, tarımsal üretim aşamalarında önemli bir yenilik oluşturmuştur. Modern tarım makineleri, iş gücünü hafifleterek üretim aşamalarını hızlandırır ve verimi yükseltir. Organik ve sürdürülebilir tarım yöntemlerinin ilerlemesi, kimyasal gübre ve pestisit kullanımına yenilikçi çözümler sunarak çevreye hassas üretim yöntemlerine teşvik etmektedir. Tarımsal üretim sistemleri ve teknikleri de büyük bir çeşitliliğe sahiptir (Aparecida et al., 2018). Geleneksel tarım yöntemleri, endüstriyel tarım uygulamaları, organik tarım, sera tarımı, dikey tarım ve hidroponik gibi alternatif üretim yöntemleri, farklı etkilere bağlı olarak kullanılmaktadır. Monokültür ve polikültür sistemleri, üretim sürdürülebilirliği bakımından karşılaştırmalı olarak değerlendirilmekte ve üreticiler tarafından çeşitli şekillerde uygulanmaktadır (Akhzari and Pessarakli, 2016). Tarımsal üretimde sürdürülebilirlik ve çevresel etkiler de önemli bir konudur. Kimyasal gübreler, pestisitlerin çevreye olumsuz etkileri dikkate alındığında, sürdürülebilir tarım sistemleri ile doğal kaynakların korunması ve üretimde verimliliğin artışı oldukça önem arz etmektedir. Tüm bu unsurlar, tarımsal üretimde izlenecek yolun belirlenmesinde ve uygulanmasında rol alır. Bölgesel koşullara uyumlu üretim stratejileri oluşturularak tarımsal verimliliği yükseltmek ve sürdürülebilirliği sağlamak olasıdır.

Sürdürülebilir tarım, doğal kaynakları muhafaza ederek, çevresel etkileri minimize ederek ve gelecek nesillerin taleplerini önemseyip üretim yapmayı hedefleyen bir sistemdir. Geleneksel ve endüstriyel tarım sistemlerinin toprak, su ve biyolojik çeşitlilik için olumsuzlukları bilinmektedir (Gómez et al., 2018a). Gereğinden fazla kimyasal gübre ve pestisit kullanımı, monokültür tarım yöntemleri, fazla toprak işleme ve bilinçsiz su kullanımı gibi faktörler, ekosistem dengesini tehdit ederek toprak erozyonu, tuzlanma, su kaynaklarının eksikliği ve biyolojik çeşitliliğin azalması gibi sorunlara neden olmaktadır (Muhammad et al., 2021). Bu sebeple, sürdürülebilir tarım uygulamalarına geçilmesi kaçınılmaz olmuştur. Toprak, canlı organizmaların yaşamı için zararlı olabilecek çoğu maddeyi dönüştürmek suretiyle canlıların yaşamı konusunda çok yönlü sürdürülebilirlik temelli katkılar sağlamaktadır. Bu makalede sürdürülebilir tarım ve örtü bitkilerinin önemi konusunda yapılmış bilimsel araştırmalar derlenmiştir.

Sürdürülebilir Tarım: Toprak ve Örtü Bitkileri

Sürdürülebilir tarımın öncelikli amaçlarından biri, toprak sağlığını muhafaza etmek ve iyileştirmektir. Toprak organik madde miktarının artırılması, biyolojik çeşitliliğin artırılması ve erozyonun engellenmesi, verimli ve uzun soluklu bir üretim sisteminin temelini oluşturmaktadır (Scavo et al., 2022). Örtü bitkilerinin kullanımı, minimum toprak işleme, doğal gübreleme yöntemleri ve dönüşümlü ekim sistemleri gibi teknikler, toprağın verimliliğini desteklerken çevresel zararları en aza indirger.

Sürdürülebilir tarımın önemli bir bileşeni de su kaynaklarının verimli kullanımıdır (Meyer et al., 2019). Fazla sulama ve hatalı su yönetimi, su kıtlığına ve toprak tuzluluğuna sebebiyet verebilir. Damla sulama, yağmurlama sulama gibi gelişmiş sulama yöntemlerinin uygulanması, suyun etkili kullanılmasını mümkün kılarak hem verimi artırır hem de çevresel sürdürülebilirliğe destek olur.

Kimyasal bağımlılığı azaltarak biyolojik çeşitliliği teşvik etmek de sürdürülebilir tarımın bir diğer önemli yönüdür. Bununla birlikte, genetik çeşitliliğin muhafazası ve yerel çeşitlerin kullanımının desteklenmesi, tarım sistemlerinin farklı çevresel şartlara uyum sağlamasında etkili olur (Fayiah et al., 2019).

Sürdürülebilir tarım tekniklerinin uygulanması, sadece çevresel yararlar oluşturmakla kalmaz, bunun yanında çiftçilerin ekonomik durumunu da artırabilir. Uzun süreli toprak verimliliğinin muhafazası, girdi maliyetlerinin düşmesi ve doğal kaynakların daha verimli kullanımı, üreticilere ekonomik destek sağlar. Tüketiciler ise, sağlıklı ve besleyici değeri yüksek ürünlere erişerek sürdürülebilir gıda ürünlerinden faydalanır.

Böylece sürdürülebilir tarımsal teknikler, doğal kaynakların muhafazası, çevresel zararın azaltılması, ekonomik sürdürülebilirlik ve gıda güvenliğinin geliştirilmesi yönünden elzemdir. Bu sebeple, tarımsal üretimde çevre dostu uygulamaların artırılması ve sürdürülebilirlik temelli politikaların oluşturulması gerekmektedir.

Ekosistemin temel bileşenlerinden biri olan toprak, canlı yaşamı için hayati bir kaynaktır. Bitkilerin büyümesi ve gelişmesi için besin maddeleri sağlar, su döngüsünde yer alır ve mikroorganizmalar için yaşam ortamı oluşturur. Birçok ekolojik süreçte (tarımsal üretim, orman ekosistemleri, doğal döngülerin devamlılığı, iklim düzenlemesi) kritik bir öneme sahiptir. Toprak dinamik bir yapı olup, biyolojik çeşitliliğe destek amacıyla önemli işlevler üstlenir (Semenov and Đukić, 2020).

Toprak, dünyanın ekolojik dengesi üzerinde önemli bir yere sahiptir. Bitkilerin kökleri sayesinde su ve besin maddelerinin alımını gerçekleştirerek birincil üreticilerin gelişimini sağlar. Bu bitkiler, otçul hayvanlardan etçillere kadar tüm canlıların besin kaynağını oluşturur. Bununla birlikte toprak, karbon döngüsünün önemli bir parçasıdır. Bitkilerin ve organik materyallerin ayrışması ile karbonun tutulmasını, atmosferdeki karbondioksit miktarının düzenlenmesinde rol oynar (Fenton, 1947).

Ekosistemin sürdürülebilirliği açısından toprakta bulunan mikroorganizmalar, mantarlar ve solucanlar, önemli bir yere sahiptir. Bu organizmalar, organik maddeleri ayrıştırarak toprağın verimliliğini yükseltir ve bitkilerin ihtiyacı olan besin maddelerini kullanılabilir duruma getirir. Bazı mikroorganizmalar, bitkilerin kökleriyle simbiyotik ilişkiler oluşturarak besin ve su alımını artırırken, atmosferik azotu bağlayan bakteriler de topraktaki azot

döngüsüne destek olur. Bu biyolojik olaylar, toprağın sağlıklı ve verimli olması için sürdürülebilir tarım uygulamalarına yardımcı olur (Tan et al., 2022).

Toprak, çevresel kirliliğin en aza indirilmesinde doğal bir filtre görevi görerek ekosistem sağlığını destekler. Ağır metaller, pestisitler ve başka kirleticiler, toprak içindeki biyolojik ve kimyasal süreçler yoluyla pasif duruma getirilebilir. Örnek olarak, bazı toprak bakterileri toksik bileşikleri biyolojik olarak ayrıştırarak zararsız duruma getirirken, kil mineralleri ve organik madde, ağır metalleri bağlayarak yeraltı sularına bulaşmasını önleyebilir (Cárceles Rodríguez et al., 2022). Toprağın bu arıtma yeteneği, su kaynaklarının muhafazasına ve çevresel kirliliğin azaltılmasına katkıda sağlar.

Tarım alanları, doğal ve insan kaynaklı sebeplerle ciddi risklerle karşı karşıyadır. Toprak bozulması, tuzlanma, erozyon ve organik madde eksikliği gibi durumlar, tarımsal üretimi ve ekosistem sağlığını olumsuz etkileyerek sürdürülebilir gıda üretimini zorlaştırmaktadır. Yine, iklim değişikliği gibi küresel olaylar da toprak sağlığı üzerinde etkilidir (Kuo et al., 1997). Bu sebeple, tarımsal üretimde karşı karşıya kalınan toprak kaynaklı problemlerin nedenleri ve sonuçları analiz edilerek uygun çözümler geliştirilmelidir.

Toprak erozyonu, su ve rüzgarın da etkisiyle üst toprak tabakasının taşınması ile meydana gelen bir durumdur. Eğimli arazilerde ve bitki örtüsünün az olduğu yerlerde erozyon daha yaygındır. Topraktaki organik maddeyi ve besin elementlerini uzaklaştıran erozyon, tarımsal verimi azaltır ve ekosistem sağlığını olumsuz etkiler (Gómez et al., 2018b).

Toprak bozulması fiziksel, kimyasal ve biyolojik özelliklerde gözlemlenen olumsuzluklar sonucunda verimliliğinin etkilenmesidir. Toprak bozulmasının nedenleri; aşırı toprak işleme, yoğun kimyasal gübre, uygun olmayan sulama teknikleri ve pestisit kullanımı, monokültür tarımı şeklindedir (Techen et al., 2020).

Tuzlanma, öncelikle uygun olmayan sulama teknikleri sebebiyle tarım topraklarında gözlemlenen ciddi bir problemdir. Yeterli olmayan drenaj, sulama ile taşınan tuzların toprağın üzerinde birikmesine ve bitkilerin su alımını zorlaştırarak büyüme ve gelişmesinin engellenmesine sebep olur. Tuzluluk, özellikle kurak ve yarı kurak yerlerde ciddi bir tehdit oluşturmaktadır (Hasan Khan Robin et al., 2016).

Yanlış tarım teknikleri ve aynı ürünün sürekli üst üste ekilmesi (monokültür) nedeniyle ortaya çıkan bir problem de besin kaybıdır. Toprakta devamlı olarak aynı besin maddelerinin harcanması, eksikliklere yol açar ve bitkilerin gelişimini engeller. Besin maddesi eksikliğinin önüne geçmek için toprak analizine göre besin takviyeleri, dengeli gübreleme, ve ekim nöbeti gibi uygulamalara yer verilmelidir (Fayiah et al., 2019).

İklim değişikliği, tarım topraklarında olumsuz etkileri sebep olmaktadır.Yükselen sıcaklıklar, düzenli olmayan yağış rejimleri ve farklı hava olayları, toprak nem dengesini değiştirerek verimliliği azaltabilir. Şiddetli kuraklık, toprakta organik madde azalmasına ve su tutma kapasitesinin azalmasına Zemin hazırlarken, şiddetli yağışlar ve seller de erozyonu tetikleyebilir. Bunun yanında, yükselen sıcaklıklar topraktaki mikroorganizmaların dengesini değiştirip, toprak sağlığını olumsuz etkileyebilir (Semenov and Đukić, 2020; Cárceles Rodríguez et al., 2022).

İklim değişikliğinin olumsuz etkilerini engellemek ve toprak sağlığının devamlılığı için sürdürülebilir tarım tekniklerinin tercih edilmesi gerekmektedir. Bilinçli toprak işleme, organik madde kullanımının artırılması, su tasarrufunu sağlayan sulama teknikleri ve karbon tutulumunu sağlayan tarımsal teknikler, iklim değişikliğinin olumsuz etkilerini en aza indirmede önemli stratejilerdendir (Abbas et al., 2017; 2020).

Uzun vadeli tarımsal üretimin devamlılığı açısından verimli ve sağlıklı topraklar, önemli bir role sahiptir. Öte yandan, hatalı tarım teknikleri, iklim değişikliği ve doğal bozulma, tarımsal toprakların verimliliği ve ekolojik dengesinde bir tehdit oluşturmaktadır. Bu durumda, toprağın korunması ve iyileştirilmesi için başlıca stratejiler arasında sürdürülebilir toprak yönetimi teknikleri, geleneksel ve modern toprak koruma teknikleri ile organik ve rejeneratif tarım teknikleri, yer almaktadır (Dumanski and Peiretti, 2013; Cárceles Rodríguez et al., 2022).

Minimum toprak işleme, toprağın fiziksel yapısını koruyarak erozyon riskini azaltırken, örtü bitkileri ve ekim nöbeti uygulamaları, toprağın organik madde içeriğini artırarak biyolojik çeşitliliği destekler. Bununla birlikte, tarımsal su yönetiminin doğru yapılması ve dengeli gübre kullanımı, toprak sağlığını iyileştirmek için önemli bir faktörlerdir (Mishra et al., 2018; Techen et al., 2020). Sürdürülebilir toprak yönetimi, doğal kaynakların ölçülü olarak kullanılması, toprak verimliliğinin muhafazası ve uzun süreli tarımsal üretimin desteklenmesi için geliştirilen bir dizi yöntem ve stratejiyi içermektedir. Bunlar arasında minimum toprak işleme, örtü bitkilerinin kullanımı, ekim nöbeti ve kompost uygulamaları bulunmaktadır.

Yıllardır çiftçiler tarafından uygulanan ve doğal süreçlerle uyumlu olan teknikler, geleneksel toprak koruma yöntemleridiri Teraslama, eğimli arazilerde toprak kaybını önlemek için kullanılan bir yöntemdir ve özellikle suyun düzenli bir şekilde toprağa nüfuz etmesini sağlayarak erozyonun önüne geçer. Yeşil gübreleme ise, toprağa azot ve diğer besin maddelerini kazandıran bitkilerin yetiştirilmesi ve toprağa karıştırılması esasına dayanır (Abbas et al., 2020).

Modern tarım biyolojik gübreler, kimyasal gübrelere alternatif olarak geliştirilmiş ve toprak mikrobiyotasını destekleyerek verimliliği artıran bir uygulamadır. Hassas tarım uygulamaları, sensörler ve veri analitiği kullanarak toprak nemi, besin seviyeleri ve bitki gelişimi hakkında bilgi sağlar ve böylece gübre ve su kullanımını optimize eder. Yine, koruyucu tarım uygulamaları kapsamında doğrudan ekim (no-till farming) yöntemi, toprağın yapısını bozmadan ekim yapılmasını sağlayarak toprak organik madde kapsamını ve su tutma kapasitesini artırmaktadır (Kraut-Cohen et al., 2020; Muhammad et al., 2021).

Kimyasal gübreler, pestisitler ve genetiği değiştirilmiş organizmalar (GDO) kullanmadan yapılan bir tarım sistemi olan organik tarım, toprak sağlığını koruyarak biyolojik çeşitliliği artırırken, su kaynaklarının kirlenmesini önlemeye de katkı sağlamaktadır (Fayiah et al., 2019). Bu sistemde doğal gübreler, biyolojik mücadele yöntemleri ve ekim nöbeti gibi teknikler öne çıkmaktadır.

Toprak ekosistemlerini iyileştirmeye yönelik uygulamalar bütününü ifade eden rejeneratif tarım ise, sürdürülebilir tarımdan bir adım öteye geçer. Toprak organik madde içeriğinin artırılması, mikrobiyal yaşamın desteklenmesi, otlatma yönetimi ve ağaçlandırma gibi yöntemler rejeneratif tarımın temel bileşenleridir. Bu yöntem, karbon tutumunu artırarak iklim değişikliği ile mücadelede önemli bir rol oynar. Bu uygulamalar sayesinde, tarımsal üretimin ekosistem üzerindeki olumsuz etkileri en aza inerken, toprağın kendini yenileyebilmesi mümkün olmaktadır (Voisin et al., 2024).

Toprağın korunması ve iyileştirilmesi tarımsal üretimin sürdürülebilirliği için büyük bir ihtiyaçtır. Geleneksel ve modern toprak koruma tekniklerinin entegre edilmesi, organik ile rejeneratif tarım uygulamalarının yaygınlaştırılması ve sürdürülebilir toprak yönetimi yaklaşımlarının benimsenmesi tarımsal verimliliği artırırken doğal kaynakların korunmasını sağlayacaktır. Bu stratejiler, hem mevcut tarım sistemlerinin iyileştirilmesine hem de gelecekte sağlıklı ve verimli toprakların devamlılığına katkıda bulunacaktır.

Tarım arazilerinde toprak kalitesini artırmak, erozyonu önlemek, su tutma kapasitesini iyileştirmek ve ana ürün ekimi dışında toprağın korunması, iyileştirilmesi amacıyla yetiştirilen bitkiler örtü bitkileri olarak bilinmektedir. Bu bitkiler, tarımsal sistemlerin sürdürülebilirliğini artırarak toprak sağlığını destekleyen önemli bir araç olarak kabul edilmektedir. Genellikle baklagiller (yonca, fiğ, mercimek) toprak azotunu artırırken, tahıllar (çavdar, yulaf, arpa) organik madde katkısı sağlar ve erozyonu önler. Yeşil gübre bitkileri (baklagiller), tahıllar, çim türleri ve çeşitli otlar gibi farklı türlerden oluşabilir. Çok yıllık çayır bitkileri ise uzun vadeli toprak iyileştirme sağlamak için tercih edilir (Fageria et al., 2005).

Toprağın besin dengesini iyileştirerek uzun vadeli verimliliği artıran örtü bitkileri, toprağın su tutma kapasitesini geliştirirken, yüzeydeki yeşil örtü erozyonu önleyerek toprak kaybını azaltır. Organik madde miktarını artırarak toprak yapısını iyileştirir ve karbon tutulmasına katkı sağlayarak iklim değişikliğiyle mücadelede önemli bir rol oynar. Bununla birlikte, örtü bitkileri tarımsal ekosistemlerde biyolojik çeşitliliği artırarak yararlı mikroorganizmalar, böcekler ve farklı toprak canlıları için yaşam ortamı sağlar (Bielenberg et al., 2023). Tarla rotasyon sistemlerinde örtü bitkileri, farklı türlerin dönüşümlü olarak ekilmesiyle toprak sağlığını koruma açısından büyük fayda sağlar. Örtü bitkilerinin kullanımı, bölgesel iklim ve toprak koşullarına bağlı olarak değişkenlik gösterebilir. Genellikle doğrudan ekim yöntemi ile toprağa karıştırılmadan yetiştirilir ve ana ürün ekimi öncesinde toprağa dahil edilir. Bazı bölgelerde yapılan araştırmalar, örtü bitkilerinin uzun vadede toprak organik maddesini artırdığını, erozyonu önemli ölçüde azalttığını ve su tutma kapasitesini iyileştirdiğini göstermektedir. Örneğin, ABD'de yapılan çalışmalar, örtü bitkilerinin kullanıldığı tarlalarda organik madde miktarının %20'ye kadar arttığını ortaya koymuştur. Avrupa'da ise bazı çiftçiler, toprak yapısını iyileştirmek ve kimyasal gübre ihtiyacını azaltmak amacıyla baklagil ağırlıklı örtü bitkileri karışımlarını tercih etmektedir (Schnitkey et al., 2023).

Örtü bitkilerinin tarımsal üretim süreçlerine entegrasyonu, toprak kalitesinin korunmasına ve iyileştirilmesine katkıda bulunur (Scavo et al., 2022). Örtü bitkileri, tarımsal üretim sistemlerine entegrasyonunda farklı yöntemlerle kullanılabilir. Örtü bitkileri, ana ürün öncesi, sırasında veya sonrasında ekilerek toprağın besin maddesi dengesini düzenler, organik madde içeriğini artırır ve erozyonu önler. Örtü bitkileri bazı uygulamalarda, ana mahsul ekimi öncesinde yeşil gübre olarak toprağa karıştırılırken, bazı sistemlerde doğrudan malçlama amacıyla yüzeyde bırakılır (Kuo et al., 1997).

Baklagiller ve otlar kurak ve yarı kurak bölgelerde tercih edilirken, nemli bölgelerde su tutma kapasitesi yüksek bitkiler daha yaygın olarak kullanılmaktadır (Aparecida et al., 2018). Kumlu topraklarda su tutma kapasitesini artırmak amacıyla lifli kök yapısına sahip bitkiler tercih edilirken, ağır killi topraklarda toprağın havalanmasını artıran türler öne çıkmaktadır. Örtü bitkilerinin kullanımı, bölgesel iklim koşulları ve toprak yapısına bağlı olarak değişiklik göstermektedir. Bununla birlikte, toprağın mevcut besin durumu da örtü bitkisi seçiminde belirleyici bir faktördür. Organik madde eksikliği bulunan alanlarda tahıllar ve geniş yapraklı otlar tercih edilirken, azot bakımından fakir topraklarda baklagil türleri daha etkili olabilir.

Örtü bitkilerinin uygulanmasında bazı zorluklarla karşılaşılmaktadır. Bunlar arasında, çiftçilerin örtü bitkilerinin faydaları konusunda yeterince bilgi sahibi olmaması, ekim ve yönetim süreçlerinde karşılaşılan teknik zorluklar, ana ürünle rekabet edebilmeleri, bazı örtü bitkilerinin su tüketiminin yüksek olması yer almaktadır. Bununla birlikte, örtü bitkilerinin uygun şekilde yönetilmemesi durumunda, bazı hastalık ve zararlılara ev sahipliği yapabileceği veya yabancı otlarla rekabeti artırabileceği bilinmektedir.

Çiftçilere yönelik eğitim programları, örtü bitkilerinin daha etkin ve verimli şekilde uygulanmasını sağlarken, teknolojik gelişmelerin entegrasyonu ile hassas tarım teknikleri kullanılarak örtü bitkilerinin daha optimize bir şekilde yönetilmesi mümkün hale gelmektedir. Tarımda sürdürülebilirliği artırmak açısından bakıldığında, örtü bitkilerinin kullanımını teşvik eden politikalar ve teşviklerin gerekli olduğu düşünülmektedir. Uzun vadede, örtü bitkilerinin daha yaygın şekilde benimsenmesi, su kaynaklarının korunmasına katkıda bulunacak, toprak sağlığını iyileştirerek verimliliği artıracak ve tarımın çevresel etkilerini en aza indirecektir.

Sonuç ve Öneriler

Bu çalışma, örtü bitkilerinin tarımsal üretimde toprak sağlığını koruma ve iyileştirme potansiyelini vurgulamaktadır. Örtü bitkileri, su tutma kapasitesini iyileştirerek kuraklık koşullarında dayanıklılığı artırmakta, toprak organik madde içeriğini artırarak verimliliği desteklemekte ve erozyonu önleyerek toprağın uzun vadeli korunmasına katkı sağlamaktadır. Yine, bu bitkiler tarımsal ekosistemlerde biyolojik çeşitliliği teşvik ederek sürdürülebilir üretim sistemlerinin temel unsurlarından biri olmaktadır.

Örtü bitkilerinin tarımsal sistemlere entegrasyonu, kimyasal gübre ihtiyacını azaltarak toprağın doğal yapısını korurken aynı zamanda çevre dostu bir üretim süreci oluşturmayı sağlamaktadır. Bu uygulamalar, ekosistem sağlığını destekleyerek tarımın uzun vadede daha sürdürülebilir hale gelmesine yardımcı olmaktadır.

Örtü bitkilerinin daha yaygın şekilde benimsenmesi ve yönetim stratejilerinin geliştirilmesi tarımsal sürdürülebilirlik açısından değerlendirildiğinde, büyük bir gerekliliktir. Gelecekte, çiftçilerin bu konuda bilinçlendirilmesi, bilimsel araştırmaların artırılması ve örtü bitkilerinin kullanımını teşvik eden politikaların uygulanması, tarımsal üretimin çevreye duyarlı bir şekilde devam etmesini sağlayacaktır. Tarımsal verimliliğin anahtarı sağlıklı topraklar olup, örtü bitkileri gibi doğal çözümler, sürdürülebilir tarımın temel taşlarından biri olarak değerlendirilmelidir. Bu nedenle, örtü bitkilerinin tarım sistemlerine entegrasyonu ve kullanımının yaygınlaştırılması büyük önem taşımaktadır.

Abstract

Precision agriculture has emerged as a transformative approach to modern crop management, integrating advanced technologies to optimize productivity, resource efficiency, and sustainability. This research presents a novel multispectral image classification algorithm specifically designed for banana cultivation (*Musa* AAA), combining aerospace technology, spectral analysis, and machine learning to address critical challenges in tropical agriculture. The study was conducted in a commercial banana plantation, where high-resolution visible and near-infrared spectral data were acquired using state-of-the-art optical sensors mounted on unmanned aerial vehicles (UAV). The methodology employed the Normalized Difference Vegetation Index (NDVI) as a primary tool for crop zoning and health assessment. Through sophisticated image processing techniques implemented in Python, we generated precise vegetation and soil fragmentation masks at the administrative plot level, enabling spatial resolution in crop monitoring. The algorithm successfully identified subtle variations in plant health and nutritional status across different sectors of the plantation, allowing for the creation of detailed sub-plots with distinct agronomic requirements. Comprehensive statistical analysis of spectral data provided actionable insights into plot-specific needs, facilitating data-driven recommendations for fertilizer application, irrigation scheduling, and pest management. This work represents a significant advancement in precision agriculture for banana cultivation, offering a scalable solution that can be adapted to diverse growing conditions in Ecuador and the around the world. The integration of aerospace technology with advanced analytics not only improves production efficiency but also contributes to sustainable farming practices by minimizing unnecessary resource inputs. With further development, this approach could be extended to other tropical crops, potentially revolutionizing agricultural practices in developing nations. The study underscores the critical role of spectral technology in addressing global food security challenges while promoting environmental stewardship.

Abstract

Increased productivity in agriculture is possible with technological developments. One of these technologies is the protection of seed quality. Synthetic seeds are artificially encapsulated plant propagation material. It is coated with special substances containing nutrients and protective compounds. The main goal of seed coating technologies is to enable small seeds to grow to larger and uniform sizes. Synthetic seed production offers the opportunity for a cheap and practical tissue culture production technique. Plant nutrients, fungicides, insecticides, herbicides and beneficial organisms can be added to the seed coating material. Seed coating technologies are mostly carried out as pelletizing, film coating or pellet+film coating methods. Owing to the seed coating method, the performance of the seeds for germination will increase and thus the ability of the plants to combat against possible diseases and pests during the germination and seedling periods will increase. One of the difficulties in agricultural practice and research today is how to cope with biotic and abiotic stress conditions, especially climatic changes, in an economically and environmentally sustainable approach. In this prepared study, information is given about seed coating and its applications in field crops.

Key Words: *Alternative control, Biofortification, Priming, Synthetic seed, Sustainable agriculture*

1. Introduction

The effective integration of technological advances into production processes is an important and also remarkable factors that increase productivity of agriculture. Among these innovations, especially the protection and improvement of seed quality has a critical role in terms of sustainable agricultural practices (Bennett et al., 2013). Seed coating technologies have been developed to increase productivity in agricultural production; however, they have made it possible for plants to become more resistant to environmental stress factors (Pedrini et al., 2017). That kind of technologies are not only increasing the germination ratio, but also they support to management of fields owing to promoting the homogeneous seed emergence (Halmer, 2006). Various nutrients, insecticides and also fungicides incorporated to coating based materials protect the plants counter to pests and diseases during the early development periods (Colla et al., 2015).

According to another related research, it was reported that combination of seed coating technologies by biologic based coating materials contributed to improvement of soil health besides increase in activity of soil microbials (Bashan et al., 2014). Particularly, hydrogel-based type coating materials are known as increasing the capacity of moisture retention in seeds under drought conditions, therefore increasing of the plant tolerance against water stress (Gao et al., 2019).

Seed coating technology cause to significant increases in seed germination percentage, and so improves the plant ability to combat wtih pests and diseases on germination period besides seedling period (Taylor et al., 1998). The main focus for seed coating technology is providing of reach to homogeneous and larger size to small seeds, therefore increase in efficiency and also success to sowing ratio (Haciyusufoğlu et al., 2015). Plant based nutrients, insecticides, fungicides, herbicides and also the beneficial microorganisms may also be integrated to seed coating materials as well (Rufino et al., 2013; Corlett et al., 2014).

According to many literature related with seed coating, the positive effects reported for germination ratio, development of root and shoot, growing of seedling, accumulation of dry matter, area of leaf and yield as well have been reported (Tavares et al., 2013; Dumanoğlu and Öztürk, 2022). Moreover, using of coated seeds has great importance in the sedd breeding based researches. Healthy plants that are obtained from the quality seeds can remarkable contribute for more controlled and also efficient results in the breeding programs (Sarıçam et al., 2018). In this study, prepared in the light of the scientific literature in question, scientific findings about seed coating and its applications in sustainable agricultural systems were presented.

2. Seed Coating Technologies

2.1. Definition and Importance of Seed Coating

Seed coating technology developed for the aim of providing more healthy and also efficient growing by additşon of variegated nutrients, protection based components and growing regulators to the exterior layer of seeds (Taylor & Min, 1991). This technique is especially important for small seeds in order to ensure their uniform distribution

in the field and to support their early development. Problems arise in machine sowing of seeds with small diameter, non-spherical shape and hairy tops compared to large diameter, smooth shaped seeds. In order to make the shape of such seeds more spherical, to increase their diameter, and to eliminate the hair and thorn-like appearance on them, it is possible to eliminate the negativities by covering the seeds with certain substances. The process of coating the seeds with certain substances in this way can be called seed coating, and the maintenance and improvement of the existing quality of the seed after harvest and the preservation of the value of the seed can be called post-harvest practices, which can be grouped as good seed storage, pre-sowing practices (priming), seed conditioning and coating technologies (pellet and film coating).

2.2. Seed Coating Techniques

Seed coating methods are techniques developed to support the early development of the plant and provide protection against environmental stress conditions. These methods are carried out by applying various substances to the outer surface of the seed and can be broadly categorized into four main groups: pelleting, film coating, pellet+film and bio-coating. Pelleting provides ease of mechanical sowing, especially for small and irregularly shaped seeds, by shaping them into a more uniform form so that sowing depth and uniform emergence can be controlled (Rehman and Farooq, 2016). Film coating, on the other hand, allows nutrients, pesticides or microbial preparations to be applied to the seed with a very thin layer without disturbing the natural shape of the seed and offers the advantage of controlled release (Scott, 1989). Pellet+film coating is one of the most advanced methods, combining these two methods to provide both physical protection and biochemical support (Pill & Finch-Savage, 1988). Bio-coating activates the plant's immune system against biotic and abiotic stresses at an early stage by applying beneficial microorganisms (e.g. Rhizobium, Trichoderma, Bacillus spp.) to the seed surface (Bashan et al., 2014). These methods can be flexibly adjusted according to environmental conditions, crop type and the objectives of the producer, contributing to the sustainability goals of modern agriculture.

Seed coating technology developed for the aim of providing more healthy and also efficient growing by additşon of variegated nutrients, protection based components and growing regulators to the exterior layer of seeds (Taylor & Min, 1991). This technique is especially important for small seeds in order to ensure their uniform distribution in the field and to support their early development. Problems arise in machine sowing of seeds with small diameter, non-spherical shape and hairy tops compared to large diameter, smooth shaped seeds. In order to make the shape of such seeds more spherical, to increase their diameter, and to eliminate the hair and thorn-like appearance on them, it is possible to eliminate the negativities by covering the seeds with certain substances. The process of coating the seeds with certain substances in this way can be called seed coating, and the maintenance and improvement of the existing quality of the seed after harvest and the preservation of the value of the seed can be called post-harvest practices, which can be grouped as good seed storage, pre-sowing practices (priming), seed conditioning and coating technologies (pellet and film coating).

2.2.1. Film coating

Film coating is a modern coating method that provides seed protection and improvement through a thin, adhesive and often clear layer applied to the seed surface (Scott, 1989). Initially developed in the pharmaceutical and food industry, this technology was later successfully applied to seed coating applications in agriculture. During the film coating process, the size and shape of the seeds remain largely unchanged, while active substances such as nutrients, fungicides, insecticides, biostimulants and color pigments can be brought into contact with the seed. One of the most commonly used equipment is the rotary coater, in which film-forming polymers are formulated to dissolve or disperse the active ingredient and applied to the seeds in a controlled manner. One of the main advantages of film coating is the high application recovery (about 90%) and uniform distribution on the seed surface. It also improves the flow ability of the seeds, offering advantages in terms of mechanical performance during both processing and planting. The weight gain achieved by film coating is typically 2% to 5% of the seed weight, which allows for active ingredient transportation without significantly affecting physical performance. Research has shown that maize seeds coated using proprietary film coating polymers (e.g. PolySeedCF) reduce dust formation and minimize environmental impacts by preventing leaching of applied insecticides. With these characteristics, film coating is an advanced seed treatment technology with both ecological and economic benefits.

2.2.2. Pelletization

Pelletization is a method of seed coating that is applied especially to small and irregularly shaped seeds in order to give them a smooth, round and evenly sized form. Thanks to this technique, the seeds become larger and more uniform, so that they can be contacted with the soil with high precision and homogeneity in precision planters (Halmer, 2006). During the pelleting process, the seed usually remains in the center as a kernel and inert materials such as lime, clay, cellulose, chalk, starch and polymers are added as a covering blanket. Nutrients, plant growth regulators and preservatives can also be added. Pelleting significantly improves seed dispersal, sowing depth and emergence rate, which is of great benefit to growers with germination problems, especially for small-seeded species such as carrots, lettuce and alfalfa (Gray & Steckel, 1999). This method also improves germination success

by increasing seed access to water and nutrients in harsh environmental conditions such as drought or nutrient deficiency. However, the quality of the coating material and the solubility time should be carefully adjusted. Otherwise, undesirable effects such as delayed germination may occur. Advanced pelleting techniques make it possible to coat seeds with biological and chemical protection agents, creating a multi-purpose application area.

2.2.3. Pellet + Film Coating

It is one of the most developed combinational approaches among seed coating technologies. In this method, the pelletizing process gives the seeds physical integrity and a standardized form, while the film coating applied on top of it enables the precise addition of pesticides, nutrients or biological agents to the outer surface of the seed (Pill & Finch-Savage, 1988). Particularly for small seeds with low germination potential, this method optimizes both emergence rate and seedling development. Thanks to the controlled release of the film coating, the substances needed by the seed can be delivered directly with minimal impact on the environment.

2.2.4. Bio - Coating

It is an innovative technique in which seeds are coated with useful microorganisms to increase both the nutritional capacity of the plant and its resistance to environmental stresses. Among the microorganisms used in this method, species such as *Rhizobium*, *Azospirillum*, *Trichoderma* and *Bacillus subtilis* stand out. These biological agents compete with harmful pathogens in the soil and inhibit their growth, while at the same time producing phytohormones that promote plant growth (Bashan et al., 2014). Bio-coating not only increases yields but also supports sustainable agriculture by maintaining soil microbial diversity and health. The fact that it helps to reduce chemical inputs makes it often preferred in ecological agriculture practices. *Rhizobium* species, on the other hand, establish symbiotic relationships, particularly with legumes, and bind atmospheric nitrogen, making it available to the plant and reduce the need for chemical fertilizers (Zahran, 1999). For example, *Trichoderma* spp. both promote root growth and provide prevention against diseases such as root rot (Harman, 2000).

3. Seed Coating Applications in Field Crops

3.1. Improving Germination and Seedling Development

Seed coating technologies play a direct impact role on germination and young seedling development. The germination process, especially in small and sensitive seeds, can be negatively affected by environmental stress factors or soil conditions. Coated seeds minimize these adverse effects by containing moisture retaining polymers, growth promoting substances (e.g. gibberellin, cytokinin), nutrients and protective agents (Halmer, 2006). Techniques such as pelleting and film coating regulate the physical interaction of the seed with its environment, promoting uniform water uptake and regular oxygen exchange. They promote rapid and simultaneous germination (Pedrini et al., 2017). Micronutrients such as phosphorus and zinc, which are provided locally around the seed, accelerate root development and enable the formation of more robust and durable individuals during the seedling period (Cakmak and Cakmak, 2008). Seeds developed with these technologies show high performance even under conditions that delay germination such as drought and low temperatures. Therefore, post-sowing emergence rate increases and yield and quality become more predictable and sustainable.

3.2. Protection Against Diseases and Pests

Seed coating treatments provide the first line of defense against pathogens and harmful organisms that plants may encounter during early developmental stages. Thanks to the fungicides and insecticides applied to the surface of the coated seeds, protection is provided from the first moment the seed comes into contact with the soil. This is an effective measure against soil-borne diseases (e.g. *Rhizoctonia solani*, *Fusarium* spp., *Pythium* spp.) and pests (e.g. earthworms and insect larvae targeting seedlings). Furthermore, the chemical agents, biological control based mechanisms are also activated by addition of the beneficial microorganisms likewise *Pseudomonas fluorescens*, *Trichoderma* sp. and *Bacillus subtilis* to seed coating based materials (Harman, 2000; Colla et al., 2015). This type of biological based agents provide to protection of both directly competing with pathogens and stimulation of the plant immune systems. Thus, it is possible to reduce pesticide use and increase environmental sustainability. This protective effect allows plants to develop better under stress and can positively affect crop yields.

3.3. Increasing Nutrient Uptake and Plant Nutrition

The enrichment of materials used in seed coating technologies with plant nutrients is of great importance to provide optimal nutrition of plants during early development. The nutrient needs of the seed during germination and seedling development can be met to a limited extent due to the incomplete development of the root system. At this stage, micronutrients and macronutrients (especially phosphorus, zinc, potassium and iron) applied directly to the seed both support plant growth and increase the bioaccessibility of nutrients present in the soil but difficult to be taken up by the plant (Welch & Graham, 2004). For example, it has been observed that both germination rates and early root elongation of wheat seeds coated with zinc significantly increased (Cakmak, 2008). Furthermore, when plant growth-promoting amino acids, humic substances or biostimulants are incorporated into coating materials,

root growth, nutrient absorption and overall plant resilience are positively affected (Colla et al., 2015). This practice supports environmental sustainability while reducing the need for fertilizer use, especially in poor or nutrient-limited soil conditions.

3.4. Resistance to Abiotic Stress Conditions

Abiotic based factors likewise drought, salinity and also temperature welded stresses, which are increasing with climate change in agriculture, pose serious threats to plant growth and productivity. The seed coating technology was used as an effective tool to increase plant tolerance to these stress conditions. By adding osmotic regulators (e.g. glycine betaine), antioxidants and biological agents to coated seeds, better germination and development of seeds under stress conditions can be achieved (Ashraf & Foolad, 2007). Additionally, some of the biological coatings facilitate the plant to combat oxidative stress by activating its defense mechanisms (Tuğrul and Kaya 2020). The mentioned practices are highly valuable to ensure the sustainability of production, especially for the marginal soils besides variable environmental conditions. Particularly, the hydrogel-containing coatings reduce water stress by retaining moisture in the micro-environment around the seeds and facilitate the plant access for water (Gao et al., 2023).

4. Conclusions

Various types of the seed coating technology are known as a versatile contribution to the productivity, environmental sustainability and stress management aims of modern agriculture. Applied through various methods such as film coating, pelleting, bio-coating and their combinations, this technology not only increases germination rates, but also promotes healthy development of young seedlings, optimizes nutrient uptake and makes plants more resilient to biotic and abiotic stress factors.

In the field crop practices, the adaptability of seed coating to species and environmental conditions increases the widespread applicability of this technology. Particularly, the bio-coatings containing microorganisms offer a solution that is compatible with sustainable agricultural policies by making it possible to reduce chemical inputs. Therewithal, the nutrients, growth regulators and protective agents incorporated into coating based materials directly provide to support of plant requirements during the development period, create potentials for high yields. In the future, the development of environmentally friendly and biodegradable coating materials, supported by digital solutions integrated with precision agriculture practices, and the dissemination of awareness-raising trainings at farmer level will further increase the effectiveness of this technology. Seed coating technologies are not only a production tool, but also a candidate solution to global challenges such as climate change, soil degradation and reducing the use of agricultural chemicals. In this context, it is of great importance to continue research and adapt the technology to local conditions.

The Use of Capsule Houses in Landscape Design Studies

Gülden Sandal Erzurumlu

[1] Department of Landscape Architecture, Faculty of Architecture, Niğde Ömer Halisdemir University, Niğde, Türkey

Abstract

The rapid development of urbanization has provided significant opportunities for the advancement of architectural landscape design while simultaneously bringing about major challenges. This pace of development has led to the rapid emergence of new urban areas and an endless array of new construction projects. For those longing for natural environments, structures such as bungalows, caravans, capsule houses, and tents have become attractive alternatives. Capsule houses stand out as innovative structures offering sustainable, aesthetic, and functional solutions in modern landscape design. Thanks to their nature-friendly designs and portable structures, they offer extensive usability in rural, natural, and recreational areas.

Natural and cultural landscape areas, which possess natural, aesthetic, functional, and economic features, provide various usage opportunities. Demand for natural spaces such as waterfronts, rural areas, historical sites, and national parks is increasing day by day. The aim of this study is to develop design proposals for living spaces to be created in these mentioned platforms. Different models will be created using SketchUp software.

Keywords: *Capsule houses, Landscape, Bungalows, Urbanization, Natural areas*

Peyzaj Tasarım Çalışmalarında Kapsül Evler Kullanımı

Özet

Hızlı kentleşme gelişimi, mimari peyzaj tasarımının gelişimi için büyük fırsatlar sunmuş, ancak buna paralel olarak çeşitli büyük zorlukları da beraberinde getirmiştir. Bu tür bir gelişim hızı, insanlara yeni kentsel alanların hızla ortaya çıkması, bitmek bilmeyen yeni inşaat projeleri gibi unsurlar sunmaktadır. Doğal ortamlara özlem duyanlar için bungalov evler, karavan ve kapsül evler, çadırlar vb. ilgi çeken mekanlar oluşturmaktadır. Kapsül evler, modern peyzaj tasarımında sürdürülebilir, estetik ve işlevsel çözümler sunan yenilikçi yapılar olarak öne çıkmaktadır. Doğayla uyumlu tasarımları ve taşınabilir yapıları sayesinde kırsal, doğal ve rekreasyon alanlarında geniş kullanım imkânı sunarlar.

Doğal, estetik, fonksiyonel ve ekonomik özelliklere sahip doğal ve kültürel peyzaj alanları farklı kullanım alanları sunmaktadır. Su veya deniz kenarları, kırsal alanlar, tarihi alanlar, milli parklar vb. doğal alanlara talepler günden güne talep artmaktadır. Bu çalışmanın amacı, adı geçen paltformlarda yaşam mekanları için oluşturulacak tasarım çalışmaları için öneriler geliştirilecektir. SketchUp yazılımı kullanılarak farklı modellemeler oluşturulacaktır.

Anahtar Kelimeler: *Kapsül evler, Peyzaj, Bungalov evler, Kentleşme, Doğal alanlar*

Giriş

Türkiye'de nüfus hızla artış göstermektedir. Şehirleşmenin hızla arttığı dönemimizde insanların yerleşim alanlarına olan ihtiyaçları sürekli artmaktadır. İmarlaşma alanlarına olan gereksinimi karşılamak için, kentlerin yeşil ve tarım alanları kullanılmaktadır. Tarım alanlarının yerlerini apartmanlar, işyerleri vb. nin yerini beton yapılar almaya başlamıştır. Binalar arasında kullanıma uygun olmayan dar mekanlar ise yeşil alan olarak değerlendirilmektedir. Avrupa standartlarına göre uygun ekolojik ortamlar için kişi başına düşen yeşil alan miktarı 9-10m^2 olması gerekirken Türkiye'de genel olarak bu miktar çok fazla düşüş göstermektedir. Yasal yönetmelklerde de belirlenen yeşil alan miktarı 10$m^{2'}$ dir.

Aksoy, 2001' de yaptığı çalışmada, 1999 yılında "İmar Planı Yapılması ve Değişikliklerine Ait Esaslara Dair Yönetmelikte kişi başına düşen yeşil alan miktarı 10 m^2 'olarak belirlenmiştir.

Ülkemizde kentsel yeşil alanlar sistemi sadece nicelik olarak ele alındığı, özellikle yeşil alanların kentsel alanın tümünde eşit ve dengeli bir şekilde dağılmadığı, yeşil alanlar arasında organik bağlantıların olmadığı, erişilebilirliğin yetersiz olduğu ve kent içinde parçalı bir dağılım gösterdiği yaygın bir şekilde kabul görmektedir(Türker ve ark., 2022).

Bu yeşil alan sıkıntısı insanların yeşil alan bulmak, dinlenmek, rekreasyon faaliyetlerini gerçekleştirmek için yerleşim alanlarından daha uzak mekanlara gitme ihtiyacını beraberinde getirmektedir. İnsanlar özellikler, tatil dönemlerinde doğal ortamlarda yaşayabilmek için taşınabilir evler (karavan vb.), yada kırsal alanlarda bulunan kapsül veya bungalov evlere ihtiyaç duymaktadır. Gerek yaz gerekse kış tatillerinde otellerin olmadığı yada konaklama mekanlarının yetersiz olduğu mekanlarda kısa süreli konaklamalar için kapsül yada bungalov evler veya karavan park alanları daha da fazla talep görmektedir.

Günümüzde, Türkiyenin sosyal ekonomisi hızla ve zamanla değişmektedir. İnsanlar doğaya olan özlemi artmakta. İnsanlar, doğa ile özlemini giderebilmek için çok fazla paralar ödemektedirler. Ve insanların sosyal faaliyetler için talepleri günden güne artış göstermektedir. İyi tasarlanmış, insanların sosyal etkinliklerinin gerçekleştireceği mekanlar, oyun alanları, yeme içme mekanları ilgi alanının artmasını sağlamaktadır. Küçük alanlarda tasarlanan evler, çevreye duyarlı bir yaşam tarzını desteklerken otel konforunu da sunarak, tamamen bağımsız yaşam ortamı sunar. Bu evlerden birisi de kapsül evlerdir.

Kapsül evler, mikro ölçekte evlerdir. Çeşitli amaçlar için alternatif konut çözümleri sunarak, inşaat malzemeleri ve enerji tüketimi açısından daha düşük çevresel etki sağlar. Küçük boyutları sayesinde bu kompakt konutlar, yenilikçi tasarım çözümlerine ilham verir. Kapsül evlerin tasarlanmasında ana amaç, sürdürülebilirliği ve evrenselliği sağlayarak konteyner tarzı konutlardan ayrışan, taşınabilir bir mikro-ev tasarlamak ve üretmektir. İki kişiyi barındıracak ve farklı iklim koşullarında ihtiyaçlarını karşılayacak şekilde geliştirilen bu konut, Ecocapsule adı verilen benzersiz küresel bir tasarıma sahiptir. Bu şekil, yağmur suyunu en iyi şekilde toplarken enerji kaybını en aza indirir.

Kapsül evler, doğayla uyumlu, sürdürülebilir ve minimal yaşam alanları sunduğundan, peyzaj tasarımları da bu konsepti desteklemelidir. Hem estetik hem de fonksiyonel çözümler sunarak doğal çevre ile bütünleşen bir ortam oluşturmak mümkündür.

Kapsül evlerin, çevresinde kullanılan bitkiler, bulunduğu bölgenin ekosistemine uygun seçilmesi ile doğal türlerin kullanılması sağlanacaktır. Doğal bitki türleri kullanılarak hem ekolojik denge korunur hem de bakım maliyetleri düşer. Peyzaj tasarım çalışmalarında kullanılacak, doğal taşlar, ahşap yollar ve yeşil çatı uygulamaları ile doğal görünüm desteklenebilcek ve ekolojiye uygun mekanlar oluşturulacaktır.

Kapsül Evlerin Ekolojiye Katkısı

Kapsül evlerin gerek kırsal alanlarda gerekse kent ortamında kullanımının bir çok faydası vardır. Özellikle doğada yada farklı ortamlarda gezerek zaman geçirmek isteyenler genelde çadır, karavan tercih etmektedirler. Belirli günlerde kalmak isteyenler bungalov evlerini kullanmaktadırlar. Alternatif ve daha ekolojik olan kapsül evler yaygın olarak tasarlanması doğaya katkı sağlamaktadır. Kapsül evler, minimal yaşam felsefesini benimseyen ve doğayla iç içe bir yaşam sunan kompakt konut çözümleridir. Peyzaj alanında kullanımları, sürdürülebilirlik, doğal çevreye entegrasyon ve ekolojik yaşamı destekleme açısından büyük avantajlar sunmaktadır.

Kapsül evler, doğaya duyarlı yapıları sayesinde sürdürülebilir bir yaşam alanı sunarak ekolojiye önemli katkılarda bulunur. Geleneksel konutlara kıyasla daha düşük karbon ayak izi, enerji verimliliği ve doğal kaynak kullanımında tasarruf sağlamaları**,** onları çevre dostu bir alternatif haline getirir.Kapsül evlerin Doğaya katkıları şu şekilde sıralanabilir:

1. Sürdürülebilir Peyzaj Tasarımı

Peyzaj tasarım çalışmalarında kullanılan kapsül evler doğaya önemli katkı sağlamaktadır. Yağmur sularının korunması, Gri su kullanımı, Kompost alanı ve güneş ve rüzgara yön vermek amaçlı kullanılabilir.

- **Yağmur Suyu Hasadı:** Çatı yüzeyinden toplanan yağmur suyu, bitkilerin su ihtiyacının karşılanması için kullanılabilir.
- **Gri Su Kullanımı:** Mutfak ve banyo atık suyu, bitkilerin sulanması için arıtılarak yeniden değerlendirilebilir.
- **Kompost Alanı:** Kapsül evler yaşam ortamları oluşturacağı için organik atıkları değerlendirmek ve toprağı zenginleştirmek için kompost alanı oluşturulabilir.
- **Güneş ve Rüzgar Yönlendirme:** Rüzgar ve güneş yönü dikkate alınmadan yapılan tasarımlar insanları rahatsız edebilmektedir. Kapsül evlerin etrafında ypılacak bitkilendirme çalışmaları ile yaşam alanları stratejik olarak konumlandırılabilir.

2.Fonksiyonel ve Estetik Ögeler

- **Doğal Yollar ve Patikalar:** Ahşap, çakıl veya taş yürüyüş yolları ekleyerek kapsül eve erişimi kolaylaştırılabileceği gibi doğal görünüm alanları oluşturmaktadır.
- **Açık Hava Oturma Alanları:** Minimalist mobilyalarla doğayla iç içe yaşam alanları oluşturmak ekolojik mekanlar tasarlanabilir.
- **Gölgelendirme Elemanları:** Ağaçlar, pergolalar veya bitkilerle oluşturulan gölgelik alanlar, kapsül evin aşırı güneşten korunmasını sağlamaktadır.

3. Besin Üretimi ve Ekolojik Yaşam

- **Dikey Bahçeler:** Küçük alanlarda bile sebze ve ot yetiştirmek için ideal bir çözüm oluşturulabilir.
- **Permakültür Bahçesi:** Kendi kendine yeten bir sistem oluşturarak doğal gıda üretimini teşvik edebilir.
- **Arı ve Kuş Dostu Bitkiler:** Yerel ekosisteme katkı sağlayarak doğayla uyumlu bir yaşam alanı oluşturur.

4. Aydınlatma ve Enerji Kullanımı

- **Güneş Enerjili Aydınlatmalar:** Bahçe yolları ve oturma alanları için çevre dostu bir çözüm sağlayabilir.
- **Düşük Tüketimli LED Lambalar:** Işık kirliliğini önlerken enerji verimliliği sunmaktadır.
- **Rüzgar Türbinleri veya Güneş Panelleri:** Yenilenebilir enerji kaynakları ile kapsül evin enerji ihtiyacı karşılanabilir.

5. Doğayla Uyumlu Tasarım:

Kapsül evler, organik ve modern tasarım anlayışıyla doğal peyzajla bütünleşerek estetik bir görüntü oluşturur.

- Küresel veya aerodinamik şekilleri sayesinde rüzgar, su ve güneş gibi doğal unsurlarla uyumlu bir şekilde konumlandırılabilirler.
- Kapsül evlerin çevresinde kullanılan bitkiler, bulunduğu bölgenin ekosistemine uygun olmalıdır.
- Yerel bitki türleri kullanılarak hem ekolojik denge korunur hem de bakım maliyetleri düşer.

6. Çevresel Etkiyi Azaltma:

- Geleneksel yapılaşmaya kıyasla doğaya daha az zarar verirler.
- Hafif yapıları sayesinde arazinin doğal dokusuna zarar vermeden kurulabilirler.

7. Taşınabilirlik ve Modülerlik:

- Peyzaj düzenlemelerinde kapsül evler, taşınabilir özellikleriyle mevsimsel veya geçici konaklama alanları için idealdir.
- Modüler yapıları sayesinde farklı iklim koşullarına ve arazilere kolayca uyum sağlayabilirler.

8.Turizm ve Ekolojik Konaklama:

- Kamp alanları, dağlık bölgeler, göl kenarları veya doğal parklar gibi turistik alanlarda çevre dostu bir konaklama çözümü sunarlar (Şekil 1).
- Ekoturizm konseptiyle doğa severler için konforlu ama çevreye duyarlı yaşam alanları oluştururlar.

Şekil 1. Kapsül evlerle Doğal alanlarda kamp alanı örneği

9.Tarım ve Doğal Yaşam Alanları ile Entegrasyon:

- Kapsül evler, tarım arazileri veya doğal yaşam alanları içinde küçük ölçekli ekolojik yerleşim alanları oluşturmak için kullanılabilir (Şekil 2).
- Kendi kendine yetebilen bir ekosistem kurarak permakültür ve dikey bahçelerle entegre edilebilirler.

Şekil 2. Küçük ölçekli ekolojik yerleşim alanları

Dünyada artan nüfus imar alanlarının artışını hızlandırmaktadır. Bu durum tarım alanlarını oluşturan verimli toprakları tehdit etmektedir. Gelecektede nüfus bu şekilde artış gösterirse küçük alanlarda daha fazla yerleşim alanlarına ihtiyaç duyulması kaçınılmazdır. Bu nedenle, ekolojik küçük yaşam mekanlarına ihtiyacımız çok fazla olacaktır. Kapsül evlerin tercihler arasında kullanılması gerekebilir. Kapsül evlerin gelecekte tercih edilme nedenleri şu şekilde sıralanabilir:

Düşük Karbon Ayak İzi

Kapsül evlerinin yapımında kullanılan inşaat malzemelerinin azalması ile;

- Geleneksel evlerin inşası büyük miktarda beton, çelik ve ahşap gerektirirken, kapsül evler hafif ve modüler olarak üretildiği için daha az malzeme tüketir.
- Önceden üretilmiş (prefabrik) bileşenler, sahada inşaat atıklarını azaltarak çevreyi korur.

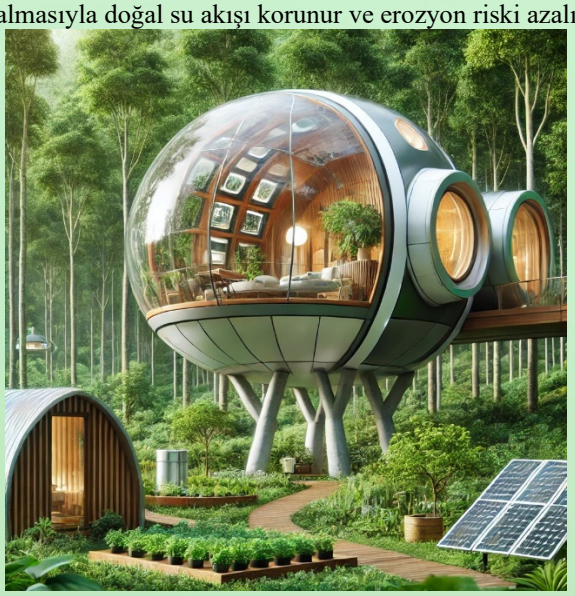
Isı Yalıtımı ve Enerji Verimliliği

1. **Yüksek Verimli Yalıtım Malzemeleri:**

- Kapsül evlerin içi yoğun yalıtımlı malzemelerle kaplandığı için ısı kaybı minimum seviyeye indirilir.
- Pasif ev standartlarına yakın bir enerji verimliliği sunarak kışın ısıtma, yazın soğutma ihtiyacını azaltır**.**

2. Doğal Havalandırma ile Klima Kullanımının Azaltılması:

- Akıllı hava akışı tasarımı sayesinde klima ve yapay havalandırma ihtiyacını en aza indirir**.**
- Kapsül evlerin çevresine yerel bitkiler dikilerek doğal yaşam korunur (Şekil 3)**.**
- Arılar ve kelebekler için doğal yaşam alanları oluşturularak ekosistemin devamlılığına katkı sağlanır.



Şekil 3. Kapsül evlerin tasarımında doğal bitki kullanımı

Toprağa Minimum Müdahale

1. **Hafif ve Taşınabilir Yapılar ile Doğanın Korunması:**

- Temelsiz veya hafif temelli inşaat teknikleri kullanılarak toprağa zarar verilmez (Şekil 4).
- Beton kullanımının azalmasıyla doğal su akışı korunur ve erozyon riski azalır**.**

Şekil 5. Temelsiz veya hafif temelli inşaat tekniklerinin kullanımı

2. **Mobilite Sayesinde Sürdürülebilir Alan Kullanımı:**

- Gerektiğinde farklı lokasyonlara taşınabilir, böylece doğa üzerinde kalıcı bir tahribat yaratmaz.
- Özellikle hassas ekosistemlerde geçici ve çevre dostu konaklama çözümleri sunar.

Gelecekte Kapsül Evlerin Kullanım Alanları

Kapsül evler, kompakt, taşınabilir ve sürdürülebilir yapılarıyla gelecekte çok daha yaygın hale gelecek. Artan nüfus, şehirleşme, çevresel sorunlar ve konut maliyetlerinin yükselmesi, bu tür yenilikçi konut çözümlerine olan ihtiyacı artırıyor. Gelecekte kapsül evlerin kullanabileceği alanlar:

1. Şehirleşme ve Yoğun Nüfus Alanlarında Kullanım

- **Metropol Alanlarında Mikro-Yaşam Konseptleri:**

Büyük şehirlerde konut fiyatları yükseldikçe, kapsül evler küçük ölçekli ve uygun maliyetli konut alternatifleri sunabilir.

- **Çatılarda ve Boş Alanlarda Modüler Yerleşimler:**

Yüksek katlı binaların çatılarına ya da kullanılmayan şehir alanlarına kapsül evler yerleştirilerek yeni yaşam alanları oluşturulabilir.

- **Öğrenci ve Bekâr Konutları:**

Üniversitelerin çevresinde uygun fiyatlı ve sürdürülebilir öğrenci konutları olarak kullanılabilir.

2. Afet Bölgelerinde ve Acil Durum Konutları

- **Deprem, Sel ve Doğal Afet Sonrası Barınma:**

Kapsül evler hızlı kurulumları sayesinde acil durumlarda konut ihtiyacını karşılamak için ideal olabilir.

3. Ekoturizm ve Doğa İçinde Yaşam

- **Off-Grid ve Şebekeden Bağımsız Yaşam:**

Güneş panelleri, rüzgar türbinleri ve yağmur suyu toplama sistemleri ile tamamen doğa içinde yaşamak mümkün hale gelecek.

- **Glamping ve Lüks Doğa Otelleri:**

Kapsül evler, modern olanaklarla donatılmış lüks kamp alanlarında tatil konaklaması olarak kullanılabilir.

- **Dağ, Orman ve Deniz Kenarı Yaşamı:**

Doğanın ortasında küçük bir yaşam alanı isteyenler için kapsül evler bireysel kaçış noktaları olabilir.

4. Mars ve Uzayda Kullanım

- **Uzay Keşiflerinde Modüler Yaşam Alanları:**

NASA ve diğer uzay ajansları, Mars ve Ay'da sürdürülebilir yaşam alanları oluşturmak için modüler kapsül ev teknolojilerine yönelebilir.

- **Ekstrem Koşullarda Dayanıklı Yaşam Üniteleri:**

Kapsül evlerin yüksek yalıtımlı yapıları, uzay kolonileri için ideal konut çözümleri sunabilir.

5. Deniz Üzerinde ve Yüzen Şehirlerde Kullanım

- **Yüzen Yaşam Alanları ve Su Üzerinde Konutlar:**

İklim değişikliği nedeniyle deniz seviyesinin yükselmesi, kapsül evlerin deniz üzerinde sürdürülebilir yaşam alanlarına dönüşmesine yol açabilir.

- **Ada ve Göl Üzerinde Özel Konutlar:**

Su kenarındaki bölgelerde, doğayla iç içe minimal yaşam isteyenler için ideal bir çözüm sunar.

6. Geleceğin Çalışma ve Mobil Ofis Alanları

- **Uzaktan Çalışma ve Taşınabilir Ofisler:**

Dijital göçebeler ve uzaktan çalışanlar için doğayla iç içe ofis çözümleri sunabilir.

- **Hareketli İş Alanları ve Mobil Klinikler:**

Sağlık hizmetleri, laboratuvarlar veya taşınabilir ofisler olarak kullanılabilir.

Sonuç

Kapsül evler için peyzaj tasarımı, doğa ile bütünleşik, sürdürülebilir ve fonksiyonellik sağlamaktadır. Kullanılan malzemeler ve bitkiler bölgenin ekosistemine uygun seçilerek doğal doku korunur, bu sayede hem ekolojik denge sağlanır hem de konforlu ve estetik bir yaşam alanı oluşturulmuş olacaktır.

Kapsül evler, gelecekte sürdürülebilir yaşamın, afet yardımlarının, ekoturizmin, uzay keşiflerinin ve mobil yaşam tarzının önemli bir parçasını oluşturacaktır. Hem çevre dostu hem de modüler yapıları sayesinde dünya genelinde çok yönlü kullanım alanları sunacaklardır.

Kapsül evler, yenilenebilir enerji kullanımı, su ve enerji tasarrufu, düşük karbon ayak izi ve doğal ekosistemle uyumlu tasarımı sayesinde çevre dostu bir konut modelidir. Geleneksel konutlara kıyasla daha az enerji tüketerek ve doğaya zarar vermeden sürdürülebilir bir yaşam sunar.

Peyzaj tasarımında kapsül evler, modern yaşamın getirdiği sürdürülebilirlik ihtiyacına yanıt veren, doğayla bütünleşen ve minimalizmi destekleyen yenilikçi çözümler sunmaktadır. Hem bireysel yaşam alanları hem de ekoturizm projeleri için ideal olan bu yapılar, geleceğin çevre dostu konut modelleri arasında önemli bir yer edinmektedir.

Accessing Drinking Water and Global Warming in Sudan

Wadah Elsheikh[1*], M. Cüneyt Bağdatlı[2]

Abstract

Sudan's primary water sources are the Nile and non-Nile water resources, including rainfall, seasonal streams, and groundwater, which support a large part of the population. However, water scarcity will worsen with declining rainfall, increasing evaporation, and more frequent extreme weather events due to global warming, affecting rural and urban communities. The climate of Sudan varies from tropical wet and dry in the southwest to desert in the north. From south to north, rainfall drastically declines, and semi-arid regions experience acute water scarcity. In this assessment, we have tried to shed light on the difficulties in guaranteeing sustainable and fair access to drinking water in the face of environmental stressors and offer suggestions for managing Sudan's water resources. To increase agricultural productivity and satisfy the nation's expanding residential and industrial water demands, it is crucial to support the development of water resources for home and agricultural use. Sudan's water resources are multi-sectoral, therefore efficient coordination is essential. Specialized authorities must investigate ways to maximize water usage and set rules to direct and regulate these initiatives.

Key Words: *Global warming, Drinking water, Sudan*

Introduction

A crucial and interrelated component of the Earth's geophysical system, the water cycle affects and reacts to climatic conditions. Earth's radiation balance changes impact cloud dynamics, winds, temperatures, energy, and atmospheric water flow. Temperature changes impact soil moisture and snow-related processes, including melting and snowfall, evaporation and transpiration rates, and cloud characteristics. The occurrence and severity of floods, droughts, and runoff patterns are all impacted by changes in precipitation. These impacts alter plant distribution, growth rates, soil and water conditions, and cloud formation (Tao et al., 2003). Long-term changes in global weather patterns, such as elevated temperatures, modified precipitation, and a rise in extreme weather occurrences, are called climate change. The availability of water resources is one area where these changes significantly impact human civilizations and natural ecosystems (Elsheikh & Nasreldin, 2022).

In sub-Saharan Africa, one of the most urgent issues in urban areas is access to clean drinking water. The situation is worsened by the increasing effects of climate change, especially extreme weather events that alter rainfall patterns and put vulnerable rural and urban households' access to water at even greater risk. Approximately half a billion people worldwide experience severe water scarcity all year, and more than four billion suffer from severe freshwater shortages for at least one month each year (Pörtner et al., 2022). About 2.3 billion people, or 29% of the world's population, did not have access to basic hygiene services, such as water at home, in 2020, according to the WHO/UNICEF-JMP (2021) report. Even though more than 90% of the world's population has access to basic drinking water services (WHO, 2021), sub-Saharan Africa still trails far behind other areas. In rural African villages, piped water is only available to around 5% of the population. By contrast, 54% (about 300 million people) rely on unimproved sources, while 41% rely on improved sources such as wells and boreholes with hand pumps. A major barrier to fulfilling the food and energy needs of the expanding population and accomplishing Sustainable Development Goal 6, which calls for universal access to water, is the pervasiveness of water insecurity (Ayanlade, 2024).

Sudan is Africa's third biggest country, with a landscape that is largely level and has heights between 200 and 600 meters, which is between latitudes 8° and 23° north and longitudes 21° and 39° east, has a "mild desert climate." The northern region experiences the rainy season from July to September for about three months, whereas the southern part experiences it from June to November for about six months. One of the most famous rivers in the world, the Nile flows across Sudan from south to north. At Khartoum, its tributary, the Blue Nile, joins the White Nile. The flow of the Blue Nile is much higher during the rainy season than during the dry season, surpassing the White Nile's normally lower levels (FAO, 2015).

With about half of the Nile River Basin inside its boundaries, Sudan boasts a surface water area of around one million hectares, dominated by a 2,000-kilometer stretch of the Nile and its tributaries. 10% of Sudan is made up of wetlands, while 4% is made up of woods. During the short rainy season, several seasonal watercourses (KHORs)

flow, but their discharge quantities, flow durations, and water quality are not assessed. Perennial rivers beyond the Nile Basin, such as the Khor Abu Habil in Southern Kordofan, the Wadi Azoom, Galol, and other rivers in Darfur, and the Gash, Baraka, and Khor Arbaat rivers in the east, produce an annual discharge of 7.0 BCM (UNEP, 2020). The distribution and availability of water resources in Sudan vary greatly, making management difficult. Climate change worsens This problem, making extreme weather events like droughts and floods more frequent and severe. These difficulties show how urgently the nation needs efficient water resource management plans to guarantee long-term water supply. Thus, we have emphasized in this analysis the challenges of ensuring sustainable and fair access to drinking water in the face of environmental stressors and offered perspectives on managing water resources in Sudan. Improving the development of water resources for household and agricultural use is a top objective to boost agricultural output and satisfy Sudan's expanding need for water for industrial and domestic usage.

Water resources in Sudan

Sudan's primary water resources include surface water sources such as rainfall, rivers, seasonal wadis, Khors, lakes, and wetlands. Groundwater and non-conventional resources like wastewater reuse and desalination are extensively utilized. The country is divided into seven main basins at the watershed level, as depicted in Map 1 (Fanack Water, 2021). Non-Nile water resources play a vital role in Sudan's economy, fulfilling 70% of domestic water needs through rainfall, seasonal streams, wadis, and groundwater. Annual rainfall, averaging 420 billion m^3, has become unreliable since the 1990s, leading to sedimentation and crop failures. Seasonal streams and wadis contribute 2-8 billion m^3 annually but are insufficient for irrigation, while groundwater, recharged at 4 billion m^3 annually, is mainly used for domestic purposes due to its depth. Agriculture, contributing 40% of GDP and employing 80% of the population, relies on rain-fed farming for 90% of cultivated land. Rain-fed agriculture, livestock, and forests collectively contribute over 17% of GDP, support 70% of the population, alleviate poverty, and generate $2.5 billion annually in exports (Bashar, 2019).

Throughout the year, the Nile River and its tributaries provide 73% of Sudan's freshwater supply. With 18.5 billion cubic meters allotted from the Nile's annual supply of 80 billion cubic meters, the 1959 Nile Water Agreement controls Sudan's yearly usage. Most of this water is from the Blue Nile, which rises in Ethiopia and travels through Sudan before entering Egypt. Sudan's Nile system consists of the White Nile, the Atbara River, the Dinder and Rahad rivers, the Blue Nile and its tributaries, and many seasonal streams. There are several seasonal streams in Sudan, which the natives refer to as wadis or khors. The streams usually have a few days of flow from July to October but otherwise stay dry for the rest of the year. The four major streams are shared with neighboring countries: Eritrea shares Gash and Baraka, Chad shares Azum and Hawar, and other streams share South Sudan and the Central African Republic. Other seasonal streams in Sudan include Khor Abu Habil, Wadi El Mugaddam, Wadi Kaja, Wadi Nyala, Alawataib, and Alhawad. The rainfall rate determines the production of most seasonal streams and is not monitored. The average annual flow of the seasonal streams is 5.5 BCM (UNEP, 2020). The annual rainfall in Sudan is estimated at 440 billion cubic meters, with the southern regions receiving the largest amounts, about 800 mm per year. Rainfall decreases northward, with little rainfall between Khartoum and the Egyptian border (120 mm/year). There is a short rainy season with intermittent rainfall in the northern regions. Due to high evapotranspiration rates, rainfall is usually insufficient throughout the year, except for August, September, and October, when runoff helps recharge aquifers and seasonal waterways. However, deforestation exacerbates watershed erosion caused by silt and debris carried by runoff (Omar, 2008). There are also several natural freshwater lakes in Sudan, such as Turdat el-Rahad in Kordofan, Abyad in Southern Kordofan, and Kundi in southern Darfur. Saline lakes may also be found in Sudan, such as Malha in Northern Darfur and the Dariba Crater in Jebel Marra in Western Sudan. With the building of dams, the nation also created artificial reservoirs. These include Merowe in the Northern state, Sennar and Roseires on the Blue Nile, Jebel Aulia on the White Nile, Khashm El-Girba and the Upper Atbara and Setit Complex on the River Atbara, and Lake Nubia in the northernmost section of Sudan, which is a reservoir for the Egyptian High Aswan Dam (UNEP, 2020).

The demands of food security, urbanization, population growth, development, and climate change all put more strain on water resources, making water resources management crucial. Water scarcity is exacerbated by rising demand and pollution, necessitating concerted efforts. The Global Water Partnership defines water resources management as the equitable and sustainable management of land, water, and related resources to preserve ecosystems and optimize economic and social benefits. Fair access to water, effective use, integrated planning, sustainable use, and the development of a fresh approach to water management are among its objectives. According to Bashar (2019), there are still difficulties in establishing sustainable policies and encouraging structural and behavioral reforms for efficient resource use.

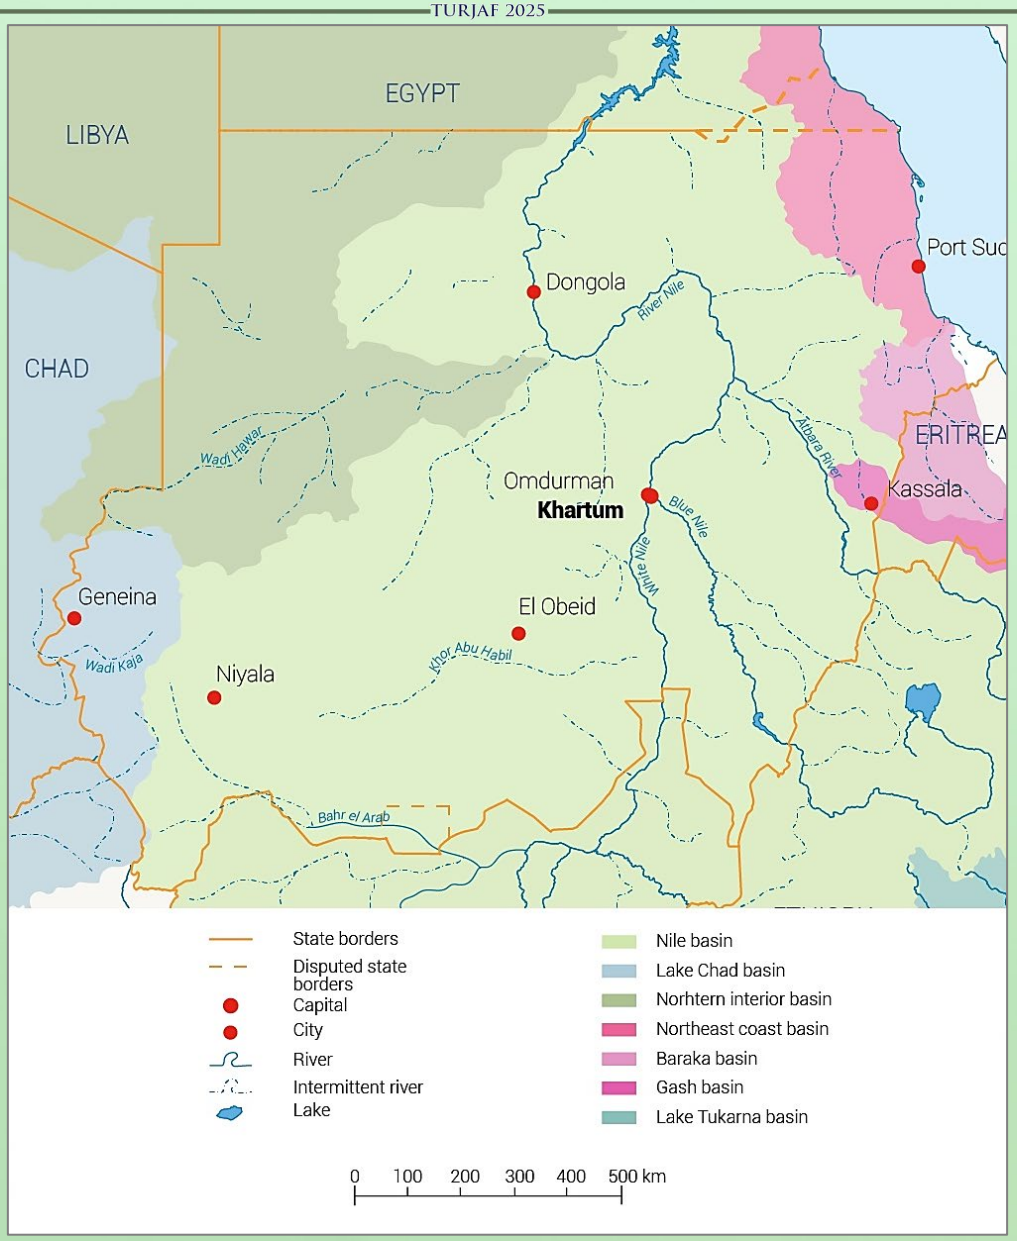

Figure 1. Hydrological basins in Sudan (Fanack Water, 2021).

Accessing Drinking Water and Global Warming in Sudan

Water is an essential and freely available natural resource that sustains life on Earth and plays a crucial role in economic and social development. However, water demand is rising rapidly, particularly in developing nations, due to population growth, urban expansion, industrialization, and agricultural advancements. Irrigation alone accounts for approximately 80% of total water usage, while household consumption is around 10%. As a result, water consumption is increasing at more than twice the rate of population growth, with significant seasonal and annual fluctuations in availability. Additionally, the agricultural sector, historically the largest water consumer, faces growing competition from industrial and domestic demands. This imbalance suggests an impending challenge in ensuring adequate water supply for humans and animals without harming the environment. Moreover, declining water quality is a significant concern, as around 90% of sewage is directly discharged into rivers, lakes, and coastal waters, reducing the availability of clean water. A thorough and organized approach is necessary to overcome these obstacles, enhance water management, and control its usage in developing nations (Omer, 2008). The water cycle, a complex and interdependent component of the Earth's geophysical system, is greatly influenced by climate conditions. Key elements, including wind patterns, temperatures, atmospheric energy distribution, and the movement of clouds and water, are all impacted by changes in the planet's radiation balance (Bağdatli & Arslan, 2019). When freshwater demand in a given area exceeds supply, water scarcity results. Numerous causes, such as population expansion, climate change, and ineffective management of water resources, may contribute to this shortfall (WHO, 2019).

Sudan's water demands are not limited to agriculture; they also include hydropower production, trade, transportation, healthcare, environmental requirements, and industry, mostly agro-based. Despite having a low population density—13 persons per square kilometer on average—more than half of Sudan's population lives on 15% of its territory, mainly in the vicinity of the Nile. 94% of the nation's extracted water is utilized for agriculture, 5% for human and animal usage, and 1% for industry and other uses (Omer, 2008). Reports indicate that Sudan may utilize up to 26 km³ of surface water annually, including its allocated share from the Nile, which is limited to 18.5 km³ per year at Aswan in southern Egypt—equivalent to 20.5 km³ within Sudan before accounting for evaporation and seepage losses—under the 1959 Nile Water Agreement. Additionally, Sudan benefits from 5.5 km³ of water from non-Nile streams. The country heavily depends on the Nile for transportation, agriculture, drinking water, electricity, and recreational activities. Other essential water sources include groundwater reserves and seasonal streams, serving humans and animals (UNEP, 2020). Given the expected impacts of climate change, Sudan must also prepare for increased climate variability and more frequent extreme weather events. Key adaptation strategies include developing policies to mitigate climate change effects, addressing water scarcity through water harvesting, optimizing seasonal streams and rainfall outside the Nile Basin, utilizing groundwater, and cultivating drought-resistant crops. Efficient water management, particularly in irrigated agriculture, is critical to maximizing available resources (Siddig et al., 2020). Water scarcity in Sudan is primarily driven by declining rainfall and rising evaporation rates, threatening food security, rural livelihoods, and public health ((Elsheikh & Nasreldin, 2022). As climate change continues to impact nations worldwide, urgent measures must be taken to minimize its consequences (Bağdatli &Arslan, 2019). Due to the constantly evolving nature of the water industry and fluctuating supply-demand dynamics, Sudan's water policy has changed over time. Limitations like seasonal streams' the Nile's limited storage capacity, and the high expense of pumping groundwater provide serious difficulties on the supply side. Further dam construction is still necessary, especially for harvesting water from seasonal streams, even if the environmental effects of projects must be carefully monitored. Technological developments may enhance the economic feasibility of groundwater monitoring, abstraction, and unconventional water supplies in the future (Omer, 2008). Despite ongoing efforts, millions of Sudanese lack access to clean drinking water. Climate change, inadequate infrastructure, and geopolitical tensions are making water shortages and access to clean and dependable water supplies worse. Regional collaboration, better infrastructure, and sustainable policies are needed to address these issues.

Conclusion

Sudan is facing severe water problems due to climate change-related variables, including rising temperatures and decreasing rainfall. Even though it has a variety of water sources, the amount of water is diminished by siltation, erosion, pollution, and unpredictable rain. To address these issues, Sudan may require costly water projects like dams and desalination plants. Reducing water use, enhancing infrastructure, and using cutting-edge technology are all successful tactics. An ecosystem-based strategy and sustainable management techniques are essential for long-term water security. The Competent authorities should investigate ways to enhance water utilization and create rules to direct and regulate these initiatives. Effective monitoring and adaptation would also be ensured by institutionalizing policy implementation through a robust inspection and audit mechanism. By incorporating sustainable development ideas into laws, Sudan might lessen the effects of climate change and guarantee future water supplies.

Abstract

The increasing resistance of microorganisms to conventional antibiotics necessitates the development of novel antimicrobial agents. Silver nanoparticles (AgNPs) have emerged as an alternative due to their unique properties, such as high surface area to volume ratio and ability to disrupt microbial membranes. This study aims at investigating the phytochemical components, synthesising silver nanoparticles using *Citrus sinensis* peel extract, characterizing, and evaluating their inhibitory activities against some test organisms. *Citrus sinensis* peel extract was used to reduce silver nitrate to AgNPs. Phytochemical analysis was done using standard procedures. UV-Visible spectrophotometry, scanning electron microscopy (SEM), transmission electron microscopy (TEM), Fourier Transform Infared (FTIR), energy-dispersive X-ray spectroscopy (EDX) and X-ray Diffraction (XRD) were used to characterise the AgNPs. The antimicrobial activity was assessed using the agar well diffusion method. Phytochemical analysis revealed that saponins, tannins, flavonoids, alkaloids and phenols were present. Alkaloids (1400 mg/100g) and flavonoids (710 mg/100g) Silver nanoparticles were synthesised and a change in colour from yellow to brown was observed, surface plasmon resonance peak was at 300 nm, the morphology of the AgNPs was spherical, cubical having size ranging from 50 - 150 nm. In the FTIR analysis, the peak at 3466.00 cm^{-1} indicates Hydroxyl groups, 1820.00 cm^{-1} is imine and 1042.00 cm^{-1} is carbonyl and are responsible for the synthesis of AgNPs. XRD analysis confirmed the formation of crystalline nanoparticles. EDX confirmed the presence of silver element. The synthesised AgNPs exhibited significant inhibitory activity against *E. coli* (15±0.32 mm), *K. pnuemonieae* (17±0.45 mm) and *Candida albican* (18±0.24 mm). The green synthesis of silver nanoparticles using *Citrus sinensis* peel extract is an eco-friendly method that utilizes natural properties of plants compounds which has inhibitory potential.

Biyolojik Mücadele Uygulanan Biber Seralarında Farklı Tonlardaki Sarı ve Mavi Yapışkan Tuzaklarda *Orius laevigatus* ve *Creontiades Pallidus*'un Yakalanma Durumunun Belirlenmesi

NurdanTopakcı[1]

[1]Çevre Koruma Teknolojileri Bölümü, Teknik Bilimler Melek Yüksekokulu, Akdeniz Üniversitesi, Antalya, Türkiye

Özet

Ticari olarak temin edilebilen faydalı organizmaların uygulanması, örtüaltı biber üretiminde zararlı türlerin biyolojik kontrolünde önemli başarılar sağlamıştır. Bunlar arasında, *Orius laevigatus* Fieber, serada yetiştirilen biberlerde önemli bir zararlı olan *Frankliniella occidentalis* (Pergande) popülasyonlarını bastırmak için entegre zararlı yönetimi (IPM) programlarında yaygın olarak kullanılmaktadır. Biyolojik ajanlara ek olarak, biber seralarında yaygın olarak sarı ve mavi yapışkan tuzaklar kullanılmakta olup, öncelikli olarak thrips ve beyazsinekleri hedef almaktadır. Ancak, bu renk tuzakları, *O. laevigatus* gibi faydalı böcekler de dahil olmak üzere hedef olmayan organizmaları istemeden yakalayabilir. Bu çalışmada biyolojik mücadele uygulanan biber seralarında zararlı türler için kullanılan farklı tonlardaki sarı ve mavi yapışkan tuzaklarda yararlı tür *O. laevigatus*'un ve özellikle biyolojik mücadele uygulanan seralarda meyvelerde önemli zararlar oluşturabilen zararlı tür *Creontiades pallidus* (Rambur)'un yakalanma durumu araştırılmıştır. Araştırma, 2022 ve 2023 yetiştirme sezonlarında Antalya ilinde bulunan iki ticari biber serasında yürütülmüştür. Toplam altı tuzak renk çeşidi (her biri üç farklı sarı ve mavi tonlarında) bitkilerin üzerine dikey olarak asılmış, haftalık olarak değiştirilmiş ve her bir tuzakta yakalanan birey sayısı kaydedilmiştir. Denemeler tesadüf blokları deneme desenine göre dört tekerrürlü olarak gerçekleştirilmiş ve her hafta toplam 24 adet tuzak kullanılmıştır. Çalışma sonucuna göre tuzak renk tonlarının *O. laevigatus* üzerindeki etkisi istatistiksel olarak anlamlı bulunurken ($P<0,01$), *C. pallidus* üzerindeki etkisi istatistiksel olarak anlamlı olmamıştır. Her iki yıla ait verilere göre, en fazla *O. laevigatus* bireyi açık mavi tuzaklarda kaydedilmiştir. Buna göre biyolojik mücadele uygulanan seralarda zararlılar için kullanılacak yapışkan tuzakların bu renk tonunda seçilmemesi, faydalı türlerin istenmeyen kayıplarının önlemesi için uygun olabilecektir. Ayrıca mavi tuzaklarda yakalanan tripsler ile sarı tuzaklarda yakalanan beyazsineklerin analizinde, her bir rengin farklı tonları arasında yakalanan birey sayılarında istatistiksel olarak anlamlı bir fark olmadığı da ortaya konulmuştur.

Anahtar Kelimeler: *Orius laevigatus, Creontiades pallidus, yapışkan tuzak, biber, sera*

Assessment of the Capture Status of *Orius laevigatus* and *Creontiades pallidus* on Yellow and Blue Sticky Traps with Varying Hues in Biologically Managed Pepper Greenhouses

Abstract

The application of commercially available beneficial organisms has yielded significant success in the biological control of pest species in greenhouse pepper cultivation. Among these, *Orius laevigatus* Fieber is widely utilized within integrated pest management (IPM) programs to suppress populations of *Frankliniella occidentalis* (Pergande), a major pest in greenhouse-grown peppers. In addition to biological agents, yellow and blue sticky traps are commonly employed in pepper greenhouses, primarily targeting thrips and whiteflies. However, these color-based traps can inadvertently capture non-target organisms, including beneficial predatory insects such as *O. laevigatus*. This study aimed to assess the capture status of *O. laevigatus* and the pest species *Creontiades pallidus* (Rambur) which can cause substantial fruit damage, particularly in greenhouses relying on biological control on sticky traps of varying hues of yellow and blue. The research was conducted in two commercial pepper greenhouses located in Antalya Province during the 2022 and 2023 growing seasons. A total of six trap color variants—three distinct hues each of yellow and blue—were deployed vertically on plants, replaced weekly and the number of individuals captured on each trap was recorded. The experiment followed a randomized complete block design with four replications, employing 24 traps per week. Statistical analysis revealed a significant effect of trap hue on *O. laevigatus* captures ($P < 0.01$), whereas no statistically significant effect was observed for *C. pallidus*. According to data from both years, the highest number of *O. laevigatus* individuals was recorded on light blue traps. These findings suggest that the use of light blue sticky traps should be avoided in biologically managed greenhouses to prevent unintended losses of beneficial predator populations. Moreover, analysis of thrips captured on blue traps and whiteflies on yellow traps indicated that there were no statistically significant differences in the number of individuals captured among the different hues of each color.

Key Words: *Orius laevigatus, Creontiades pallidus, sticky trap, pepper, greenhouse*

The Use Of Installation Art In Landscape Desıgns Of Urban Areas

Gülden Sandal Erzurumlu[1], Umut Poyraz[2]

[1] Department of Landscape Architecture, Faculty of Architecture, Niğde Ömer Halisdemir University, Niğde, Türkey

Abstract

One of the fundamental characteristics of the nature of visual arts is the deep presence of an aesthetic dimension; this feature makes visual arts unique. However, they not only carry aesthetic value but also possess functional qualities, thus becoming a discipline with striking potential by combining beauty and functionality. In this context, the field of visual arts encompasses both functional and aesthetic features and contributes significantly to the visual appeal of public spaces. Standard design practices often reduce the effectiveness of a space. Therefore, it is necessary to continuously integrate new approaches into design efforts. One such approach is the use of installation art.

As a result, this study aims to increase awareness and appreciation for landscape design practices. In this regard, it is recommended that governments and local communities commission works from artists by considering their emotional and therapeutic effects, which enrich public spaces. Furthermore, artists should be encouraged to produce larger-scale works that serve as monumental structures and enhance the aesthetic experience of the public environment.

The purpose of this study is to identify the areas of use for installation applications in landscape design, to present visual examples, and to develop recommendations.

Key Words: *Installation Art, Niğde, Landscape Architecture, Urban Design, Public Art*

Kent Alanlarının Peyzaj Tasarımlarında Enstalasyon Sanat Kullanımı

Özet

Görsel sanatların doğasının temel niteliklerinden birisi, estetik boyutun derin bir şekilde yer almasıdır; bu özellik, görsel sanatları benzersiz kılmaktadır. Bununla birlikte, sadece estetik bir değer taşımakla kalmayıp işlevsel niteliklere de sahiptir; yani, hem güzelliği hem de işlevselliği bir araya getirerek dikkat çekici bir potansiyele sahip bir disiplin hâline gelmektedir. Bu bağlamda, görsel sanatlar alanı hem işlevsel hem de estetik özellikleri bünyesinde barındırır ve tasarım alanlarının görsel çekiciliğine önemli katkılar sunar. Standart tasarım uygulamaları alanın etkililik derecesini düşürmektedir. Bu nedenle, tasarım çalışmalarına sürekli yeni uygulamalar eklemek gerekmektedir. Bunlardan birisi enstalasyon çalışmasıdır.

Sonuç olarak bu araştırma, peyzaj tasarım çalışmalarına yönelik farkındalığı ve takdiri artırmayı hedeflemektedir. Bu nedenle, hükümetlerin ve yerel toplulukların, kamusal alanları zenginleştiren, duygusal ve terapötik etkileri de göz önünde bulundurarak sanatçılardan eserler sipariş etmeleri önerilmektedir. Ayrıca sanatçılar, hem anıtsal yapılar olarak hizmet edecek hem de kamusal çevrenin estetik deneyimini artıracak daha büyük ölçekli eserler üretmeleri konusunda teşvik edilmesi amaçlanmaktadır. Aynı zamanda, enstalasyon uygulamalarının peyzaj tasarım çalışmalarında kullanım alanlarını belirlemek, çizim örnekleri sunmak ve öneriler geliştirmektir.

Anahtar Kelimeler: *Enstalasyon, Niğde, Peyzaj Mimarlığı, Tasarım, Sanat*

Giriş

Enstalasyon sanatı, postmodern felsefe ve estetiğin etkisi altında ortaya çıkan yeni bir sanat kategorisi olan çağdaş bir sanat türüdür. Enstalasyon sanatı, insanların yaşam deneyimlerinin bir uzantısıdır ve izleyicinin katılımı, enstalasyon sanatının ayrılmaz bir parçasıdır. Enstalasyon sanatı yaratım ortamı, izleyiciyi belirlenmiş bir mekânda pasif izleyicilikten aktif hissetme durumuna dönüştürür. Bu süreçte yalnızca zihinsel düşünme ve bedensel müdahale değil, aynı zamanda görme, işitme, dokunma, koku alma ve tat alma duyuları da kullanılır.

Enstalasyon sanatının en önemli özelliklerinden biri, gündelik hayatın olağan akışını bozmasıdır. Bu tür bir yer değiştirme sonucunda izleyici, eseri kolayca kabul etmek yerine çok boyutlu bir anlamlandırma sürecine girmek zorunda kalır. Kullanılan malzemeler çoğunlukla günlük nesneler ve endüstriyel ürünlerden oluşur. Zemine yerleştirilen heykeller gibi unsurlar nedeniyle, geleneksel çerçeve sanatlarından ayrılır ve izleyicinin eseri farklı açılardan değerlendirmesini, çeşitli çağrışımlar yapmasını ve hatta eserin sergilendiği ortamla ilişkisini sorgulamasını ister.

Enstalasyon sanatı herhangi bir türle sınırlandırılmaz ve resim, dokunsal modeller, mimari, müzik, tiyatro, şiir, deneme, sinema, televizyon, ses, video ve fotoğraf gibi çeşitli sanat dallarını özgürce bir arada kullanabilir (Liang, 2007). Enstalasyon sanatı, basitçe ifade edilirse, "mekân + malzeme + duygu" bileşiminden oluşan bir sanat biçimidir.

Günümüzde, insanlar kentsel tasarıma giderek daha fazla önem vermekte ve sanatsal beğenileri giderek yükselmektedir. İyi bir kentsel alan tasarımı, insanların bu alanlara olan ilgisini artırırken, ekonomik gelişime de büyük katkı sağlamaktadır. Kentin manevi kültürünü temsil eden unsurlar olarak görülebilir ve bu alanlardaki enstalasyon sanatının tasarımı, kamusal alanın bireyselliğini, sanatsal yönünü ve kompozisyonunu doğrudan etkilemektedir.

Bu nedenle, insanların kentlerde beklentilerini karşılamak ve şehrin manevi gelişimiyle uyum sağlamak adına, kentsel alanlarında enstalasyon sanatının tasarımını incelemek büyük bir pratik öneme sahiptir. Kentsel alanlardaki sanat tasarımları, sadece şehrin sanat anlayışını yansıtmakla kalmaz, aynı zamanda kentsel alan tasarımına dair düşünce yapısını da ortaya koyar ve en önemlisi, halkın şehrin ruhuna yönelik ihtiyaçlarını karşılamayı amaçlar.

İnsanların manevi dünyaya yönelik artan beklentileriyle birlikte, sanat tasarımının içeriği günlük yaşamın her alanında görülmektedir. Kentsel kamusal alanlar, yalnızca bir şehrin kültürünü temsil etmekle kalmaz, aynı zamanda insanların kente ruhsal bakış açısını da yansıtır. Bu nedenle, kentsel alanlarda dekoratif sanat tasarımının uygulanması, şehrin dikkatini sürekli olarak artıracak ve farklı yenilikçi tasarım fikirlerinin şehir içinde hayata geçirilmesine olanak tanıyacaktır .

Günümüzde, enstalasyon sanatının kentsel alanlarda uygulanması, toplumsal gelişimin kaçınılmaz bir trendi haline gelmektedir. Bu yalnızca yüksek bir uygulanabilirliğe sahip olmakla kalmaz, aynı zamanda yerel ekonomik kalkınmayı da teşvik etme konusunda önemli bir rol oynar.

Kentsel alanların peyzaj enstalasyon sanatı tasarımı, sanatın kapsayıcılığını ve açıklığını gösteren bir olgudur. Bu anlayış, enstalasyon sanatının tasarımında hem ön koşul hem de temel oluşturur. Bu tasarım sadece sanat formunun yeniliğini değil, aynı zamanda şehir sakinlerinin estetik algısını ve estetik gelişimini de içerir.

Kentsel alanların kendine özgü bir sürdürülebilirliği vardır ve insanların günlük yaşamlarında dinlenmek için tercih ettikleri yerler arasında bulunur. Bu nedenle, kentsel alanlarda yapılan enstalasyon sanatı tasarımları, doğrudan şehir sakinlerinin mutluluğunu etkileyebilir. Sanatın farklı ifade biçimleri vardır ve her kentin kendine özgü sanatsal biçimlerini sergiler.

Dekoratif sanat tasarımı, kentsel alanlara ruh katar; bu da şehrin genel yapısını ve kent sakinlerinin estetik anlayış seviyesini yansıtır. Günümüzde insanların sanatsal beğenisi giderek daha fazla çeşitlilik gösterse de enstalasyon sanatının işlevi kanıtlanmış olup, toplum tarafından kolayca kabul edilebilir bir hale gelmiştir. Böylece, instalasyon sanatı zamanla kent estetiğinin önemli bir temsilcisi olma yolunda ilerlemektedir.

Toplumun gelişmesi ve zamanın değişmesiyle birlikte geleneksel estetik anlayışı da sürekli dönüşmektedir. Kentsel alanlarla enstalasyon sanatının bütünleşmesi, bu güzelliği somutlaştırarak kent medeniyetinin gelişimini teşvik edecek ve topluma farklı yaşam deneyimleri sunacaktır.

Kentsel alan tasarımı ve enstalasyon sanatı, her ikisi de sanatın birer biçimi olup, hatta belirli benzerlikler taşımaktadır. Bu durum analiz edildiğinde, iki unsurun birbirine entegre olmasında büyük bir direnç olmadığı görülebilir.

Günümüzde ülkemizin gelişimi nispeten istikrarlı bir seyir izlemekte, sosyal ekonomi de ilerlemekte ve toplum sanata geniş bir hoşgörü ile yaklaşmaktadır. Bu olumlu sosyal ortam, sanat tasarımına daha geniş bir yaşam alanı sunarak, kültürel çeşitliliğin ve kültürel kapsayıcılığın bir göstergesi haline gelmiştir.

Kentsel alan enstalasyon sanatının tasarımı, bir şehrin sembolü olmasının yanı sıra, aynı zamanda kentin ruhsal perspektifinin de bir yansımasıdır. Şehir gelişim sürecinde vazgeçilmez ve önemli unsurlardan biridir. Enstalasyon sanatı bir sanat ifade biçimi olarak ele alındığında, kent gelişiminin özelliklerini yansıtan tasarım içeriklerine odaklanabilir. Aynı zamanda, bu sanat biçimi, kentsel ekonomik ve kültürel gelişimi teşvik eden temel itici güçlerden biri olarak da öne çıkmaktadır.

İnteraktif sanat ve çevresel tasarımın kesişim noktası olarak kabul edilen instalasyon sanatı, peyzaj tasarımında salutojenik etkiler yaratma potansiyeline sahiptir. Salutojenik tasarım, bireylerin sağlığını ve refahını destekleyen mekânlar oluşturmayı amaçlayan bir yaklaşımdır. Bu bağlamda, instalasyon sanatı aşağıdaki yollarla peyzaj tasarımında salutojenik etkiler yaratabilir:

Enstalasyon Sanatına Salutojenik Etki

Salutojenik yaklaşım, kişilerin/toplumların fiziksel ve zihinsel yönden sağlıklı olmalarını teşvik ederken hastalığın kaynakları yerine sağlığın kökenlerine odaklanan bir modeldir (Karaca, 2018). Bu yaklaşım mimari tasarımlarda uygulama alanı bulmaktadır. Salutojenik tasarımda mekanın insanlar üzerinde yarattığı olumsuz etkiyi en az seviyeye indirgemenin yanısıra diğer yandan bozulmuş sağlığın tedavi edilmesi açısından da kritik bir rol oynamaktadır (Özgön, 2022). Bu çerçevede toplum ruh sağlığı merkezlerde yapılan uygulamalar büyük önem arz etmektedir. Örneğin, bitki terapi bahçeleri hastaların ihtiyaç, istek ve becerilerine uygun olarak tasarlandığında tedavi sürecine olumlu etki eden uygulamalardan birisi olmuştur (Satıl & Aktaş, 2021). Bir başka deyişle, mekansal örüntü içerisinde öznenin eyleyici kılınmasının tedavi üzerine olumlu etkileri görülmektedir.

Bu süreci, katılımın odak olduğu, mekan ile birlikteliğin sağlandığı bir sanat türü olan enstalasyon uygulamaları destekleyecektir. "Enstalasyon sanatı, tıpkı mimarlık, bilim ve teknolojide olduğu gibi, peyzaj mimarlığı alanına dahil edilmiştir." (Durdymyradov & Ak Erken, 2023). Enstalasyon, kullanımına el verdiği farklı materyaller açısından çeşitli peyzaj unsurlarının da değerlendirilebileceği bir sanat türü olarak da yorumlanabilir. Bu bağlamda, salutojenik mimari uygulanarak tasarlanmış toplum sağlığı merkezlerinde tedavi gören hastalara, peyzaj materyalleri ile enstalasyon sanatı uygulama alanları sunulması planlanmaktadır. Hastaların üreteceği ya da parçası olacakları sanat eserlerinin belirli aralıklarla sergilenmesi sağlanarak toplumsal entegrasyon ve farkındalığın geliştirilmesi hedeflenmektedir.

1. Duyusal ve Estetik Uyarım

Sanat enstalasyonları, doğayla etkileşim içinde olan renkler, formlar, ışık oyunları ve malzeme kullanımlarıyla psikolojik rahatlama sağlayabilir**.** Doğayla bütünleşen sanat eserleri, stres seviyelerini düşürerek dinginlik ve huzur hissi yaratır (Şekil 1)**.**

Şekil 1. Doğayla bütünleşen sanat eserleri (Sağ resim (Anonim, 2021)).

2. Katılımcı ve Etkileşimli Mekânlar

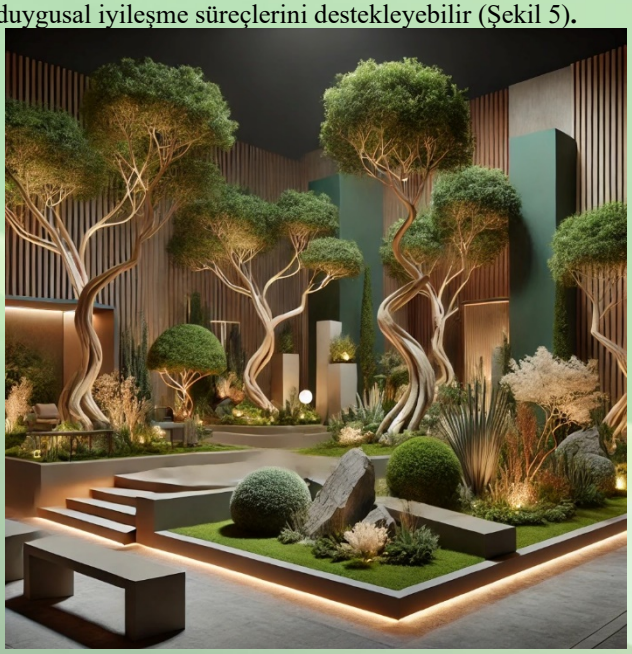
Özellikle kentsel peyzajlarda konumlandırılan sanat enstalasyonları, bireylerin mekânla etkileşime girmesine ve fiziksel aktiviteyi teşvik etmesine olanak tanır. Örneğin, dokunulabilir yüzeyler, akustik deneyimler veya hareketle değişen sanat eserleri**,** bireylerin çevreyle bağ kurmasını sağlar (Şekil 2).

Şekil 2. Hareketle değişen sanat eserleri

3. Doğa ile Bağlantıyı Güçlendirme

Biyofilik tasarım ilkeleriyle harmanlanan sanat enstalasyonları, insanların doğayla duygusal bağ kurmasına yardımcı olabilir. Örneğin**,** su öğeleriyle bütünleşen sanat eserleri**,** meditasyon alanları veya doğadan ilham alan formlar, bireylerde zihinsel rahatlama ve yenilenme hissi yaratır (Şekil 3)**.**

Şekil 3. Doğadan ilham alma sanatı (Anonim, 2020).



Doğal unsurlardan yararlanarak yapılan tasarımlar insanlar üzerinde görsel etkililik yaratmaktadır. Bitkiler, su öğeleri, doğal ışık kullanımı vb. öğeler doğayı yansıtmaktadır (Şekil 4).

Şekil 4. İnstalasyon tasarımında bitki kullanımı (Anonim, 2020).

4. Duygusal İyileşme ve Anlamlı Deneyimler

Sanat, bireylerin kendilerini ifade etmelerine, anılarını canlandırmalarına ve topluluklarla bağ kurmalarına yardımcı olabilir. Özellikle hastane bahçeleri, terapi bahçeleri veya kentsel alanlarda yer alan anlam yüklü enstalasyonlar, bireylerin duygusal iyileşme süreçlerini destekleyebilir (Şekil 5).

Şekil 5. Kentsel alanlarda yer alan anlam yüklü enstalasyonlar

5. Mekânsal Algıyı ve Harekete Geçirici Gücü Artırma

İyi tasarlanmış bir sanat enstalasyonu, insanları belirli bir rotada hareket etmeye teşvik edebilir. Örneğin**,** ışık ve gölge oyunlarıyla yönlendirilmiş yürüyüş yolları, bireyleri mekânın farklı köşelerini keşfetmeye itebilir. Bu durum, peyzajda aktif kullanım ve keşif duygusunu artırabilir (Şekil 6)**.**

Kısacası, instalasyon kullanılarak yapılan salutojenik tasarım, sağlığı ve iyilik halini teşvik eden mekanlar yaratmayı amaçlar. Bir enstalasyon tasarımında bu etkiyi görselleştirmek için doğal unsurlar **(** Bitkiler, su öğeleri, doğal ışık kullanımı), Akışkan formlar (Organik ve yuvarlak hatlı yapılar), duyusal deneyim (Yumuşak dokular, doğal malzemeler, rahatlatıcı renkler), etkileşimli alanlar kullanıcıların zihinsel ve fiziksel olarak aktif olabileceği tasarım ögelerinden yararlanılarak mekanlar oluşturmak kentlerde olumlu etkiler yaratmaktadır.

Şekil 6. Işık ve gölge oyunlarıyla yönlendirilmiş yürüyüş yolları (Anonim, 2021).

Sonuç

Peyzaj tasarımında instalasyon sanatı, estetik deneyimin ötesine geçerek zihinsel rahatlama, fiziksel aktivite, toplumsal bağ ve doğayla etkileşim gibi pek çok salutojenik fayda sağlayabilir. Bu nedenle, sanat ve doğayı birleştiren yenilikçi yaklaşımlar**,** sürdürülebilir ve sağlığı destekleyen kamusal alanlar yaratmada önemli bir rol oynayabilir.

Sanat enstalasyonlarının salutojenik etkisi, bireylerin hem bireysel hem de kolektif düzeyde daha sağlıklı, mutlu ve bağlı hissetmelerine katkıda bulunur. Bu tür tasarımlar, kentlerin ve yaşam alanlarının daha yaşanabilir, sürdürülebilir ve insan merkezli olmasını sağlar**.**

Abstract

The most important variable in ensuring production independent of climate conditions in greenhouses is the provision of heating facilities. Especially in conditions where the air temperature is low, the desired temperature must be provided in the greenhouse for optimum plant development. In addition, the high cost of heating facilities has caused greenhouse farming to remain limited in some of our regions. In this respect, the provision of heating facilities provided by natural resources has become important in terms of the regional spread of greenhouse farming. Sustainable and low-cost heating facilities can be used without harming the environment by using natural resources in greenhouses. In this study, the development of heating facilities with geothermal resources in Kırklareli province, where greenhouse farming is not very developed, was investigated. In this context, potential geothermal resources in Kırklareli province were investigated within the scope of the literature and the heating potentials of the obtained geothermal resources were revealed. In the study, the potential for use of the newly found geothermal energy source in the Kırklareli - Asılbeyli region was revealed. Within the scope of this potential, the current status of greenhouse activities in Kırklareli province was determined in terms of heating with geothermal resources. With the research conducted, it can be concluded that greenhouse farming has a development potential with the increase in studies on finding existing geothermal resources in Kırklareli province. In addition, further research on heating greenhouse activities with natural resources in the region will have a positive impact on greenhouse-based production. The results obtained have shown that production in greenhouses using geothermal resources in Kırklareli province will contribute to the development of greenhouse farming in the province.

Key Words: *Greenhouse, Geothermal energy, Greenhouse Air Conditioning, Heating, Kırklareli.*

Introduction

Greenhouses are facilities where suitable environments for plant cultivation are created by controlling the environmental conditions depending on the climate. Creating optimum conditions in the greenhouse is only possible by equipping the greenhouses with systems such as heating, cooling, lighting, ventilation and humidification. Today, cultivation is carried out in automatic and fully controlled greenhouses in countries with cool climate zones such as England and the Netherlands. In countries with temperate climate zones, including our country, greenhouse cultivation has developed depending on ecological conditions (Tüzel et al., 2010).

The most important variable in ensuring production in greenhouses independent of climate conditions is the provision of heating facilities. Especially in conditions with low air temperatures, the desired temperature inside the greenhouse must be provided for optimum plant development. In this respect, temperature is one of the most important elements of the climate to be created inside the greenhouse. It is a known fact that every 10 °C increase in the temperature inside the greenhouse increases plant development approximately two-fold, provided that the other elements that make up the greenhouse climate are also at appropriate values and that the highest temperature allowed for the plant being grown is not exceeded (Yağcıoğlu, 2005).

The desired level of cultivation in greenhouses can be achieved by providing the desired conditions for the plants in the greenhouse. The purpose of heating, which has an important place in greenhouse air conditioning, is to increase yield and quality by successfully using heating systems to create the temperature desired by the plants in the greenhouse during cold times. One of the most important inputs of production in greenhouses is heating. Heating costs constitute 60% of all costs in the greenhouse. (Harzadın, 1994).

In greenhouse heating, some factors should be taken into consideration in terms of plant cultivation. The critical factor in the effectiveness of the heating system is not the air temperature inside the greenhouse, but the leaf and root temperature of the plant. The photosynthetic activity of the plant depends not only on the leaf temperature but

also on the speed and direction of air flow. The heat balance of the plant canopy also depends on the root temperature. It is possible to affect the air temperature by changing the root temperature (Gül et al., 1994).
One of the most important inputs in greenhouse production is heating. Heating costs constitute 60% of all greenhouse costs. Heating is done in very few greenhouses in our country. In most greenhouses, heating is done for a very limited time as a frost protection measure. Not heating greenhouses reduces yield, but it is possible to get products at certain times when the price is not high, hormone use for fertilization is difficult and therefore unhealthy products are produced (Harzadın, 1994).

Heating systems that can be used in greenhouses can be classified under different names. These heating systems are named as stove heating, central heating, hot air heating, heat pump heating, solar energy heating and geothermal energy heating. (Yağcıoğlu, 2005;Günay, 1999).

Among the renewable energy sources, geothermal, which is one of the most important, offers many benefits, like other renewable energy sources, to the energy sector and therefore to the countries. According to one definition, geothermal energy is a type of energy that is formed when the heat formed under the earth's crust heats the underground waters and then this water rises to the surface (Çukurçayır and Sağır, 2008). Geothermal energy is a type of energy that is difficult to consume, provided that it is used correctly. On the other hand, it is easy to detect and produce. It is also low-cost and the investment returns in a short time. It is also less harmful to the environment compared to other sources. Due to all these features, it is preferred not only in electricity production but also in different areas of the industry, in the health sector, in agriculture and tourism sectors, which are different but support each other (Külekçi, 2009).

Our country ranks 1st in Europe and 7th in the world in terms of geothermal energy potential with 31,500 MWt. As of 2004, we have only been able to benefit from 3-3.5% of this potential. Turkey ranks 5th in the world with 992 MWt in terms of direct use applications such as regional heating, greenhouse heating and thermal spring utilization (Dağdaş, 2004).

In the first studies on the use of geothermal resources in greenhouse heating, the use of fluids with a temperature of at least 60 °C was recommended. Later, it was determined that this lower limit was sufficient to be 20 - 25 °C. For example, it is known that projects using geothermal waters with a temperature of 40 °C in Italy, 34 °C in Greece, and 52 °C in Czechoslovakia have yielded quite successful results. In Israel, geothermal waters with a temperature of 30 - 60 °C are used for greenhouse heating in the winter, while some of these resources are also used for irrigation in the summer. In Sivas, it has been shown that greenhouse heating by circulating hot water with a temperature of 46 °C in plastic pipes located above and below the ground is sufficient for plant production (Kasap et al., 1990).

In this study, the development of heating opportunities with geothermal resources in Kırklareli province, where greenhouse farming has not shown much development, has been investigated. In this context, potential geothermal resources in Kırklareli province have been investigated. The heating potentials of the obtained geothermal resources have been revealed. In the study, the potential use of the newly found geothermal energy source in the Kırklareli Asılbeyli region has been revealed. Within the scope of this potential, the potential that can be heated with geothermal resources has been determined within the scope of the literature within the scope of the current situation of greenhouse farming in Kırklareli province. With the research, it can be concluded that greenhouse farming has a development potential with the increase in the studies on finding the existing geothermal resources in Kırklareli province. In addition, conducting more and detailed studies on heating greenhouse farming studies with natural resources in the region will have positive effects on greenhouse-based production. According to the results obtained within the scope of the literature, it has been seen that production in greenhouses by utilizing geothermal resources in Kırklareli province will contribute to the development of greenhouse farming in the province.

Materials and Methods

The research investigated the possibilities of developing heating opportunities with geothermal resources in Kırklareli province, where greenhouse farming has not shown much development. In this context, potential geothermal resources in Kırklareli province were investigated. The geographical location of the research area Kırklareli province is given in Figure 1.

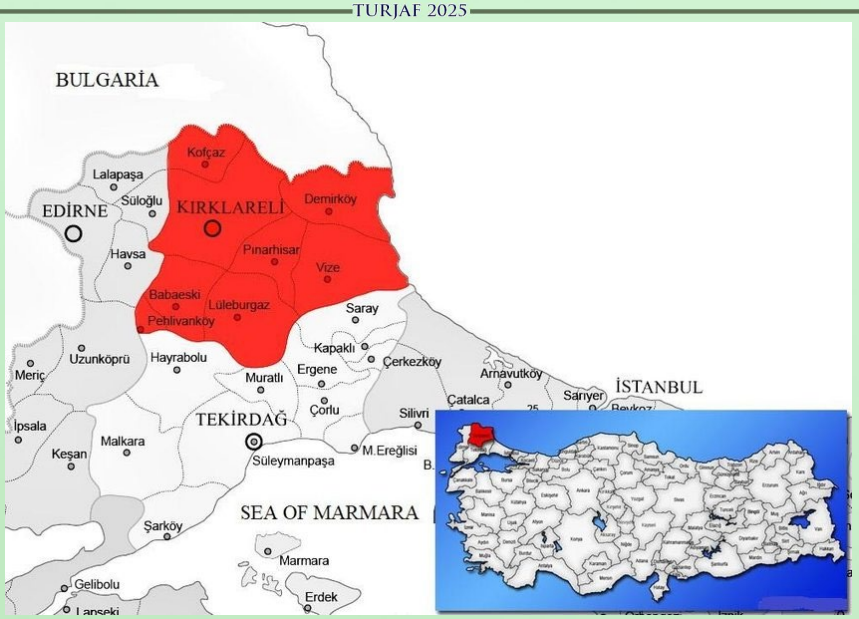

Figure 1. Research area

Kırklareli is located in the Thrace Region of Turkey and the annual average temperature is determined as 13.4 °C. The average sunshine duration is 4.6 hours and the average number of rainy days is determined as 98.6 days. When the maximum temperature values are examined, it is seen that the lowest temperature is -15.6 °C and the highest temperature is 42.5 °C. (MGM, 2025) The climatic values of the region are given in Table 1.

Table 1. Climatic values of Kırklareli province (MGM, 2025)

Kırklarelı/Months	1	2	3	4	5	6	7	8	9	10	11	12	Annual
Average Temperature (°C)	3,0	4,2	6,9	12,1	17,1	21,5	23,9	23,7	19,4	14,1	9,3	5,2	13.4
Average Highest Temperature (°C)	6,9	8,7	12,2	18,0	23,0	28,1	30,7	30,7	26,2	20,0	13,9	8,8	19,0
Average Minimum Temperature (°C)	0,1	1,0	3,0	7,2	11,6	15,6	17,9	17,8	14,1	9,9	5,9	2,4	8.9
Average Sunbathing Time (hours)	2,0	2,6	3,6	4,8	6,4	7,0	7,6	7,6	5,6	4,0	2,7	1,8	4,6
Average Number of Rainy Days	11,05	9,05	9,26	10,33	10,00	8,58	4,71	3,59	4,85	6,91	8,55	11,29	98.2

Lowest Temperature (°C)	-15,8	-15,0	-11,8	-3,0	1,4	5,8	8,8	8,7	3,0	-3,4	-7,2	-11,1	-15.8

Results and Discussion

When the greenhouse presence of Kırklareli province is examined, it is seen that greenhouses with plastic covers come to the forefront according to the covering material. Although there are no glass greenhouses, when the data of the last 20 years are examined, it is seen that the amount of greenhouses with plastic covering material has increased approximately 20 times. (TÜİK, 2025) The greenhouse amounts of Kırklareli province in the last 20 years are given in Figure 2.

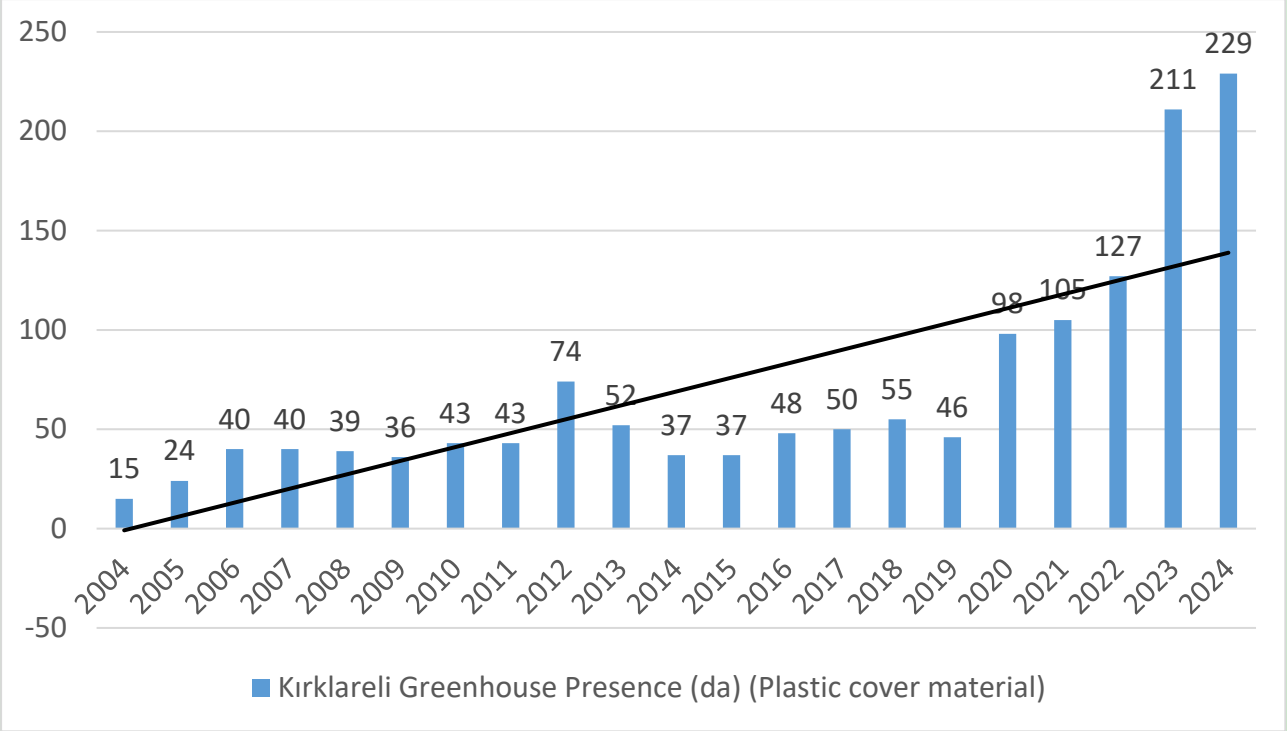

Figure 2. Greenhouse presence in Kırklareli province

Within the scope of the research, in order to determine the geothermal energy capacity in the region, research was conducted from many sources such as the Ministry of Energy and Natural Resources, Mineral Research and Exploration (MTA), Energy institutes and organizations. An existing geothermal energy potential was found in Asilbeyli Village, which is affiliated to the central district of Kırklareli province. (MTA, 2017-a). The people of Asilbeyli, which is 6 km away from the city center, generally work in agricultural areas. The area with potential geothermal energy is given in Figure 3.

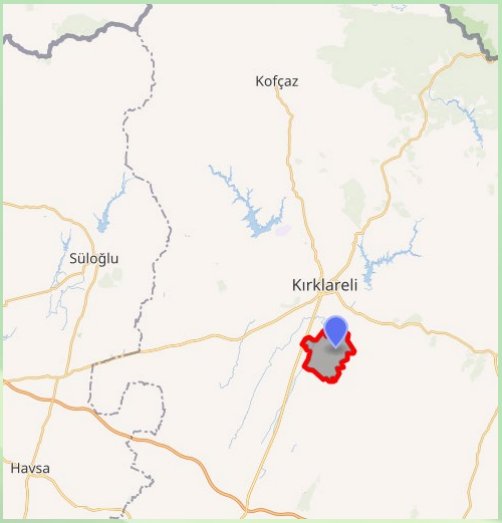

Figure 3. Potential geothermal energy field of Kırklareli province

The depth of the geothermal reservoir in the region is 1500 m. According to well test data, the maximum well static temperature is 74.38 °C at 1476 meters. According to the water loss test, the reservoir level is approximately 1100-1200 meters, which shows that the temperature is between 55 °C and 64 °C. The energy potential of the well is suitable for direct use applications such as home heating, greenhouse farming and thermal tourism. (MTA, 2017-a).

According to the data obtained as a result of the studies carried out in the first stage, the well has an energy potential of 2.38 MWt (MW thermal). Since Kırklareli has an important agricultural production, using this resource in

agricultural production in a reliable and environmentally friendly manner will be one of the best evaluation methods. (MTA, 2017-b).

In terms of using geothermal energy in greenhouse heating, it is aimed to find an optimum value in terms of flow rate with water inlet-outlet and pipe-environment equation combinations. As a result of the studies carried out in this context, greenhouses can be heated in an area of approximately 15 decares according to the thermal energy potential of the well in the region (MTA, 2017-b). This rate is approximately 20% of the plastic greenhouse assets of Kırklareli province. (TÜİK, 2025). This amount may vary with the type of greenhouse, the cover material used in greenhouses, the climatic requirements of the agricultural products to be grown and the detailed determination of the greenhouse heating needs.

Conclusion

Within the scope of the research, it has been seen that it is possible to use geothermal energy in greenhouse heating in Kırklareli province in the light of the literature. According to the current data and initial studies, the geothermal resource in the region can be used in a greenhouse of approximately 15 decares. This amount may vary depending on the product to be grown, the type of greenhouse and the new resources that may be found in the future. This situation may accelerate the development of greenhouse farming in Kırklareli province. The availability of geothermal energy in the region will also increase the use of different renewable energy resources. The use of geothermal energy will positively contribute to the design of greenhouse heating systems that integrate wind and solar energy. It will positively contribute to the development of the region and employment conditions. The decrease in cost with the use of geothermal resources, which is a renewable energy, in greenhouses will be positively reflected in food prices.

As a result, it can be said that the discovery of a new geothermal source in the province of Kırklareli will have a positive effect on the development of greenhouse farming in the region. In this context, considering the potential of finding new geothermal sources in the future, it is recommended to increase the development of geothermal heating systems in greenhouses. Optimum use of geothermal energy according to the plant requirements to be grown in greenhouses, calculation of system capacities and creation of the most appropriate architectural design for the region will accelerate the development of greenhouse farming.

Yenilebilir Peyzaj Bahçelerinin Üniversite Öğrencileri Üzerindeki Etkileri: Selçuk Üniversitesi Örneği

Ahmet Akay[1], Gözdenur Yılmaz[2]

[1]Peyzaj Mimarlığı Bölümü, Mimarlık ve Tasarım Fakültesi, Selçuk Üniversitesi, Konya, Türkiye
[2]Peyzaj Mimarlığı Anabilim Dalı, Fen Bilimleri Enstitüsü, Selçuk Üniversitesi, Konya, Türkiye

Özet

Bu çalışma, Selçuk Üniversitesi kampüsünde oluşturulan yenilebilir peyzaj bahçesinin üniversite öğrencileri üzerindeki etkilerini araştırmayı amaçlamaktadır. Günümüz kentlerinde sosyolojik, ekonomik, ekolojik ve kültürel farkındalıkların artmasıyla birlikte yenilebilir peyzaj kavramı büyük önem kazanmıştır. Bu yaklaşım, kent sakinlerine doğrudan ve sağlıklı gıda sağlama, kentsel biyoçeşitliliği destekleme, topluluklar arası iş birliğini güçlendirme, çevre eğitimi fırsatları yaratma ve sürdürülebilirlik hedeflerine ulaşma gibi çeşitli önemli katkılar sunmaktadır. Çalışmanın temelini oluşturan ilk aşamada, Selçuk Üniversitesi öğrencilerinin yenilebilir peyzaj kavramına dair mevcut bilgi düzeyleri incelenecek ve bu alanların potansiyel faydalarına ilişkin farkındalıkları bir anket çalışması aracılığıyla belirlenecektir. Anketin sonraki bölümlerinde ise bahçeyi aktif olarak kullanan öğrencilere yönelik sorular yöneltilecektir. Bu sorular aracılığıyla öğrencilerin bahçeyi ne sıklıkta ziyaret ettikleri, hangi amaçlarla kullandıkları ve bahçeye yönelik genel memnuniyet düzeyleri gibi önemli veriler toplanarak kullanım sonrası değerlendirmeler yapılacaktır. Elde edilen verilerin analiz edilmesiyle, öğrencilerin yenilebilir peyzaj konusundaki genel bilgi birikimleri ve bilinç düzeyleri ile birlikte kampüs içerisindeki yenilebilir peyzaj bahçesine karşı geliştirdikleri tutumlar ve bahçeyi kullanma alışkanlıkları bütüncül bir şekilde ortaya konulacaktır. Araştırma sonucunda, bir üniversite kampüsünde hayata geçirilen yenilebilir bitkiler bahçesinin öğrencilerin yaşamları üzerindeki çeşitli etkileri değerlendirilecektir. Buna ek olarak, elde edilen bulgular ışığında gelecekte benzer yenilebilir peyzaj uygulamalarının daha başarılı bir şekilde hayata geçirilmesi için somut ve uygulanabilir öneriler sunulması temel hedeflerden biridir.

Alışveriş Merkezi Otoparklarında Gölge Ağaçlarının İncelenmesi ve Peyzaj Tasarım Önerisi: Konya M1 AVM Örneği

Ahmet Akay[1], Gözdenur Yılmaz[2]

[1]Peyzaj Mimarlığı Bölümü, Mimarlık ve Tasarım Fakültesi, Selçuk Üniversitesi, Konya, Türkiye
[2]Peyzaj Mimarlığı Anabilim Dalı, Fen Bilimleri Enstitüsü, Selçuk Üniversitesi, Konya, Türkiye

Özet

Bu çalışma, Konya M1 AVM otoparkındaki gölge ağaçlarının detaylı bir incelemesini yaparak, sürdürülebilirlik prensipleri ve kullanıcı ihtiyaçları doğrultusunda geliştirilmesine yönelik kapsamlı bir peyzaj tasarım önerisi sunmayı hedeflemektedir. Günümüzde kentlerdeki geniş geçirimsiz yüzeylerin önemli bir bölümünü oluşturan otoparklar, kentsel ısı adası etkisini tetikleyerek, çevresel sorunlara ve kent estetiğinin olumsuz etkilenmesine neden olabilmektedirler. Bu nedenle, otopark alanlarına yapılacak bitkisel tasarım, özellikle uygun ağaç türlerinin seçimi ve doğru konumlandırılması ile doğrudan gölgeleme sağlayarak otopark yüzeylerinin ve çevredeki havanın sıcaklığını önemli ölçüde düşürebilir. Bu çalışma, Konya M1 AVM otoparkında bulunan mevcut ağaçların tür çeşitliliğini, büyüklüklerini, taç yapılarının gölgelendirmedeki etkinliğini ve genel sağlık durumlarını bilimsel yöntemlerle değerlendirecektir. Ayrıca, otopark kullanıcılarının gölge beklentileri, termal konfor algıları ve otoparkın genel estetiğine yönelik görüşleri dikkate alınarak otopark için ekolojik açıdan sürdürülebilir, estetik ve kullanıcı konforunu ön planda tutan yenilikçi bir peyzaj tasarım projesi geliştirilecektir. Önerilen proje, maksimum düzeyde gölge sağlayacak, park halindeki araçların aşırı ısınmasını engelleyecek ve dolayısıyla araç içi sıcaklığı düşürerek klima kullanımını azaltmaya yardımcı olacaktır. Bu doğrultuda proje kapsamında kullanılacak ağaç türleri, ideal dikim mesafeleri ve yerleşim planları detaylı olarak sunulacaktır. Aynı zamanda, seçilecek ağaçların mevcut ortama görsel bir zenginlik katması ve otopark kullanıcılarının memnuniyet düzeyini artırması hedeflenmektedir. Bu çalışmanın sonuçlarının, benzer özelliklere sahip alışveriş merkezi otoparklarının termal konforunu iyileştirme ve kullanıcı deneyimini zenginleştirme konularında uygulanabilir ve ilham verici bir model sunması öngörülmektedir.

Abstract

In many rural areas of West Africa, the consumption of lipids by farmers is one of the problems affecting their nutrition and even their health. In Côte d'Ivoire, tiger nut, consumed as part of the traditional diet of rural populations in the north and centre of the country, is a potential source of dietary lipids. The aim of this study was to contribute to the valorisation of tiger nuts (*Cyperus esculentus*) through the physico-chemical characterisation of the oil extracted from tubers from three regions of Côte d'Ivoire. To do this, samples of tiger nut tubers were collected and the oil was extracted using standard methods. Tiger nut oils exhibited satisfactory physicochemical characteristics, with acid value ranging from 0.13 to 3.14 mg KOH/g oil, iodine value from 68.92 to 94.54 g I_2/100 g oil and saponification value from 174.2 to 185.13 mg KOH/g oil. The oils were rich in polyunsaturated fatty acids, with oleic acid being the most abundant (73 - 80%) and demonstrated greater oxidative indexes. Tiger nut oil from the three regions contained significantly higher levels of α-tocopherols and polyphenols. Due to these characteristics and nutritional properties, tiger nut oil presents significant potential for application in food, nutraceutical and cosmetic industries.

Keywords**:** *Tiger nut tubers; oil extract, physicochemical properties, fatty acids; antioxidants.*

Introduction

In Côte d'Ivoire, as in many other countries in West Africa, the nutritional needs of the population, estimated at 1 800 000 tonnes/year to ensure a quality diet, are far from being met (FAO, 2023). The population of Côte d'Ivoire, like that of most underdeveloped countries, consumes too few calories from fat. There is a significant difference between rural and urban populations; the former consumes less fat than the latter and their lipid diet is not necessarily balanced (Sahoré et al, 2017). Several oilseed crops are grown in the countryside, the best-known being cotton seeds, shea butter and oil palm. It seemed attractive to target additional oilseeds with very low value added and significant scientific and technological interest (Kanaté et al., 2025). Increasing the amount of lipids produced from these oilseeds will almost certainly lead to an improvement in the diet and hence the health of the population (Ouilly et al., 2017). Several species, including tiger nut (*Cyperus esculentus* L.), have been identified as a result of a number of studies carried out in different parts of the country (Yao et al., 2020; Nikiema et al., 2024).

Tiger nut is a sedge that also grows as a perennial or annual herb which is currently distributed mainly in Spain, Australia, North and South America, China and Africa (Yapi et al., 20121; Zhang et al., 2023). It is a high-yielding, high-value and commercially useful crop with multiple uses (Okoye & Ene, 2018). Tiger nut is rich in starch, with a content of 25-40 %, in carbohydrates (15-20 %) and protein (5-10 %) (Kouame et al., 2022; Wu et al., 2024). In addition, tiger nut is rich in dietary fibre (8-10 %), vitamins C and E (8-14 mg/100g), minerals (potassium, phosphorus, sodium, calcium, magnesium), polyphenols and other bioactive substances (Djikeng et al., 2022; Imo et al., 2024). Tuber has recently gained popularity as a functional food due to its biological properties, which include antioxidants, antibacterial, anti-inflammatory, anticancer, anti-sickling, aphrodisiac, anti-atherosclerotic and hepatoprotective effects (Olabiyi et al., 2017; Rebezov et al., 2021).

Tiger nut is widely used in Côte d'Ivoire, where it is known as tchongon in Malinké, Bété, Dida, and Bambara, atadjo in Apolo, shop in Koulango, and maguélé in Sénoufo (Alloko et al., 2022a). It is mostly produced in the country's northern and central regions, with three forms including black, brown, and yellow. Tiger nut tubers can be consumed raw, roasted, or ground into beverages and flour. Edible oil potentials of tiger nut tuber grown in Côte d'Ivoire was investigated (Alloko et al., 2022a; Yao et al., 2020). Despite its high value in industrial applications, tiger nut oil is undervalued in Côte d'Ivoire. In fact, the oil from the tubers is still not part of the local diet. Therefore, this study investigates the physiochemical properties and nutritional benefits of tiger nut oil. The data will inform on the nutritional value of the seed and assist in assessing seed oils for additional applications, including biodiesel and oleochemical sources, thereby enhancing the value of these oils in the country.

Materials and Methods

Materials

The tiger nut tubers used in the research were provided from three regions in the North and the centre north of Côte d'Ivoire. The regions were Dabakala (Hambol region, 7° 41'north, 5° 01'west), Ferké (Tchologo region, 9° 35'north, 5° 11'west) and Korhogo (Poro region, 9° 25'north, 5° 38'west). Yellow tiger nut tubers were collected from January to March 2024 from a pool of women traders in each zone at a rate of 5 kg per woman. A total of 50 kg of tiger nut tubers were collected from each zone and taken to the laboratory for further examination. The tubers were sorted to eliminate those with defects and 5 kg was deducted after homogeneous mixing of the samples collected from each zone. This final quantity was sun dried for one week. The dried seeds were then ground using a hammer mill (Forplex). The ground seeds were sealed and stored in a desiccator until analysis.

Oil extraction

Tiger nut oil was obtained after maceration of the ground tiger nuts mixed with n-hexane at a ratio of 1:10 (g/v) for 6 hours at room temperature. The hexane was removed after extraction using a rotary evaporator (BÜCHI). The oil obtained from each sample was stored in a dark bottle in a refrigerator at 4°C until it was used for various analyses. The yield of lipid extraction was calculated according to formula (1): Yield (%) = (m0/m1) × 100 (1) m0 is the mass of the extracted fat (g), m1 is the mass of the ground tiger nuts.

Analysis of oil quality

Quality indexes

The standard methods of the International Organisation for Standardisation (ISO) were used to analyse oil quality. Acid value and free fatty acid content (ISO 660); iodine value (ISO 3961); peroxide value (ISO 3960); saponification and ester values (ISO 3657); unsaponifiable matter (ISO 3596); refractive index (ISO 6320); relative density (ISO 6883); insoluble impurities (ISO 663); anisidine value (ISO 6885); unsaponifiable matter (ISO 3596). The Totox value was calculated according to the following equation as mentioned by Djikeng et al. (2024): Totox = 2 PV + AV. Titrimetric methods were used to determine the acid, peroxide, iodine and saponification values of all samples.

Polyphenols content

Polyphenols content was evaluated by the Folin-Ciocalteu colorimetric method according to Michui et al. (2022) with slight modifications. The samples were prepared according to the following procedure: 2 g of the tiger nut was dissolved in 5 mL of hexane in an Erlenmeyer flask. Liquid-liquid extraction of antioxidants from the oil sample was then performed three times with 5 mL of methanol. Then the methanolic phase is recovered using a separating funnel. A total of three identical extractions are performed and the methanolic phases are collected and concentrated in the rotary evaporator. 50 µL of the methanol fraction was treated with 1 mL of Folin-Ciocalteu reagent diluted tenfold in distilled water. This mixture was incubated for 10 min. To this sample, 1 mL of sodium carbonate solution (7%, m/v) was added. Absorbance was measured at $\lambda = 760$ nm relative to distilled water. The total polyphenols were expressed in mg GAE/100g oil. A blank solution was also prepared in the same way, using an equivalent amount of methanol instead of the extract.

Vitamin A and Tocopherol Content

Analysis of retinol and α-tocopherol was performed by high pressure liquid chromatography (Acquity UPLC chromatograph, Waters Corporation, Milford, MA, USA) according to ISO 14565. Vitamin and tocopherols were identified based on retention times determined separately for retinol and α-tocopherol, and their contents were estimated using external calibration curves.

Analysis of Fatty Acids

To evaluate the fatty acid content of tiger nut oil, fatty acid methyl esters were prepared according to the SRPS EN ISO 12966-2 method. Fatty acid composition was analysed by gas chromatography (3900, Varian CPG, Sydney, Australia) equipped with a flame ionisation detector and a capillary column CP - select CB for FAME fused silica WCOT (50 m × 0.25 mm, d = 0.25 µm). Helium was used as the carrier gas. The initial column temperature of 140 ◦C was held constant for 3 min, then increased to 220 ◦C (at a rate of 3 ◦C/min) and held for 5 min. Finally, the column temperature was raised to 240 ◦C (at a rate of 2 ◦C/min) and held for 10 min. The injector and detector temperatures were set at 250 ◦C. The individual peaks were identified by comparison of their retention times with the standard mixture of 18 FAME methyl esters. The results were expressed as percentage by weight of the total fatty acid content.

Statistical Analysis

The results of the chemical analyses performed in triplicate were analysed statistically using IBM SPSS Statistics 20 (IBM, Chicago, IL, USA). Tukey's multiple comparison procedure was used to compare the obtained results to each other. Identical letters in rows denote the lack of differences at a significance level $\alpha = 0.05$.

Results and Discussion

Results

Physico-chemical parameters

The physico-chemical parameters of tiger nut oil from the different regions are shown in Table 1. The analysis indicated that there was not a significant difference (P>0.05) in all the parameters analysed except for insoluble impurities. The same observation was noted on the oil yield percentage obtained for these three regions (P>0.05). Regarding the insoluble impurities, values obtained from the tiger nut oil samples ranged from 0.005 to 0.02%. Regarding the acid value of the tiger nut oil samples, the results show a significant difference (p<0.05) with the three regions and all the tiger nut oil samples have lower values (from 0.13 to 3.14 mg KOH/g oil) than the recommended value of 4 mg KOH/g oil. The same observation was made for free fatty acid with values varying significantly (p<0.05) from 0.07% to 1.57%. The Korhogo department recorded the highest percentage. Similarly, the results showed that the iodine value of tiger nut oil from the different regions ranged from 68.92 ± 0.79 to 94.54 ± 6.50 g I_2/100 g oil. The highest value was recorded in Korhogo Department and the lowest in Dabakala Department. The analysis of chemical properties revealed that there was no significant difference (P> 0.05) in the parameters of saponification value, ester value and unsaponifiable matter content with values ranging from 174.2 ± 2.70 to 185.13 ± 6.43 mg KOH/g oil, 171.05 ± 2.88 to 183.02 ± 6.15 mg KOH/g oil and 1.48 ± 0.03 to 1.62 ± 0.01 %

Table 1. Physico-chemical properties of tiger nut oil from the three regions

Parameters	Dabakala	Ferké	Korhogo
Yield (%)	14.17 ± 0.93[a]	14.73±0.74[a]	14.68±0.64[a]
Relative density at 20°C	0.91 ± 0.0[a]	0.91±0.0[a]	0.91±0.0[a]
Refractive index	1.4567 ± 0.01[a]	1.460±0.01[b]	1.459±0.01a[b]
Moisture and volatile contents (%)	8.52± 0.01[a]	8.57± 0.01[a]	8.49± 0.01[a]
Insoluble impurities (%)	0.005±0.003[a]	0.01±0.001[a]	0.02±0.001[b]
Acid value (mg KOH/g)	0.13 ± 0.0[a]	2.11 ± 0.27[b]	3.14 ± 0.22c
Free fatty acid (%)	0.07 ± 0.0[a]	1.1 ± 0.14[b]	1.57 ± 0.11c
Iodine value (g I_2/100 g)	68.92 ± 0.79[a]	76.92 ± 3.83[a]	94.54 ± 6.50[b]
Saponification value (mg KOH/g)	174.38 ± 5.84[a]	175.13 ± 6.43[a]	174.20 ± 2.70[a]
Ester value (mg KOH/g)	174.25 ± 5.84[a]	173.02 ± 6.15[a]	171.05 ± 2.88[a]
Unsaponifiable content (%)	1.53 ± 0.01[a]	1.48 ± 0.03[a]	1.62 ± 0.01[a]

n=3 values are presented as mean±SD. Values followed by the same letters in the same row are are not significantly different at p ≤ 0.05.

Table 2. Oxidative indexes of tiger nut oil from the three regions

Parameters	Dabakala	Ferké	Korhogo
Peroxide value (meq O_2/kg)	3.17 ± 0.29[a]	3.83 ± 1.15[a]	4.05 ± 0.30[a]
Anisidin value	2.59 ± 0.12[a]	3.40 ± 0.46[b]	3.58 ± 0.90[b]
Totox value	8.92 ± 0.70[a]	11.06 ± 2.76[a]	11.68 ± 0.69[a]

n=3 values are presented as mean±SD. Values followed by the same letters in the same row are are not significantly different at p ≤ 0.05.

Oxidative indexes

The oxidative indexes analysis of tiger nut oil extracted from the three regions are presented in Table 2. With values ranging from values 3.17 ± 0.29 to 4.05 ± 0.30 meq O_2/kg oil, the peroxide index revealed no significant difference (P> 0.05) from the three regions. For the anisidin value, significant differences were found between the tiger nut oil values according to the regions (p<0.05). The tiger nut samples from the regions of Ferké and Korhogo had the highest para-anisidine values. As for the Totox value, all types of tiger nut oil samples showed no significant difference (P> 0.05) regardless of the three regions.

Polyphenols and vitamins content

The polyphenols and vitamins parameters of tiger nut oil from the different regions are shown in Table 3. The analysis showed that there was a significant difference (P<0.05) in all the parameters analysed. Indeed, the content of polyphenols in the evaluated tiger nut oil ranged from 14.81 to 22.54 mgGAE/100 g. Tiger nut oil from Korhogo department contained approximately 1.2 to1.5 times more polyphenols than tiger nut oils from the other regions. In addition, tiger nut oil from the Korhogo department had the highest vitamins content, with a value of α-tocopherol of 54.12 mg/kg and 7.93 ± 0.37 mg/kg for retinol.

Fatty acids composition of tiger nut oil from the different regions

The fatty acid composition is given in Table 4. The GC analysis results show a significant difference (P<0.05) between the free fatty acid compositions of tiger nut oil from the three regions. The most abundant fatty acids in

the tiger nut oil samples were oleic acid (C18:1), linoleic acid (C18:2), palmitoleic acid (C16:1) and stearic acid (C20:0). The main fatty acid found in both materials was oleic acid, 72.69 ± 1.1% to 79.68 ± 0.98% in tiger nut oil from the three regions, with Korhogo showing a higher value. Linoleic acid (C18:2) was the second most abundant fatty acid determined in the tiger nut oil sample. The high content of SFA in the tiger nut oil samples from the three regions was attributed to the presence of oleic, linoleic and palmitoleic acids. The PUFA content was slightly higher in tiger nut oil from Korhogo (88.73%) than in tiger nut oil from Ferké and Dabakala (83.42 and 84.51%).

Table 3. Polyphenols and vitamins (tocopherols, retinol) content of tiger nut oil from the three regions

Parameters	Dabakala	Ferké	Korhogo
Polyphenol (mg/100g GAE)	14.81 ± 0.14^{a}	19.50 ± 0.19^{b}	22.54 ± 0.59^{c}
α-tocopherol (mg/kg)	144.11 ± 0.37^{b}	136.07 ± 0.41^{a}	154.12 ± 1.03^{c}
Retinol (mg/kg)	7.37 ± 0.31^{ab}	6.70 ± 0.40^{a}	7.93 ± 0.37^{b}

n=3 values are presented as mean±SD. Values followed by the same letters in the same row are are not significantly different at $p \leq 0.05$.

Table 4. Composition of fatty acids of tiger nut oil from the three regions

Parameters	Dabakala	Ferké	Korhogo
Lauric acid (C12:0)	0.44 ± 0.16^{b}	0.10 ± 0.0^{a}	0.13 ± 0.04^{a}
Myristic acid (C14 :0)	1.29 ± 0.03^{c}	1.13 ± 0.02^{b}	0.88 ± 0.06^{a}
Palmitic acid (C16 :0)	0.34 ± 0.0^{a}	0.24 ± 0.01^{a}	0.33 ± 0.10^{a}

Linoleic acid (C18: 2)	9.64 ± 0.47^{b}	11.42 ± 0.23^{c}	8.48 ± 0.30^{a}
Linolenic acid (C18 :3)	0.13 ± 0.02^{a}	0.16 ± 0.02^{a}	0.25 ± 0.03^{b}
Arachidic Acid (C20 :0)	0.29 ± 0.02^{b}	0.43 ± 0.04^{b}	0.72 ± 0.06^{c}
SFA	16.32	15.09	11.08
MUFA	73.65	72.93	80
PUFA	83.42	84.51	88.73

n=3 values are presented as mean±SD. Values followed by the same letters in the same row are are not significantly different at $p \leq 0.05$.

Discussion

The results of oil extraction from tiger nut tubers showed no significant difference between the different regions. Oil contents ranged from 14.17 ± 0.93% to 14.73 ± 0.74%. The oil yield values obtained in this study were lower compared to the one reported by Zhen-Shan Zhang et al (2023) and Keskin et al (2024). However, our values are similar to those of Djikeng et al (2022). These differences can be attributed to the extraction methods and the maturity stage of the tubers (Hsu *et al.,* 2006). The results of the physical characterisation of the tiger nut oil samples show no significant difference in origin, except for impurities. The physical parameters studied were relative density, refractive index, moisture content and impurities. The relative density obtained for the three oil samples is 0.91. This value is comparable to that obtained by Yao et al. (2018) and Aljuhaimi et al. (2018). As for the refractive index values, values obtained were between 1.459 and 1.460 and are comparable to those reported by Adel et al. (2015).

The evaluated tiger nut oils exhibited acid value (AV) ranging from 0.13 to 3.14 mg KOH/g of oil which remained well below the Codex Alimentarius's standard limit of 4 mg KOH/g. These low acid values obtained for tiger nut oil are an indication that the triglycerides present in the tiger nut sample have not been hydrolysed, an indication that the oil is less susceptible to lipase action. Keskin et al (2024) reported that AV values for yellow tuber tiger nut oil obtained through cold-press machine extraction of 3.63 ± 0.02 mg KOH/g of oil. The free fatty acidity (FFA) of the oil ranging from 0.07 to 1.57% linoleic acid. Similar trends were observed for tiger nut oils extracted by different method (Duman, 2019; Miao *et al*., 2022). The iodine value provides information on the degree of unsaturation of the fatty acids present in the oil. In the current study, iodine values ranged from 68.92 to 94.54 g I_2/100 g of oil. The results are comparable to those reported by Sabah et al. (2019), with an iodine value ranging from 70 to 80 g I_2/100 g of oil. The tiger nut oil samples from the three regions analysed showed an average saponification index of between 174.20 and 175.13 mg KOH/g oil, which is higher than the values reported by Dumas (2019) from chufa seeds varieties in Turkey. The ester indices were of the same order and all slightly lower than their saponification index. The unsaponifiable fraction content varied from 1.48% to 1.62% among the various tiger nut oil samples studied. The unsaponifiable fraction content of the oils examined is higher than that of certain conventional oils such as cotton seed oil (0.52%) and peanut oil (0.33%) (Zoué et al., 2012). The presence of unsaponifiable compounds could add value to these oils, making them suitable for use in the food sectors. The

determination of the PV of oils and fats informed on their primary oxidation state which must be less than 15 meq O_2/kg of oil, the limit recommended by the FAO for vegetable oils intended for human consumption (Codex, 2023). In this study, the peroxide values, between 3.17 and 4.05 meq O_2/kg of oil, were well in line with this recommendation. For an accurate evaluation of the oil's oxidation state, it is crucial to integrate the measurements of the para-anisidine and peroxide values. Para-anisidine value measures the level of secondary oxidation products, such as aldehydes, ketones, hydrocarbons, alcohols, esters, and acids, formed from the breakdown of primary oxidation products (Djikeng et al., 2024). The relatively low *p*-anisidine value of the tiger nut oils suggests that primary oxidation products have not significantly degraded, indicating that the oils were safe for consumption concerning oxidation and hydrolysis products. A Totox value of 10 is the threshold for determining acceptable quality in edible oils (Bojanowska and Lamarska, 2016). The calculated Totox value, as a measure of the total oxidation profile of the tiger nut oils from the three regions, ranged from 8.92 to 11.68 indicates high primary and secondary oxidative stability. Polyphenols are natural antioxidants with the ability to inhibit the oxidation process in oils (Rakita et al., 2024). Results showed an average total polyphenol content ranging from 14.81 to 22.54 mg GAE/100 g which was much lower than total phenol content in tiger nut oil reported by Alloko et al (2022b). However, these results are quite similar to those reported by Zhang et al (2023). The significant quantity of tocopherols found in all tiger nut oil from the three regions could contribute to its high oxidative stability. Similar to this study, previous studies have reported higher concentrations of α-tocopherols in tiger nut oils (Zhang et al., 2023). The low levels of vitamin A (retinol) observed in the tiger nut oils samples could be explained by the absence or very low presence of vitamin A in the form of retinol in tubers plants from which these oils are extracted (Yao et al., 2018). The results obtained could also be influenced by the degradation process of the samples during the assay procedure. The most dominant MUFAs in tiger nut oils from the three regions were oleic acid. Other researchers have shown similar levels of these fatty acids. Higher percentages of oleic acid (66-78%) were reported by several authors (Hu et al., 2018; Guo et al., 2021). Due to its unique fatty acid profile, tiger nut oil could be suitable for direct consumption, including use in the enrichment of various food products. Its potential nutraceutical benefits suggest its use in the development of functional foods and nutraceuticals aimed at promoting health (Zhang et al., 2023).

Conclusion

This paper evaluated the physico-chemical parameters of tiger nut oil from three regions of Côte d'Ivoire. The analysis of physico-chemical parameters showed that the oils obtained from the three regions had similar yields and were of satisfactory quality. Tiger nut oils were rich in polyunsaturated fatty acids (83 - 88%), of which oleic acid was the most abundant (73 - 80%). High content of unsaturated fatty acids raises the possibility of including tiger nut oils in the human diet. Tiger nuts oils from the three regions exhibited a higher content of α-tocopherols and polyphenols and demonstrated greater oxidative indexes. In view of all these potentialities and qualities, tiger nut oils from the three regions presents significant opportunities for application across diverse industries, including food, nutraceuticals, animal feed, and cosmetics. Future investigations may focus on investigating the toxicological and antimicrobial effects of tiger nut oils before using them as supplements in food, nutraceutical and cosmetic industries.

Abstract

Food security risks are increasing due to the global population explosion and climate change. Therefore, it is necessary to develop plans to conserve resources and ensure their sustainability using modern technologies to achieve this purpose. This report aims to examine the advancements in the European Food Industry 4.0. The Fourth Industrial Revolution (Industry 4.0) is gaining traction as a critical driver of sustainable growth and a valuable catalyst for resolving global issues. Technology from the Fourth Industrial Revolution is now widely used in the food business, and its use has increased dramatically in recent years. These innovations will lower manufacturing costs, improve food safety and quality, use less energy and resources, and decrease food loss and waste. The use of technology 4.0 has accelerated over the past few years due to its high efficiency in the food industry. Therefore, this review aims to shed light on technology 4.0 in Europe and its development over the past. The food processing business is one of the numerous industrial sectors that industry 4.0 technologies have redefined and transformed in the last few years. Several Industry 4.0 technologies have become more well-known and thriving in the food, safety, and quality sectors.

Key Words: *Food Industry 4.0, Agriculture, Europe*

Introduction

In the last several years, our world has faced unheard-of difficulties, chief among them being climate change's severe and pervasive effects. In the meantime, as the world's population rises and is predicted to reach 9.7 billion by 2050, there will be a 56% increase in the need for food (van Dijk et al., 2021). Globally, the effects of climate change on government policies are complex and affect many facets of society, including the environment, politics, economy, and ecology. The consequences of different climates in different countries vary, as do the socioeconomics, infrastructure, institutional capacity, and resilience of health systems. Consequently, there are regional differences in the complexity and capability associated with the impacts of climate change on health (Abbass et al., 2022). The pace of population expansion and climate change will significantly disrupt the global food supply, leading to a host of nutritional issues shortly. As the world's population approaches 8 billion people, it will become more difficult for humanity to meet the expanding population's food demands. Climate change may impact food production, a severe worry (Bağdatlı et al., 2023). For instance, forests, crucial food sources in many places, may be destroyed by increasing sea levels brought on by climate change (Elsheikh et al., 2023). Climate change directly affects food security and the source of income for those working in the food industry, including value chains. Currently, the global population affected by famine reached its peak in 2014. Climate conditions hav an imbat on the Food Distributions rotu, makin it difficult for people to visit markets in a variety of ways physically. Heavy rain, snow, storms, bridges, road vandalism, and overflowing transit channels all imbat the infrastructure (Raj et al., 2022).

Food shortages are a growing concern, driven by rising temperatures. The likelihood of several 'breadbasket failures' leading to a shock in food prices is rising. For instance, the likelihood of maize production misplacement is more than 10% among the top four divisions that produce the most maize (87% of total output); this percentage increased from 7% each year under a two °C temperature rise to 86% under a four °C increase (Ogunkalu, 2024). However, there is hope in the potential of technological advancements. The food processing industry is expected to evolve to produce foods with higher nutritional value, less resource consumption, biodiversity preservation, and minimal environmental impact in resilient systems to meet this growing demand with complementary initiatives to end hunger and food insecurity (Sachs et al., 2019). Significant adjustments are required, particularly in the food processing business, even if this requirement is hoped to be satisfied. It is anticipated that the fundamental principles of our society will change and become more robust, adaptable, flexible, and sustainable. Technological advances are vital components that will enable progress in food processing toward solving current and future issues. Elevated connectivity and automation via computer power are critical elements that might revolutionize food production systems (Augusto, 2020). Over the last twenty years, advancements in artificial intelligence (AI), consumer technology, computer power, and connection have all contributed to increased accessibility and a surge in biotechnology, robotics, e-commerce, and nanotechnology research and development. Food production is

undergoing significant changes due to 'Big Data.' Beyond these developments, blending technologies not usually combined is starting to encroach on the digital, physical, and chemical-biological domains, encouraging the fusion of new scientific fields with the so-called conventional food sciences (Chapman et al., 2022).

The aforementioned alterations, in tandem with technology integration across the food production, storage, and packaging process and throughout the value chain, define the fourth industrial revolution. Among other things, his fourth revolution is determined by the absence of borders and rapid business changes (Lee et al., 2018). In essence, the goal of the Fourth Industrial Revolution, also known as Industry 4.0, is to establish intelligent processing systems by increasing high-level automation and connectivity (between sensors, devices, machines, and people, for example) (Morella et al., 2021). One of the fundamental elements of Industry 4.0 is its interdisciplinary character, which incorporates a wide variety of information from the digital, biological, and physical domains (Chapman et al., 2021). This combination of qualities is needed to improve food quality, decrease food loss, and encourage the development of more efficient production techniques. It is crucial to note that there is no global consensus on the elements of Industry 4.0 (Ghobakhloo, 2018). This study analyzes Europe's Food Industry 4.0 developments, highlighting the industry's prospects and challenges.

Developments of Food Industry 4.0 in Europe

The Industrial Revolutions were defined by the advent of revolutionary developments in industrial production, which were primarily connected to technological advancements. The first industrial revolution (18th–early 19th century) defined the initial shifts towards intensifying working activities by creating and upgrading steam engine-driven equipment. During this period, the textile, coal, iron, and chemical industries flourished, and the production of certain food items shifted from home to factory settings (Koetsier, 2019).

The first industrial revolution's increasing mechanization and the extension and intensity of working activities led to the second industrial revolution in the 19th–early 20th century.

In addition, electricity became more common and replaced steam-powered equipment in industrial settings, which made large-scale production possible (Zhang & Yang, 2020). In the second decade of the 20th and early 21st centuries, the transition from analog to digital electronic systems signaled the start of the third industrial revolution, often known as the digital revolution. Significant technology developments like computers and the Internet have made it possible to communicate more quickly and interact with people worldwide. Electronic systems were also used for automation in manufacturing. To fulfill the growing demand from industrial, public, and domestic users throughout this time, nuclear energy research and application became more crucial (Xu et al., 2018).

Industry 4.0, or the contemporary 4IR (early 21st century), is defined by fully automated processes, integration with digital technology, and an emphasis on the Internet above all other factors. This ongoing change, which combines digital, biological, and physical components, enables real-time networking and communication among all industry stakeholders (Maynard, 2015). Mass production automation incorporates customization and personalized products. The growth of Industry 4.0 is linked to several essential variables, including digital twins, CPS, big data, blockchain, artificial intelligence (AI), intelligent sensors, cybersecurity, the Internet of Things (IoT), robotics, and cybersecurity. The food industry's production and operational efficiency have increased thanks to these cutting-edge digital and other emerging technologies. However, they have also negatively affected environmental sustainability and particular disturbances to the food supply chain (Olah et al., 2020). Robots are predominantly used in the food processing sector for pick-and-place operations such as packaging, sorting, and packing (Wang et al., 2022).

Robotic automation functions optimally when it addresses or improves specific manufacturing and processing scenarios (Dzedzickis et al., 2022). Robotics allows for rapid and straightforward reconfiguration into new work environments and procedures. Repetitive motion also reduces worker injuries, improving the working environment. Reduced production times and costs, as well as reduced waste material, were guaranteed by increased productivity. These benefits ensure that the company will always have an advantage over competitors. Robotics and Sector 4.0 technologies have long been used in food processing applications. However, their adoption rates are still low because of specific issues that need to be resolved before they can be widely used in the food sector.

For example, the food industry's stringent hygienic standards to guarantee food safety are among these problems, as are financial obstacles resulting from the exorbitant prices of buying and operating robotics at the moment (Wang et al., 2022). Artificial biomimetic technologies (E-noses, E-tongue, and computer vision) are clever techniques used in food processing based on appearance, taste, and smell variations. Chemical sensors, equipped with an AI system with access to a database of potentially harmful odors, can accurately discern between different food odors.

E-noses might be helpful in a food processing setting to help detect pollutants. For example, an E-nose with chemo-metric methods might be a trustworthy tool for tracking food drying procedures (Sun et al., 2019). Additionally, computer vision can disclose food's nutritional content (Kakani et al., 2020). Imaging and sensing sensors can also detect food residue on equipment. AI can also grade food cleanliness, monitor temperatures, and ensure employees wear the appropriate PPE. Monitoring tools can identify and follow individuals, their movements, and their clothes.

Face and object recognition may detect Masks or hair coverings (Kumar et al., 2021). Food safety is a critical concern in the food industry. Better monitoring using networked sensors makes it easier to identify food processing safety concerns and take action before the contamination spreads. As a result, IoT can identify safety concerns earlier than conventional techniques and instantly communicate the relevant data to take immediate action. It guarantees little production disruption and minimizes safety hazards while avoiding the need to spend resources for a batch that would otherwise have to be thrown out and squandered (Hassoun et al., 2023). IoT and biosensors can detect food contamination and send notifications that immediately cut off supply lines (Zhang et al., 2022). Food quality evaluations, food safety, and food production use IoT technologies in various ways.

The technologies that constitute Industry 4.0 as a whole and food processing technologies grew simultaneously as advancements in food science. Combining these two improves food safety and quality while catering to customer tastes and developments in the food processing sector (Hassoun et al., 2023). By leveraging our technical expertise on the global food system, we can develop standards, guidelines, and testing protocols that will enable the food business to adopt sustainable and, most importantly, safer practices. Furthermore, one area where technology may profit from a deeper comprehension of the content of food is native production (Serazetdinova et al., 2019). Therefore, technology 4.0 has accelerated over the past few years due to the food industry's high efficiency.

Conclusion

The Fourth Industrial Revolution is becoming increasingly popular as a catalyst for sustainable growth and a way to address previously recognized global problems. The food industry has recently significantly increased its use of Fourth Industrial Revolution-era technologies. These developments will lower production costs, improve food quality and safety, conserve energy and resources, and reduce food loss and waste. One of the numerous industrial areas in which business 4.0 technologies are redefining and transforming is the food processing industry, which has recently attracted much attention.

Advances in food science have led to a corresponding rise in food processing technology and the technologies that make up Industry 4.0 as a whole. Several Industry 4.0 technologies have been more widely accepted and thriving in the food, safety, and quality sectors in recent years. We can develop standards, guidelines, and testing procedures that will enable the food sector to adopt sustainable and, most crucially, safer practices by pooling our technical knowledge of the global food system.

Abstract

The study was conducted to determine the sensory properties of beef burgers manufactured with different levels of camel hump fat. The hump fat, which has low cholesterol, is successfully used in many regional countries.is almost neglected as a binder in processed meat production in Sudan. The samples were weighed and burger patties were formulated in 5 treatments T1: 0% T2: 10%, T3: 15%, T4: 20% and T5: 25% hump fat, respectively. The treatments were subjected to 4 replications. The sensory evaluations included tenderness, juiciness, colour, flavour and overall acceptability. The data were statistically analyzed using variance analysis for a completely randomised design using the SPSS version 8.0 computer program. LSD did mean separation, and the values were expressed as means and standard error. The difference between mean values was significant at $P < 0.05$. The flavour (T1: 5.54 ,T5: 5.11).juiciness (T1: 5.64 T5: 5.45) and total acceptability (T1: 6.11, T5: 5.57) decreased by increase of camel hump fat. The study concluded that camel hump fat can be added to the beef burger formulation. However, the negative effect of flavour can be solved by increasing the level of spices.

Introduction

Sudan has a huge livestock population, estimated to be more than one hundred and seven million heads. Camels are important livestock species uniquely adapted to hot and arid environments. One-third of the total camel population is found in Somalia, and 60% is found within the borders of Somalia, Sudan, Kenya, and Ethiopia. Australians have lately started to look at camel as a source of meat (Fathi, 2005). Meat and meat products are essential components in human diets; their consumption is affected by various factors. The most important are product consumer and environment-related characteristics (Colmenero et al., 2001). A burger is a minced meat product. The minced meat is mixed with condiments and spices, shaped, and cooked by frying or baking (Gurjral et al., 2002). The types of seasoning used vary depending on the taste requirement, from mild to hot and spicy. Humans' use of animal fats may well predate civilisation. As the depot fats in animals are readily visible during the butchering of a slaughtered animal, are easily harvested, and are available without the need for plant domestication or the adoption of established agriculture, animal fats were probably the first lipids consumed by humans. Lipids support multiple biological functions in the body. They serve as the structural building materials of all cell and organelle membranes. Lipids are the most efficient fuel for living organisms, containing more than twice the energy content of carbohydrates and proteins on a weight basis (Sbihi et al., 2013).

Fat in meat products plays an important role in stabilising meat emulsions, reducing cooking loss, improving water holding capacity, providing juiciness and tenderness and has considerable effects on the binding, rheological and structural properties of the meat products (Yoo et al.2007). Fat is important in meat products since it affects technological properties and sensory aspects, mainly hardness and juiciness (Ozvural et al., 2008). The level and type of fat in emulsion-type sausages affect the percentage of cooking losses. In this regard, Serdaroglu et al. (2004) found a possible relationship between increasing cooking yield and higher fat retention in beef patties. In addition to the serious health concerns associated with animal fat, lipid and protein oxidation poses a significant threat to meat quality. Oxidative reactions occurring in muscle foods during handling, processing, and storage can lead to undesirable sensory changes and a decline in nutritional value. Therefore, reducing fat content is widely recognized as a key strategy for improving the nutritional profile of foods and producing healthier products. This is particularly important in the meat industry, where certain meat products contain high levels of fat (Huda et al., 2014). From a chemical perspective, camel meat contains more moisture than beef. Studies have shown that camels have a slightly higher moisture-to-protein ratio compared to beef or lamb (Babiker & Tibin, 1989). Babiker and Tibin (1989) found that, compared to beef, camel meat has significantly higher protein content and lower intramuscular fat. Additionally, camel meat contains notably lower levels of sarcoplasmic protein than beef. Given these characteristics, camel meat presents a viable alternative for addressing animal protein shortages.

Camel meat is the least studied and is wrongly believed to be of lower nutritive value and quality than other red meat, despite their ability to produce good quality meat at comparatively low cost under highly harsh environments (Skidmore, 2005). Camel is suitable for exploiting arid areas, which constitute an important resource for some countries such as Sudan, Somalia, and Mauritania. Its meat represents about 8% of the meat production in the Arab countries (Kadim et al., 2008). Therefore in The objectives of this study were To determine the sensory properties of burgers manufactured with different levels of camel hump fat.

Materıals And Methods

Materials: Seven and half Kilo grams of beef meat and 100 gm of beef fat were purchased from the University of Khartoum project for animal production. One kilogram of sample camel hump fat was purchased from Tambull Meat Market (East Gazira State) and stored in ice in a thermal container before travelling to Shambat (Khartoum North), University of Khartoum and stored in a deep freezer at -18c till use. Mixes of spices were purchased from Khartoum North Market, Khartoum State, Sudan and were cleaned and grind by an electric grinder separately (cardamom, cinnamon, coriander, and fennel).

The meat samples were thawed overnight in a refrigerator at 4°c. Each of the samples was thoroughly ground. Random samples were taken from each batch to determine the fat content. The person square method was adopted to formulate treatments with different fat percentages. The remaining samples were thoroughly wrapped and frozen at -18°C until later used.

Treatments formulation: Five treatments were formulated (T1: Control 0%, T2: 10%, T3: 15%, T4: 20% and T5: 25% hump fat) with four replications as listed in table (1). It contained Meat, Beef fat, hump fat, salt, ice water, powdered milk, bread, sugar, and spices (Cardamom, Cinnamon, Coriander and Fennel).

Table 1: Treatments formulation of burger meat

Treatments	Composition of burger (%)							
	Meat	Hump fat	Bread crumps	Salt	Sugar	Ice water	Spices	Milk powder
1	71.5%	0	13	1.5	1	8	2	3
2	61.5%	10	13	1.5	1	8	2	3
3	56.5%	15	13	1.5	1	8	2	3
4	51.5%	20	13	1.5	1	8	2	3
5	46.5%	25	13	1.5	1	8	2	3

All spices (cardamom, cinnamon, coriander and fennel) and salt were added equally to each treatment.

Burger formulations: Meat and fat for each treatment group were ground separately through an electrical meat grinder, the meat through an 8 mm plate and the fat through a 6 mm plate. Samples were taken from the meat for proximate analysis, as AOAC (1990) described. Then, the rest of the ingredients were thoroughly mixed by hand, and the mixture was reground through a 5 mm plate. Finally, burgers were formed weighing 100 gm with 9 cm diameter and 5 – 10 mm thick. After formulation, the burger was packed into suitable plastic bags, labelled, and immediately transported to a freezer at -18°C until it was analysed.

Sensory evaluations: Sensory panel evaluation was conducted in sensory evaluation facilities of Meat Production Department, Faculty of Animal Production, University of Khartoum. Samples were thawed overnight in the refrigerator at 4°C and cooked by peanut oil frying for 2-5 minutes on each side. The samples were turned every few minutes until cooked. Each patty was cut into small pieces and served warm to the panellist. Twelve semi-trained panellists evaluated the warm meat samples. Panellists evaluated each meat sample for tenderness, colour, flavour, juiciness and overall acceptability using an 8-point scale score (hedonic scale) card described by Cross et al. (1978). The highest score of 8 is extremely colourful, tender, flavorful, juicy and acceptable, and the lowest score of 1 is inferior in colour, tenderness, flavour, juiciness and overall acceptability (appendix). Tap water was available for use between testing samples.

Statistical analysis: The statistical analysis for recorded data was done using variance analysis for a completely randomized design (CRD) using a general linear model (statistical program, version 8.0). LSD did mean separation, and the values were expressed as means and standard error.

Results

Colour: The effect of the addition of different levels of hump fat to beef burger colours is illustrated in Table (2). The results showed that T4(20% hump fat) and T3 (15% hump fat) had the highest colour, followed by T2, T1 and T5, respectively, with no significant difference (P ≤0.05) between the treatments.
Tenderness: The effect of adding different levels of hump fat to beef burger tenderness is presented in Table (2). The results showed that T4 (20 % hump fat) showed the highest tenderness, followed by T1, T2, T3 and T5, with no significant difference (P ≤ 0.05) between these four treatments.
Flavour: The effect of the addition of different levels of hump fat to the beef burger is presented in Table (2). The results showed that T1 (0% hump fat) showed the highest flavour, followed by T2, T3, T4 and T5, respectively, with no significant difference (P ≤ 0.05) between the treatments.
Juiciness: The effect of adding different levels of hump fat to beef burgers on juiciness is illustrated in Table (2). The results showed that T4 (20 % hump fat) showed the highest juiciness content, followed by T3, T1, T5 and T2 lowest, respectively, with no significant difference (P ≤ 0.05) between the treatments.
Overall acceptability: The effect of the addition of different levels of hump fat on beef burger acceptability is presented in Table (2). The results showed that T1 (0% hump fat) showed the highest acceptability score with no significant difference (P > 0.05) with the other treatments, followed by T3, T4, T2 and T5 respectively.

Table (3): The effect of adding different levels of hump fat to beef burger panel test

Parameter / Treatments	Color	Tenderness	Flavor	Juiciness	Overall acceptability
T1 0%	5.68	6.04	5.54	5.64	6.11
T2 10%	5.79	5.71	5.32	5.29	5.68
T3 15%	5.82	6.25	5.21	5.68	5.96
T4 20%	5.82	6.14	5.18	5.89	5.82
T5 25%	5.50	5.39	5.11	5.43	5.57
Mean	5.72	5.91	5.27	5.59	5.83
SE	0.131	0.126	0.127	0.124	0.115
LS	N.S	N.S	N.S	N.S	N.S

* The same letter mean on the row indicates no significance (P<0.05).
* SE: Standard Errors

The effect of the addition of different levels of hump fat to beef burgers is presented in Table (2). The results showed that T2 (10% hump fat) showed the highest acceptability score with no significant difference (P ≤ 0.05) with the other treatments, followed by T3, T4, T2, and T1, respectively. These three characteristics of meat (tenderness, juiciness, and flavour) are greatly influenced by various factors, such as the animal (breed, sex, age), meat production activities (feeding, transporting, and slaughtering conditions), and processing (storing time/temperature condition) (Liu et al., 2003).
Treatment A (control) received the highest scores in flavour and overall acceptability, while treatment C received the highest scores In colour and tenderness while in juiciness T.D. Treatment E received the lowest scores of all the treatments, which were generally acceptable by the panel. There were no significant differences (P<0.05) between all the primeless treatments. Raw meat has little aroma, but meat flavour is developed because of many compounds produced in post-mortem muscle (Toldrá, 2002). Park et al. (1989) reported that a reduction in fat content in frankfurters results in decreased juiciness. Beef flavour can vary significantly due to a number of factors ranging from breed type to cattle diets or even meat processing/ageing techniques (Montgomery & Leheska, 2008). Overall acceptability, as evaluated by consumers, is a mixture of flavour and tenderness scores and other sensations that consumers perceive when they taste meat lamb samples. Overall acceptability was highly correlated with flavour and tenderness. These attributes are affected by fatty acid composition. This parameter differs among production systems (Sanudo et al., 2000) and by the cultural background and culinary habits since the kind of meat that consumers are used to eating is generally evaluated with higher scores.

Conclusion

Sensory evaluation showed that tenderness increased with the increase in the level of camel hump fat, while colour was not affected significantly by adding camel hump fat. On the other hand, flavour, juiciness and total acceptability decreased by an increase in the level of camel hump fat. Camel hump fat can successfully be added to beef burgers. Studies on the effects of hump fat on the sensory evaluation of other types of processed meat products are needed.

Abstract

Garlic (*Allium sativum*), known for its bioactive compounds, antimicrobial properties, and widespread availability, serves as an effective natural feed additive in broiler diets. The present study was conducted to investigate the combined effects of either (i) commercially available imported (CIGP) or (ii) locally produced (LGP) garlic powders in combination with probiotics on the performance of broiler finishers. The experimental design was a completely randomized design evaluating five (05) treatments (Control: Basal diet containing 0.1% probiotic; T1: Basal diet containing probiotic at 0.1% and CIGP at 0.025%; T2: Basal diet containing probiotic at 0.1% and LGP at 0.025%; T3: Basal diet containing probiotic at 0.05% and CIGP at 0.025%; T4: Basal diet containing probiotic at 0.05% and LGP at 0.025%). A total of 150, 21-day-old, unsexed Indian River broiler chickens (BW±SD: 1096±46 g) were assigned randomly into five (05) treatments. Each treatment had two (02) replicates (15 birds/replicate). Proximate composition and gross energy (GE) content of both garlic powders and treatment diets were evaluated. Performance was also assessed. The LGP had higher crude protein (CP), crude fiber (CF), nitrogen-free extract (NFE), and GE than CIGP ($P<0.05$). The moisture, CP, ether extract (EE), ash, and NFE across the treatment diets were similar ($P>0.05$). The birds fed T1, T2, T3, and T4 diets showed comparatively a higher feed intake (FI), body weight gain (BWG), and lower feed conversion ratio (FCR) (21-28 d) than those fed the control diet ($P<0.05$). The broilers fed garlic-incorporated diets reduced FCR ($P<0.05$) over the period tested. The local garlic when combined with probiotic at a rate of 0.05% resulted the least production cost. Overall, the present study concluded that inclusion of LGP in combination with probiotic supplementation improves the performance of broiler finishers.

Abstract

Litter materials play a crucial role in optimizing broiler performance, welfare, and environmental sustainability within the poultry industry. This study aimed to assess the effect of paddy husk (PH), wood shavings (WS) and paddy straw (PS) as alternative litter materials for performance of broilers. The experiment was conducted in a completely randomized design (CRD) evaluating three litter materials (paddy husk: PH, WS and PS). A total of 72, 14-day old Indian River (IR) broilers were weighed (540.55±23 g) and assigned randomly to three (03) treatments. Each treatment was replicated two (02) times (12 birds/replicate). Performance of birds was recorded weekly for the period of 14-35 days. Litter material had no effect (P>0.05) on the feed intake, body weight gain, feed conversion ratio and mortality of broilers. The litter material did not have any influence (P>0.05) on the dressing percentage (DP%) of broilers. The present study demonstrates that the tested litter materials has no effect on the performance, DP% in IR broiler chickens.

Enrichmet of cakes with elderberry extract : Effects of different formulations on bioactive properties and cake quality*

Müberra Birkan[1], Hatice Bekiroğlu [1,2], Görkem Özülkü[1]

[1]Department of Food Engineering, Chemical and Metallurgical Faculty, Yıldız Technical University, Istanbul, Turkey
[2]Department of Food Engineering, Faculty of Agriculture, Şırnak University, Şırnak, Turkey

Abstract

Cake varieties differ due to formulation and production methods. Numerous studies have focused on enhancing the bioactive properties of bakery products by adding various fruit extracts. However, due to variations in formulations, significantly different results particularly in terms of bioaccessibility are obtained. In this study, elderberry (Sambucus nigra L.) (EB), a berry known for its high antioxidant capacity due to its phenolics, was used in the powdered extract form to enrich cakes. The effect of different cake formulations on the *in vitro* bioaccessibility of EB extract was investigated to determine the type of cake that provides the highest bioaccessibility of EB extract. The powdered extract was added 2% to four formulations: foam-type (sponge cake), cream-type (pound cake), a mix of foam and cream type (chiffon cake), and the AACC cake formulation. Quality characteristics of the cakes (baking loss, color, texture) and batter viscosity were evaluated. Changes in antioxidant capacity were examined using total phenolic content, total antioxidant capacity, and *in vitro* digestion model. Control cakes without extract were also produced for each formulation and analyzed. The highest baking loss, lowest batter viscosity, and lowest cake hardness were observed in chiffon cake ($p<0.05$). While no significant difference was found in crumb color change (ΔE) ($p>0.05$) , chiffon cake showed the least crust color change (16.28) ($p<0.05$). When the pre-digestion samples were compared with their control samples, the sponge cake showed higher total phenolic content and antioxidant activity (ABTS and CUPRAC) than the other formulations ($p<0.05$). However, after intestinal digestion, except for ABTS, chiffon cake exhibited significantly higher antioxidant activity (CUPRAC: 527.83 mg TE/100g; FRAP: 186.5 mg TE/100g), total phenolic content (165.59 mg GAE/100g), and bioaccessibility index (138.82%–230.82%) compared to the other formulations ($p<0.05$). Findings indicate that ıncorporating elderberry extract into chiffon cake more effectively enhances bioactive properties without affecting quality.

Key Words: *In vitro bioaccessibility, total phenolic content, antioxidant capacity, texture, viscosity*

Keklerin kara mürver ekstraktı ile zenginleştirilmesi: Farklı formülasyonların biyoaktif özellikler ve kek kalitesi üzerine etkisi*

Özet

Kek, formülasyondaki ve üretim şekillerindeki farklılıklardan dolayı değişik çeşitlerde (krema veya köpük tipi gibi) üretilebilmektedir. Farklı meyve ekstraklarının fırıncılık ürünlerine ilavesi ile bu ürünlerin biyoaktif özelliklerini artırmaya yönelik çok sayıda çalışma mevcuttur. Fakat kullanılan formülasyonlardaki farklılıklardan dolayı, özellikle biyoerişebilirlikleri açısından çok farklı sonuçlar alınmaktadır. Bu çalışmada, içerdiği fenolik bileşikler sayesinde yüksek antioksidan kapasiteye sahip üzümsü meyvelerden biri olan "kara mürver" (*Sambucus nigra* L.) meyvesi (KMM), toz ekstrakt şeklinde keklerin antioksidanlarca zenginleştirilmesinde kullanılmıştır. KMM ekstraktının *in-vitro* biyoerişebilirliğinde farklı kek formülasyonlarının etkisi araştırılmıştır ve en yüksek KMM biyoerişebilirliğinin elde edildiği kek tipinin belirlenmesi amaçlanmıştır. Toz ekstrakt; köpük tipi (sponge kek), krema tipi (pound kek), köpük tipi+krema tipi (şifon kek) formülasyonları ve standart AACC kek formülasyonuna %2 olarak eşit oranda eklenmiştir. Üretimi yapılan keklerin bazı kalite özellikleri (pişme kaybı, renk ve tekstür) ve kek hamuru viskozitesi incelenmiştir. Ayrıca biyoaktif özellikleri (toplam fenolik madde ve toplam antioksidan kapasite) ve *in vitro* sindirim modeli kullanılarak antioksidan kapasitelerindeki değişiklikler araştırılmıştır. Her bir formülasyonun ekstraktsız kontrol kekleri de üretilip aynı analizler gerçekleştirilmiştir. En yüksek pişme kaybı, en düşük hamur viskozitesi ve en düşük kek sertliği şifon kekte görülmüştür ($p<0,05$). Formülasyonların kendı arasında iç (gözenek) renk değişimi (ΔE) anlamlı bulunmazken ($p>0,05$) dış (kabuk) ΔE değeri en az bulunan şifon kek olmuştur (16,28) ($p<0,05$). *In- vitro* sindirim öncesi örnekler kontrolu ile kıyaslandığında sponge kekin diğer formülasyonlardan daha yüksek toplam fenolik madde ve antioksidan aktiviteye (ABTS ve CUPRAC) sahip olduğu görülmüştür ($p<0,05$). Ancak bağırsak sindirimi sonrası şifon kek örneklerinde ABTS dışında antioksidan aktivite (CUPRAC 527,83 mg TE/100g FRAP 186,5 mg TE/100g) toplam fenolik miktarı (165,59 mg GAE/100 g) ve biyoerişilebilirlik indeksi (%138,82 - 230,82) diğer formülasyonlardan önemli düzeyde yüksek bulunmuştur ($p<0,05$). Elde edilen sonuçlara göre, kara mürver ekstraktının şifon kek formülasyonunda kullanılmasının, kek kalitesini olumsuz etkilemeden, biyoaktif özelliklerinin geliştirilmesinde daha etkili olduğu tespit edilmiştir.

Anahtar Kelimeler: *In vitro biyoerişebilirlik, toplam fenolik madde, antioksidan kapasite, tekstür, viskozite*

Abstract

Taxonomic zoology, a sub-discipline of biology, encompasses the rules governing the classification of animals and integrates insights from various scientific fields. While traditional taxonomy relies primarily on morphological character analysis, modern approaches incorporate geometric morphometrics, population genetics, molecular biology, and bioinformatics. Currently, honey bee diversity is represented by more than 29 subspecies, although this number is still controversial among researchers. Micro-diversitys in diagnostic characters within honey bees have often been overlooked. From this perspective, SEM offers a rapid analytical method for distinguishing between subspecies or ecotypes. This study aims to assess the applicability of SEM morphological analysis in characterizing honey bee biodiversity. Specifically, it evaluates the maxillary palpus segment as a supporting character for both classical and modern taxonomic methodologies.

Abstract

The main objective of the study was to assess the perceived impact of tea farming on livelihoods of the smallholder tea growers. The research was conducted in the Tetulia upazila under Panchagarh district. A total of 550 farmers constituted the population of the study, and 118 small tea growers were selected as samples of the study following simple random sampling techniques. An interview schedule was used for data collection, and data was collected from 28 August to 12 October 2023. Perceived impact on livelihood of the small tea growers were assessed based on a five-point Likert scale. In contrast, both Pearson's product-moment correlation coefficient (r) and multiple linear regressions were performed to determine the relationships, influence and contribution of the selected characteristics to perceived impact of tea farming on livelihood of smallholder farmers. The results of the study showed that tea farming had a medium perceived impact on livelihood of the 67.8 percent farmers. The selected characteristics of the farmers such as education status, farm size, tea cultivating area, income from tea farming, innovativeness, knowledge on tea farming, and attitude towards selling price of tea leaves have significant and positive effect on perceived impact of tea farming on livelihood of the small holder tea growers. Multiple regression analysis revealed that the whole model explained 63.9 percent of the total variation in the perceived impact of tea farming on livelihood of the small holder tea growers. Education status, innovativeness, knowledge on tea farming, and attitude towards selling price of tea leaves showed significant positive contributions to the perceived impact of tea farming.

Lamiaceae (ballıbabagiller)Türlerinin Peyzaj Tasarımında kullanım Olanakları

Nisanur Alaca

Niğde Ömer Halisdemir, Niğde, Türkiye

ÖZ

Küresel ısınma ile artan sıcaklık, azalan su kaynakları peyzaj tasarımında kullanılan bitki türlerinin seçiminde sınırlama getirmiştir. Bu çalışmada, belirlenen koşullarda uygun olabilecek, kekik *(Thymus sp.)* ve adaçayı *(Salvia sp.)* türlerinin botanik özellikleri, ekolojik gereksinimleri, yetiştirme teknikleri ve peyzaj tasarım çalışmalarında kullanımını incelenmektedir. Her iki bitki de tıbbi ve aromatik bitkiler arasında önemli bir yere sahip olup sağlık, kozmetik ve gıda sektörlerinde geniş kullanım alanına sahiptir. Ayrıca, ekolojiye uygun sürdürülebilir peyzaj tasarımlarında fazlasıyla tercih edilmektedir. Kekik türleri, özellikle Akdeniz iklimine adapte olmuş olup, iyi drene edilen, kireçli ve kumlu-tınlı topraklarda başarılı şekilde yetiştirilmektedir. Uçucu yağ içeriği açısından yüksek değere sahip olan kekik, antimikrobiyal, antioksidan ve antiinflamatuvar özellikleriyle öne çıkmaktadır. Adaçayı ise ılıman iklim koşullarına uyum sağlayan ve toprak seçiciliği düşük olan bir bitkidir. Bununla birlikte, adaçayı bitkisi aynı zamanda antioksidan ve iltihap önleyici bileşenleri sayesinde bağışıklık sistemini destekleyici etkileriyle bilinmektedir. Ayrıca, adaçayının beyin fonksiyonlarını destekleyici etkileri olduğu, hafızayı güçlendirdiği ve sinir sistemine olumlu katkılar sunduğu belirlenmiştir. Kekik *(Thymus sp.)* ve adaçayı *(Salvia sp.)* türlerinin polinatörleri çekerek biyolojik çeşitliliği desteklediği ve sürdürülebilir tarım için önemli olduğu belirtilmektedir. Aynı zamanda, *Thymus* sp. ve *Salvia sp.* türlerinin kuraklığa dayanıklı olması, xeriscaping uygulamalarında avantaj sağlamaktadır. Bu bitki türlerinin doğal zararlılara karşı dirençli olması, kimyasal pestisit kullanımını azaltarak ekolojik tarım uygulamalarına katkı sunmaktadır. Sonuç olarak, kekik ve adaçayı türleri tıbbi, aromatik ve peyzaj uygulamaları açısından büyük potansiyele sahiptir. Ekonomik değeri yüksek bu bitkilerin, ekolojik sürdürülebilirlik ve çevresel iyileştirme açısından da önemli katkılar sunduğu görülmektedir. Ayrıca, iklim değişikliğine bağlı olarak artan kuraklık koşullarında, su kullanımını optimize eden bitkilerin seçilmesi, gelecekte tarımsal üretimde ve peyzaj tasarımlarında önemli bir strateji olacaktır. Çalışmamızda, değerlendirilecek bitkilerle oluşturulmuş peyzaj alanlarında Sketchup, Lumion programlarında titizlikle detaylı modelleme yapılarak görseller oluşturulacaktır.

Abstract

The aquaculture sector is developing in both Mediterranean countries and in our country in parallel with the developing technology. However, the increasing amount of production has also caused new problems. Especially in terms of fish health and product quality improvement, new additives are being defined in the recent days. Glycyrrhizic acid has recently started to be widely used both in human health and in agriculture and aquaculture. n this study, the effects of glycyrrhizic acid on growth as well as acid and alkaline protease activity in juveniles of meagre (*Argyrosomus re*gius), one of the potential new species produced in our country, were investigated. In this study which lasted for 60 days and 3 replicates, total 180 meagre juveniles with an average length of 8.38±0.23 cm and weight of 9.86±0.29 g were fed with 2 different diets in 2 groups as control (0 ml.kg^{-1} GA) and experimental group (4 ml.kg^{-1} GA). At the end of the experiment, significant differences were found in both feed conversion ratio (FCR) and specific growth rate (SGR) ($p<0.01$) and acid and alkaline protease activities ($p<0.05$) obtained from the group to which 4 ml.kg^{-1} GA was added. However, no difference was observed between the experimental groups in terms of survival rate ($p>0.05$). As a result, it was determined that the addition of 4 ml.kg^{-1} GA to the feed provided significant positive results in growth performance, enzymatic activity and nutritional parameters in meagre culture.

Farklı Oranlarda Glisirizik Asit Kullanımının Sarıağız (*Argyrosomus regius*) Juvenillerinde Büyüme Parametrelerine Olan Etkileri

Özet

Akuakültür sektörü, gelişen teknoloji ile paralel olarak Akdeniz ülkeleri ve ülkemizde gelişim göstermektedir. Ancak artan üretim miktarı da beraberinde yeni sorunları gündeme getirmiştir. Özellikle balık sağlığı ve ürün kalitesinin geliştirlşmesi açısından her geçen gün yeni katkı maddeleri tanımlanmaktadır. Glisirizik asitte (GA) son yıllarda hem insan sağlığı hemde tarım ve akuakültürde kullanımı yaygınlaşmaya başlamıştır. Bu çalışmada ülkemizde üretilen potansiyel yeni türlerin başında gelen sarıağız (*Argyrosomus regius*) juvenillerinde glisirizik asidin büyümenin yanında asit ve alkalin proteaz aktivitesine olan etkileri incelenmiştir. Toplamda 60 gün ve 3 tekrarlı süren denemelerde ortalama 8,38±0,23 cm boy ve 9,86±0,29 g ağırlığa sahip 180 adet sarıağız yavrusu 2 grupta kontrol (0 ml.kg^{-1} GA) ve deneme grubu (4 ml.kg^{-1} GA) olmak üzere 2 farklı diyetle beslenmiştir. Deneme sonunda 4 ml.kg^{-1} GA eklenen gruptan elde edilen hem yem dönüşüm oranı (FCR) ve spesifik büyüme oranı (SGR) ($p<0.01$) hem de asit ve alkalin proteaz aktivitelerinde önemli farklılıklar tespit edilmiştir ($p<0.05$). Bununla birlikte yaşama oranı oranı açısından deneme grupları açısından bir farklılık gözlenmemiştir ($p>0.05$). Sonuç olarak yeme 4 ml.kg^{-1} GA eklenmesinin sarıağız kültüründe başta büyüme performansı olmak üzere enzimatik aktivitede ve besleme parametlerinde de önemli olumlu sonuçlar sağladığı tespit edilmiştir.

Abstract

Many plants from the Fabaceae family have long been used for their pharmacological and protective properties, gaining popularity for commercial and academic purposes. Therefore, a study was conducted to evaluate the phytochemical potential of eight high-value species from the Bangladesh Agricultural University Botanical Garden namely: Lojjaboti (*Mimosa pudica* L.), Krisnachura (*Delonix regia* (Bojer ex Hook.) Raf.), Edanchi (*Senna tora* (L.) Roxb.), Kolka-sunda (*Senna occidentalis* (L.) Link), Koroi (*Albizia lebbeck* (L.) Benth.), Karanja (*Pongamia pinnata* (L.) Pierre), Shingra (*Cynometra ramiflora* L.) and Rati (*Abrus precatorius* L.). Total phenolic content (TPC), total flavonoid content (TFC), total antioxidant capacity (TAC) and major pigments (chlorophyll a and b, total carotenoids) were measured using standard protocols. The findings indicated that *S. tora* had the highest TPC (15.999 mg GAE/g DW) and total antioxidant capacity (TAC) with 8.25 mg AA/g FW, while *A. lebbeck* exhibited maximum TFC (27 mg QUE/g DW). *M. pudica* had the highest levels of chlorophyll a and total chlorophyll (a+b), with 1.58 mg/g FW and 2.62 mg/g FW, respectively. *D. regia* leaf showed the highest amount of chlorophyll b (1.81mg/g FW) and carotenoids content (4.52 mg/g FW). Significant positive relationships were found between different phytochemicals such as TPC and TAC; total chlorophyll and total carotenoids, while a non-significant relationship was found between TAC and other pigments. The species were categorized into three clusters and the phytochemicals were grouped into two groups. Variations were observed among all the species, but *S. tora* and *M. pudica* were placed into cluser-1 containing highest phytochemical contents while *C. ramiflora* showed lowest phytochemicals which placed into cluser-3 and remaining others were in cluster-2. These findings suggested the potential of these plants as promising sources for medicine development, with their bioactivity supporting their strong recommendation for their use in traditional medicine.

Reduction of Live Feed in the Early Life of Sea Bream (*Sparus aurata*, L.) Larviculture: Effects on Enzymatic and Histomorphological Development

Özge Aksu[1], Cüneyt Suzer[2], Onurkan Antepli[1], İbrahim Köse[1], Kürşat Fırat[2], Şahin Saka[2]

[1]Yetiştiricilik Bölümü, Fen Bilimleri Enstitüsü, Ege Üniversitesi, İzmir, Türkiye
[2]Yetiştiricilik Bölümü, Su Ürünleri Fakültesi, Ege Üniversitesi, İzmir, Türkiye

Abstract

During the recent years, increasing production costs have caused alternative feeding strategies to reduce costs and increase sustainability in marine fish culture. The fact that live feed production requires high labour force and application has led producers to limitations and the use of new feed additives in this field. In this study, the enzymatic and histological effects of gradual reduction of rotifer (*Brachionus plicatilis*), which is a live food commonly used in the feeding of gilthead sea bream (*Sparus au*rata) larvae produced intensively in our country, were investigated. Within the scope of the experiment, a total of 4 experimental groups, one of which was a control group and the remaining three were experimental groups, were designed with three replications. While the amount of rotifer given to the bream larvae in the control group was not decreased, the other experimental groups were reduced by 25, 50 and 75%, respectively. Natura Pro®, a commercial product, was used instead of the reduced amount of live food. At the end of the experiment, larvae fed with 25 and 50% rotifer reduction had similar growth performance, total protease activity and gastrointestinal histomorphology with the control group receiving full rotifer supplementation and there was no statistical difference ($p>0.05$). However, 75% reduction in rotifer administration resulted in significantly lower growth rate, enzymatic activity and developmental disorders in gastrointestinal histomorphology and higher mortality, suggesting that rotifer supplementation constitutes a critical threshold for larval health and development ($p<0.05$). As a result, it was determined that it is economical and meaningful to reduce the live feed by 25% to 50% with the support of additives added by considering the nutritional requirements of the larvae in the early period in sea bream larviculture.

Key Words: *Sea bream, Sparus aurata, Live food, Digestive enzymes, Histology.*

Çipura (*Sparus aurata*, L.) Larva Yetiştiriciliğinde Erken Dönemde Canlı Yem Kullanımının Azaltılması: Enzimatik ve Histomorfolojik Gelişime Olan Etkileri

Özet

Son yıllarda artan üretim maliyetleri deniz balığı yetiştiriciliğinde maliyetleri düşürmeye ve sürdürülebilirliği artırmaya yönelik alternatif beslenme stratejilerini gündeme getirmiştir. Canlı yem üretiminin yüksek iş gücü ve uygulama gerektirmesi üreticileri bu alanda kısıtlamalara ve yeni katkı maddelerinin kullanımına yönlendirmiştir. Bu çalışmada, ülkemizde yoğun olarak üretimi yapılan çipura (*Sparus aurata*) larvalarının beslenmesinde yaygın olarak kullanılan canlı yem olan rotiferin (*Brachionus plicatilis*) kademeli olarak azaltılmasının enzimatik ve histolojik açıdan etkileri incelenmiştir. Deneme kapsamında biri kontrol kalan üçü deneme grubu olmak üzere toplamda 4 deneme grubu üç tekrarlı olarak tasarlanmış ve kontrol grubundaki çipura larvalarına verilen rotifer miktarı azaltılmaz iken diğer deneme gruplarında sırasıyla %25, %50 ve %75 oranlarında azaltılma yapılmıştır. Azaltılan oranda yerine ticari bir ürün olan Natura Pro® kullanılmıştır. Deneme sonunda, %25 ve %50 rotifer azaltımı ile beslenen larvaların, tam rotifer takviyesi alan kontrol grubuyla benzer büyüme performansı, total proteaz aktivitesi ve gastrointestinal histomorfolojiye sahip olduğunu ve istatistiksel farklılık olmadığını göstermiştir ($p>0.05$). Ancak, rotifer kullanımının %75 oranında azaltılması, önemli şekilde düşük büyüme hızı, enzimatik aktivite ve gastrointestinal histomorfolojide gelişim bozuklukları ile daha yüksek mortaliteye yol açmış ve rotifer takviyesinin larva sağlığı ve gelişimi için kritik bir eşik oluşturduğunu ortaya koymuştur ($p<0.05$). Sonuç olarak çipura larva kültüründe erken dönemde larvanın besinsel gereksinimi göz önünde bulundurularak eklenen katkı maddeleri desteği ile canlı yemin %25 ile %50 oranlarında azaltılmasının ekonomik ve anlamlı olduğu tespit edilmiştir.

Effect of Needle Micro-Perforation Pretreatment as an Alternative to Alkaline Dipping Solution in Grape Drying on Bioactive Compounds

Ebru Köroğlu, Berkay Berk, Sevcan Ünlütürk

Abstract

Grape (*Vitis sp.*) is widely consumed and cultivated globally. In addition to being consumed fresh as wine, juice or dried fruit. It is known for its bioactive compounds, such as flavonoids, polyphenols, anthocyanins, and tannins, which provide health benefits, including antioxidant, anti-inflammatory, and cardioprotective effects. However, grapes are highly susceptible to microbial spoilage due to their high water content, limiting their shelf life. Drying is one of the most common methods used to extend grape shelf life. Pretreatments before drying facilitate moisture removal, accelerating the drying process and preserving nutrients, This study investigates the potential of needle micro-perforation (0.5 mm, 1 mm, and 1.5 mm needle lengths) as an alternative to the widely used dipping method. The total phenolic content, antioxidant capacity (DPPH and CUPRAC), and anthocyanin content of Kavacık grapes (*Vitis vinifera L.* "Alphonse Lavallée" variety) were analyzed. Pretreated grapes were dried using static and convective methods at 60°C, 70°C, and 80°C, and their bioactive compounds were evaluated. Results showed that different pretreatments had varying effects on bioactive compounds. Needle micro-perforation was as effective as the dipping method in preserving total phenolics, antioxidants, and anthocyanins. In static drying, the total phenolic content of samples with needle micro-perforation was approximately 250 mg per 100 g of dry matter higher than that of samples with the dipping treatment. In convective drying, this difference increased to about 400 mg per 100 g of dry matter. Similarly, antioxidant capacity was about 10 µmol Trolox equivalent per gram of dry matter higher in needle micro-perforation samples under static drying and 20 µmol higher under convective drying. In conclusion, needle micro-perforation effectively preserves bioactive compounds and can be considered an alternative to the dipping method.

Key Words: *Kavacık grape, pretreatment, needle micro-perforation, total phenolic content, antioxidant capacity.*

Introduction

Grapes are among the most widely cultivated fruits globally, with an annual production of around 75 million tons (Srivastava et al., 2021). Data from the 2019–2020 period indicates that China leads in grape production, followed by India and Turkey (Sabra et al., 2021; Topalović et al., 2020). According to the Institute of Agricultural Economics and Policy Development, Turkey produced about 3.8 million tons of grapes during the 2023/2024 season, with Manisa being the leading region. Grapes are consumed fresh, used in wine production and processed into products like fruit juice, jam, seed extract, and grape seed oil (Sabra et al., 2021; Srivastava et al., 2021). Approximately 50% of global grape production is allocated to wine, one-third is consumed as fresh fruit, and the remain is used for drying (Srivastava et al., 2021). Grape cultivation depends on climate, disease resistance, fruit color, taste, and whether the variety is seeded or seedless (Sabra et al., 2021). There are between 8,000 and 10,000 *V. vinifera* grape varieties used for commercial purposes (Sabra et al., 2021). Grapes consist of skin, seeds, and pulp. They are rich in bioactive compounds, especially polyphenols, which vary across fruit components (Zhou et al., 2022). These include flavonoids, phenolic acids, and anthocyanins (Kupe et al., 2021). The concentration of these compounds varies by grape variety and is linked to health benefits. Polyphenols in grapes may help prevent cardiovascular diseases, reduce cholesterol, control blood pressure, and protect against several cancers, including breast, skin, lung, colon and prostate (Aubert & Chalot, 2018; Sabra et al., 2021; Topalović et al., 2020). Grapes are also rich in sugars and contain vitamins (A, B1, B3, C) and minerals (iron, potassium, calcium, sodium) (Kirazcı, 2022). Kavacık grapes are grown in Kavacık village in the Karabağlar district of Izmir, Turkey, from the *Vitis vinifera L. 'Alphonse Lavallée'* variety. They are known for their high phenolic content and have received geographical indication as a table grape (Ministry of Culture and Tourism, 2023). Studies confirm the high polyphenol and bioactive compound content of this variety (Aubert & Chalot, 2018). Besides fresh consumption, Kavacık grapes are used to produce molasses and Turkish delight.

Due to their high water content, grapes are susceptible to spoilage from microbial and chemical reactions. Drying is commonly used to extend shelf life by reducing water content and water activity, slowing microbial growth and chemical degradation (Adeyeye et al., 2022). Drying is simple, cost-effective and reduces weight and volume, lowering packaging. Transportation, and storage costs (Ozkan et al., 2022). The drying method affects processing time, energy use and product quality (Ozkan et al., 2022). Hot air drying (HAD) is a faster alternative to sun drying. It offers benefits like reduced drying time, ease of use, low operational costs and better preservation of food safety and quality (Senadeera et al., 2020). Cabinet dryers, commonly used in HAD, prevent microbial spoilage, improving product quality (Yasmin et al., 2022). However, uneven air distribution in these dryers can be addressed by modifying fan placement or using dual fans (Günaydın et al., 2022). Hot air drying of grapes is a widely studied topic in the literature, Hermassi et al. (2017) investigated the drying of seedless Sultani grapes using a hot air dryer at various temperatures, evaluating moisture loss, shrinkage and drying rates through mathematical models. They found that moisture diffusivity increased with temperature, ranging from 3.56×10^{-10} to 12.6×10^{-10} m^2/s, and calculated an activation energy of 57.76 kJ/mol. Similarly, Shafiq et al. (2022) studied seedless grapes using different pretreatments (K_2CO_3 + ethyl oleate, olive oil, hot water and control) and three drying methods (cabinet-type tray dryer, sun tunnel, and open-air drying). The results showed that grapes pretreated with K_2CO_3 + ethyl oleate and dried in a tray dryer had the shortest drying time (26.08 h), with a lighter yellow-green appearance and softer texture.

Drying is energy-intensive and time-consuming, leading to the use of pretreatments to enhance drying efficiency, reduce energy costs and preserve food quality (Gavahian et al., 2024). Pretreatments can be physical (thermal and non-thermal) or chemical (Bassey et al., 2021; Deng et al., 2019). Chemical pretreatments involve immersing the product in solutions or exposing it to gases (Deng et al., 2019). Alkaline dipping in a potash solution is a common chemical pretreatment for grape drying, typically containing 5% potassium carbonate and 1–2% olive oil (Çoban & Abuşka, 2024). Potassium carbonate removes the waxy layer on the grape skin, facilitating moisture loss and shortening drying time (Carranza-Concha et al., 2012). This method preserves color and reduces drying time in seedless and black grapes (Doymaz, 2006; Shafiq et al., 2022). However, concerns about chemicals in food and water safety have increased interest in sustainable, chemical-free methods (Deng et al., 2019). Physical pretreatments, such as ultrasonic field, microwave, pulsed electic field enhance drying efficiency without chemicals (Bassey et al., 2021; Deng et al., 2019). Needle micro-perforation, which is a physical pretratment, creates small pores in the fruit peel, increasing diffusion and accelerating moisture removal. This method is more effective than some chemical methods in reducing drying time (Jazini & Hatamipour, 2010; Mabellini et al., 2013). Olives, plums, and cherries benefit from this technique, as the waxy layer on their skin acts as a barrier to moisture removal (Mabellini et al., 2012). In a study on olives, different pretreatments such as perforation with a metal brush, blanching, a combination of perforation and blanching and perforation followed by immersion in brine were applied before hot air drying. It was found that perforation had a positive effect on the drying process, enhancing moisture loss and improving overall drying efficiency (Gambella, 2000).

In this study, Kavacık grapes were dried at 60, 70, and 80°C using static and convective dryers. Needle micro-perforation and alkaline dipping pretreatments were applied, with needle lengths of 0.5, 1.0, and 1.5 mm tested. The aim of this study is to determine and evaluate the effects of needle micro-perforation pretreatment on bioactive compounds of Kavacık grapes by comparing with alkaline dipping pretreatment.

Materials and Methods

Materials

Kavacık village (Karabağlar, Izmir) sourced *Alphonse Lavallée (Vitis vinifera L.)* grapes were harvested at optimum ripeness. To reduce fungal contamination, grapes were immersed in 5% vinegar for 15 minutes, rinsed with water, air-dried, and stored in 500 g polyethylene bags at 4 °C for up to 15 days. Average berry diameter and length were 25.23 ± 3.80 mm and 25.99 ± 4.92 mm. Respectively, with a mean weight of 8.90 ± 0.48 g. Initial moisture content was 4.04 ± 0.02 kg water/kg dry matter (AOAC method, 100 °C). Grapes were divided into two pretreatment groups as alkaline dipping (control) and needle micro-perforation.

Pretreatments

In this study, needle pretreatment was compared with the industry-standard alkaline dipping method, which is widely used for grape drying. Accordingly, the control group (DG) was prepared for drying by immersion in an alkaline solution containing 5% (v/v) potassium carbonate (K_2CO_3) and 1% (v/v) extra virgin olive oil at 25 °C for 2 minutes, following the method described by Doymaz and Altıner (2012). Needle micro-perforated grapes (MG0.5, MG1.0, and MG1.5) were punctured using micro-perforators with the same number of needles but varying needle lengths: 0.5 mm for MG0.5, 1.0 mm for MG1.0 and 1.5 mm for MG1.5. These lengths were selected to be shorter than, equal to or longer than the average skin thickness of the grapes.

Drying Process

Grape samples (approximately 25 g per group), including the needle micro-perforated (MG0.5, MG1.0, MG1.5) samples and the alkaline-dipped control group (DG), were dried at 60, 70, and 80 °C using a static cabinet dryer and a convective hot air dryer. Both systems featured temperature control to ensure consistent thermal conditions throughout the drying process. The airflow velocity in the convective dryer was measured as approximately 2.5 m/s using a mini anemometer (UT363, Uni-T, China). The drying process continued until the sample weights reached a final moisture content of 0.24 kg water/kg dry matter.

Bioctive Compound Analysis

Total Phenolic Content (TPC)

The total phenolic content was determined using a modified version of the method outlined by Akbaş et al. (2017). For this analysis, extracts were prepared from both dried and fresh grape samples. For the dried grape extracts, approximately 2–3 grams of dried grapes were weighed and immersed in a sealed container with a solvent at a ratio of 1:10 (dried grape:solvent). The solvent comprised 80% methanol, 19.9% distilled water and 0.1% hydrochloric acid (HCl). The samples were incubated at +4 °C for 24 hours. Similarly, for the fresh grape extracts, approximately 10 grams of fresh grapes were weighed and combined with the same solvent at a 1:10 ratio. Following extraction, the grapes were ground in a mortar and filtered. Similarly, for the fresh grape extracts, approximately 10 grams of fresh grapes were weighed and combined with the same solvent at a 1:10 ratio.

For the phenolic content analysis, 0.5 ml of the extract was mixed with 2.5 ml of 0.2 N Folin–Ciocalteu reagent, vortexed, and allowed to incubate in the dark for 3 minutes. Following this, 2 ml of 7.5% sodium carbonate solution was added and, the mixture was vortexed again and incubated for 30 minutes. After the incubation period, absorbance was measured at 760 nm using a UV-Vis spectrophotometer (PG Instruments. United Kingdom). Calibration was performed using gallic acid standard solutions of varying concentrations (10, 20, 40, 50, 80, and 100 mg/ml). The same procedure was applied to each standard solution, and a standard curve was generated from the absorbance values. The total phenolic content was then calculated and expressed as milligrams of gallic acid equivalent (mg GAE) per 100 grams of dry matter.

Total Antioxidant Capacity

The total antioxidant capacity was evaluated using the DPPH (2.2-Diphenyl-1-picrylhydrazyl) radical scavenging method, as described by Özkan (2022) with some modifications. In this procedure, 0.1 mL of the grape extract was added to a test tube, followed by 4.9 mL of 0.1 mM DPPH solution. The mixture was vortexed and incubated in the dark at room temperature for 20 minutes. Absorbance of the DPPH solution was measured at 517 nm using a UV-Vis spectrophotometer (PG Instruments. United Kingdom). Calibration was performed with Trolox standard solutions at concentrations of 100, 500, 1000, 1500, 2000, and 2500 µmol/L, following the same procedure. A standard calibration curve was generated based on the absorbance values, and the total antioxidant capacity was calculated and expressed as milligrams of Trolox Equivalent (TE) per gram of dry matter.

The total antioxidant capacity was also measured using the CUPRAC (Cupric Ion Reducing Antioxidant Capacity) method, following the modified procedure by Özkan (2022). In this method, 0.1 mL of grape extract (fresh or dried) was transferred to a tube, and sequentially, 1 mL of each of the following solutions was added: $CuCl_2$ (10 mM), neocuproine (7.5 mM, alcoholic), NH_4Ac buffer (1 M. pH 7.0), and distilled water. The mixture was incubated in the dark at room temperature for 1 hour. Absorbance was then measured at 450 nm using a UV-Vis spectrophotometer (PG Instruments, United Kingdom). For calibration, Trolox standard solutions with concentrations of 1000, 1500, 2000, 2500, 3000, and 4000 µmol/L were prepared, and the CUPRAC method was applied for each. A calibration curve was constructed based on the absorbance values and the antioxidant capacity was calculated and expressed as milligrams of Trolox Equivalent (TE) per gram of dry matter.

Total Anthocyanin Content (TAC)

The total anthocyanin content was measured using the pH differential method as described by Özkan (2022). In this method, 0.025 M potassium chloride (KCl) and 0.4 M sodium acetate ($CH_3COONa \cdot 3H_2O$) solutions were prepared using distilled water. For the measurement, 0.8 mL of the grape extract was mixed with 3.2 mL of the potassium chloride solution, and a second 0.8 mL of the extract was mixed with 3.2 mL of the sodium acetate solution in different test tubes. The mixtures were incubated in the dark at room temperature for 30 minutes.

Absorbance values were then recorded at 510 nm and 700 nm using a UV-Vis spectrophotometer (PG Instruments. United Kingdom).

The total anthocyanin content was calculated using Equations 1 and 2:

$$A = [\text{A510nm} - \text{A700nm}]\text{pH1.0} - [\text{A510nm} - \text{A700nm}]\text{pH4.5} \quad (1)$$

$$TA = \frac{A \times MW \times D_f \times 1000}{\varepsilon \times L} \quad (2)$$

Where A is absorbance, A510 is absorbance at 510 nm, A700 is absorbance at 700 nm, MW is molecular weight of malvidin 3-glucoside (463.3 g/mol), D_f is dilution factor, ε is molar absorption coefficient (28.000 L/mol*cm), L is optical path length of the cuvette (1 cm), The results were expressed as mg malvidin-3-glucoside per 100 g dry matter.

Statistical Analysis

In this study. the effects of alkaline dipping and needle micro-perforation pretreatments on bioctive compounds of Kavacık grape were examined using selected independent variables (needle length, drying temperature). All measurements were repeated three times, and statistical differences between pretreatments were determined using analysis of variance (ANOVA) and Tukey's post-hoc test ($P \leq 0.05$). The data are presented in tables containing the means and standard deviations of the results from the three repeated trials.

Result and Discussion

Bioactive contents of fresh grapes are given in Table 1. Total phenolic value of fresh Kavacık grape was found as 1097.97 mg GAE/100 g dw, antioxidant capacity was found as 32.49 µmol TE/g dw by DPPH method, 151.59 µmol TE/g dw by CUPRAC method and total anthocyanin content was found as 14.45 mg mlv-3-glc/100 g dw. Özkan (2022) reported the total phenolic content of the black-scented 'Isabella' grape (Vitis labrusca L. × Vitis vinifera L.), which is rich in bioactive compounds, as 1101.61±35.12 mg GAE/100 g dw. The DPPH Free Radical Scavenging Activity was reported as 34.51±1.21 µmol TE/g dw, the antioxidant activity value by the CUPRAC method was 175.82±5.35 µmol TE/g dw, and the total anthocyanin (TAC) content was 341.88±4.42 mg mlv-3-glc/100 g dw. The total phenolic content (TPC) of the Kavacık grape variety used in this study was found to be similar to that of the black-scented grape, while the TAC value was lower. This difference can be attributed to the use of different grape varieties in the studies, as well as the varying climatic and soil conditions in which the grapes were grown, leading to differences in their bioactive properties.

Table 1. Bioactive content of fresh grape.

	Fresh Grape
TPC (mg GAE/100 g dw)	1097.97 ± 168.95
Antioxidant Capacity (DPPH - µmol TE/g dw)	32.49 ± 2.01
Antioxidant Capacity (CUPRAC -µmol TE/g dw)	151.59 ± 25.99
TAC (mg mlv-3-glc/100 g dw)	14.45 ± 0.36

The bioactive contents of the samples dried with a static dryer are shown in Table 2. While the total phenolic values of dipped grapes (DG) ranged between 440.50 and 604.40 mg GAE/100 g dw, the total phenolic values of micro-perforated grapes (MG) ranged between 427.30 and 886.40 mg GAE/100 g dw. Phenolic compounds not only contribute to the color, taste, and aroma of grapes but also provide significant nutritional and health benefits (Çoklar & Akbulut, 2017). As shown in Table 2, different pretreatments applied to samples dried using a static dryer did not lead to a significant difference in the total phenolic content (TPC) ($P > 0.05$). Additionally, it was found that temperature increase did not cause a significant difference in the TPC of DG and MG0.5 samples ($P > 0.05$), but both low (60°C) and high (80°C) temperatures resulted in a significant difference in TPC for M1.0 and MG1.5 samples ($P < 0.05$). The values obtained in this study are consistent with those reported in the literature. For instance, Barbosa da Silva et al. (2023) found that the total phenolic content of BRS Vitoria grapes ranged from 340.98 to 1794.80 mg GAE/100 g dw following convective drying after ethanol and ultrasound pretreatments. In a previous study, the total phenolic content of freeze-dried and oven-dried BRS Magna grape skin was found to be 148.3 and 149.9 mg/100 g dw, respectively. The total phenolic content in this study is similar to those reported in previous studies (da Silva et al., 2020).

*If means ± standard deviation within a row are shown with different capital letters, there is a statistically significant difference ($P < 0.05$).
**If means ± standard deviation within a column are shown with different lower case letters, there is a statistically significant difference ($P < 0.05$).

Antioxidants are compounds that neutralize free radicals, which are produced through various mechanisms in the human body and contribute to oxidative stress and cellular damage (Kunter & Keskin, 2019). Antioxidant capacity can be measured using different methods, and in this study, antioxidant levels were assessed using the DPPH and CUPRAC methods. The CUPRAC method is based on the reduction of Cu^{2+} to Cu^{+}, while the DPPH method based on the color change resulting from the neutralization of the DPPH radical (Munteanu & Apetrei, 2021). In this study, it was observed that the antioxidant capacity of Kavacık grapes dipped and micro-perforated by DPPH method varied between 60.58 and 77.44 µmol TE/g dw (Table 2). When evaluating the antioxidant capacity of Kavacık grapes measured by the DPPH method, it was found that pretreatments applied during drying at low temperature (60°C) did not significantly affect the antioxidant capacity ($P > 0.05$). After drying at 70°C, the antioxidant capacities of DG samples differed from those of MG samples ($P < 0.05$), with MG samples showing similar antioxidant capacity values ($P > 0.05$). At 80°C, antioxidant capacities of DG and MG1.0 samples were similar but differed significantly from those of MG0.5 and MG1.5 samples ($P < 0.05$). Overall, the data obtained from the DPPH method indicate that drying temperature significantly affected the antioxidant capacity of DG samples, but had no significant effect on MG samples. Furthermore, it was observed that the antioxidant capacity of MG samples (except at high temperatures) was generally higher than that of DG samples. Antioxidant capacity values of Kavacık grapes measured by the Cuprac method ranged between 124.24 and 178.28 µmol TE/g dw (Table 2). When considering the antioxidant capacity values measured by the CUPRAC method, high temperature appeared to significantly influence both DG and MG samples, creating a notable difference ($P < 0.05$). The results from the two methods differed, likely due to the distinct measurement principles. The CUPRAC method evaluates the antioxidant capacity based on the reduction of the Cu^{2+}–neocuproine (2,9-dimethyl-1,10-phenanthroline) complex to the Cu^{+} form at pH 7, with maximum absorbance at 450 nm. Meanwhile, the DPPH (2,2-diphenyl-1-picrylhydrazyl) method assesses antioxidant activity through the sample's ability to scavenge the stable DPPH• free radical, leading to a decrease in absorbance at 517 nm (Patricia and Syaputri, 2021). In a previous study, the antioxidant content of black grapes dried using hot air was reported as 13.71 µmol TE/g dry matter by the DPPH method and 70.71 µmol TE/g dry matter by the CUPRAC method (Özkan et al., 2022). However, the total antioxidant capacity of Kavacık grapes was significantly higher when measured using these two methods.

Anthocyanins are pigments responsible for the red, purple, blue, and black colors in grapes (Eroğlu, 2012). In this study, it was found that the anthocyanin content of Kavacık grapes was significantly influenced by pretreatment only during the drying process at 70°C ($P < 0.05$). Specifically, MG samples dried at 70°C exhibited higher anthocyanin levels. The effect of drying temperature was more pronounced in DG samples, where the temperature caused a significant difference in total anthocyanin content (TAC) values ($P < 0.05$). In general, the TAC values of MG samples were not significantly affected by changes in drying temperature. In a previous study, the anthocyanin content of black grapes dried using the hot air method was reported to be 46.81 mg mlv-3-glc/100 g

dry matter (Ozkan et al., 2022). In contrast, the anthocyanin content of Kavacık grapes in this study ranged from 61.81 to 70.51 mg mlv-3-glc/100 g dry matter (Table 2), which was higher than the previous findings. This difference can be attributed to variations in grape variety and the pretreatment methods used.

The bioactive contents of the samples dried with a convective dryer are shown in Table 3. It was found that pretreatments caused a significant difference in terms of total phenolic content (TPC) at all drying temperatures ($P < 0.05$). Total phenolic values of MG samples were found to be higher than DG samples for all drying temperatures. While the TPC values of DG samples ranged between 802.70-992.40 mg GAE/100 g dw, the TPC values of MG samples ranged between 953.15-1364.50 mg GAE/100 g dw (Table 3). The results are similar to previous studies and it is thought that the differences are due to the grape variety. For example, it was previously found that the total phenolic content of BRS Vitoria grapes after ethanol and ultrasound pretreatments and convective drying had values between 340.98 and 1794.80 mg GAE/100 g dw (Barbosa da Silva et al., 2023). In another study, the effect of different drying methods on the total phenolic content (TPC) of seedless purple raisins was investigated. The TPC values for room-dried (PRD), shielding film-dried (PFD), and sun-dried (PSD) samples were reported as 536.8 ± 22.3, 436.8 ± 9.2, and 220.5 ± 2.2 mg GAE/100 g, respectively (Qin et al., 2020). These results indicate that the drying method has a significant influence on the preservation of phenolic compounds. In addition, it was observed that the TPC amounts of Kavacık grapes used in these experiments were higher than those used in the static method (Table 2).

In this study, the antioxidant content of Kavacık grapes was evaluated using the DPPH and CUPRAC methods. The results indicated that the antioxidant capacities measured by the DPPH method were significantly influenced by the drying pretreatments, particularly at 60°C and 80°C ($P < 0.05$). It was observed that antioxidant capacity decreased with increasing drying temperature for all samples, and both DG and MG samples showed a significant temperature effect on their antioxidant capacities. However, when the antioxidant capacities measured by the CUPRAC method were considered, pretreatments did not significantly affect the samples dried at the same temperature ($P > 0.05$). Also, it was found that the antioxidant capacities of MG samples were significantly influenced by the drying temperature, while no significant effect was observed in DG samples. The antioxidant values obtained using the DPPH and CUPRAC methods ranged from 57.02 to 161.90 µmol TE/g dry matter and 156.96 to 234.60 µmol TE/g dry matter, respectively (Table 3). The antioxidant values of Kavacık grapes were found to be higher than those reported in studies on black grapes in the literature. For example, the antioxidant content of black grapes dried using the hot air method was 13.71 µmol TE/g dry matter by the DPPH method and 70.71 µmol TE/g dry matter by the CUPRAC method (Ozkan et al., 2022). Similarly, a study by Çoklar and Akbulut (2017) reported the antioxidant capacity of freeze-dried Ekşikara black grapes (Vitis vinifera L.) as 60 µmol TE/g dry matter by the DPPH method. These findings highlight that the antioxidant values of Kavacık grapes are generally higher than those of black grape varieties.

Table 3. Bioactive content of dried grapes (Convective dryer).

Dryer Type		TPC (mg GAE/100 g dw)			
		DG	MG0.5	MG1.0	MG1.5
Convective	60°C	802.70 ± 34.20^{Cb}	1020.00 ± 58.90^{ABb}	953.15 ± 7.80^{Bb}	1128.10 ± 16.90^{Aab}

	80°C	96.99 ± 6.16^{ABb}	122.60 ± 15.70^{Ab}	77.40 ± 22.40^{ABb}	57.02 ± 8.06^{Bc}
		Antioxidant Capacity (CUPRAC -µmol TE/g dw)			
	60°C	156.96 ± 8.06^{Aa}	199.28 ± 12.69^{Aab}	180.28 ± 1.64^{Ab}	205.72 ± 8.06^{Aab}
	70°C	173.63 ± 1.19^{Aa}	178.80 ± 12.09^{Ab}	187.14 ± 0.90^{Ab}	190.52 ± 1.79^{Ab}
	80°C	182.20 ± 19.90^{Aa}	229.67 ± 1.94^{Aa}	232.31 ± 8.06^{Aa}	234.60 ± 17.00^{Aa}
		TAC (mg mlv-3-glc/100 g dw)			
	60°C	12.49 ± 8.20^{Ab}	9.15 ± 1.58^{Ab}	25.55 ± 3.31^{Ab}	18.18 ± 2.68^{Aa}
	70°C	50.76 ± 3.00^{Aa}	14.06 ± 4.10^{Bb}	13.05 ± 2.37^{Bc}	18.63 ± 7.42^{Ba}
	80°C	14.84 ± 8.68^{Ab}	33.02 ± 1.58^{Aa}	33.13 ± 0.47^{Aa}	26.11 ± 2.84^{Aa}

*If means ± standard deviation within a row are shown with different capital letters, there is a statistically significant difference ($P < 0.05$).
**If means ± standard deviation within a column are shown with different lower case letters, there is a statistically significant difference ($P < 0.05$).

Total anthocyanin values of convective dryer-dried, pretreated Kavacık grapes ranged between 12.49 and 50.76 mg mlv-3-glc/100 g dw, while those of micro-perforated Kavacık grapes ranged between 61.69 and 70.51 mg mlv-3-glc/100 g dw (Table 3). In this study, it was found that pretreatments at both low (60°C) and high (80°C) temperatures did not significantly affect the anthocyanin content of Kavacık grapes ($P > 0.05$). A significant difference was observed between DG and MG samples at 70°C, although no significant difference was noted among MG samples with varying needle lengths. Furthermore, the drying temperature influenced the anthocyanin content in all samples except for the MG1.5 samples. In a previous study conducted with Carmenere grapes, the anthocyanin content of freeze-dried and oven-dried grape skins was found to be 14.33 and 12.38 mg mlv-3-glc/100 g dw, respectively (de Torres et al., 2010). In the current study, the anthocyanin content of Kavacık grapes was found to be similar to that of the previous study. The observed differences are likely attributed to variations in pretreatment methods and grape variety.

Conclusion

This study showed that needle micro-perforation is an effective pretreatment method for drying grapes and offers equivalent or superior performance to the traditional immersion method in preserving bioactive compounds. Needle micro-perforation significantly increased the retention of total phenolics, antioxidant capacity and anthocyanins in Kavacık grapes during both static and convective drying processes. Higher bioactive compound values were observed in needle micro-perforated grapes, especially at increasing drying temperatures. The differences were evident in convective drying, indicating the combined effectiveness of airflow and micro-perforation in preserving nutritional quality. Overall, needle micro-perforation is a non-chemical pretreatment alternative that can be used to improve the quality of dried fruits.

Analysis of Heavy Metals in Soil and Medicinal Plants (*Bryophyllum Pinnatum[BPi]* and *Vernonia Amygdalina [VA]*) using Risk Assessment Indices

Oluwadurotimi O. Akintade[1*], Kehinde A. Oyegoke[1], Fausat O. Odujebe[1], Grace O. Ayorinde[1]

[1]Department of Chemical Sciences, Faculty of Applied Sciences, KolaDaisi University, Ibadan, Oyo State, Nigeria.
*Corresponding Author: tsnakin@gmail.com; oluwadurotimi.akintade@koladaisiuniversity.edu.ng

Abstract

The study of heavy metal contamination in soil and plants is crucial in environmental science because it has significant implications for ecosystem health and human well-being. Heavy metals have become environmental pollutants due to human activities such as industrialization, agricultural intensification, and urbanization. The aim of this research is to analyse heavy metals in soil and medicinal plant of Bryophyllum Pinnatum (BPi) and Vernonia Amygdalina (VA) using environmental and health risk indices.

The soil and medicinal plant (leaves, stem, root) for heavy metals (Mn, Fe, Cu, Zn, Cr and Pb) were analysed using Atomic Absorption Spectrophotometer (AAS). The soil and medicinal plant (leaves, stem, root) calculated environmental and health risk assessment. Data were evaluated using descriptive statistics and Pearson correlation. The heavy metal concentrations in soil for BPi and VA ranged from 15.82-217.33 and 366.38-513.60 mg/kg for Mn; 8541.78-9632.78 and 6500.23-16045.03 mg/kg for Fe; 16.30-18.93 and 5.95-23.58 mg/kg for Cu; 161.18-202.35 and 18.88-255.28 mg/kg for Zn; 12.93-18.63 and 6.00-15.58 mg/kg for Cr while Pb is 24.60-30.20 and 0.00-23.65 mg/kg. Heavy metal concentrations in medicinal plants (leaves, stem and root) of BPi and VA ranged from 3.08-72.60 and 8.53-109.13 mg/L for Mn; 36.05-2546.34 and 159.23-382.63 mg/kg for Fe; 5.55-13.68 and 4.13-14.05 mg/kg for Cu; 6.55-104.85 and 9.78-58.78 mg/kg for Zn; 0.0020.75 and 0.00-6.15 mg/kg for Cr while Pb was 0.00-18.08 and 0.00-0.00 mg/kg. Mn, Cu, Zn, Cr and Pb were below the WHO allowable level while Fe especially in the soil was above the WHO permissible limit. The heavy metals was positively correlated in medicinal plants and soil of BPi and VA which are: Mn (1.00 and 1.00); Fe (0.99 and 0.93); Cu (0.93 and 0.77); Zn (0.96 and 0.68); Cr (0.70 and 0.87); Pb (0.95 and 0.67). Ecological risk assessment shows that the soil of the medicinal plants indicates severe pollution. Health risk assessment observes HI < 1, and do not pose non-carcinogenic risk in both plants and soil for adults and children. Also, the two medicinal plants did not pose carcinogenic risk because their Pb and Cr value are 0.00 which is less than $1*10^{-4}$. Non-carcinogenic and Carcinogenic risks assessed on the soil and leaf of plants indicates that the two samples (BPi and VA) can be used for the cure of some illnesses such as cancer and malaria already specified in literature because they have been proven to be below the threshold value.

Keywords: *Heavy metals, Non-carcinogenic risk, Soil, Medicinal plants, Ecological risk*

Use of Digital Technologies in Agriculture: Comparative Analysis in terms of Production and Marketing

Nebi Seren[1]

[1]Computer Technologies, Orhangazi Yeniköy Asil Çelik Vocational School, Bursa Uludağ University, Bursa, Turkiye

Abstract

This study first analyses the use of digital technologies in agriculture from two different perspectives. Then, correlation analyses using these data aim to show which countries that focus on which of the two perspectives are ahead in agricultural exports. In the study, publications containing the word 'agriculture' in the title, abstract or keywords section of the Scopus database and the keywords 'digital technology' and 'production' in the all fields section were selected and recorded as publications in which digital technologies in agricultural production were investigated. Then, in the Scopus database, publications containing the word 'agriculture' in the title, abstract or keywords section and the words 'digital technology' and 'marketing' in the all fields section were kept in a separate category and recorded as publications in which digital technologies in marketing of agricultural products were investigated. These two data sets were subjected to correlation analysis with export data obtained from OECD databases, and interactions on the axis of agriculture, digital technologies, production and marketing were revealed. After selecting the OECD member countries with export data from all the data obtained, the number of academic publications of these countries with the specified conditions is given in separate tables. The correlation analysis carried out on OECD member countries revealed a statistically significant and strong positive relationship between the average agricultural export volumes for 2020-2024 and the number of scientific publications containing the terms agriculture, digital technologies and production indexed in the Scopus database. The Pearson correlation coefficient was calculated as $r = 0.813$, and the significance level was $p = 0.004$. When a similar correlation analysis was conducted with publications containing agriculture, digital technologies and marketing terms, the Pearson correlation coefficient was $r = 0.958$ with a significance level of $p < 0.001$. This finding indicates that countries that produce higher levels of academic output in agriculture (publications containing both production and marketing terms) tend to have higher export performance in the agricultural sector. The results suggest that there may be a significant relationship between academic productivity and economic output in international agricultural trade.

Key Words: *Digital Agriculture Technologies, Agricultural Production, Agricultural Marketing, Agricultural Exports, Correlation Analysis*

Introduction

Nowadays, when digital technologies have taken a prominent place in all areas of life, the agricultural sector is also experiencing its share of transformation. This transformation manifests itself both in production processes and marketing processes. On the other hand, businesses that internalise digital technologies in supply chain management and consumer relations have an advantageous position in the competitive market. Digitalisation plays an important role in changing the traditional understanding of agriculture by directly affecting food safety, environmental sustainability and rural development (MacPherson et al., 2022; Lin et al., 2020).

The contributions of digital technologies to the agricultural sector are emphasised at many different points. In their study, Prashanth et al. (2025) emphasise that digital technologies are widely used to increase production efficiency, optimise the use of resources, reduce environmental impacts and improve marketing strategies (Prashanth et al., 2025). In other case studies, it is emphasised that artificial intelligence, Internet of Things (Iot), blockchain, big data analytics and remote sensing technologies contribute to the transformation and development of agriculture (Wolfert et al., 2017; Lin et al., 2020). When all these comprehensive areas are evaluated, the increase in technology-based agricultural practices in developing and developed countries shows that digital agricultural practices have become a global research topic.

This study aims to analyse the effects of digital technologies on agricultural production and marketing processes comparatively. It also reveals the interaction of the use of these technologies with the agricultural export performance of countries. Thus, it tries to show how agricultural digital transformation contributes to production, marketing, foreign trade and global competitiveness.

Turkish Science and Technology Publishing (TURSTEP)
www.turstep.com.tr

In the context of production, Iot-based innovative agricultural applications strengthen decision support processes in areas such as crop management, irrigation systems, crop monitoring and environmental control through data processing (Prashanth et al., 2025). In addition, soil condition and weather conditions can be monitored through sensors and satellite data, making it possible to intervene at the right time (Wolfert et al., 2017). Artificial intelligence and machine learning algorithms facilitate operations in areas such as disease detection, crop recommendation, yield estimation and management of automated agricultural machinery (MacPherson et al., 2022).

In marketing, digital technologies can significantly contribute to delivering agricultural products to the target audience, increasing brand value and making market analyses more accurate (Zhang et al., 2021). Thanks to digital channels such as email marketing, social media, SEO, mobile applications and e-commerce platforms, producers can provide direct access to consumers, thus reducing traditional intermediary structures and improving profit margins (Zhang et al., 2021). In addition, digital marketing has facilitated the opening of agricultural products to global markets.

Considering all these effects, the relationship between academic publication outputs and the agricultural export performance of countries will be evaluated comparatively through the production and marketing perspectives of digital technologies. This evaluation aims to provide guiding information to policymakers, agricultural sector producers, and those who want to market these products by revealing which digitalisation approach is more closely related to agricultural export success.

Materials and Methods

Conceptual Framework

Digital technologies offer support that can provide intensive contributions in the short term in terms of productivity, sustainability and marketing strategies in agriculture to producers and those who want to market agricultural products. At this point, it is important to detail how digital technologies are used in agriculture and to reveal how they are examined in the literature. How digital technologies are used in production and marketing processes in agriculture will be analysed under two main categories. Digital technologies in production and marketing are examined in the literature, respectively.

Digital Technologies in Agriculture Production

Information technologies enable agricultural data storage, transmission and reuse through hardware and software systems. Birt et al. (2012) state that these systems improve data flow in agricultural activities and contribute to decision-making processes. Producers manage resources more effectively by providing accurate and timely access to data; thus, agricultural productivity can increase. In the study by Yechin et al. (2021), business technology contributes to efficiency and coordination in agricultural supply chains.

Communication technologies enable the connection between users and devices through digital networks. Kiambi (2018) states that these technologies facilitate farmers' information sharing in regions such as Africa and increase market access. In production processes, these tools help drive efficient workflows and stronger coordination along the value chain.

Operational technologies secure agricultural systems and support field operations by combining software and hardware. Wei et al. (2024) emphasise that these technologies enable the execution of autonomous processes in large-scale agricultural areas and reduce the need for manual labour. Thus, productivity is increased and cost control is facilitated.

Artificial intelligence technologies enable agricultural processes to be carried out more efficiently from planting to distribution through real-time data and learning algorithms. Akintuyi (2024) states that artificial intelligence increases operational efficiency and contributes to sustainable production choices. Thanks to artificial intelligence technologies, applications that can go beyond autonomy, make their own decisions, and determine their next steps by making inferences from past data add value to agricultural production.

Digital Technologies in Agricultural Marketing

The importance of digital marketing applications in agriculture is addressed from various perspectives. In their analysis, Leng and Tong emphasise the role of digital technologies in supporting the sustainable development of agriculture-related industries (Leng & Tong, 2022). Leng and Tong's research shows that aligning digital marketing with sustainable practices can positively impact producers (Leng & Tong, 2022).

Addressing the regional dimensions of digital technologies in agriculture, Nemchenko et al. emphasise that adopting an innovative approach to agricultural production is essential for the competitive advantage of digitalisation and the change of technological structures (Nemchenko et al., 2020). Beksultanova et al. discuss the comprehensive restructuring required for the agricultural sector to adapt to digital innovations, stating that it increases productivity and enables reaching broader audiences (Beksultanova et al., 2023).

In addition to these studies, some look at the phenomenon from different perspectives and examine the challenges and opportunities sustainable digital marketing can offer in agriculture. Kosior discusses how digital technologies such as big data and Iot can effectively increase productivity and ensure sustainable use of resources in the agri-food sector (Kosior, 2018). Moreover, the role of e-commerce in agricultural wholesale markets should not be ignored. Luo and Wang state that e-commerce platforms can significantly increase farmers' access to broader markets, thus reducing information complexity and minimising agricultural waste (Lou & Wang, 2024).
E-WOM (electronic word-of-mouth marketing) is an important tool in marketing agricultural products, as it is effective in all other sectors. Arslan and Güven's study investigates the effect of online comments on consumers' purchasing behaviour. The role of electronic word-of-mouth communication in shaping consumers' product preferences provides guiding information on the marketing of agricultural products (Arslan & Güven, 2020).
Blockchain technology offers a secure, web-based financial system with encrypted data to ensure the traceability and security of agricultural products. Chiaraluce et al. (2024) state that blockchain technology increases security in agricultural supply chains and prevents fraud (Chiaraluce et al., 2024). This technology is an important tool for providing reliability and transparency in marketing agricultural products.

Method

This study was created with a quantitative research design to comparatively examine the use of digital technologies in production and marketing processes in agriculture. The data in this study were obtained from Bursa Uludağ University, Scopus database and OECD databases between April 5 and April 10, 2025. Within the scope of the research, publications containing the term "agriculture" in the title, abstract or keywords section and the keywords "digital technology" and "production" in the all fields section were identified in the Scopus database. Similarly, to identify the literature on the use of digital technologies in the marketing of agricultural products, publications containing the term "agriculture" and the keywords "digital technology" and "marketing" were searched.
The two data sets obtained were analysed on a country basis to examine the level of adoption of digital technologies in production and marketing processes in agriculture. These data were matched with OECD agricultural export data and used in a correlation analysis. The correlation analysis was conducted to determine how agricultural production and marketing-oriented use of digital technologies relate to export performance.
In the analyses, Pearson correlation analysis was performed using SPSS 26.0 software to determine the interaction between the research of digital technologies in agricultural production and marketing and countries' export performance. The results are visualised and interpreted in order to comparatively assess the effectiveness of digital technologies in the context of agricultural production and marketing.

Results and Discussion

Results

Studies where agriculture and digital technologies intersect with the concept of production

When the publications in the Scopus database containing the term "agriculture" in the title, abstract or keywords section and the keywords "digital technology" and "production" in the all fields section are filtered with the date restriction of 2020-2024, a total of 2370 academic publications appear in the Scopus database. When these publications are analysed bibliometrically, the scientific fields in which the most publications are produced are shown in Table 1 for the Scopus database.
As a result of the query in the Scopus database, the top three scientific fields with the highest number of publications related to the use of digital technologies in agricultural production processes are Agricultural and Biological Sciences (769 publications), Computer Sciences (692 publications) and Environmental Sciences (681 publications). This spatial distribution reveals the interdisciplinary nature of digital agriculture studies. It reveals that technological applications are widely researched and analysed in the agricultural field and different scientific fields.

Table 1: Scientific fields and number of publications obtained in the Production Cluster

	Scientific fields	# of Publications
1	Agricultural and Biological Sciences	769
2	Computer Science	692
3	Environmental Science	681
4	Engineering	551
5	Social Sciences	531
6	Business, Management and Accounting	326
7	Energy	279
8	Economics, Econometrics and Finance	266
9	Earth and Planetary Sciences	219
10	Decision Sciences	153

Table 2: Number of publications by country in the Production Cluster

	Countries	# of Publications
1	China	400
2	Russian Federation	345
3	India	273
4	United States	209
5	Germany	140
6	Italy	137
7	United Kingdom	133
8	Australia	93
9	Canada	79
10	France	77

When the number of academic studies conducted in the context of digital agricultural technologies and production is analysed by countries, China (400 publications) ranks first, followed by Russia (345 publications) and India (273 publications). The academic productivity of these countries in digital agriculture is linked to both their agricultural potential and their interest in technological development. Moreover, this finding reveals that Asian countries make many scientific contributions to digital agriculture.

Table 3: Universities and research institutions producing the most publications in the Production Cluster

	Universities and research organizations	# of Publications
1	Wageningen University	42
2	INRAE	34
3	Russian Academy of Sciences	32
4	University of Guelph	28
5	Northwest University	28
6	Universität Hohenheim	27
7	Russian State Agrarian University - Moscow Timiryazev Agricultural Academy	27
8	University of Johannesburg	21
9	Kuban State Agrarian University	20
10	Université de Montpellier	20

When the universities and research institutions producing the highest number of publications are analysed, Wageningen University ranks first with 42 publications. This institution is followed by INRAE (34 publications) and the Russian Academy of Sciences (32 publications). This situation shows that academic institutions, especially in Europe and Russia, carry out intensive research activities in digital agriculture and are in a leading position.

Studies where agriculture and digital technologies intersect with the concept of marketing

In Scopus databases, when the publications containing the term "agriculture" in the title, abstract or keywords section and the keywords "digital technology" and "marketing" in the all fields section are restricted to 2020-2024, a total of 698 academic publications are obtained in the Scopus database. When these publications are analysed bibliometrically, the scientific fields in which the most publications are produced are shown in Table 4 for the Scopus database.

In the Scopus database, the top three scientific fields with the highest number of publications were Agricultural and Biological Sciences (223 publications), Social Sciences (196 publications) and Computer Sciences (188 publications). This distribution shows that the technical and social aspects of digital marketing are intensively addressed academically. The high ranking of social sciences, in particular, indicates that digital agricultural marketing also focuses on consumer behaviour, communication, and social interaction.

When the publications on digital agricultural marketing are analysed by country, China (115 publications) leads the way, followed by India (87 publications) and the United States (61 publications). This result shows that Asian countries invest in digitalisation not only in production but also in marketing processes. At the same time, the academic productivity of developing countries in this field has been observed at a high level.

Wageningen University (11 publications) ranks first among the institutions with the highest number of publications on digital agricultural marketing, followed by the University of Johannesburg (10 publications) and Northwest University (9 publications). Table 6 shows that universities in Europe and Africa have pioneered digital agricultural marketing research. The fact that universities in South Africa are particularly prominent in this field reveals that regional innovation and digitalisation are also reflected in the academic field.

Table 4: Scientific fields and number of publications obtained in the Marketing Cluster

	Scientific fields	# of Publications
1	Agricultural and Biological Sciences	223
2	Social Sciences	196
3	Computer Science	188
4	Environmental Science	170
5	Business, Management and Accounting	162
6	Engineering	134
7	Economics, Econometrics and Finance	104
8	Energy	83
9	Decision Sciences	53
10	Earth and Planetary Sciences	27

Table 5: Number of publications by country in the Marketing Cluster

	Countries	# of Publications

10	School of Agriculture	7

Correlation analyses

The correlation analyses conducted in the study were carried out in two different categories, as in the previous sections. The purpose of the correlations in the context of production and marketing is to observe whether there is a correlation between the number of academic research papers and the agricultural export figures of countries.

Table 7 shows the relationship between average agricultural export volumes and the number of academic publications on digital agricultural production in selected OECD countries for 2020-2024. While the United States has the highest number of publications (210 publications), it also has the highest average export volume (28,276.6 tonnes). Countries such as the United Kingdom, Australia and Canada stand out with both high publication productivity and high export figures. This supports a strong positive relationship between academic productivity and export performance. In addition to this finding, another finding that should be noted is that although the number of publications is high in countries such as New Zealand, Colombia and Norway, export volumes are pretty low.

Table 7. Number of Academic Publications on Digital Agricultural Production and Average Agricultural Export Volumes (2020-2024) in Selected OECD Countries

Countries	# of Publications	Agricultural Export data 2020 -2024 Average
United States	210	28276.6
United Kingdom	134	1332.6
Australia	93	16131.7
Canada	79	16906.6
Switzerland	29	89.1
Mexico	19	1053.0
New Zealand	17	0.5
Colombia	17	3.06
Norway	14	1.3
Chile	12	8.6

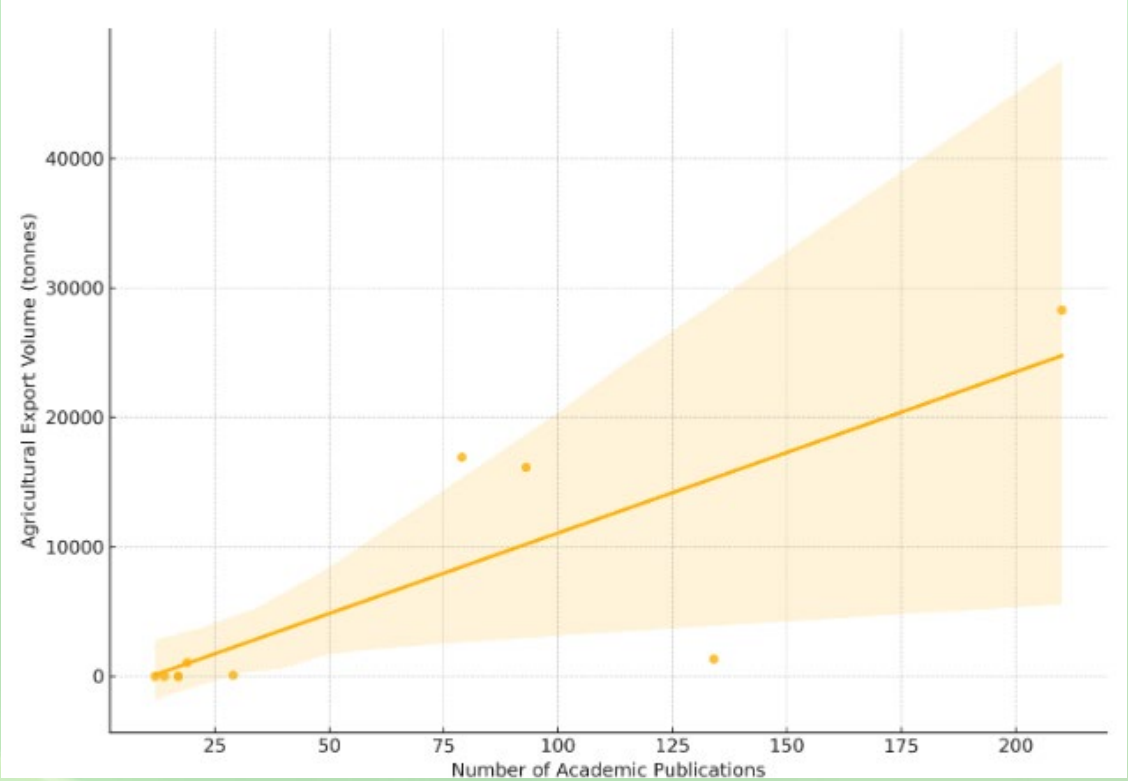

Figure 1. Correlation between Academic Publications on Digital Agricultural Production and Export Volume

The scatter plot in Figure 1 shows the relationship between the average agricultural export volumes in OECD member countries between 2020 and 2024 and the number of academic publications on digital agricultural production. As a result of the correlation analysis, the Pearson correlation coefficient r = 0.813 and the significance level p = 0.004. This strong and statistically significant positive relationship shows that countries that produce more academic publications in digital agricultural production also tend to have higher agricultural export performance.

Table 8 compares the number of academic publications on digital agricultural marketing with the average agricultural export volumes of OECD countries for 2020-2024. The country with the highest number of academic publications is the United States of America (61 publications), which also has the highest export volume (104,526 tonnes). The United States is followed by Canada (19 publications, 53,978 tonnes) and Australia (29 publications, 34,591 tonnes). Turkey is on the list with 11 publications, with an average export volume of 7,644 tonnes. This table provides a numerical result that there may be a strong relationship between the number of academic publications in digital marketing and agricultural export performance.

Table 8. Academic Publications on Digital Agricultural Marketing and Agricultural Export Volumes among OECD Countries (2020-2024)

Countries	# of Publications	Agricultural Export data 2020 -2024 Average
United States	61	104526.38
Canada	19	53978.72
Turkiye	11	7644.79
Australia	29	34591.71
Japan	4	381.57
South Korea	3	613.05
Mexico	5	1223.22
New Zealand	5	117.45
Norway	7	5.01
Switzerland	6	174.92

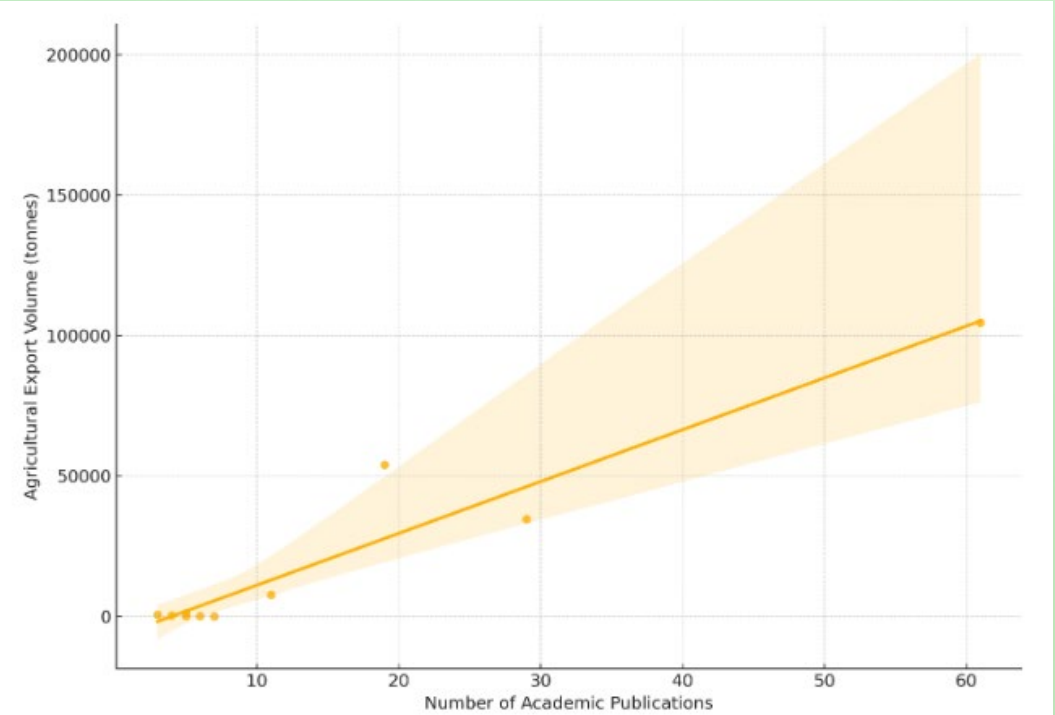

Figure 2. Correlation between Academic Publications on Digital Agricultural Marketing and Export Volume

The correlation analysis conducted on OECD member countries revealed a statistically significant and strong positive relationship between the average agricultural export volumes for 2020-2024 and the number of scientific publications indexed in the Scopus database. The Pearson correlation coefficient was calculated as $r = 0.958$, and the significance level was $p = 0.001$. This result shows a powerful and significant positive statistical relationship between the number of publications related to digital technologies in agricultural marketing and the amount of agricultural exports among OECD members and the 10 highest exporting countries.

Discussion

This study emphasises the power of digital agricultural technologies to improve agricultural production and marketing. The findings obtained from analysing the data draw attention to the positive effects of researching these technologies on the country's export figures by examining how digital technologies are involved in marketing and production areas. The results obtained coincide with the achievements emphasised in the literature. This is in line with previous findings showing that digital technologies can increase production and productivity and are a method of opening up to new markets (Yaman, 2021; Gedik, 2023).

Technologies such as artificial intelligence, remote sensing, and digital sales platforms within the scope of digital agricultural technologies have an important place in changing agricultural production and marketing structures. Digital agricultural technologies reduce production costs in decision-making processes and add value to the product in all processes from the field to the market. While production-oriented innovations contribute to efficient production, they also help sustainable resource utilisation. On the other hand, marketing technologies increase the value of agricultural products by increasing brand visibility and consumer access. The importance of digital technologies for competitive agriculture, emphasised by Yaman et. al (2021) in their study, is also supported in this study.

While this study emphasises the impact of digital technologies in agricultural production through two different phenomena, it has some shortcomings. The first can be summarised as focusing only on countries where agricultural export data are available in OECD databases. Some countries outside these datasets that have a voice in digital agricultural technologies and can actively apply these technologies are not included in the study due to a lack of data. In addition, inconsistencies in the representation of European Union member countries in academic and statistical databases led to their exclusion from the study. This deficiency can be overcome by accessing the export figures of the European Union member countries one by one.

Similar future studies can be repeated using datasets that include export data from alternative sources such as FAO, UN Comtrade, or national statistical agencies. Thus, the mentioned limitations can be overcome. Expanding the scope to include more countries and a more extended time period would allow for a more comprehensive conclusion and evaluation of how digitalisation shapes agricultural trade on a global scale.

This study supports the literature by indicating that digital technologies can be used to improve economic performance in agricultural systems in addition to being facilitative tools. Gedik (2023) emphasises that digital platforms have changed how producers interact with consumers. In their study, Yaman et al. (2021) argue that technological specialisation can significantly affect regional economic outcomes. In this context, it seems possible for researchers and policymakers to maximise regional and global gains by keeping sustainable digital transformation in agriculture more on their agenda.

Abstract

In this study, the effect of debittered orange albedo on the nutritional, functional and cooking properties of pasta samples was investigated. Orange albedo was substituted into durum wheat semolina at 2.5%, 5% and 10% levels and the moisture, ash, protein, fat, carbohydrate, energy, total phenolic content, antioxidant activity, water uptake and cooking loss of the pasta samples were determined. Albedo substitution increased the fat content ($p>0.05$), ash content ($p<0.05$), carbohydrate content ($p>0.05$) and energy value ($p>0.05$) of pasta samples. Pasta sample without added albedo was found to have the lowest total phenolic content, antioxidant activity, water uptake and cooking loss, and as the albedo substitution rate increased, total phenolic content ($p>0.05$), antioxidant activity ($p<0.05$), water uptake ($p>0.05$) and cooking loss ($p<0.05$) of pasta samples increased. The use of albedo, one of the by-products of the food industry, in pasta production has both increased the functionality of the pasta and recovered a product separated as waste.

Key Words: *Albedo, Debittering process, Functional food, Orange, Pasta*

Introduction

In recent years, the demand for functional foods has increased due to constantly changing consumption habits and increasing population. Pasta is one of the most produced and consumed staple foods in the worldwide (Sissons, 2022). Neutral taste, ease of cooking, low cost and long shelf life are the reasons for its preference (Bustos et al., 2015; Obadi et al., 2021). In pasta production, firstly, durum wheat semolina and water are mixed and kneaded. Then, the obtained dough is shaped by extrusion and lamination. Lastly, the obtained product characterized by its own shape is dried (maximum moisture content 12.5%) and made ready for consumption (Costa et al., 2010). Although durum wheat semolina is rich in carbohydrates (Singh et al., 2023), it is poor in phenolic compounds, vitamins, minerals and dietary fibers (Nilusha et al., 2019). There are studies in the literature where various food industry by-products are included in the formulation in order to increase the functionality of pasta (Carpentieri et al., 2022). Tomato (Padalino et al., 2017), olive (Padalino et al., 2018), grape (Iuga and Mironeasa, 2021), carob (Rodríguez-Solana et al., 2021) and raspberry (De Santis et al., 2022) by-products are some of the materials used to enrich the pasta.

Fruit pulp and peels, which are one of the biggest by-products of the fruit juice industry, are rich in phenolic substances as well as containing high dietary fiber (Sindhu et al., 2019). Citrus fruits are one of the most widely produced and consumed fruits worldwide and contain many phytochemicals that are beneficial for human health (Rafiq et al., 2018). Among citrus fruits, orange is the most preferred type in terms of consumption and processing (Aşık, 2019). Citrus fruit peels consist of two layers called flavedo and albedo. Flavedo is the outer layer, which ranges in color from yellow to orange. Flavedo layer contains carotenoid pigments and lipid cells. Underneath the flavedo is the albedo, a white/cream colored, felt-like layer (Çoksever, 2009). Albedo layer contains loose tissues consisting of large intercellular spaces. It forms a structure consisting mostly of hesperidin and pectin. The majority of pectin, which is found in the citrus fruit peel at a rate of 30-35%, is found in the albedo layer at 73% (Schröder et al., 2004). Albedo layer is preferred because it is an important source of pectin. It has a higher dietary fiber potential and is of better quality than other dietary fiber sources because it contains bioactive compounds with antioxidant properties (Lliso et al., 2007).

The aim of this study is to improve the functional properties of pasta by adding orange peels, one of the by-products of the food industry, to the pasta formulation after subjecting them to various processes. First, the albedo obtained from the orange peel was subjected to the debittering process and then substituted into durum wheat flour at 2.5%, 5% and 10% levels. The nutritional (moisture, ash, protein, fat, carbohydrate, energy), functional (total phenolic content and antioxidant activity) and cooking (water uptake and cooking loss) analyses of the produced pasta were performed.

Materials and Methods

Materials

Durum wheat flour (*Triticum durum* L.) used in the study was supplied by a local producer in Gaziantep, Türkiye and oranges (*Citrus sinensis* L.) were supplied by a local market in Istanbul, Türkiye. All chemicals were used analytical grade.

Albedo production

The methods suggested by Sarıçoban and Unal (2022) and Chaudhary et al. (2024) were used with modifications in the production of albedo. First, the albedo layer was separated from the orange peels. Then, it was subjected to heat treatment at 100 °C for 10 minutes and kept in the same water for 18 hours. At the end of the period, the water was changed and kept in new water for 24 hours and filtered. The albedos, whose bitter taste was removed, were lyophilized (Bruker Co., Germany). The dried albedos were ground and sieved (<500 µm).

Pasta production

100 g durum wheat flour (2.5%, 5% and 10% albedo were substituted) was mixed with 50-70 mL distilled water at 40-45 °C and kneaded. The obtained dough was thinned in a pasta making machine and given the shape of tagliatelle. Pasta cut into 8-10 cm lengths were dried at 50 °C for 5 hours. Pasta without albedo was evaluated as the control (P0) and pasta with 2.5%, 5% and 10% albedo were named P2.5, P5 and P10, respectively.

Determination of nutritional properties

Moisture content of pasta samples was determined by AACC Method No: 44-15.02, ash content by AACC Method No: 08-01.01, protein content by AACC Method No: 46-11.02 and fat content by AACC Method No: 30-25.01 (AACC, 1990). The formula "CHO% = 100 – (Moisture% + Ash% + Protein% + Fat%)" was used to calculate carbohydrate content; the formula "Energy (kcal/100 g) = 4 x (CHO% + Protein%) + 9 x (Fat%)" was used to calculate energy value (Karaağaoğlu et al., 2008).

Determination of functional properties

For the extraction of phenolic compounds, 1 g sample was weighed and 5 mL 80% (v/v) methanol was added. After 15 min in an ultrasonic water bath (Protech, Turkey) and 10 min in an orbital shaker (Stuart SSL1, England), it was centrifuged (Hettich Rotofix 32A, Germany) at 1460 g for 10 min. The supernatant was collected, the sediment was subjected to the same procedures again and the supernatants were combined. The combined supernatants were passed through a 0.45 µm filter and the volume was completed to 10 mL with 80% (v/v) methanol (Czaja et al., 2020). For total phenolic content analysis, 0.1 mL extract was taken into analysis tubes. 2 N 0.2 mL Folin-Ciocalteu reagent and 2 mL distilled water were added. After mixing, it was waited at room temperature for 3 min. At the end of the period, 1 mL 20% (w/v) Na_2CO_3 solution was added. After mixing, it was waited at room temperature for 1 hour. At the end of the period, absorbance was read at 765 nm via the spectrophotometer (PG Instruments Ltd. T60, England). The standard for creating the calibration curve was gallic acid (Wojdyło et al., 2007). For the CUPRAC method (antioxidant activity), 1 mL $1.0x10^{-2}$ M $CuCl_2$ solution, 1 mL 1 M ammonium acetate buffer solution, 1 mL $7.5x10^{-3}$ M Neocuproin solution were taken into the analysis tubes. Then, x mL extract and (1.1-x) mL distilled water were added to make the final volume 4.1 mL. After mixing and waiting in the dark for 1 hour, absorbance was read at 450 nm via the spectrophotometer (PG Instruments Ltd. T60, England). The standard for creating the calibration curve was trolox (Apak et al., 2008).

Determination of cooking properties

In order to determine the optimum cooking time, which is the minimum necessary time required for the starch to completely gelatinize, the pasta was pressed between two glass plates every 30 seconds and the process was repeated until the white part in the middle of the pasta disappeared and the elapsed time was recorded as minutes (Oh et al., 1985). In order to determine water uptake, 20 g pasta was cooked in 250 mL distilled water for the optimum cooking time. The weights of the cooked pasta were determined after draining. The ratio between dry and cooked pasta weights was calculated as water uptake (%) (Özkaya, 2005). In order to determine the cooking loss, the cooking water was evaporated until a fixed weight of 135 °C was reached. The residue was detected. Cooking loss (%) was calculated based on the percentage of the dry pasta weight (Özkaya, 2005).

Statistical analysis

Experimental data were subjected to Variance Analysis using Minitab Version 16.0 (Minitab Inc., PA, USA) program in the form of tables prepared in accordance with the experimental design. Tukey Multiple Comparison Test was used to check whether the differences between the group means were significant. Duplicate measurements were made in all analyses.

Results and Discussion

Nutritional properties

The nutritional analysis results of the pasta samples are presented in Table 1. According to the nutritional analysis results, the moisture content of the pasta samples varied between 13.82-16.43%, ash content between 1.00-1.23%, protein content between 14.15-14.68%, fat content between 0.31-1.19%, carbohydrate content between 67.95-69.73% and energy value between 331.84-345.74 kcal/100 g. Although no statistically significant difference was found between the moisture, protein, fat and carbohydrate contents and energy values of the pasta samples ($p>0.05$), pasta sample without added albedo (P0) was found to have the lowest fat and carbohydrate content and energy value. In addition, as the albedo concentration increased, the fat contents and energy values of the pasta samples increased. P0 pasta was found to have the lowest ash content ($p<0.05$) and ash content increased as albedo concentration increased ($p>0.05$).

Table 1. Nutritional properties of pasta samples.

Sample	Moisture (%)	Ash (%)	Protein (%)	Fat (%)	Carbohydrate (%)	Energy (kcal/100 g)
P0	16.43±0.06^{a}	1.00±0.07^{b}	14.32±0.26^{a}	0.31±0.05^{a}	67.95±0.23^{a}	331.84±0.31^{a}
P2.5	13.95±2.15^{a}	1.05±0.08^{ab}	14.55±0.12^{a}	0.73±0.22^{a}	69.73±2.14^{a}	343.65±10.03^{a}
P5	14.28±1.61^{a}	1.13±0.01^{ab}	14.68±0.46^{a}	1.09±0.36^{a}	68.82±1.73^{a}	343.83±8.27^{a}
P10	13.82±2.21^{a}	1.23±0.02^{a}	14.15±0.22^{a}	1.19±0.20^{a}	69.61±2.21^{a}	345.74±9.79^{a}

Values were given as means ± standard deviation. In the same column, different superscripts show significant differences between samples ($p<0.05$). Nutritional properties except moisture are based on dry matter. P0, P2.5, P5, P10 represent pasta samples with 0, 2.5, 5, 10% albedo substitution, respectively.

Dietary fiber was produced from by-products obtained from the orange juice industry and the produced dietary fiber was substituted in the pasta formulation at a level of 25-75%. The ash content of the produced pasta varied between 0.68-0.81%, protein content between 10.92-11.67%, fat content between 0.14-0.24% and carbohydrate content between 80.51-83.56% (Crizel et al., 2015). In the studies carried out, it was determined that as the albedo concentration in breads (Demir and Olcay, 2020) and biscuits (Demirel, 2017) increased, the ash content increased while the protein content decreased.

Functional properties

The functional analysis results of the pasta samples are shown in Figure 1. According to the functional analysis results, the total phenolic content (TPC) value of the pasta samples varied between 21.65-26.30 mg GAE/100 g dm and the antioxidant activity (CUPRAC) value of the pasta samples varied between 81.50-147.75 mg TE/100 g dm. Pasta sample without added albedo (P0) was found to have the lowest TPC ($p>0.05$) value and CUPRAC ($p<0.05$) value. Although the TPC value and CUPRAC value of the pasta samples increased as the albedo concentration increased, no statistically significant difference was found between the pasta samples ($p>0.05$).

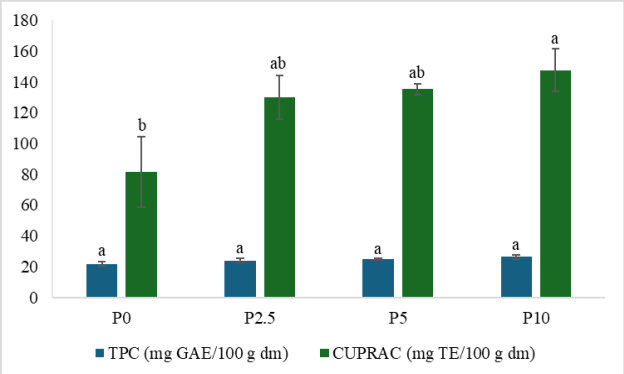

Figure 1. Functional properties of pasta samples. a-b represent the significant differences between samples ($p<0.05$). P0, P2.5, P5, P10 represent pasta samples with 0, 2.5, 5, 10% albedo substitution, respectively.

Orange by-products were substituted into pasta and total polyphenol (1.19-1.68 mg GAE/g) increased as the substitution rate increased (Crizel et al., 2015). Grapefruit albedo was substituted into pasta and DPPH (17.60-38.76%), FRAP (8.57-18.38 µmol AAE/g) and TPC (69.09-167.89 mg GAE/100 g) increased as the substitution rate increased (Chaudhary et al., 2024).

Turkish Science and Technology Publishing (TURSTEP)

Cooking properties

The cooking analysis results of the pasta samples are presented in Table 2. According to the cooking analysis results, the water uptake value of the pasta samples varied between 55.20-64.19% and the cooking loss value of the pasta samples varied between 1.82-2.18%. Pasta sample without added albedo (P0) was found to have the lowest water uptake ($p>0.05$) value and cooking loss ($p<0.05$) value. Although the water uptake value and cooking loss value of the pasta samples increased as the albedo concentration increased, no statistically significant difference was found between the pasta samples ($p>0.05$).

Table 2. Cooking properties of pasta samples.

Sample	Water Uptake (%)	Cooking Loss (%)
P0	55.20±1.47^{a}	1.82±0.07^{b}
P2.5	62.15±4.26^{a}	1.93±0.06^{ab}
P5	64.12±1.82^{a}	1.99±0.12^{ab}
P10	64.19±2.60^{a}	2.18±0.02^{a}

Values were given as means ± standard deviation. In the same column, different superscripts show significant differences between samples ($p<0.05$). P0, P2.5, P5, P10 represent pasta samples with 0, 2.5, 5, 10% albedo substitution, respectively.

Orange by-products were substituted for pasta and as the substitution rate increased, water uptake increased from 85.53% to 88.19% and cooking loss increased from 5.57% to 7.98% (Crizel et al., 2015). Grapefruit albedo was substituted for pasta and as the substitution rate increased, swelling index increased from 5.34% to 6.49% and cooking loss increased from 3.47% to 5.02% (Chaudhary et al., 2024).

Abstract

In animal nutrition, it is important to provide a balanced diet that is sufficient in terms of protein to ensure the continuity of vital activities. The protein composition of the feed given to the animal should be both economical and sustainable and environmentally friendly. When the protein given to the animal is sufficient, it strengthens the animal's immunity and reduces the risk of contracting diseases, but when it is insufficient, the animals' productivity decreases and if the insufficiency is not met for a long time, it can result in death. In broiler chicken production, where high live weight gain is targeted in a short time, it is important to meet the high protein and energy needs of the animals. In this context, animal and plant protein sources are used to meet the protein needs in poultry nutrition. Today, as a solution to the problems experienced in the supply of these resources as a result of their insufficiency and high cost, sustainable alternative protein and feed raw material searches continue. Insects, potentially requiring less space and water and also being able to be produced quickly on organic wastes, show that they are economically feasible alternative protein sources. In this review, the advantages and disadvantages of using insects in animal nutrition are discussed and studies conducted on poultry nutrition of some insects are mentioned.

Key Words: *Animal nutrition, Insects, Protein source, Poultry, Sustainability*

Introduction

Today, protein sources used in animal feeds are mainly soybean meal, fish meal and processed animal origin proteins. While an increase in resources is expected to meet the protein needs of animals, the decrease in soybean lands and fish stocks worldwide, as well as the last 10 years of information, has caused the price of soybean meal and fish meal to almost double (Jozefiak & Engberg, 2015). The reason for such a pricing increase is the imbalance between supply and demand. One of the main costs in poultry production is feed, and feed costs constitute 60-70% of the production cost. Reducing production costs and providing a cheap protein source that is nutritious for animals is important for sustainability and the environment, and it also provides an important step for people to access animal protein more cheaply (Özek, 2016).

It is important to identify economical and sustainable alternative raw material sources in animal nutrition and to conduct research in this direction. In broiler chicken production, where high live weight gain is targeted in a short time, it is important to meet the high protein and energy needs of the animals. Some protein sources used in broiler chicken rations for high protein requirements are soybean meal, sunflower seed meal, meat meal, meat-bone meal, fish meal. 25-35% of poultry rations contain full-fat soybean and soybean meal (Ergül, 2008; Işık & Kırkpınar, 2017). However, the inadequacy of plant protein sources in meeting the protein needs of broiler chickens has made it necessary to use animal-based protein sources. In our country, in this context, the use of slaughterhouse wastes causes problems due to Salmonella and the inability to fully determine feed values. Of the aforementioned slaughterhouse wastes, meat meal, meat-bone meal and blood meal carry the risk of Salmonella if they are not processed with appropriate methods (Aslantaş, 2004). Insects are thought to be potentially effective in reducing feed costs in broiler feeding. In addition, studies have shown that there is no significant difference in the nutrient composition of insects compared to fish meal and soybean meal, and therefore their use will have a positive effect on production profitability.

Insects

Although they are in the Arhropoda phylum of the animal kingdom, insects (Insecta) constitute the richest class in terms of species diversity (Gillespie et al., 2018). There are almost 1 million insect species named so far, and it has been stated that approximately 2000 of them are suitable for use as human and animal food (Van Huis, 2013). Recently, the use of insects as animal feed in addition to human food has frequently come to the fore and many studies are being carried out in various parts of the world (Erwin, 2004; Sánchez-Muros et al., 2014; Van Zanten et al., 2015; Yüksel & Canhilal, 2018). Insects are natural protein and feed sources for poultry, fish and birds, which are rich sources of protein (Ssepuuya et al., 2017).

Insects may need very different nutrients at different stages of their lives and can feed on a wide variety of waste (restaurant waste, post-harvest plant waste) (Van Huis, 2013). Raising them on biological waste (Khan et al., 2016) has a positive effect on preventing environmental pollution. The rapid growth and high reproductive power of some insect species under suitable conditions are important for the sustainability of production. Insect farming is much more economical when compared to the areas allocated for the cultivation of other protein sources such as forage crops and water requirements, as small areas are used in the cultivation of insects and they generally meet their water requirements from the food they consume. In addition, insect farming is more environmentally friendly when compared to cattle farming, as less greenhouse gas and ammonia are released into nature. In addition, the rate of benefiting from the food consumed by insects is also quite high (Van Huis, 2013). In addition to varying according to insect species and biological period, many insects have protein content ranging from 40-80% and important essential amino acids. Insects are also rich in some minerals (Van Huis, 2013; Sánchez-Muros et al., 2014; Barroso et al., 2014; Henry et al., 2015). The insect species with the highest potential for use as animal feed in the European Union (EFSA, 2015) are shown in Table 1.

Table 1. Insect species with the highest potential for use as animal feed and their information (EFSA, 2015).

Scientific Name	English Name
Musca domestica L. (Diptera: Muscidae)	Common Housefly,
Hermetia illucens L. (Diptera: Stratiomyidae)	Black Soldier Fly
Tenebrio molitor L. (Coleoptera: Tenebrionidae)	Mealworm,
Zophobas atratus F. (Coleoptera: Tenebrionidae)	Giant Mealworm
Alphitobius diaperinus P. (Coleoptera: Tenebrionidae)	Lesser Mealworm
Galleria mellonella L. (Lepidoptera: Pyralidae)	Greater Wax Moth,
Achroia grisella F. (Lepidoptera: Pyralidae)	Lesser Wax Moth
Bombyx mori L. (Lepidoptera: Bombycidae)	Silkworm,
Acheta domesticus L. (Orthoptera: Gryllidae)	House Cricket
Gryllodes sigillatus L. (Orthoptera: Gryllidae)	Banded Cricket,
Locusta migratora migratorioides (Orthoptera: Acrididae)	African Migratory Locust,
Schistocerca Americana D. (Orthoptera: Acrididae)	American Grasshopper,

Advantages and Limitations of Using Insects in Animal Nutrition

The ability to grow insects used in feed on manure and organic waste is important in terms of sustainability as well as preventing environmental pollution. Insects are used not only in their adulthood but also in developmental stages such as larvae and pupae. In addition to their very fast development, their feed utilization is very high. Approximately 2 kg of organic waste and 1 m^2 of area are sufficient to produce 1 kg of insect protein (Van Broekhoven et al., 2015). When considered from an environmental perspective, insects release much less greenhouse gas and ammonia into the atmosphere compared to cattle and pigs for the production of 1 kg of meat (Smith & Pryor, 2014). In addition, it is stated that the use of insects in feed will minimize the damage caused by insects to the product in the field, limit the use of pesticides and contribute to the reduction of environmental pollution (Odabaşı and Yeşilbağ, 2020).

Insects, in addition to their advantages, also bring some risks that need to be considered. These risk factors can be listed as microbial, chemical, toxicological and allergic risks (Odabaşı and Yeşilbağ, 2020). Insects can digest the food they consume thanks to the microbiota in their intestines, and this microbiota can vary depending on the type of insect, the food they feed on and the place where they are grown (El-Tabey, 1951). The microorganisms (bacteria, viruses, etc.) that insects host in their intestines and on their body surfaces can also be found in feeds by participating in the processing stage. These microorganisms can have a pathogenic effect on other insects and the animals that consume them. The most important point to note is that although there is a possibility of pathogenic effects that can reach humans within the food chain, there are few articles reported on this subject. There are studies showing that some microorganisms (Entomopathogens) that cause the death of insects can also be pathogenic for humans (Gerrard et al., 2003; 2004). Insects can contain heavy metals (cadmium and arsenic, etc.), pesticide residues, mycotoxins and plant toxins depending on the plants they feed on. In addition, it is known that some insects can produce their own toxins (Hogan & Razniak, 1991; Devkota & Schmidt, 2000; Zhuang et al., 2009). Although it is known that some insects contain various allergens, no allergic condition has been encountered in the literature as a result of feeding insects to farm animals or pets. (EFSA, 2015).

The Use of Different İnsects in Poultry

The need for animal protein is increasing day by day and it is predicted that the need for animal protein will increase by 45% between 2010 and 2030 (İpçak & Alçiçek, 2015). However, the scarcity of protein-rich raw materials used in animal nutrition may pose a significant threat to the sector.

Our country faces difficulties in both domestic and foreign markets due to its dependence on imports of some protein-based feed raw materials. Considering that almost 70-80% of the costs in poultry production are feed-based and that primarily rendering products and soybeans are rich in essential amino acids used in feed, changes in the prices of these raw materials can lead producers into financial difficulties. Therefore, it is of critical importance to identify sustainable alternative raw material sources in animal feeding, as well as being economical (Odabaşı & Yeşilbağ, 2021).

The maintenance protein requirement in chickens is low. In other words, a large portion of the protein consumed is used to meet the yield protein requirement. When looking at broiler diets; it is known that the crude protein (CP) rate is 22-25% in the starter period, 21-23% in the grower period, and 19-23% in the finisher period (Ross Broiler Handbook, 2014). Meeting these high levels of crude protein requirements is only possible with animal protein sources. In addition, the protein amount calculated according to the survival and yield period must be balanced with essential amino acids (Odabaşı & Yeşilbağ, 2021).

The protein sources mainly used in broiler nutrition in poultry nutrition are divided into vegetable protein sources (such as soybean meal, sunflower meal, cottonseed meal and canola meal) and animal protein sources (such as fish meal, meat-bone meal, bone meal). Vegetable protein sources are found in lower amounts and have restrictive properties compared to animal protein sources in terms of essential amino acid content, especially lysine and methionine. Animal protein sources can pose a potential risk to animals and humans in terms of contamination with pathogenic bacteria such as Salmonella spp. For this reason, the European Union banned the use of animal protein in food animal husbandry with regulation 999/2001. In Turkey, the use of poultry rendering products in poultry nutrition has been terminated as of January 1, 2017 (Odabaşı & Yeşilbağ, 2021). This review includes studies on the use of different insect species in poultry nutrition.

In order to determine whether maggots can be used as an alternative to fish meal, they used them in broiler feeds at different rates (25-50-75-100%) and it was reported that the most effective maggot usage rate was 25%. As a result, they reached the conclusion that maggots are a cheap feed raw material that can be used instead of fish meal (Awoniyi et al. 2003).

It has been stated that adult field grasshoppers can be used in broiler feeds and that grasshopper meal used up to 15% as an alternative to fish meal did not have any negative effects on live weight gain, feed consumption and feed conversion ratio and can be evaluated especially in disadvantaged regions to fill the protein gap (Wang et al. 2005).

In a study conducted to evaluate Cirina forda larvae as a raw material for poultry feed, 50% and 100% Cirina forda larvae were substituted for fish meal in broiler feeds. As a result of the trial, it was observed that Cirina forda larvae did not significantly change the weight gain and growth rate of the animals. As a result, it was stated that C. forda larvae could be an alternative to traditional fish meal as a protein source (Oyegoke et al. 2006). In another study conducted on Westwood (Crina forda), they conducted a study to determine the effects of using its larvae in laying hen diets as an alternative to fish meal in tropical regions at different rates (0, 25, 50, 75 and 100%) on egg-laying performance and egg quality. As a result of the study, a significant decrease was observed in daily egg production when 100% (Crina forda) larvae were substituted for fish meal in laying hen feeds, and it was concluded that other egg quality parameters, such as egg yolk score, shell thickness and Haugh unit, were not significantly affected. However, it was concluded that Crina forda larvae can be used as up to 75% of fish meal in laying hen diets (Amao et al., 2010).

(Awoniyi, 2007) stated in the study maggots are a good source of protein that can be used in egg production as well as in poultry meat production.

In a study conducted using different rates (5, 10, 15 and 20%) of house fly maggots in broiler diets, the effects of house fly maggots on broiler performance and meat quality were investigated and it was determined that the most effective dose level for broilers was 10-15% of house fly maggots in the diet. It was found that the mentioned dose levels significantly increased carcass yield, breast muscle and thigh muscle ($P<0.05$) (Hwangbo et al., 2009). In a different study, it was reported that Musca domestica (house fly) larvae significantly increased weight gain and feed consumption in broilers when compared to soybean meal containing diets and it was determined that the larvae did not cause any toxicity in the gizzard. It was observed that the carcass and breast muscle ratio increased significantly in the groups receiving 10% house fly larvae compared to the group receiving soybean meal, however, it was concluded that the breast, thigh muscle color and pH parameters were not significantly affected (Pretorius, 2011).

In a study evaluating the meat of chickens raised in pastures with a predominantly locust population in Tibet, it was determined that chickens raised in such pastures had a stronger antioxidant potential and a longer preservation period (Sun et al., 2012).

Jacob (2013) stated that the nutritional components of poultry meat and eggs may differ depending on the type of insect consumed, and it was also determined that the fat content of eggs increased as a result of insect consumption. It has been stated that Hermetia illucens (Soldier Fly), a fly species belonging to the stratiomyidae family of the order of insects (insecta), diptera (Robinson, 2005), can be used for poultry feeding due to its nutrient content (more than 40% protein and more than 30% fat) (Newton et al., 2005). At the same time, it has been determined that thanks to the insect production system combined with chicken coops, it significantly reduces environmental pollution caused by manure (50-60%) and reduces the development of harmful bacteria (Erickson et al., 2004).
Musca domestica (Housefly) is found in the diptera order of insects, in the muscidae family, and it has been stated that it can be evaluated as an excellent protein source, especially in the nutrition of poultry (Işık and Kırkpınar, 2017). When housefly larvae meal was used by replacing fish meal in rations containing 25% fish meal in poultry and when a comparison was made, it was concluded that housefly larvae meal provided a better live weight (Awoniyi et al., 2003).
(Wang et al., 2005) prepared 4 different formulation groups containing different proportions of meadow crickets (0%, 5%, 10% and 15%) in a study conducted with castrated roosters and determined the amino acid properties of meadow crickets and the actual metabolizable energy values accordingly and compared them with fish meal. As a result, the actual digestible amino acid levels of meadow crickets and the actual digestible amino acid levels of fish meal were determined as 92.9% and 91.3%, respectively. As a result of the experiment, no significant difference was observed between the groups when live weight gain, feed consumption and feed utilization rates were taken into consideration in roosters.
In a study conducted by Açıkgöz and Tolon, they stated that silkworm chrysalis flour has the potential to be applied in poultry nutrition (Açıkgöz & Tolon, 2003).

Conclusion and Recommendations

As a result of the predictions of the International Feed Industry Federation (IFIF) and the Food and Agriculture Organization (FAO) that the need for animal protein will increase further by 2050, it is estimated that the cost of animal product production and consumption will be negatively affected. The need for protein sources in the poultry sector, which is among the advanced sectors of our country, will also cause insects, which are among the alternative protein sources, to be considered as a potential protein source in this field. While it has many advantages such as being economical as well as being environmentally friendly, it is one of the alternative protein sources, and it increases concerns due to issues such as the microbial, chemical, toxicological and allergic effects caused by insect production and the lack of standardization in production. It should not be forgotten that more research is needed on the use of different insects in broiler feeds, and it is evaluated that the use of insect-origin protein sources in poultry feed should be implemented within the scope of legislation to be prepared based on scientific data.

Abstract

Fermentation is an effective and economical method used to make a food more durable than it is. Fermented products have an important place in culinary cultures. In Turkish cuisine, which is very comprehensive and rich in terms of fermented products, ayran, vinegar, boza, milk-based and bioactive peptide koumiss, kefir and pickles produced from many vegetables can be consumed as beverages with brine. Shalgam juice is also a fermented beverage and is a part of Turkish culture. Permeate is the liquid part of milk passing through the membrane during ultrafiltration. Permeate, which is a by-product of the ultrafiltration method, contains high levels of protein. Permeate, which is generally not used in factories, is considered as dairy waste and causes environmental pollution. Strained yoghurt is one of the fermented milk products consumed in our country. The yoghurt water released in strained yoghurt production is rich in minerals and lactose. In this study, the usability of strained yoghurt water and permeate water, which are known as waste materials in dairy industry, was investigated. These waste materials are known to be rich in LAB and bioactive substances. Strained yoghurt juice and permeate water were used instead of water in the formulation. Furthermore, the study aimed to determine the effect on the physical and sensory properties of the produced shalgam juice. For this purpose, strained yoghurt juice and permeate water were obtained from the industry for shalgam juice production, and drinking water was used as a control sample. The changes in the processed samples were determined during and after fermentation. Meanwhile, the samples were analysed for pH, acidity, colour and sensory analysis to determine the effects of wastewater on both the progress of fermentation and the final product after fermentation.

Key Words: *Waste treatment, Permeate water, Dairy wastewater, Strained yoghurt juice, Shalgam juice fermentation*

Şalgam Benzeri bir Ürün Üretiminde Sütçülük Yan Ürünü Olarak Ayrılan Permeat ve Süzme Yoğurt Suyunun Kullanılabilirliğinin Belirlenmesi

Özet

Fermantasyon bir gıdayı olduğundan daha dayanıklı hale getirmek için kullanılan etkin ve ekonomik bir yöntemdir. Mutfak kültürlerinde fermente ürünlerin önemli bir yeri vardır. Fermente ürünler bakımından oldukça kapsamlı ve zengin olan Türk mutfağı içerisinde ayran, sirke, boza, süt temelli ve biyoaktif peptit olan kımız, kefir ve birçok sebzeden üretilen turşular salamura sularıyla içecek olarak tüketilebilir. Mevzubahis olan şalgam suyu da fermente bir içecek olup, Türk kültüründe yer almaktadır. Permeat sütün ultrafiltrasyon sırasında membrandan geçen sıvı kısımdır. Ultrafiltrasyon yönteminin bir yan ürünü olan permeat yüksek düzeyde protein barındırır. Fabrikalarda genellikle kullanılmayan permeat sütçülük atığı olarak kabul edilir ve çevre kirliliğine neden olmaktadır. Süzme yoğurt ülkemizde tüketilen fermente süt ürünlerinden biridir. Süzme yoğurt üretiminde açığa çıkan yoğurt suyu mineraller ve laktoz bakımından zengindir. Bu çalışmada, süt ürünleri endüstrisinde atık madde olarak bilinen süzme yoğurt suyu ve permeat suyunun kullanılabilirliği araştırılmıştır. Bu atık maddelerin LAB ve biyoaktif madde açısından zengin olduğu bilinmektedir. Formülasyonda su yerine süzme yoğurt suyu ve permeat suyu kullanılmıştır. Ayrıca, çalışmada, üretilen şalgam suyunun fiziksel ve duyusal özellikleri üzerindeki etkisini belirlemeyi amaçlamıştır. Bu amaçla, şalgam suyu üretimi için sanayiden süzme yoğurt suyu ve permeat suyu temin edilmiş, kontrol örnek olarak ise içme suyu kullanılmıştır. İşlenmiş numunelerdeki değişiklikler fermantasyon süresince ve fermantasyondan sonra belirlenmiştir. Bu sırada örnekler, pH, asitlik, renk analizleri ve duyusal açıdan analiz edilerek, atık suların hem fermantasyonun ilerlemesi hem de fermantasyon sonrası nihai ürün üzerindeki etkileri belirlenmiştir.

Anahtar Kelimeler: *Atık değerlendirme, Permeat suyu, Sütçülük ürünü atık suları, Süzme yoğurt suyu, Şalgam suyu fermantasyonu*

Biostimulants Commonly Preferred in Potato Cultivation in Nevşehir Region and Their Effects on Production

Serap ÖZER[1],

[1]Plant Protection, Agricultural Credit Cooperative, Nevşehir, Türkiye

Abstract

Today, agricultural production faces great challenges in terms of efficiency and sustainability. These challenges require the adoption and implementation of environmentally friendly and innovative solutions in agricultural methods. Biostimulants are materials of natural or biological origin that can be applied to seeds, plants and soil, which promote growth, optimize plant health, and strengthen the cultivated plant against abiotic stress factors when applied in the agricultural production field. Since it is of biological origin and supports environmental sustainability, it is important to make its definition and promotion effective in order to activate and spread it in production. In 1997, Zhang and Schmidt, experts in the Department of Plant and Soil Environmental Sciences at Virginia Tech and State University, defined biostimulants as "small amounts of material that promote plant growth." Some researchers consider biostimulants in the same category as plant nutrition products, based on their similarity in helping plants absorb nutrients and improving product quality. Although the classifications of biostimulants are not completely finalized, important categories have been determined as a result of some studies. Some of these categories have been determined as a result of some studies. Some of these categories are seaweed and plant extracts, amino acids and other nitrogenous compounds, beneficial fungi and bacteria, humic and fulvic acids. In this study biostimulants belonging to different companies were tested and their effects were observed on potato plant, which is widely cultivated in Nevsehir region, in different areas and under different ecological conditions. The aim of this study is to reveal the effects of biological materials on potato production and to raise awareness. As a result of the study, the effects of the biostimulants used on the physiology of the potato plant, its access to nutrients and stress tolerance were compiled.

Key Words: *Biostimulant, Patato, Fulvic acids, Bacteria,Plant extracts*

Nevşehir Yöresinde Patates Yetiştiriciliğinde Yaygın Olarak Tercih Edilen Biyostimülantlar ve Üretimdeki Etkileri

Özet

Günümüzde tarımsal üretimde verimlilik ve sürdürülebilirlik konularında büyük zorluklar ile karşılaşılmaktadır. Bu zorluklar tarımsal metodlarda çevre dostu ve yenilikçi çözümlerin benimsenmesini ve uygulanmasını gerektirmektedir. Biyostimülantlar, tarımsal üretim sahasında uygulandığında büyümeyi teşvik eden, bitki sağlığını optimize eden, abiyotik stres faktörlerine karşı yetiştiriciliği yapılan bitkiyi güçlü kılan, tohuma, bitkiye ve toprağa uygulanabilen doğal veya biyolojik kökenli materyallerdir. Biyolojik kökenli oluşu ve çevresel sürdürülebilirliği desteklemesi nedeniyle üretimde aktifleşmesi ve yaygınlaşması için tanımının ve tanıtımının etkin bir şekilde yapılması önem arz etmektedir.1997 yılında, Virginia Tech ve Eyalet Üniversitesi Bitki ve Toprak Çevre Bilimleri bölümü uzmanları Zhang ve Schmidt, biyostimülanları "bitki büyümesini destekleyen az miktarda malzeme" olarak tanımladılar. Bazı araştırıcılar biyostimülantları bitkilerin besinleri almasına yardımcı olma ve ürün kalitesini artırma konusundaki benzerliklerine dayanarak bitki besleme ürünleri ile aynı kategoride değerlendirmektedir. Biyostimülantların sınıflandırmaları tamamen kesinleşmemekle birlikte önemli kategorileri bazı çalışmalar sonucunda belirlenmiştir. Bu kategorilerden bazıları deniz yosunu ve bitki ekstraktları, amino asit ve diğer azotlu birleşikler, yararlı mantar ve bakteriler, humik ve fulvik asitler olup yapılan bu çalışmada Nevşehir yöresinde yetiştiriciliği yaygın olarak sürdürülen patates bitkisi üzerinde farklı firmalara ait biyostimülantlar farklı alanlarda ve farklı ekolojik koşullarda denenmiş ve etkileri gözlemlenmiştir.Yapılan bu çalışmanın amacı biyolojik kökenli materyallerin patates üretimindeki etkilerini ortaya koymak ve farkındalık oluşturmaktır.Çalışmanın sonucunda kullanılan biyostimülantların patates bitkisinin fizyolojisi, besin elementlerine ulaşımı ve stres toleransına etkileri derlenmiştir.

Anahtar Kelimeler: *Biyostimülant, Patates, Fulvik Asit, Bakteri, Bitki ekstraktları*

A Traditional Fermented Food: Miso

Hümeyra Duymaz[1], Berna Öztürk[1]

[1]Department of Gastronomy and Culinary Arts, Faculty of Art and Design, Istanbul Nişantaşı University, Istanbul, Türkiye

Abstract

In recent years, the importance of fermented foods such as Miso has become increasingly apparent with the growing interest in healthy nutrition. Miso is a significant fermented product produced and consumed for centuries. In the first century BC, the Miso-like product called "Chiang" in China later spread to Japan and other Eastern countries and was called "Miso". To produce Miso, cooked rice, barley, or soybeans are crushed and fermented with wild mold spores (Koji). Then, the Koji obtained is mixed with salt and water and left for the second fermentation in clay vessels. The duration of fermentation varies depending on the type of Miso, and the color and flavor intensity increase in parallel with the longer fermentation period. While traditional Miso was made in small batches at home, this has been replaced by commercial Miso production in recent years. Miso is particularly rich in essential amino acids. The microorganisms present in Koji and Miso contribute to the product's unique taste, texture, nutritional profile, and positive health effects. Miso is used as a flavor enhancer in both savory and sweet dishes. This review discusses in detail the physical, chemical, bioactive, and sensory properties of Koji and Miso.

Key Words: *Fermantation, Koji, Miso*

Geleneksel Fermente Bir Gıda: Miso

Özet

Son yıllarda sağlıklı beslenmeye olan ilginin artmasıyla birlikte, Miso gibi fermente gıdaların önemi ortaya çıkmaktadır. Miso, çok eski yıllardan bu yana üretilen ve tüketilen önemli bir fermente gıdadır. M.Ö. birinci yüzyılda, Çin'de "Chiang" olarak isimlendirilen Miso benzeri ürün, daha sonra Japonya ve diğer Doğu ülkelerine yayılarak "Miso" olarak adlandırılmıştır. Miso üretimi amacıyla öncelikle pişmiş pirinç, arpa veya soya fasulyesi ezilerek yabani küf sporlarıyla fermente edilmekte (Koji), ardından elde edilen Koji, tuz ve suyla karıştırılarak çömleklerde ikinci fermantasyona bırakılmaktadır. Fermantasyon süresi Miso'nun çeşidine bağlı olarak değişmekte, renk ve lezzet yoğunluğu daha uzun fermantasyon süresine paralel olarak artmaktadır. Geleneksel Miso, evlerde küçük partiler halinde yapılırken, bunun yerini son yıllarda ticari Miso üretimi almıştır. Miso, özellikle esansiyel aminoasitler açısından oldukça zengindir. Koji ve Miso'da yer alan mikroorganizmalar, ürünün benzersiz tadının, dokusunun, besin profilinin ve sağlık üzerine olumlu etkilerinin oluşumunu sağlamaktadır. Miso hem tuzlu hem de tatlı yiyeceklerde lezzet arttırıcı olarak kullanılmaktadır. Bu derlemede, Koji ve Miso'nun fiziksel, kimyasal, biyoaktif ve duyusal özellikleri ile ilgili çalışmalar ayrıntılı olarak tartışılmaktadır.

Abstract

Yoghurt is a fermented milk product obtained by fermenting milk with lactic acid cultures. It has been the subject of many studies due to its high nutritional value and positive effects on health. Shalgam juice is a traditional drink produced by lactic acid fermentation and is known for its distinctive sour taste and dark red colour. With the increase in shalgam juice production in recent years, a large amount of production surplus is generated in the factories and if it cannot be utilised, it causes economic losses. This study aims to investigate the potential of utilising the black carrot residues released during shalgam juice production in yoghurt production. In this context, shalgam juice residue black carrots were freeze-dried, powdered and added to yoghurt formulations at different ratios (0%, 0.1%, 0.25%, 0.25%, 0.5%, 1.0%, 2.5%) after separating the black carrot from the drinkable shalgam juice. The produced yoghurt samples were analysed for pH, total acidity, dry matter, protein, antioxidant capacity and colour (L*, a*, b*) and the changes in these parameters during storage (1st, 7th, 15th and 21st days) were investigated. The results showed that the addition of fermented carrot powder to shalgam juice residue caused a decrease in pH, L* and b* values of yoghurt, while total acidity, dry matter, antioxidant capacity and a* values increased. In conclusion, fermented black carrot residues resulting from shalgam juice production were found to have functional properties.

Keywords: *Residue, fermented black carrot, Shalgam beverage, Yoghurt*

Şalgam suyu artığı havuç tozunun yoğurt üretiminde değerlendirilmesi

Özet

Yoğurt, sütün laktik asit kültürleriyle mayalanması sonucu elde edilen fermente bir süt ürünüdür. Yüksek besin değeri ve sağlık üzerindeki olumlu etkileri nedeniyle birçok araştırmaya konu olmuştur. Şalgam suyu ise laktik asit fermantasyonu ile üretilen, kendine özgü ekşi tadı ve koyu kırmızı rengiyle bilinen geleneksel bir içecektir. Son yıllarda şalgam suyu üretiminin artmasıyla birlikte fabrikalarda büyük miktarda üretim artığı ortaya çıkmakta ve değerlendirilemediği takdirde ekonomik kayıplara yol açmaktadır. Bu çalışma, şalgam suyu üretimi sırasında açığa çıkan siyah havuç artıklarının değerlendirilerek yoğurt üretiminde kullanım potansiyelini araştırmayı amaçlamaktadır. Bu kapsamda, şalgam suyu artıkları siyah havuç, içilebilir şalgam suyundan ayrıldıktan sonra dondurularak kurutulmuş, toz haline getirilmiş ve farklı oranlarda (%0, %0.1, %0.25, %0.5, %1.0, %2.5) yoğurt formülasyonlarına eklenmiştir. Üretilen yoğurt örneklerinde pH, toplam asitlik, kuru madde, protein, antioksidan kapasite ve renk (L*, a*, b*) analizleri gerçekleştirilmiş, ayrıca depolama sürecinde (1., 7., 15. ve 21. günler) bu parametrelerdeki değişimler incelenmiştir. Elde edilen sonuçlar, şalgam suyu artığı fermente havuç tozu ilavesi yoğurdun pH ve L* ile b* değerlerinde azalmaya neden olurken, toplam asitlik, kurumadde, antioksidan kapasite ve a* değerlerinde artış sağladığını göstermiştir. Sonuç olarak, şalgam suyu üretimi sonucu ortaya çıkan fermente siyah havuç artıklarının fonksiyonel özellikleri artırılmış yoğurt üretiminde değerlendirilebileceği ve böylece gıda endüstrisinde atık yönetimi açısından önemli bir katkı sağlayabileceği belirlenmiştir.

Anahtar Kelimeler: *Atık ürün, Fermente siyah havuç, Şalgam suyu, Yoğurt*

Giriş

Yoğurt kökenine dair kesin bilgiler bulunmamakla birlikte, bazı dini kaynaklar üretiminin M.Ö. 18-17. yüzyıllarda Harran'da başladığını öne sürülen fermente bir gıda ürünüdür (Konar, 1998). TSE 1330, yoğurt standardına göre "Yoğurt, çiğ süt veya pastörize süt standartlarına uygun, tercihen homojenize edilmiş sütlerin *Streptococcus* (*St.*) *thermophilus* ve *Lactobacillus* (*Lb.*) *delbrueckii* subsp. *bulgaricus*'un etkisiyle laktik asit fermantasyonu sonucu elde edilen ve yoğurt kültürlerini canlı olarak ihtiva eden fermente bir süt ürünü" olarak belirtilmektedir (TSE, 2006). Bununla birlikte, yoğurda özgü laktik asit bakterilerinin sütün bileşimindeki karbonhidratı (laktoz) fermente ederek laktik asit üretmesi sonucu oluşan, yüksek besin değerine sahip bir süt ürünüdür. İçeriğindeki canlı mikroorganizmalar yanında, protein ve yağ başta olmak üzere önemli bir besin kaynağı olarak bilinmekte olup

(Çoban, 2017), insan beslenmesinde önemli bir yere sahiptir. Bileşiminde bulunan önemli miktarda su (%83.9-89.5) yanında, laktoz (%3.4-4.5), protein (%3.2-5.6), süt yağı (%1.4-5.6), mineraller (kalsiyum, fosfor, %0.5-1.2) ve vitaminler açısından zengin bir kaynaktır (Gür, 2012; Kürdal ve Demirci, 1980).

Yoğurt üretimi sürecinde, sütün işlenmesinde uygulanan ısıl işlem, mikroorganizmaların zararlı etkilerinin ortadan kaldırılması, yoğurt jelinin ideal şekilde oluşabilmesi için gerekli koşulların sağlanması ve starter kültürlerin sağlıklı bir şekilde aktivasyonunun desteklenmesinde önemli bir rol oynar. Bu işlem, genellikle 80-85°C sıcaklık aralığında 20-30 dakika veya 90-95°C sıcaklıkta yalnızca 5 dakika süreyle uygulanmakta olup, bu işlem sütteki vejetatif mikroorganizmaların öldürülmesini sağlar. Ayrıca, bu işlem, sütün protein yapısında önemli değişikliklere yol açarak serum proteinlerinin denatürasyonunu tetikler. Denatürasyon, proteinlerin üç boyutlu yapılarının bozulması sonucu, sütün kıvamının artmasına ve yoğurt jelinin oluşumuna zemin hazırlar. Bu şekilde, hem mikrobiyolojik güvenlik sağlanırken hem de yoğurt üretimi için uygun fiziksel ve kimyasal ortam oluşturulmuş olur (Tamime ve Robinson, 2000).

Fermantasyon, gıda ve içeceklerin üretiminde kullanılan önemli bir yöntemdir ve bu yöntemle elde edilen ürünler arasında peynir, yoğurt, kefir, kımız, miso, tempe, boza, alkollü içecekler gibi hem evrensel hem de yerel/yöresel nitelikte birçok farklı seçenek bulunur. Bu bağlamda, şalgam suyu da Adana ve çevresine ait, laktik asit fermantasyonu yöntemiyle üretilen, karakteristik asidik tadı ve zengin lezzetiyle öne çıkan bir içecektir. Şalgam suyu üretimi, geleneksel ve direkt yöntemler ile gerçekleştirilen, siyah havuç, tuz, bulgur unu ve su gibi temel bileşenlerin kombinasyonunu içerir. Siyah havuç, şalgam suyunun rengini belirleyen ana bileşen olup, bu bileşenin yoğun mor-kırmızı pigmentleri, şalgamın kendine özgü estetik görünümünü sağlar. Şalgam suyunun üretimi sırasında, mikroorganizma faaliyetleri sonucunda asidik bileşiklerin oluşumu, içeceğin özgün ekşiliğini sağlar ve bu da, şalgam suyunun tüketiciler tarafından beğenilen özel tadım profiline katkı yapar (Canbaş ve Deryaoğlu, 1993; Erten ve ark., 2008; Erten ve Tangüler, 2010).

Gıda üretim süreçlerinde büyük miktarlarda gıda atığı ortaya çıkmakta ve bu atıklar, yanlış yönetildikleri takdirde çevre kirliliğine ve ekosistem üzerinde olumsuz etkilere yol açmaktadır. Bu tür atıkların uygun şekilde işlenmesi, hem ekonomik kayıpların azaltılması hem de çevresel sürdürülebilirliğin sağlanması açısından büyük bir önem taşır. Gıda atıkları, yalnızca çevresel zararın önlenmesi açısından değil, aynı zamanda ekonomik değer yaratma potansiyeli açısından da önemli fırsatlar sunmaktadır. Özellikle meyve ve sebze atıkları, beslenme açısından önemli faydalar sağlayan bir dizi biyolojik aktif bileşen içermektedir. Bu atıklar, diyet lifi, antioksidanlar, pektin, vitaminler gibi besin öğelerinin zengin kaynakları olup, sağlığa faydalı fonksiyonel gıda bileşenlerinin üretimi için kullanılabilir (Carson ve ark., 1994; Jayaprakasha ve ark., 2001).

Son yıllarda, şalgam suyu tüketimindeki belirgin artış, buna paralel olarak üretim süreçlerinde de önemli bir yükselmeye yol açmıştır (Tangüler ve ark., 2024). Bu artış, şalgam suyunun popülaritesinin giderek arttığını ve bunun sonucunda üretim miktarlarında gözle görülür bir yükselişin meydana geldiğini göstermektedir. Bu bağlamda, üretimde kullanılan ana hammaddeler olan siyah havuç (*Daucus carota*), şalgam (*Brassica rapa*) ve setik (bulgur kepeği veya setik) gibi fermente yan ürünlerin artık miktarları da önemli ölçüde artmıştır (Tangüler ve ark., 2021). Bu artan yan ürün miktarı, gıda endüstrisinde sürdürülebilirlik hedefleri doğrultusunda bu atıkların değerlendirilmesi ve potansiyel kullanım alanlarının araştırılması gerekliliğini gündeme getirmiştir. Ancak, şalgam suyu üretimi gibi yerel ve geleneksel gıda işleme süreçlerinden elde edilen atıkların değerlendirilmesine yönelik yapılan bilimsel çalışmalar, henüz yeterli düzeye ulaşmamıştır. Bu durum, özellikle gıda endüstrisinin çevresel etkilerinin azaltılması ve atıkların yeniden kullanımı konusunda yapılacak araştırmaların önemini vurgulamaktadır. Bu yan ürünlerin geri kazanım ve kullanım potansiyelinin değerlendirilmesi, hem ekonomik hem de ekolojik açıdan büyük fırsatlar sunabilir, ancak bu alanda yapılacak daha fazla araştırma ve geliştirme çalışmasına ihtiyaç duyulmaktadır.

Dolayısıyla bu çalışmada, ülkemizde üretimi son yıllarda önemli düzeylerde artan, tüketimi ise ülke sınırlarını aşan şalgam suyu üretiminde bir artık olarak kalan ve genellikle atılan veya hayvan yemi olarak değerlendirilen fermente havuçların değerlendirilmesi yoluna gidilmiştir. Dolayısıyla gerçekleştirilen bu çalışmanın amacı: Şalgam suyu artık ürünü olan havucu değerlendirerek bir katma değer oluşturmak, yoğurdun kurumadde oranını arttırmak, antosiyanince zengin kurutulmuş havuç tozu sayesinde yoğurdun fonksiyonel özelliğini arttırmaya çalışmak, tüketiciler için farklı bir lezzet ve aromada yoğurt üretimini denemek ve ayrıca yoğurt üretiminde kullanılacak havuç tozunun en uygun miktarını belirlemeye çalışmaktır. Bu kapsamda öncelikle artık fermente havuçlar dondurarak kurutulmuş ve toz haline getirilmiş ve farklı oranlarda yoğurt üretiminde kullanılmıştır.

Materyal ve Metod

Materyal

Şalgam suyu artığı havuçlar (ŞAHT) şalgam suyundan içilebilir sıvı kısmın ve setiğin uzaklaştırılması sonucu kalan havuçların temizlenmesi ve karıştırılması ile elde edilmiştir. Öte yandan; pastörize ve homojenize edilmiş süt Niğde'den yerel bir firmadan temin edilmiştir. Yoğurt üretiminde CSL Jointec VH800 (İtalya) karışık starter kültür kullanılmıştır. Yoğurt üretiminde kullanılan sütün pH değeri 6,70, yağ miktarı %3.50 ve kurumadde miktarı %11.8 olarak belirlenmiş ve herhangi bir mikroorganizmaya rastlanmamıştır.

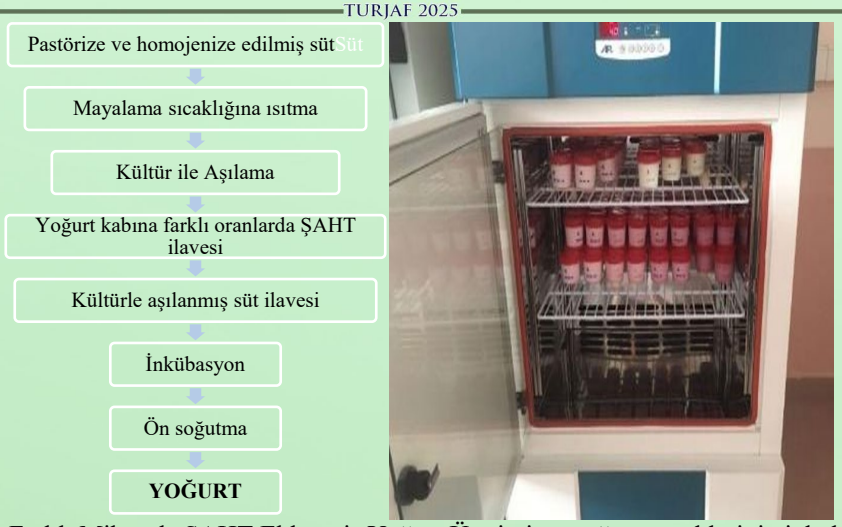
Metod

Şalgam suyu artığı tozunun üretimi

Şalgam suyu artığı havuçlar (ŞAHT) Niğde Ömer Halisdemir Üniversitesi Mühendislik Fakültesi Gıda Mühendisliği Bölümünde üretilen şalgam sularından sıvı kısmın (şalgam suyunun) alınmasının ardından setiğin uzaklaştırılması sonucu kalan havuçların karıştırılmasıyla elde edilmiştir. -50°C sıcaklıkta dondurulmasının (DW-86L628 model, VWR Symphony Ultra-Low Temperature Freezer, Kanada) ardından liyofilizatörde (CoolSafe 95-15 Pro Laboratory Freeze Dryer model, ScanVac LaboGene, Ardından, Kopenhag, Danimarka) düşük sıcaklık (-100oC) ve basınçta (0,001 mbar) 13 kurutulmuştur (Şekil 1). Kurutulan şalgam suyu artık havuçları blender (SHB 3100S model, Sinbo, İstanbul, Türkiye) yardımıyla öğütülerek toz haline getirilmiş ve yoğurt üretiminde kullanılıncaya kadar kapalı cam kavanozlarda muhafaza edilmiştir.

Şekil 1. ŞAHT örneklerinin dondurularak kurutulması

Farklı miktarlarda ŞAHT ilave edilmiş yoğurt üretimi



Farklı miktarlarda ŞAHT ilave edilmiş yoğurt üretimi Şekil 2'de yer alan prosese göre gerçekleştirilmiştir. Yoğurt üretimi için pastörize edilmiş homojenize süt çelik bir kap içerisinde 46°C'deki su banyosuna koyulmuş ve süt sıcaklığının 46°C'ye ulaştığında karışık yoğurt starter kültürler üretici firmanın talimatlarına göre %1 oranında ilave edilerek aktifleştirilmiştir. Diğer yandan, 6 ayrı 100 mL'lik kaba sırasıyla %0.0 (kontrol), %0.1 (A), %0.25 (B), %0.5 (C), %1.0 (D) ve %2.5 (E) oranında ŞAHT ilave edilmiştir. Hazırlanan 6 gruptan her biri için 16 adet 100 mL'lik kap hazırlanmıştır. Kültür ilavesi yapılan örnekler, önceden ayarlanmış ve 45°C'ye ısıtılmış inkübatörde (SH-IB149R model, APIN, Ankara, Türkiye) 4 saat inkübasyona bırakılmış ve süre sonunda örneklerin pH değeri kontrol edilmiştir. pH 4,6'ya ulaşınca örnekler analizler için buzdolabına alınmıştır. Depolamanın 1., 7., 15. ve 21. günlerinde 14 kimyasal analizler yapılmıştır. Depolamanın 1.günü protein tayini gerçekleştirilmiştir. Tüm analizler paralelli olarak yapılmıştır.

Protein tayini

ŞAHT ve yoğurt numunelerinin toplam azot içeriği Kjeldahl metodu kullanılarak (Behr Labor-Technik GmbH, Düsseldorf, Almanya) belirlenmiş ve protein miktarları hesaplanmıştır (Kurt ve ark., 1993).

Kurumadde tayini

ŞAHT ve yoğurt örneklerinin (%) kurumadde değerleri gravimetrik yöntem kullanılarak tespit edilmiştir. Kurumadde analizi için kullanılacak kaplar 105±2°C'lik etüvde sabit tartıma gelene kadar kurutulmuş ve ardından desikatörde oda sıcaklığına gelene kadar soğutulmuştur. Ardından kapların darası alındıktan sonra ŞAHT örneklerinden 1'er gram veya homojen yoğurt örneklerinden 3'er gram tartılmış ve yoğurtlar 105±1°C'deki etüvde (Termal G11600S model, Termal Laboratuvar Aletleri San. ve Tic. Koll. Şti., İstanbul) kurutulmuştur. Kurutulan örnekler desikatöre alınarak oda sıcaklığına kadar yaklaşık 25-30 dakika soğutulmuş ve son tartımları yapılmış ve örneklerdeki yüzde (%) kuru madde miktarı belirlenmiştir (A.O.A.C., 1990).

Şekil 2. Farklı Miktarda ŞAHT Eklenmiş Yoğurt Üretimi ve yoğurt örneklerinin inkübasyonu

pH ve toplam asitlik tayini

Üretilen yoğurt örneklerinin pH'sının belirlenmesinde pHenomenal 1000L model (VWR International Ltd., Dublin, İrlanda) dijital pH metre kullanılmıştır. Toplam asitlik tayini, alkali titrasyon yöntemiyle belirlenmiştir. Elde edilen veriler laktik asit cinsine çevrilmiş ve g/L olarak ifade edilmiştir (Cemeroğlu, 2007).

Renk analizleri

Homojen hale getirilen yoğurt örneklerinin ve ŞAHT örneğinin [L* (açıklık (100) - koyuluk (0)), a*(kırmızı (+) - yeşil (-)), ve b* (sarı (+) – mavi (-))] değerleri (Uluslararası Aydınlatma Komisyonu tarafından geliştirilen CIELAB sistemi) kolorimetre (Minolta, CR-400 model, Konica Minolta Optics Inc., Tokyo, Japonya) kullanılarak ölçülmüştür. Kolorimetrenin kalibrasyonu standart beyaz plaka yardımıyla yapılmıştır (standart C ışık kaynağı ile Y=87,1, x=0,3157 ve y=0,3234). Kolorimetrenin koruma başlığı (CR-A33a) takılı optik ucu yoğurt ve ŞAHT örneklerinin yüzeyine (boşluk kalmayacak şekilde) temas ettirilerek C ışık kaynağı kullanılarak ölçülmüştür.

Antioksidan kapasite

Yoğurt ve ŞAHT örneklerinin antioksidan kapasiteleri TEAC yöntemi kullanılarak belirlenmiş olup referans madde olarak Troloks kullanılmıştır. Elde edilen sonuçlar Troloks eşdeğeri olarak kaydedilmiştir. Standart eğri için 1000 ppm'lik Trolox çözeltisi sırasıyla 50-5 ppm arası seyreltilmiş, absorbans ölçülüp % inhibisyon hesaplanarak eğri oluşturulmuştur.

SONUÇLAR VE TARTIŞMA

ŞAHT numunesinin kurumadde, protein ve renk değerleri

Yoğurtlara farklı oranlarda ilave edilen ŞAHT örneğinde kurumadde miktarı %94,51 olarak tespit edilmiş olup, protein miktarı kurumadde üzerinden %13,35 olarak belirlenmiştir.

Protein değerleri

Yoğurtların hem duyusal hem yapısal özelliklerini sütte bulunan protein etkilemektedir. Farklı oranlarda şalgam atığı havuç tozu kullanılarak üretilen yoğurt örneklerinin 0. gününde tespit edilen protein miktarı Tablo 1'de belirtilmiştir.

Tablo 1. Farklı oranlarda ŞAHT ilave edilerek üretilen yoğurt örneklerinin protein değerleri (%)

Yoğurt Örnekleri	Protein Değerleri
K	2,915±0,16
A	2,985±0,19
B	2,990±0,57
C	2,850±0,21
D	2,855±0,01
E	3,195±1,10

K: Kontrol Örneği, A: %0,1 oranında şalgam artığı havuç tozu içeren yoğurt, B: %0,25 oranında şalgam artığı havuç tozu içeren yoğurt, C: %0,5 oranında şalgam artığı tozu içeren yoğurt, D: %1 oranında şalgam artığı havuç tozu içeren yoğurt, E: %2,5 oranında şalgam artığı havuç tozu içeren yoğurt.

Yoğurt örneklerinin protein oranlarının %2,85 ile %3,195 arasında değiştiği belirlenmiştir (Tablo 1). En yüksek protein miktarı %2,50 oranında ŞAHT eklenen numunede ölçülürken, en düşük değer %0,5 ŞAHT içeren numunede tespit edilmiştir. Dolayısıyla genel olarak ŞAHT ilavesinin yoğurtlardaki protein miktarını artırmış olduğu söylenebilir. Çayır (2007) tarafından yapılan araştırmada, yoğurtların protein içeriğinin %3,44 ile %3,74 arasında değiştiği belirlenmiştir. Rahman ve ark. (2001) ise, %5, 10 ve 15 oranında meyve ilave edilen yoğurtlarda, meyve miktarının artışıyla protein oranlarının azaldığını tespit etmiştir.

Hong ve ark. (2020) çalışmalarında, farklı renklerdeki paprika suyu (kırmızı, turuncu ve sarı) ilavesinin yoğurdun biyokimyasal ve antioksidan aktiviteleri üzerindeki etkilerini incelemişlerdir. Çalışmada, *St. thermophilus* ve *Lb. delbrueckii* subsp. *bulgaricus* bakteri kültürleri ile inoküle edilen ve paprika suyu eklenen yoğurt örnekleri hazırlanmış, paprika suyu içermeyen kontrol grubu da oluşturulmuştur. Paprika suyu ilavesinin yoğurdun peptit konsantrasyonunu önemli ölçüde artırdığını belirtmişlerdir. Kontrol yoğurdunun peptit konsantrasyonu 0,11 mg/mL iken, paprika suyu eklenmesiyle bu değer 0,21 mg/mL'ye yükselmiştir. Bu artışın, paprika ilavesi ile birlikte laktik asit bakteri sayısının artırarak, proteinleri önemli miktarda parçalaması ve serbest amino asit miktarını yükseltmesinden kaynaklanmış olabileceği ifade edilmiştir. Ancak, %2,5 oranında turuncu paprika suyu içeren yoğurdun 4°C'de 15 gün boyunca depolanması sırasında peptit konsantrasyonunda önemli bir değişiklik gözlemlenemediği de bildirilmiştir. Hem kontrol hem de paprika içeren yoğurtlarda peptit seviyelerinin depolama süresince sabit kaldığı ve bu durumun depolama sırasında proteinlerin belirgin bir şekilde parçalanmaması ve laktik asit bakteri sayısında büyük bir değişim olmamış olmasına bağlanmıştır.

Depolama süresince yoğurt örneklerinde pH ve toplam asitlik değeri

Üretilen yoğurt örneklerinde pH serbest halde bulunan H+ iyonları konsantrasyonunu ifade etmekte olup, yoğurtlarda raf ömrü, depolama stabiliteleri üzerine etki eden faktörlerdir. Üretilen yoğurt örneklerinin depolamalarının 1., 7., 15. ve 21. günlerinde pH değerleri belirlenmiş ve Tablo 2'de belirtilmiştir.

Tablo 2. Depolama süresince yoğurt örneklerinde pH ve toplam asitlik değişimi

Yoğurt örnekleri	pH				Toplam asitlik			
	Depolama Süresi				Depolama Süresi			
	1. Gün	7.Gün	15.Gün	21.Gün	1. Gün	7.Gün	15.Gün	21.Gün
K	4,28±0,02	4,16±0,005	4,13±0,03	4,13±0,005	0,795±0,014	0,846±0,004	0,849±0,002	0,875±0,005
A	4,19±0,005	4,10±0,005	4,10±0,02	4,12±0,005	0,800±0,009	0,910±0,03	0,824±0,012	0,820±0,029
B	4,20±0,065	4,05±0,01	4,08±0,035	4,11±0,01	0,847±0,003	0,965±0,005	0,874±0,004	0,865±0,055
C	4,09±0,05	4,08±0,005	4,07±0,02	4,12±0,005	0,872±0,0018	0,885±0,005	0,899±0,027	0,865±0,025

E	4,22±0,005	4,14±0,03	4,16±0,04	4,13±0,04	0,825±0,01	0,870±0,001	0,915±0,055	0,900±0,001

K: Kontrol Örneği, A: %0,1 oranında şalgam artığı havuç tozu içeren yoğurt, B: %0,25 oranında şalgam artığı havuç tozu içeren yoğurt, C: %0,5 oranında şalgam artığı tozu içeren yoğurt, D: %1 oranında şalgam artığı havuç tozu içeren yoğurt, E: %2,5 oranında şalgam artığı havuç tozu içeren yoğurt.

Yoğurt örneklerinin inkübasyon sonrası pH değerleri Tablo 2'de gösterildiği gibi 4,09 ile 4,28 arasında değişim göstermiştir. En yüksek pH değeri, ŞAHT ilavesi yapılmayan kontrol grubunda ölçülmüş, diğer örneklerde ise farklı seviyelerde değişimler gözlenmiştir. ŞAHT içeren yoğurt örneklerinde pH değerlerinin kontrol grubuna kıyasla genellikle daha düşük olduğu ve ŞAHT ilavesinin pH'yı düşürdüğü belirlenmiş olmakla birlikte, ilave miktarının artışıyla düzenli bir yükseliş veya azalış eğilimi gözlemlenmemiştir. Kontrol örneğinde depolamanın ilk gününden itibaren pH değerinde azalma meydana gelmiş ve 21. gün itibarıyla pH 4,13 olarak belirlenmiştir. ŞAHT içeren örneklerde ise genellikle 15. güne kadar pH'da bir azalma gözlenmiş, ancak 21. gün itibarıyla artış kaydedilmiştir. 21 günlük depolama işlemi sonunda en yüksek pH değeri (4,13), K, D ve E numunelerinde tespit edilirken, en düşük pH değeri (4,11) B numunesinde belirlenmiştir.

Önceki çalışmalarla karşılaştırıldığında, Karagözlü (1997) tarafından meyveli yoğurtlar üzerinde yapılan araştırmada 28 günlük depolama süresince pH değerlerinin 4,07-4,70 arasında değiştiği belirlenmiştir. Alzamara (2015) tarafından farklı oranlarda kuşburnu marmelatı ilave edilen yoğurtlarda 21 günlük depolama süresince pH değerlerinin 3,88-4,00 arasında değiştiği, Gündoğan (2015) tarafından karamuk konsantresi ve kavut ilavesiyle üretilen yoğurtlarda ise 21 gün boyunca pH değerlerinin 5,32'den 4,22'ye düştüğü bildirilmiştir. Wang ve ark. (2020) yapmış oldukları çalışmada elma posası ilavesi, özellikle %2 ve %3 oranlarında uygulandığında yoğurtların pH değerinde anlamlı bir düşüşe yol açtığını gözlemlemişlerdir. Örneklerde pH değerinin, soğuk depolama süresince azalmış olduğu, buna karşılık titre edilebilir asitlik miktarının arttığı ve 28. gün sonunda en yüksek seviyeye ulaştığı bildirilmiştir. Bu değişiklikler, yoğurtta laktik asit üreten bakterilerin (özellikle *St. thermophilus* ve *Lb. delbrueckii subsp. bulgaricus*) aktivitesine bağlanmaktadır. pH düşüşü ve asitlik artışı en belirgin şekilde ilk 7 gün içinde gözlemlenmiştir. Çakmakçı ve ark. (2012), muz marmelatı ilave edilmiş yoğurt ürünlerinin üretiminde probiyotik bakterilerin (*Lb. acidophilus, Bifidobacterium bifidum* veya bu 2 suşun eşit karışımı) kullanılma olasılığını araştırdıkları çalışmada soğuk depolama süresi boyunca yoğurt örnekleri arasında titre

edilebilir asitlik açısından anlamlı farklar gözlemlenmiştir. Tüm örneklerde asitlik zamanla artarken, pH değerleri azalma eğilimi göstermiştir. Bu durumun, *Lb. delbrueckii subsp. bulgaricus* ve *St. thermophilus*'un neden olduğu postasitifikasyon süreciyle ilişkili olduğu düşünülmüş ve başlangıçta 4,49–4,60 aralığında olan pH değerlerinin, 14 gün sonunda 4,07–4,16 düzeyine gerilediği tespit edilmiştir.

Cho ve ark. (2020) şekerli omija meyvesi ilavesinin yoğurdun kalitesini ve antioksidan aktivitesini iyileştirip iyileştirmediğini belirlemek için yaptıkları çalışmada başlangıçta tüm grupların (şekerli omija ekstraktı eklenmiş, sadece çiğ omija ekstraktı eklenmiş ve herhangi bir ekleme yapılmamış yoğurt örnekleri) pH değerlerinin benzer aralıklarda olduğunu (4,55-4,57), ancak depolama süresi boyunca tüm gruplarda pH değerlerinin düştüğünü bildirmişlerdir (14. günde 4,22-4,38). 7. güne kadar gruplar arasında pH açısından anlamlı bir fark gözlemlenmezken, 7. günden sonra anlamlı farklılıklar ortaya çıkmış ve bu pH düşüşü, laktik asit bakterilerinin laktozu laktik aside dönüştürmesiyle açıklanmıştır. Başlangıçta titrasyon asitliği değerleri %0,94-1,01 arasındayken, 14 gün sonra %0.99-1.05 arasına yükselmiş ve depolama süresi boyunca bu değerler artmıştır.

Nguyen ve Hwang (2016) tarafından yapılan çalışmada, aronia suyu ilavesinin yoğurdun fermantasyon sürecindeki pH ve titrasyon asitliği üzerine etkileri incelenmiştir. Tüm yoğurt örneklerinde fermantasyon süresince pH değerleri düşerken, titrasyon asitliği artış göstermiştir. Aronia suyu içeren gruplarda pH değerleri, içeriğindeki asidik bileşikler nedeniyle kontrol grubuna kıyasla daha düşük bulunmuştur. Özellikle %2 ve %3 aronia suyu eklenen yoğurtlar, 6. saatten itibaren daha yüksek titrasyon asitliği göstermiştir.
Hong ve ark. (2020) yapmış oldukları çalışmada, farklı renklerdeki paprika suyu (kırmızı, turuncu ve sarı) ilavesinin yoğurt üzerinde etkilerini incelemiş ve paprika suyu ilavesi yoğurdun pH değerini düşürmüş ve özellikle %5 sarı paprika suyu içeren yoğurdun pH'ı kontrol grubundan daha düşük bulunmuştur. Ayrıca, paprika suyu, yoğurdun titrasyon asitliği değerini artırmıştır. Depolama süresinin sonunda, her iki grup da pH değerinde düşüş göstermiş, ancak paprika içeren yoğurtlar, kontrol yoğurduna göre daha düşük pH değerine sahip olmuştur. Titrasyon asitliği değerleri ise her iki grupta artmıştır.
Bu çalışmada elde edilen sonuçlar, Karagözlü (1997), Çakmakçı ve ark. (2012), Nguyen ve Hwang (2016), Hong ve ark. (2020) ve Wang ve ark. (2020) tarafından bildirilen bulgularla benzerlik gösterirken, Alzamara (2015) tarafından elde edilen pH değerlerinden daha yüksek bulunmuştur.
Yoğurt üretiminde, süte eklenen laktik asit bakterileri, laktozun fermente edilmesiyle laktik asit üretir. Bu fermantasyon süreci, bakterilerin laktaz enzimi aracılığıyla laktozu glikoz ve galaktoza dönüştürmesiyle başlar ve sonrasında bu şekerler, bakteriler tarafından laktik asit olarak metabolize edilir. Üretilen laktik asit, yoğurdun pH değerini düşürerek ortamın asidik özellik kazanmasına yol açar. pH değeri 4,6'nın altına düştüğünde, süt proteinleri (özellikle kazein) çökelmeye başlar ve bu süreç, yoğurdun karakteristik jelleşmesini sağlar. Toplam asitlik miktarı, kullanılan starter kültürlerin mikroorganizma türlerine, sütün kimyasal bileşimine (özellikle kurumadde ve protein içeriği) ve üretim sürecindeki depolama koşullarına bağlı olarak değişkenlik gösterebilir. Ayrıca, fermente edilen süt ürünlerinin pH ve asidik seviyeleri, yoğurdun fermente edilme süresi, sıcaklık ve saklama koşullarıyla da doğrudan ilişkilidir. Gerçekleştirilen çalışma kapsamında ŞAHT ilavesiyle üretilen yoğurt örneklerinin toplam asitlik değerlerindeki değişimler, depolamanın 1., 7., 15. ve 21. günlerinde ölçülerek Tablo 2'de sunulmuştur.
Araştırmada farklı miktarlarda ŞAHT ikamesi ile üretilen yoğurtların asitlik değerleri 0,795 ile 0,965 arasında değişmiş olup, en düşük değer kontrol grubunda ölçülmüştür. ŞAHT ilavesi, yoğurt örneklerinde asitliği artırmış ancak bu artış %0,5 oranında ŞAHT içeren C örneğine kadar devam etmiştir. Daha yüksek ŞAHT seviyelerinde ise toplam asitlikte azalma gözlenmiştir. Kontrol numunesinde depolama süresince asitlik artmaya devam etmiş ve 21. gün sonunda %0,875 olarak belirlenmiştir. A, B ve D örneklerinde asitlik artışı 7. güne kadar devam ederken, C ve E örneklerinde bu durum 15. güne kadar sürmüştür. Ancak, kontrol grubu dışındaki tüm numunelerde 21. güne kadar az da olsa bir düşüş gözlenmiştir.
Literatürde gerçekleştirilmiş olan çalışmalara bakıldığında, Karagözlü (1997) tarafından yapılan çalışmada, meyveli yoğurtların 28 günlük depolama sürecinde titrasyon asitliği değerlerinin %0,85 ile 1,38 arasında değiştiği ve asitlik seviyesinin zamanla arttığı tespit edilmiştir. Santo ve ark. (2012), çarkıfelek meyvesi lifi içeren probiyotik yoğurtlarda 14 gün boyunca depolama sürecinin titrasyon asitliğini artırdığını raporlamıştır. Uzuner (2012), pirinç sütüyle üretilen probiyotik yoğurtlarda 21 günlük depolama sonunda titrasyon asitliği değerlerinin %0,41 ile %1,14 arasında değiştiğini saptamıştır. Çoban (2017) ise kefir danesi ilavesi yapılan yoğurtlarda depolama süresince genel olarak titrasyon asitliğinin arttığını gözlemlemiştir. Bu çalışmada elde edilen veriler, 15. güne kadar Çoban (2017) tarafından bildirilen sonuçlarla paralellik gösterirken, 15. günden sonra asitlikte hafif bir düşüş gözlenmiş ve bu değişim önemli bir seviyede olmamıştır. Genel olarak, depolama sonunda elde edilen asitlik değerleri, önceki araştırmaların (Karagözlü, 1997; Santo ve ark., 2012; Çakmakçı ve ark., 2012; Nguyen ve Hwang, 2016; Cho ve ark., 2020) bulgularıyla uyumludur.

Depolama süresince yoğurt örneklerinde kurumadde oranı ve antioksidan kapasite değeri

Yoğurt örneklerinin depolama sürecinde yapılan analizlerle elde edilen kurumadde ve antioksidan kapasite değerleri Tablo 3'te verilmiştir. Kurumadde oranları depolamanın 1. gününde %11,76 (kontrol) ile %13,89 arasında değişiklik göstermiş olup, artan ikame maddesi ile artış göstermiştir. Depolama ile beraber genellikle kurumadde değerlerinde azalma gözlenmiştir. 21 günlük depolama sonunda ise yine benzer şekilde en düşük kurumadde miktarı kontrol örneğinde belirlenmişken, en yüksek değer en çok ikame maddesi ilave edilen denemede %13.93 olarak elde edilmiştir.

Tablo 3. Farklı oranlarda ŞAHT İlave edilerek üretilen yoğurtların depolama süresince kurumadde (%) ve antioksidan kapasitelerinin (µmol Trolox Eşdeğeri) değişimi

Yoğurt örnekleri	Kurumadde				Antioksidan kapasite (µmol Trolox Eşdeğeri)			
	Depolama Süresi				Depolama Süresi			
	1. Gün	7.Gün	15.Gün	21.Gün	1. Gün	7.Gün	15.Gün	21.Gün
K	11,76±0,07	11,55±0,03	11,42±0,01	11,50±0,32	35,18±2,7	31,27±3,86	39,18±3,34	27,45±1,80
A	11,81±0,02	11,60±0,11	11,57±0,115	11,61±0,005	40,81±1,67	39,27±4,89	41,81±1,29	27,90±10,16
B	11,87±0,03	11,83±0,05	11,77±0,05	11,62±0,09	57,68±3,28	43,09±14,08	56,99±1,16	37,22±0,19
C	12,21±0,05	11,95±0,03	11,76±0,145	11,95±0,1	85,45±0,64	62,72±7,07	102,95±15,11	69,31±14,46
D	12,88±0,08	12,61±0,2	12,35±0,025	12,55±0,11	136,36±18,64	113,63±3,86	125,681±3,54	89,54±9,0
E	13,89±0,04	14,02±0,005	13,93±0,02	13,39±0,025	217,27±3,21	270,9±2,57	236,81±4,50	190,68±12,53

K: Kontrol Örneği, A: %0,1 oranında şalgam artığı havuç tozu içeren yoğurt, B: %0,25 oranında şalgam artığı havuç tozu içeren yoğurt, C: %0,5 oranında şalgam artığı tozu içeren yoğurt, D: %1 oranında şalgam artığı havuç tozu içeren yoğurt, E: %2,5 oranında şalgam artığı havuç tozu içeren yoğurt.

Öztürk ve Akyüz (1995) meyveli yoğurtlarla ilgili yaptıkları bir çalışmada, sade yoğurdun kurumadde oranlarının meyveli yoğurda göre daha düşük olduğunu ve bu farkın eklenen meyve ve sakkarozdan kaynaklandığını belirtmiştir. Ayar (2002) ise, kızılcık ilaveli yoğurtlarla ilgili çalışmasında, meyve ilaveli yoğurtların kontrol örneğine göre daha yüksek kurumadde oranlarına sahip olduğunu ifade etmiştir. Rahman ve ark. (2001) benzer bir çalışmada, meyve katkılı yoğurtların kontrol yoğurduna göre daha yüksek kurumadde içerdiğini belirtmişlerdir. Bu çalışmada elde edilen sonuçlar, Öztürk ve Akyüz (1995), Ayar (2002) ve Rahman ve ark. (2001) bulgularıyla benzerlik göstermektedir.

ŞAHT örneğine ait antioksidan kapasite değerlerini belirlemek için farklı çözücüler kullanılmıştır. ŞAHT örneğine "Aseton;Su" (%70;30) kullanıldığında antioksidan kapasite 33,63 µM Trolox (v/v) olarak belirlenmişken, "Etanol;Su" (%70;30) (v/v) kullanıldığında 41,35 µM Trolox olarak elde edilmiştir. Buna karşılık, sadece su kullanıldığında antioksidan kapasite 55,43µM Trolox (v/v) olarak bulunmuştur. Dolayısıyla yoğurtlarda antioksidan kapasite değerlerini belirlemek için çözücü olarak sadece su kullanılmıştır.

Yoğurt örneklerinin 21 günlük depolama süresince antioksidan değerlerindeki değişim Tablo 3'te yer almaktadır. ŞAHT ilavesi arttıkça, tüm örneklerde antioksidan kapasite değerlerinde artış gözlemlenmiştir. Depolamanın ilk gününde en düşük değer 35,18 µmol Trolox Eşdeğeri ile kontrol örneğinde, en yüksek değer ise 217,27 µmol Trolox Eşdeğeri ile E örneğinde tespit edilmiştir. Dolayısıyla ilave edilen ŞAHT miktarı arttıkça antioksidan kapasite değerlerinde artış gözlenmiştir. Depolamanın ilk gününden 7. güne kadar antioksidan değerlerinde bir düşüş yaşanırken, 7. günden 15. güne kadar bir artış gözlenmiş, ancak 15. günden sonra değerlerde tekrar bir azalma olmuştur. 21. günün sonunda ise 1. gün değerlerine göre tüm denemelerde azalma gözlenmiş ve en düşük antioksidan değeri 27,45 µmol Trolox Eşdeğeri ile kontrol örneğinde belirlenmişken, en yüksek değer ise 190,68 µmol Trolox Eşdeğeri ile E örneğinde bulunmuştur.

Alzamara (2015) tarafından yapılan bir çalışmada, kuşburnu ve kızılcık marmelatları ilave edilerek üretilen yoğurtların depolama süresince antioksidan aktivite değerlerinin azaldığı ve depolamanın ilk gününde en yüksek değerin 8,43 µmol Trolox Eşdeğeri, son gününde ise 4,35 µmol Trolox Eşdeğeri olduğu belirtilmiştir. Sıçramaz (2025) yapmış olduğu çalışmada, zerdeçal tozunun yoğurda eklenmesinin antioksidan aktiviteyi doza bağımlı bir şekilde artırdığını gözlemlemiş ve zerdeçal ilavesinin yoğurdun antioksidan özelliklerini önemli ölçüde iyileştirdiğini tespit etmiştir. Cho ve ark. (2020) yaptıkları çalışmada, DPPH radikal giderme aktivitesinin depolama süresi boyunca en yüksek çiğ omija ekstraktı içeren yoğurt grubunda gözlemlendiği bildirilmiştir. Şekerli omija ekstraktı ve kontrol grupları arasında 7. güne kadar anlamlı bir fark bulunmazken, 14. günde şekerli omija grubu, kontrol grubuna kıyasla daha yüksek antioksidan aktivite gösterdiği bildirilmiştir. Nguyen ve Hwang (2016) çalışmasında, aronia suyu içeren yoğurtların DPPH ve ABTS radikal giderme aktiviteleri, kontrol grubuna kıyasla önemli ölçüde daha yüksek bulunmuştur. Aronia suyu konsantrasyonu arttıkça antioksidan aktivite değerleri artmıştır. Araştırmacılar tarafından, yüksek antioksidan aktivitenin, aronia suyunun fitokimyasal içeriği ve mikrobiyal metabolik aktivite ile ilişkili olduğu düşünülmektedir.

Amirdivani ve Baba (2015) tarafından yapılan çalışmada, yeşil çayın (*Camellia sinensis*) sütün fermantasyonuna etkisi incelenmiştir. Çalışmada, yeşil çay ekstresi eklenmiş sütün antioksidan aktivite, fenolik bileşikler ve laktik asit bakterilerinin büyümesi üzerindeki değişiklikleri değerlendirilmiştir. Fermantasyon sürecinde, yeşil çay infüzyonu eklenmiş süt, başlangıçta sade süte göre daha yüksek antioksidan aktivite göstermiştir. Fermantasyon sonunda, MGTY (Malezya yeşil çayı yoğurdu) en yüksek DPPH inhibisyonuna sahip olurken, onu Japon yeşil

çayı yoğurdu ve Sade yoğurt izlemiştir. FRAP değerleri açısından da MGTY en yüksek değeri elde etmiştir, ancak fermantasyon süreci, FRAP değerlerinde önemli bir artışa neden olmamıştır. Yeşil çayın mikrobiyal büyümeyi teşvik etmesi ve antioksidan aktiviteye sahip metabolik bileşiklerin oluşumu, antioksidan aktivitedeki artışın olası sebepleri olarak gösterilmektedir. Çalışma ayrıca, soğuk depolamanın yeşil çaylı yoğurtlar üzerindeki bazı fenolik bileşiklerin miktarını etkilediğini ancak bu değişikliklerin yoğurdun antioksidan aktivitesini önemli ölçüde etkilemediğini belirtmiştir. Yeşil çayın sağladığı antioksidan özelliklerin, depolama süresi boyunca nispeten kararlı kaldığı sonucuna varılmıştır. Hong ve ark. (2020) çalışmalarında, farklı renklerdeki paprika suyu (kırmızı, turuncu ve sarı) ilavesinin yoğurdun su ve metanol ekstraktlarının antioksidan aktiviteleri üzerinde önemli bir artış sağladığını belirtmişlerdir. Metanol ekstraktlarının antioksidan aktiviteleri, su ekstraktlarına göre 2 ila 4 kat daha yüksek bulunmuştur. Araştırmacılar tarafından %2,5 oranında turuncu paprika suyu içeren yoğurdun metanol ekstraktının antioksidan aktivitesi en yüksek olarak belirlenmiştir. Ayrıca, depolama süresi boyunca, paprika içeren yoğurtların su ve metanol ekstraktlarının antioksidan aktivitelerinin kontrol yoğurduna göre daha yüksek olduğu bildirilmiştir.

Depolama Süresince Yoğurt Örneklerinde Renk Değerleri

Şalgam artığı havuç tozlarında L* değeri 43,01 olarak belirlenmiş olup, a* ve b* değerleri sırasıyla 32,40 ve 2,02 olarak elde edilmiştir. Bununla birlikte farklı oranlarda ŞAHT eklenerek üretilen yoğurt örneklerinin renk ölçümleri, L* (açıklık-koyuluk) değerleri Tablo 4'te a* ve b* değerleri ise Tablo 5'te sunulmuştur.

Şalgam artığı havuç tozu (ŞAHT) ilavesi arttıkça, yoğurtların koyulaştığı gözlemlenmiştir. Bunun nedeni, şalgam suyu üretiminde kullanılan havuçların antosiyanin pigmentleri açısından zengin olup kırmızı-mor renkte pigmentler içermesidir. Depolamanın 1. gününde L* değeri kontrol örneğinde 88,66 olarak belirlenmişken, ŞAHT ilave edilen denemelerde en düşük değer 58,96 ile E örneğinde ve en yüksek değer 83,46 ile A örneğinde belirlenmiştir. Öte yandan, depolama süresince L* değerlerinde genellikle düzenli bir artış görülmüş, yani renk solmuş ve yoğurtlar daha açık hale gelmiştir. 21 günlük depolama sonunda kontrol örneğinde L* değeri 97,3 ile yine en yüksek değer olarak belirlenmiştir. Bununla birlikte, ŞAHT ilave edilen denemelerde en düşük değer yine E örneğinde (66,5) ve en yüksek değer A örneğinde 92,16 olarak bulunmuştur.

Alzamara (2015) tarafından yapılan bir çalışmada, kuşburnu ve kızılcık marmelatları ilave edilen yoğurtlarda L* değerlerinin depolamanın ilk gününde 85,37 ve 21. gününde ise 83,49 olduğu ve 21 gün boyunca L* değerlerinin azaldığı belirtilmiştir. Bizim denememizde ise elde edilen L* değerleri depolamanın başlangıcında benzer iken, depolama ile kısmen de olsa azalması bakımından çalışmamızdan farklı olarak görülmüştür. Bu farklılığın meyvedeki karoten pigmentlerinden kaynaklanıyor olabileceği düşünülmektedir.

Tablo 4. Depolama süresince yoğurt örneklerinin L* değerlerindeki değişim

Yoğurt Örnekleri	Depolama Süresi			
	1. Gün	7.Gün	15.Gün	21.Gün
K	88,66±0,08	88,47±0,27	88,69±0,14	97,30±0,33
A	83,46±0,095	86,19±2,51	83,94±0,11	92,16±0,21
B	79,67±0,0235	79,63±0,495	80,41±0,285	87,96±0,18
C	74,97±0,24	75,07±0,01	77,04±0,29	82,87±0,225
D	69,23±0,7	69,36±0,075	70,95±1,14	76,68±0,17
E	58,96±0,62	59,38±0,335	60,88±0,57	66,50±0,55

K: Kontrol Örneği, A: %0,1 oranında şalgam artığı havuç tozu içeren yoğurt, B: %0,25 oranında şalgam artığı havuç tozu içeren yoğurt, C: %0,5 oranında şalgam artığı tozu içeren yoğurt, D: %1 oranında şalgam artığı havuç tozu içeren yoğurt, E: %2,5 oranında şalgam artığı havuç tozu içeren yoğurt.

Kontrol örneğinde a* değeri negatif değerde olup, ŞAHT ilave edilen örneklerde pozitif olarak belirlenmiştir. Dolayısıyla kontrol örneği diğer örneklerden daha yeşil bir renk tonuna sahiptir. Depolamanın 1. gününde artan ŞAHT ilavesi ile a* değerinin arttığı belirlenmiş olup, ŞAHT oranı arttıkça yoğurt örneklerinde kırmızılık değerlerinin arttığı gözlemlenmiştir (Tablo 5). Bunun nedeni, siyah havuçta bulunan antosiyanin pigmentleridir. Kontrol örneğinin a* değeri depolamanın başlangıcında -3,25 iken, en düşük miktarda ŞAHT ilave edilen örnekte a* değeri +4,52 ve en yüksek değeri E örneği ile +23,08 olarak belirlenmiştir. 21 gün sonunda, tüm denemelerde (A örneği hariç) a* değerlerinde artış gözlemlenmiştir ve a* değerleri -3,195 ile 24,875 arasında değişmiştir. Alzamara (2015) tarafından yapılan bir çalışmada, kuşburnu ve kızılcık marmelatları ilave edilen yoğurtlarda a* değeri depolamanın 1. gününde 5,35 ve 21. gününde ise 4,09 olarak tespit edilmiştir. Çoban (2017) ise kefir danesi ilavesi yapılan yoğurtlarda kontrol örneğinde a* değerini -4,32 olarak belirlemiştir. Gerçekleştirilen çalışmamızda ise, kontrol örneğinin a* değeri -3,25 olup, Çoban (2017) ile benzer sonuçlar elde edilmiştir.

Tablo 5. Depolama süresince yoğurt örneklerinin a* ve b* değerlerindeki değişim

K: Kontrol Örneği, A: %0,1 oranında şalgam artığı havuç tozu içeren yoğurt, B: %0,25 oranında şalgam artığı havuç tozu içeren yoğurt, C: %0,5 oranında şalgam artığı tozu içeren yoğurt, D: %1 oranında şalgam artığı havuç tozu içeren yoğurt, E: %2,5 oranında şalgam artığı havuç tozu içeren yoğurt.

Denemelerde, yoğurt örneklerine eklenen ŞAHT oranı arttıkça, yoğurtların sarılık değerlerinde azalma gözlemlenmiştir, bu durum Tablo 5'te gösterilmiştir. Kontrol örneğinde b* değeri 7,38 olarak belirlenirken, en düşük ŞAHT ilave edilen A denemesinde 3,80 ve en fazla ŞAHT eklenen E örneğinde bu değer 0,86 olarak tespit edilmiştir. Depolama süresi boyunca b* değerinde düzensiz bir değişiklik gözlemlenmiştir. Bununla birlikte, depolamanın başlangıcına göre, depolamanın 21. Gününde elde edilen b* değerlerinde (E denemesi dışında) azalma gözlenmiştir. Depolama sonunda, en yüksek b* değeri (6,67) kontrol örneğine aitken, en düşük değer ise E örneğinde 1,23 olarak bulunmuştur. Alzamara (2015) tarafından yapılan bir çalışmada, kuşburnu ve kızılcık marmelatları eklenen yoğurtlarda b* değeri 1,03 olarak tespit edilirken, 21. gün sonunda bu değer 2,58'e yükselmiş ve b* değerinin arttığı bildirilmiştir.

Wang ve ark. (2020) yapmış oldukları çalışmada, elma posası ilavesiyle birlikte yoğurtların renk parametrelerinde anlamlı farklılıklar gözlemlendiğini bildirmişlerdir. Açıklık (L*) değeri azalmış, buna karşılık kırmızımsılık (a*) ve sarılılık (b*) değerlerinin artmış olduğu belirlenmiş ve bu durumun elma posası ile zenginleştirilmiş yoğurtların kontrol grubuna kıyasla daha yoğun kırmızımsı ve sarımsı bir renge sahip olduğunu gösterdiğini bildirmişlerdir. Sıçramaz (2025) yapmış olduğu çalışmada, ilave edilen zerdeçal tozu konsantrasyonu arttıkça yoğurdun L* ve a* değerlerinin azaldığını, b* değerinin ise önemli ölçüde arttığını tespit etmiştir. Bu renk değişikliklerinin tamamen artan zerdeçal tozu konsantrasyonundan kaynaklandığı belirtilmiştir. Cho ve ark. (2020) çalışmasında, yoğurtlara çiğ ve şekerli omija ekstraktı ilavesinin renk parametrelerini etkilediği bildirilmiştir. Açıklık (L*) değeri en yüksekten en düşüğe doğru kontrol, şekerli omija ve çiğ omija ekstraktı şeklinde sıralanmış; çiğ omija ekstraktı daha koyu renk oluşumuna neden olduğu bildrilmiştir. Depolama süresi boyunca ise tüm gruplarda L*, a* (kırmızılık) ve b* (sarılık) değerlerinde azalma gözlemlenmiştir. En yüksek a* değeri çiğ omija ekstraktı grubunda bulunmuş, bu da antosiyanin içeriğiyle ilişkilendirilmiştir. Nguyen ve Hwang (2016) çalışmasında, aronia suyu ilavesinin yoğurtların daha kırmızı, daha koyu ve daha az sarı renge sahip olduğunu bildirmiştir. Fermentasyon süresince tüm gruplarda açıklık (L*) değerlerinde artış gözlemlenirken, kırmızılık (a*) ve sarılık (b*) değerlerinde farklı eğilimler gözlemlenmiştir. Hong ve ark. (2020) çalışmalarında, paprika suyu ilavesinin yoğurdun rengini belirgin şekilde değiştirdiğini belirtmişlerdir. Kırmızı paprika ilavesinin kırmızılık (a*) değerini artırdığını, turuncu paprika ilavesinin ise parlaklık (L*) değerini azaltıp, kırmızılık ve sarılığı (b*) artırmış olduğunu belirlemiştir. Sarı paprika ilavesinin ise parlaklık değerini korurken, sarılığı artırdığı ifade edilmiştir.

Sonuç

Bu çalışmada, şalgam suyu üretiminde ortaya çıkan önemli miktardaki siyah havuç artığının kurutularak toz haline getirilmesi (ŞAHT) ve bu tozun farklı oranlarda yoğurt üretimine (%0, %0.1, %0.25, %0.5, %1.0, %2.5) dahil edilmesinin yoğurdun bazı özellikleri üzerindeki etkileri incelenmiştir. Gerçekleştirdiğimiz bu çalışmadan elde edilen sonuçlar, ŞAHT'nin yoğurtların protein içeriği, pH, toplam asitlik, kurumadde oranı, antioksidan kapasite ve renk özellikleri üzerinde önemli değişikliklere yol açtığını göstermektedir. Elde edilen sonuçlar, *b* değerinde düşüşe, buna karşılık toplam asitlik, kurumadde, antioksidan kapasite ve a* değerlerinde ise artışa neden olduğunu göstermiştir. Fonksiyonel özellikler açısından bakıldığında, ŞAHT ilavesiyle yoğurtların antioksidan kapasitesinde önemli bir artış sağlanmıştır. Sonuç olarak, bu çalışma şalgam suyu endüstrisinden kaynaklanan siyah havuç atığının yoğurt üretiminde kullanımı açısından büyük bir potansiyele sahip olduğunu, yoğurt üretiminde başarılı bir şekilde kullanılabileceğini ve bu sayede hem atık değerlendirilerek ekonomik bir kazanç sağlanabileceğini hem de yoğurdun fonksiyonel özelliklerinin zenginleştirilebileceğini göstermektedir. Özellikle düşük konsantrasyonlarda ŞAHT ilavesinin yoğurdun kalitesini olumlu yönde etkileyebileceği ve tüketiciler için farklı özelliklere sahip yeni yoğurt çeşitlerinin geliştirilebileceği düşünülmektedir. Elde edilen veriler, çevresel sürdürülebilirlik açısından da önemli bir yer tutmaktadır, çünkü şalgam suyu üretiminden çıkan atıkların değerlendirilmesi, gıda atıklarının yönetimi konusunda yeni bir yaklaşım sunmaktadır. Gelecek çalışmalarda, farklı ön işlemlerin ve daha düşük ŞAHT konsantrasyonlarının etkileri detaylı olarak incelenebilir.

Professional Practice Knowledge in Interior Architecture Education, Exploration, Quantity Surveying and Approximate Cost

Ali Akçaova[1]

[1]Department of Interior Architecture, Faculty of Architecture and Design, Selcuk University, Konya, Turkey

Abstract

Interior architecture education is a branch of science that covers topics such as design knowledge and skills, material knowledge, construction site application information and cost calculations as well as theoretical knowledge. In addition to the basic design knowledge of the students in the education process, there are also courses on professional practice. The aim of these courses is to address the procedures to be done before and during the application phase of the project in the construction site environment. In the interior design project, the quantity quantities of the materials decided in the design process according to the units, wastage calculations, position numbers, approximate cost (discovery) should be managed by the interior architect before proceeding to the application phase. In this context, the study examines the course content applied within the scope of Building Quantity Surveying and Exploration, which is a compulsory course in the 7th semester curriculum of Selçuk University Faculty of Architecture and Design, Department of Interior Architecture. Within the scope of the course, the interior design project stages of the physically determined space, survey, quantity survey, exploration and approximate cost calculations are discussed. Within the scope of the study, 4th year interior architecture students were asked to redesign the classroom number 411, where the Building Quantity Surveying and Exploration course was carried out, with the same function. Within the scope of the project, the design process, survey, quantity surveying, exploration and organization order of the works to be applied and approximate cost calculations were requested. It is expected that this study will contribute to the literature and provide an example of how approximate bill of quantities and cost calculations can be made in the field of interior architecture.

Key Words: *Interior Architecture, Professional Practice, Quantity Surveying, Estimated Cost*

İç Mimarlık Eğitiminde Mesleki Uygulama Bilgisi, Keşif, Metraj ve Yaklaşık Maliyet

Özet

İç mimarlık eğitimi, teorik bilgilerin yanı sıra tasarım bilgi ve becerisi, malzeme bilgisi, şantiye uygulama bilgileri ve maaliyet hesapları gibi konuları kapsayan bilim dalıdır. Öğrencilerin eğitim sürecinde temel tasarım bilgileri yanı sıra, mesleki uygulama içerikli dersleri de yer almaktadır. Bu derslerin amacı, öğrencileri şantiye ortamında projenin uygulama safhasın ve öncesinde yapılması gereken işlemleri ele almaktır. İç mimari projede tasarım sürecinde karar verilen malzemelerin birimlerine göre metraj miktarlarının çıkartılması, fire hesapları, pozisyon numaraları, yaklaşık maaliyeti (keşif), uygulama aşamasına geçmeden önce, iç mimar tarafından yönetilmelidir. Bu kapsamda çalışma Selçuk Üniversitesi Mimarlık ve Tasarım Fakültesi İç Mimarlık bölümü 7. Dönem müfredatında zorunlu ders olarak yer alan Yapı Metraj ve Keşif kapsamında uygulanan ders içeriğini incelemektedir. Ders kapsamında fiziki olarak belirlenen mekânın iç mimari proje aşamaları, rölöve, metraj, keşif ve yaklaşık maaliyet hesaplamaları ele alınmıştır. Çalışma kapsamına İç mimarlık 4. Sınıf öğrencilerinin, Yapı metraj ve Keşif dersinin yürütüldüğü 411 numaralı dersliğin aynı fonksiyon ile yeniden tasarlanması istenmiştir. Proje kapsamına tasarım süreci, rölöve, metraj, keşif ve uygulanacak işlerin organizasyon sıralaması ve yaklaşık maaliyet hesapları istenmiştir. Bu çalışmanın iç mimarlık alanında yaklaşık metraj cetveli ve maliyet hesaplamalarının nasıl yapılabileceğine yönelik bir örnek oluşturması ve literatüre katkı sağlaması beklenmektedir.

Gluten-free Noodles from Cassava-Bambara groundnut Composite Flour: Physicochemical Properties and Consumer Acceptability

Rosemond Godbless Dadzie[1], Jerry Ampofo-Asiama[2], Nazir Kizzie-Hayford[2], Gifty Serwaa Otoo[3], Isaaca Adade[1], Sandra Voryehor[4], Jesse Baidoo[4] Emmanuel Azeedan Ayoobe[2]

[1]Department of Agricultural Engineering, School of Agriculture, University of Cape Coast
[2]Department of Biochemistry, School of Biological Sciences, University of Cape Coast
[3]Department of Food Science and Postharvest Technology, School of Applied Sciences and Technology, Cape Coast Technical University
[4]Fountain Foods Limited, Ghana

Abstract

The aim of this study was to develop gluten-free noodles with enhanced nutritional quality using cassava and Bambara groundnut flours as alternative ingredients. A combined mixture-process design was applied to investigate the effects of two mixture components (cassava and Bambara groundnut flours) and two process factors (whole egg and xanthan gum) on the quality attributes of noodles. The responses (protein content, ash content, L*-values, Hue, chroma, browning index, weight gain, and cooking loss) were modelled by mixture-process equations. The results indicated that the protein, ash, and weight gain of the noodles increased with an increase of both cassava and Bambara groundnut flours. The noodles were optimised based on the desirability function and three optimal formulations were selected for sensory evaluation. The formulation with the highest desirability index (0.82) consisted of 70.4 % cassava flour, 29.57 % Bambara groundnut flour, 40 % whole egg, and 0.49 % xanthan gum. However, the sensory panel preferred the formulation without Bambara groundnut flour (100% cassava flour, 36.92% whole egg, and 0.23% xanthan gum), although the addition of Bambara groundnut flour enhanced protein, ash, fat and fibre contents, weight gain, phytochemical composition, hardness, chewiness and gumminess of the noodles, while reducing cooking loss.

Keywords: *Cassava flour, Bambara groundnut, Nutritional composition, Cooking loss*

Methods Used in Calculating Water Footprint in Agricultural Production

Burak Şen[1], Ayşe Topal[2], Ali Kaan Yetik[1]

[1]Department of Biosystems Engineering, Faculty of Agricultural Sciences and Technologies, Nigde Ömer Halisdemir University, Nigde, Turkey
[2]Department of Business, Faculty of Economics and Administrative Sciences, Nigde Ömer Halisdemir University, Nigde, Turkey

Abstract

The water footprint in agricultural production is a critical assessment tool for the sustainable management of water resources. By analyzing the amount of water used in agricultural production, the water footprint helps enhance both environmental sustainability and economic efficiency. Water management in the agricultural sector is becoming increasingly complex due to factors such as diminishing water resources, climate change, and a growing population. Water footprint calculation methods are based on a combination of direct measurements and computed values. Factors such as irrigation methods, crop types, soil structure, and climate conditions determine water requirements. These calculations provide agricultural enterprises with opportunities to develop sustainable water management strategies. In particular, wireless sensors and remote sensing technologies enable real-time monitoring of water use, contributing to more efficient water utilization. The effective implementation of water management policies helps maintain ecosystem balances and improve agricultural sustainability. The involvement of farmers, water managers, and local communities in these processes promotes water conservation. Educational programs and awareness campaigns can ensure the implementation of proper irrigation techniques, thereby optimizing agricultural water use. In conclusion, accurately calculating and managing the water footprint in agricultural production is of great importance for the conservation of water resources and ensuring sustainable agricultural development in the future. As water efficiency increases, environmental and economic benefits can be achieved, optimizing agricultural productivity.

Key Words: *Water footprint, Agriculture, Sustainability, Climate change, Economy*

Tarımsal Üretimde Su Ayak İzinin Hesaplanmasında Kullanılan Yöntemler

Özet

Tarımsal üretimde su ayak izi, su kaynaklarının sürdürülebilir yönetimi için kritik bir değerlendirme aracıdır. Su ayak izi, tarımsal üretimde kullanılan su miktarını analiz ederek hem çevresel sürdürülebilirliği hem de ekonomik verimliliği artırmaya yardımcı olur. Tarım sektöründe su yönetimi, azalan su kaynakları, iklim değişikliği ve artan nüfus gibi faktörler nedeniyle giderek daha karmaşık hale gelmektedir. Su ayak izi hesaplama yöntemleri, doğrudan ölçümler ve hesaplanmış değerlerin kombinasyonuna dayanır. Sulama yöntemleri, bitki türleri, toprak yapısı ve iklim koşulları gibi faktörler su ihtiyacını belirler. Bu hesaplamalar, tarımsal işletmelere sürdürülebilir su yönetimi stratejileri geliştirme fırsatı sunar. Özellikle kablosuz sensörler ve uzaktan algılama teknolojileri, su kullanımının gerçek zamanlı izlenmesini sağlayarak suyun daha verimli kullanılmasına katkıda bulunur. Su yönetimi politikalarının etkin uygulanması, ekosistem dengelerinin korunmasına ve tarımsal sürdürülebilirliğin artırılmasına yardımcı olur. Çiftçilerin, su yöneticilerinin ve yerel toplulukların bu süreçlere dahil edilmesi, su tasarrufunu teşvik eder. Eğitim programları ve farkındalık kampanyaları, doğru sulama tekniklerinin uygulanmasını sağlayarak tarımsal su kullanımını optimize etmeye yardımcı olabilir. Sonuç olarak, tarımsal üretimde su ayak izinin doğru hesaplanması ve yönetilmesi, gelecekte su kaynaklarının korunması ve sürdürülebilir tarımsal kalkınmanın sağlanması açısından büyük önem taşımaktadır. Su verimliliği artırıldıkça, çevresel ve ekonomik faydalar sağlanarak tarımsal üretkenlik optimize edilebilir.

Anahtar Kelimeler: *Su ayak izi, Tarım, Sürdürülebilirlik, İklim değişikliği, Ekonomi*

Giriş

Su ayak izi, tarımsal üretimde kaynakların etkin kullanımını analiz etme amacıyla geliştirilen bir değerlendirme aracıdır. Bu kavram, tarımsal ürünlerin üretimi sürecinde kullanılan su miktarını belirleyerek, hem çevresel sürdürülebilirlik hem de ekonomik verimlilik açısından kritik bir öneme sahiptir. Tarım sektöründeki su yönetimi, su kaynaklarının giderek azalması, iklim değişikliği ve artan nüfus baskısıyla daha da karmaşık bir hale gelmiştir.

Dolayısıyla, tarımsal üretimde su ayak izinin hesaplanması, etkili su yönetimi stratejilerinin geliştirilmesine yardımcı olarak, tarımsal sürdürülebilirliği desteklemekte ve çevresel etkileri azaltmaktadır. (Batan, 2021; Tanrıverdi; Demirci, 2024)

Günümüzde, su ayak izi hesaplama yöntemleri, çeşitli çevresel, sosyo-ekonomik ve teknik faktörlere dayalı olarak şekillenmekte ve bu hesaplamalar, tarımsal işletmelere daha bilinçli ve sürdürülebilir su kullanımı sağlama imkânı sunmaktadır. Bu süreçte, su ihtiyacını belirleyen unsurlar arasında sulama yöntemleri, bitki türleri, toprak yapısı ve iklim koşulları gibi etmenler bulunmaktadır. Su ayak izinin hesaplanmasında kullanılan yöntemler, genellikle doğrudan ölçümler ve hesaplanmış değerlerin kombinasyonlarını içermektedir. Ayrıca, bu yöntemler yerel su kaynaklarının durumu ve mevcut yönetim politikalarının etkinliği gibi unsurları da göz önünde bulundurarak, tarımdaki su kullanımını optimize etmeyi amaçlamaktadır. (Ediz, 2023;Aydın, 2023; Carfi, 2022; Bağmancı, 2022)

Tarımsal üretimde su ayak izinin hesaplanması, sürdürülebilir tarım uygulamalarının geliştirilmesi için önemli bir araç olmaktadır. Bu bağlamda, çiftçiler ve tarımsal işletmeler, su kaynaklarını verimli bir biçimde kullanarak hem doğal kaynakların korunmasına katkıda bulunmakta hem de üretim süreçlerinin ekonomik sürdürülebilirliğini sağlamaktadır. İlgili yöntemlerin ve hesaplamaların etkin kullanımı, tarımsal üretimde su ayak izinin minimize edilmesine yönelik stratejilerin geliştirilmesi açısından belirleyici bir faktör teşkil etmektedir. Bu nedenle, su ayak izinin anlaşılması ve bu doğrultuda doğru yöntemlerin tercih edilmesi, gelecekte daha az su kullanarak daha fazla üretim yapma hedefinin gerçekleştirilebilmesi için elzemdir. (Çakmak & Torun, 2023; Batan, 2021; Yımam, 2023; Dikel ve Demirkale 2023; Demirci, 2024; Ağızan, 2024)

Materyal ve Yöntem

1. Su Ayak İzi Kavramı

Su ayak izi, bireylerin, toplulukların veya belirli faaliyetlerin su kullanımını ölçen bir kavramdır. Bu kavram, tarımsal üretimle ilişkilendirilmiş olduğunda, bir ürünün yetiştirilmesi, işlenmesi ve dağıtım süreçlerinde doğrudan veya dolaylı olarak harcanan su miktarını ifade eder. Su ayak izinin hesaplanması, tarım sektöründe su kaynaklarının yönetimi için kritik bir araç sağlayarak, suyun verimli ve sürdürülebilir bir biçimde kullanılmasına yönelik stratejilerin geliştirilmesine olanak tanır. Bu ölçüm, hem yüzeysel hem de yer altı su kaynaklarının tüketimini kapsamaktadır ve suyun belirli bir ürün türü için gereksinimlerini belirlemek amacıyla kullanılabilir. (Demirci, 2024; Başkılıç, 2023; Karakayaci ve Tuyluoğlu, 2022; Dikel ve Demirkale, 2023; Turgut, 2024)

Su ayak izi kavramı, çeşitli bileşenlerden oluşarak karmaşık bir yapıya bürünmektedir. Bu bileşenler arasında, tarımda kullanılan sulama yöntemleri, iklim değişkenleri, toprak özellikleri ve bitki türleri gibi faktörler yer alır. Örneğin, sulama sistemleri, suyun etkin kullanımını etkileyen en önemli unsurlardan biri haline gelirken, iklim koşulları ve çeşitliliği, ürünlerin su ihtiyaçlarını belirlemede önemli bir rol oynar. Diğer yandan, toprak yapısının da su tutma kapasitesini doğrudan etkileyerek bitkilerin su alımını etkileyebileceği gerçeği göz önünde bulundurulmalıdır. Bu durum, daha sürdürülebilir ve çevresel olarak uyumlu tarımsal uygulamaların benimsenmesi için bir temel oluşturur. (Başoğlu, 2024)

Su ayak izi, tarımsal üretim süreçlerinin su tüketimini nicel olarak değerlendirmeye yarayan önemli bir indikattır. Bu kavram, yalnızca suyun fiziksel miktarını değil, aynı zamanda su kullanımıyla ilgili çevresel etkileri ve sürdürülebilirlik açısından kritik olan faktörleri de kapsamaktadır. Tarım sektörü, su kaynaklarının etkin kullanımı açısından bu tür bir değerlendirmeyi benimseyerek, hem ekonomik verimliliği artırabilir hem de ekosistem dengesini sağlamak amacıyla gerekli adımları atabilir. Su ayak izinin doğru bir şekilde hesaplanması, su kaynaklarının üzerinde daha az baskı oluşturan tarımsal stratejilerin geliştirilmesinde hayati bir rol oynamaktadır. (Turgut, 2024; Eryılmaz, 2024; Körbalta, 2023; Ergani, 2024)

2. Tarımsal Üretimde Su Ayak İzinin Önemi

Tarımsal üretimde su ayak izinin önemi, su kaynaklarının sürdürülebilir yönetiminde kritik bir rol oynamaktadır. Su ayak izi, bir ürünün üretim süreci boyunca doğrudan ve dolaylı olarak tükettiği su miktarını nicel olarak tanımlayan bir ölçüdür. Özellikle tarımsal üretimde, bu veri çiftçilere ve politika yapıcılara, suyun daha verimli kullanılmasının yanı sıra tedarik zincirindeki her aşamada su sürdürülebilirliğini artıracak stratejiler geliştirmeleri açısından önemli bilgiler sunmaktadır. Bu bağlamda, su ayak izi analizi, iklim değişikliği gibi çevresel sorunların etkileri altında tarımsal faaliyetlerin su talebini tahmin etmek ve yönetmek için kullanılabilir. (Tanrıverdi; Demirci, 2024; Karaman, 2024; Başkılıç, 2023; Çetintaş, 2024)

Su ayak izinin tespiti, farklı tarım ürünlerinin su gereksinimlerinin anlaşılmasını sağlar; bu durum, su kısıtlılığının olduğu bölgelerde tarım uygulamalarının adaptasyonunda hayati bir araç haline gelir. Örneğin, su ayak izinin yüksek olduğu ürünlerin yerine, daha az su tüketen alternatif ürünlerin teşvik edilmesi gibi stratejiler, hem ekonomik hem de ekolojik sürdürülebilirliğe katkıda bulunabilir. Aynı zamanda, tüketici bilincinin arttığı günümüzde, su ayak izinin ölçülmesi, gıda ürünlerinin pazar değerini de etkileyen bir faktör haline gelmiştir. Bu gerekçelerle, su ayak izinin analizi yalnızca çevresel sürdürülebilirliği sağlamakla kalmaz, aynı zamanda toplum için ekonomik faydalar da oluşturur. (Turgut, 2024; Karlı & Artar, 2021; Karakayaci ve Tuyluoğlu, 2022; Karlı et al.; Boz ve Tunalioğlu, 2024)

Su ayak izinin belirlenmesi ve bu verilerin etkin kullanımı, tarımsal üretimin geleceği için kritik bir unsurdur. Daha etkin su yönetimi ve su tasarrufu uygulamaları, hem tarım sektörü için hem de genel çevre sağlığı için vazgeçilmezdir. Bu nedenle, su ayak izinin anlaşılması ve uygulanması, tarımsal üretimde su kaynaklarının korunmasına yönelik atılacak adımların temelini oluşturur ve böylece sürdürülebilir tarım uygulamalarının güçlendirilmesine zemin hazırlar. Bu süreç, yalnızca çevresel değil, ekonomik ve sosyal boyutlarıyla birlikte ele alındığında, tarımsal üretimin bütünsel bir bakış açısıyla geliştirilmesine yardımcı olmaktadır.

3. Hesaplama Yöntemleri

Hesaplama yöntemleri, tarımsal üretimde su ayak izinin kapsamlı bir şekilde ölçülmesi, analiz edilmesi ve değerlendirilmesi açısından son derece büyük bir önem taşımaktadır. Su ayak izi, belirli bir ürünün yaşam döngüsü boyunca tükettiği toplam su miktarını gösterir ve bu bağlamda çeşitlilik arz eden farklı hesaplama teknikleri kullanılmaktadır. Genel olarak, bu hesaplama yöntemleri, fizyolojik, ekolojik ve yönetsel faktörlere dayalı olarak geliştirilmiştir ve bu faktörler, tarımsal üretimdeki su kullanımını büyük ölçüde etkileyen unsurlardır. Bu yöntemler, ürün bazında, bölge bazında veya sistem bazında detaylı analizler yapılarak uygulanabilmektedir. Hesaplama yöntemleri, incelemeye tabi tutularak daha da kategorize edilebilir. Bu sayede, doğrudan yanıtlara odaklanan yaklaşımlar ile dolaylı olarak ele alınan ve daha geniş bir perspektiften bakan yöntemler şeklinde ayrıştırılmaktadır. Bu ayrım, su ayak izinin daha derinlemesine anlaşılmasını ve buna bağlı olarak daha etkili su yönetim stratejilerinin oluşturulması sürecinin mümkün hale gelmesini sağlamaktadır. Su ayak izinin belirlenmesi ve analizi, hem çevresel sürdürülebilirlik hem de tarımsal verimlilik açısından kritik bir rol oynamaktadır. (Turgut, 2024; Karlı & Artar, 2021)

Doğrudan hesaplama yöntemleri, belirli bir ürünün veya üretim sürecinin su tüketimini doğrudan ölçmeyi amaçlar ve bu yöntemler, suyun etkin bir şekilde nasıl kullanıldığını daha iyi kavramaya yardımcı olur. Bu hesaplamalar, bitkinin su ihtiyacını daha iyi anlamak için sulama uygulamaları ve doğal yağış gibi etkenlerin yanı sıra, toprak nem durumu, iklim koşulları ve sulama sisteminin verimliliği gibi çeşitli faktörleri dikkate alarak gerçekleşmektedir. Bu tür hesaplamalar genellikle, tanımlanmış su kaynakları üzerinden ve gerçek zamanlı verilerle yürütülmektedir ve bu sayede sulama uygulamalarıyla ilgili hassas bilgiler elde edilir. Dolaylı hesaplama yöntemleri ise, belirli bir ürünün su ayak izini tahmin etmek amacıyla genel verilerden yararlanarak bir tahmin süreci yürütür. Bu yöntemler, ürünün tarımsal üretiminde kullanılan toplam su miktarını hesaplamak için farklı iklim koşulları, toprak yapısı ve bitki türlerine dayanan verileri kullanarak daha geniş ve kapsamlı bir çerçevede analiz imkanı sunar. Örneğin, FAO (Food ve Agriculture Organization) tarafından geliştirilen AquaCrop modeli, bitki su stresini değerlendirirken bu tür dolaylı yöntemlere güzel bir örnek olarak öne çıkmaktadır. AquaCrop, tarımda suyun verimli bir şekilde kullanılmasına dair önemli bilgiler sağlar. Su yönetimi alanında sağladığı faydalar ile tarımsal verimliliği artırmaya yardımcı olmaktadır; böylece hem üreticilerin hem de çevrenin yararına katkıda bulunur. (Karakayaci ve Tuyluoğlu, 2022; Karlı et al.; Boz ve Tunalioğlu, 2024)

Aynı zamanda, modellerin ve hesaplama yöntemlerinin uygulanabilirliğini artırmak amacıyla, bazı yeni teknolojik gelişmelerin tarımsal üretimde su ayak izinin hesaplanmasında kullanılmaya başlandığı gözlemlenmektedir. Özellikle uydu görüntüleme, hava durumu veri entegrasyonu ve sensör teknolojisi gibi güncel araçlar, hem doğrudan hem de dolaylı yöntemlerin etkinliğini artırmakta ve daha hassas ölçümler yapılmasını sağlamaktadır. Bu tür yenilikçi yöntemler, yalnızca su kaynaklarının daha etkili bir şekilde yönetilmesine değil, aynı zamanda sürdürülebilir tarımsal uygulamalar ve stratejilerin geliştirilmesine katkı sunmaktadır. Dolayısıyla, hesaplama yöntemleri, tarımsal üretimde su ayak izinin daha iyi anlaşılmasını ve yönetilmesini sağlayan önemli ve esnek bir araç olarak karşımıza çıkmaktadır. Su yönetimi, yalnızca tarım alanında değil, su kaynaklarının yeterliliği açısından da büyük önem taşımaktadır. Tüm bu teknolojik gelişmeler, tarımsal sürdürülebilirlik hedeflerine ulaşmak için bir temel oluşturmaktadır. Ayrıca, bu gelişmelerin yanı sıra, çiftçilerin eğitimine verilen önem de artmaktadır, çünkü bilinçli ve eğitilmiş çiftçiler, daha sürdürülebilir uygulamaları benimseyerek kaynakları daha etkin kullanabilir ve su ayak izini küçültmede etkin rol oynayabilirler. Bu bütünsel yaklaşım, su yönetiminin ve tarımsal verimliliğin iyileştirilmesi için kritik öneme sahiptir. (Turgut, 2024; Karlı & Artar, 2021; Karakayaci ve Tuyluoğlu, 2022; Karlı et al.; Boz ve Tunalioğlu, 2024)

3.1. Doğrudan Ölçüm Yöntemleri

Doğrudan ölçüm yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında son derece önemli ve kritik bir yer tutmaktadır. Bu yöntemler, su kullanımını doğrudan ve belirli ölçüm teknikleriyle inceleyerek analiz eder ve tarımsal faaliyetlerin çevresel etkilerini daha net bir şekilde ve kesin bir biçimde ortaya koyar. Bu bağlamda, en yaygın doğrudan ölçüm sistemleri arasında, alan bazlı ölçümler ve bileşen bazlı analizlerle birlikte, farklı tarım uygulamalarının su tüketim profillerini güvenilir bir şekilde belirlemekte kullanılmaktadır. Bu ölçüm teknikleri, su kaynaklarının sürdürülebilir yönetimi açısından da büyük bir önem taşımaktadır. (Turgut, 2024; Karlı & Artar, 2021; Karakayacı ve Tuyluoğlu, 2022; Karlı et al.; Boz ve Tunalıoğlu, 2024)

Su tüketim ölçümleri genellikle, belirli bir zaman diliminde sulama miktarının, yağış etkisinin yanı sıra bu süreçte gerçekleşen buharlaşma kayıplarının da doğrudan kaydedilmesine dayanmaktadır. Bu tür ölçümler, çeşitli hassas sensörler ve gelişmiş cihazlar aracılığıyla gerçekleştirilir. Örneğin, toprak nem sensörleri, suyun bitki kök bölgesine ulaşma oranını ölçerken, yağış ölçerler ise, yağış miktarını doğrudan kaydedebilir. Bu ölçüm süreçleri,

bir tarımsal üretim alanında büyük önem taşır. Ayrıca, bu tür doğrudan ölçüm yöntemleri, suyun etkin yönetimi açısından kritik öneme sahiptir; çünkü bu değerli bilgiler, tarım arazilerinin sulama verimliliğini artırmaya yönelik stratejilerin geliştirilmesine olanak tanır ve böylece sulama uygulamalarının optimize edilmesine yardımcı olur. Bu sayede, çiftçiler su kaynaklarını daha verimli kullanarak maliyetlerini azaltabilirler. (Yımam, 2023; Rustamov, 2023)

Bununla birlikte, doğrudan ölçüm yöntemlerinin dezavantajları da göz önünde bulundurulmalıdır. Bu yöntemler genellikle yüksek maliyetli ekipman ve uzmanlık gerektirirken, aynı zamanda uzun dönemli veri toplama ve analiz süreçlerini de zorlaştırabilir. Bununla birlikte, bu yöntemlerin sağladığı kesin veriler, su ayak izinin değerlendirilmesinde büyük bir avantaj sunmakta ve tarımsal üretimde su kaynaklarının sürdürülebilirliğini sağlama yolunda kritik bir adım teşkil etmektedir. Sonuç olarak, doğrudan ölçüm yöntemleri, tarımsal üretimde su yönetiminin optimize edilmesine yönelik faydalı bilgiler sağlarken, çevresel etkilerin minimize edilmesi konusunda da önemli bir rol oynamaktadır. (Yımam, 2023; Başakcı, 2023)

3.2. Dolaylı Ölçüm Yöntemleri

Dolaylı ölçüm yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında ve su tüketiminin yanı sıra çevresel etkilerin değerlendirilmesinde oldukça önemli bir rol oynamaktadır. Bu yöntemler, doğrudan su kullanım verileri yerine, belirli varsayımlara ve gelişmiş modelleme tekniklerine dayanarak su ayak izini dolaylı yoldan tahmin etme sürecini içermektedir. Dolaylı ölçüm yöntemleri kapsamındaki en yaygın ve tercih edilen yaklaşım, su döngüsü ve bitkilere yönelik su tüketim kalıplarını belirleyen detaylı su hesaplama modelleridir. Bu karmaşık modeller, iklim, toprak özellikleri ve tarımsal uygulamalar gibi çeşitli etkenleri entegre ederek su ihtiyacını tahmin eder. Böylece, su ayak izinin hesaplanmasında kullanılan önemli bir veri kaynağı sağlar ve tarımda su kaynaklarının daha etkin bir şekilde yönetimine katkıda bulunur. Bu bağlamda, dolaylı ölçüm yöntemlerinin önemi, sadece tahmin yapma ile sınırlı kalmayıp, aynı zamanda sürdürülebilir tarım uygulamalarının geliştirilmesine de işaret etmektedir. (Demirci, 2024; Turgut, 2024; Sak, 2024; Ağızan, 2024)

Bunların yanı sıra, dolaylı ölçüm teknikleri, uzaktan algılama ve coğrafi bilgi sistemleri (CBS) gibi teknolojilerin entegrasyonu ile zenginleştirilmektedir. Uzaktan algılama, tarımsal alanların büyüklüğünden su varlığına; bitki sağlığından toprak nemine kadar pek çok parametreyi gözlemleme imkanı sunar. Bu tür veriler, büyük alanların kapsamlı bir şekilde değerlendirilmesine olanak tanıyarak, su ayak izinin belirlenmesinde kritik bir temel oluşturur. Ayrıca, bu yöntemler, su kaynaklarının daha verimli bir şekilde yönetilebilmesi için gerekli stratejilerin geliştirilmesine de katkıda bulunmaktadır. (Sezer ve Önder, 2024; Akpınar, 2022)

Bununla beraber, dolaylı ölçüm yöntemlerinin uygulanması, bazı sınırlamaları da beraberinde getirmektedir. Modelleme ve varsayımlar, gerçek dünyadaki karmaşık etkileşimleri yeterince temsil edemeyebilir; bu durum, hesaplamaların doğruluğunu etkileyebilir. Bu nedenle, dolaylı ölçüm sonuçlarının doğrulanması, gerektiğinde doğrudan ölçümlerle desteklenerek sağlanması önemlidir. Bu bağlamda, dolaylı ölçüm yöntemleri, tarımsal üretimde su ayak izinin hesaplanması sürecinde önemli bir yenilik sağlarken, aynı zamanda dikkatli bir uygulama ve değerlendirme gerektirmektedir. (Karakoç, 2022; Sak, 2024)

3.3. Farklı Modelleme Yöntemleri ve Teknikleri

Modelleme yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında kritik bir rol oynamaktadır ve bu süreçte önemli bir yer tutar. Bu yöntemler, özellikle su tüketim miktarının ve niteliğinin belirlenmesinde çeşitli modellerin entegrasyonunu gerektirirken, tarımsal süreçlerin dinamik yapısını anlamak için faydalı bir araç sunar. Su ayak izi hesaplamasında kullanılan başlıca modelleme yaklaşımlarından biri, su tüketiminin mekânsal ve zamansal verilerini analiz eden hidrolojik modellerdir. Bu modeller, topografya, yağış, buharlaşma ve tarımsal faaliyetlerin etkilerinin bir arada değerlendirilmesini sağlayarak daha hassas ve güvenilir tahminler yapılmasını mümkün kılar. Bu bağlamda, su ayak izinin belirlenmesi yalnızca tarımsal faaliyetlerin sürdürülebilirliğini artırmakla kalmaz, aynı zamanda çevresel etkilerini de daha iyi anlamamıza yardımcı olur. Dolayısıyla, bu modelleme yöntemleri, su kaynaklarının yönetimi ve korunması açısından son derece önemlidir. (Demirci, 2024; Adiyan, 2024; İpekçi, 2023)

Bir diğer önemli yöntem, üretim sistemlerini simüle etmeye yönelik stokastik modellemelerdir. Bu yaklaşımlar, belirsizliklerin ve değişken koşulların su tüketimi üzerindeki etkilerini daha ayrıntılı bir şekilde nicel olarak değerlendirme imkânı sunar. Zira, tarımsal üretimde iklim değişikliği gibi karmaşık dışsal faktörlerin yanı sıra, sulama yöntemlerinin etkinliği de su ayak izini önemli ölçüde etkileyebilmektedir. Dolayısıyla, bu modelleme yöntemleri, hem mevcut durumu detaylı bir şekilde analiz etmekte hem de gelecekteki olası senaryoları daha etkili bir şekilde değerlendirmekte ve sürdürülebilir su yönetimi stratejilerinin geliştirilmesinde büyük bir katkı sağlamaktadır. Bu süreç, tarımsal üretimin sürdürülebilirliğini sağlamak için kritik öneme sahiptir ve aynı zamanda su kaynaklarının daha verimli kullanılmasına yönelik öneriler sunmaktadır. (Sezer ve Önder, 2024)

Ayrıca, hayvan üretimi ve bitkisel üretim arasındaki su kullanım ilişkisini daha derinlemesine anlamak için entegre modelleme teknikleri de giderek daha fazla kullanılmaktadır. Bu yenilikçi yöntemler, farklı bitki türlerinin ve hayvan beslenme sistemlerinin su gereksinimlerini sistemli bir şekilde karşılaştırarak, suyun etkin ve verimli kullanımını optimize etmeye olanak tanır. Sonuç olarak, tarımsal üretimde su ayak izinin hesaplanmasında modelleme yöntemleri, yalnızca su tüketiminin net bir fotoğrafını sunmakla kalmamakta, aynı zamanda sürdürülebilir tarım uygulamalarının geliştirilmesinde kritik bir araç olarak öne çıkmaktadır. Bu bağlamda,

tarımsal üretimin çevresel etkilerini en aza indirmek için doğru stratejilerin belirlenmesi, bu modelleme süreçleri aracılığıyla daha etkili bir şekilde gerçekleştirilmesi mümkündür. Bu tür modellemeler, ilerleyici yöntemleri kullanarak, su kaynaklarının korunmasına katkıda bulunmakta ve tarımsal üretimde kaynak yönetimini daha sürdürülebilir hale getirmektedir. (Demirci, 2024)

3.4. Anket ve Anket Tabanlı Yöntemler

Anket ve anket tabanlı yöntemler, tarımsal üretimde su ayak izinin hesaplanmasında kritik bir rol oynamaktadır. Bu araştırma yöntemleri, özellikle çiftçiler, su yönetimi uzmanları ve tarım ekonomistleri tarafından etkili veri toplama aracı olarak sıklıkla kullanılmakta, su tüketimi ve kullanım alışkanlıklarına dair ayrıntılı ve güvenilir bilgiler sunmaktadır. Anketler, çeşitli soru türleri aracılığıyla, çiftçilerin su kullanımındaki alışkanlıklarını, su kaynaklarına erişim durumlarını ve sulama yöntemlerini daha iyi anlamakta yardımcı olur. Bu tür veriler, su ayak izinin hesaplanmasında temel bir girdi olarak kabul edilmektedir; zira su ayak izi, tarımsal ürünün üretimi sırasında kullanılan toplam su miktarını, bu suyun kaynağına göre ayrıştırarak ortaya koymayı hedefler. Dolayısıyla, bu veriler, sürdürülebilir tarım uygulamalarının geliştirilmesi ve su kaynaklarının daha verimli yönetimi için son derece önemlidir. Elde edilen bilgiler, aynı zamanda su yönetiminde stratejik kararların alınmasına da katkıda bulunmaktadır. (Çetintaş, 2024; Sak, 2024; Adiyan, 2024; İşler, 2022; Özyiğit)

Anket tabanlı yöntemlerin etkili bir şekilde kullanılabilmesi için öncelikle dikkatli, titiz ve özenli bir anket tasarımı gereklidir. Anketlerin geçerliliği ve güvenilirliği, kullanılan soru tipleri, soru cümleleri yapılarına ve anketin genel akışına bağlı olarak değişiklik göstermektedir. Açık uçlu sorular, çiftçilerin su kullanımı ile ilgili detaylı ve kapsamlı bilgi vermesini sağlarken, kapalı uçlu sorular ise belirli kategorilerde verilerin hızlı, kolay ve sistematik bir şekilde toplanmasına olanak tanır. Anket uygulamalarında aynı zamanda, örneklem büyüklüğünün dikkatlice belirlenmesi ve hedef kitle ile ilgili demografik bilgilerin toplanması, elde edilen verilerin temsil yeteneği açısından son derece ve kritik derecede önemlidir. Bu aşamada, anketin uygulanacağı coğrafi bölgeyi, tarımsal üretim türlerini ve çiftçilerin sosyo-ekonomik durumlarını göz önünde bulundurmak, sonuçlanacak verilerin daha isabetli bir şekilde yorumlanmasına zemin hazırlayacaktır. Ayrıca, katılımcıların anket sürecindeki rahatlıkları ve motivasyonları da, elde edilen verilerin kalitesini etkileyen önemli unsurlardan biri olarak değerlendirilmelidir. Bu nedenle, anketin uygulanması esnasında dikkatli bir iletişim kurmak ve katılımcılara anketin önemi ile ilgili bilgi vermek, verilerin daha güvenilir hale gelmesini sağlayabilir. (İlhan ve Deniz, 2021; İlhan ve Deniz, 2021; Öntaş et al., 2024)

Anket ve anket tabanlı yöntemler, tarımsal üretimde su ayak izinin hesaplanmasının yanı sıra, su yönetimi stratejilerinin geliştirilmesinde de faydalı bilgiler sunmaktadır. Bu tür verilerin analizi, su kaynaklarının sürdürülebilir yönetimi için gereksinim duyulan stratejilerin oluşturulmasına ve uygulanmasına katkıda bulunmakta, aynı zamanda tarımsal üretimin çevresel etkilerini değerlendirmeye olanak tanımaktadır. Uygulayıcılar, anket verilerinin mevcut tarımsal pratiklerde nasıl kullanılacağını anlamak suretiyle, su tasarrufunu teşvik eden ve daha verimli su yönetimini sağlayan politikalar geliştirebilirler. Bu bağlamda, anketlerin etkinliği yalnızca veri toplamayla sınırlı kalmayıp, aynı zamanda karar alma süreçlerinde de önemli bir araç haline gelmektedir.

Bulgular ve Tartışma

4. Yöntemlerin Etkinliği

4.1. Doğrudan Ölçüm Yöntemlerinin Avantajları ve Dezavantajları

Doğrudan ölçüm yöntemleri, su ayak izinin hesaplanmasında çeşitli avantajlar ve dezavantajlar sunmaktadır. Bu yöntemler, tarımsal üretimde su kullanımını direkt olarak ölçerek, su tüketimi ile ilgili daha kesin veriler sağlar. Gerçek zamanlı veri toplamayı mümkün kılması, tarım uygulamalarının daha iyi yönetilmesine yardımcı olur. Örneğin, bu yöntemler ile toprağın nem içeriği, sulama miktarları ve bitki su tüketimi gibi parametreler doğrudan izlenebilir. Böylelikle, kaydedilen verilerin doğruluğu, uygulanan stratejilerin etkinliğini artırabilir ve çiftçilerin kayıplarını minimize etmelerine olanak tanır.

Ancak doğrudan ölçüm yöntemlerinin, sınırlı bir uygulama alanı ve belirli dezavantajları bulunmaktadır. Öncelikle, bu yöntemlerin uygulanması maliyetli olabilir; gerekli ekipmanların temini ve kurulumu ile birlikte sürekli bakım ve kalibrasyon gerektirmeleri, ekonomik olarak sürdürülebilirliği zorlaştırabilir. Ayrıca, bu yöntemler belirli bir alan veya belirli koşullar altında uygulanabilir ve bu durum, genel geçer sonuçlar elde edilmesini engelleyebilir. Örneğin, toprak tipleri, iklim koşulları veya bitki çeşitliliği gibi değişkenler, ölçüm sonuçlarını etkileyebilir. Sonuç olarak, doğrudan ölçüm yöntemlerinin elde ettiği veriler çoğu kez belirli durumlara özgü nitelikte olabilmektedir.

Bu yöntemlerin sağladığı verilerin yanı sıra, bu verilerin analizi ve yorumlanması süreci de karmaşık bir boyut taşımaktadır. Dört mevsim ve farklı iklim koşullarında gerçekleştirilen ölçümler, değişkenler dikkate alınmadan genel ilişkilere ulaşımın önünde engel teşkil edebilir. Dolayısıyla, doğrudan ölçüm yöntemlerinin elde ettiği bulguların, bütünsel bir anlayış için dikkatli bir şekilde değerlendirilmesi gerekmektedir. Bu bağlamda, doğrudan ölçüm yöntemleri, hem hesaplamada sağladığı kesinlik hem de belirli dezavantajları ile birlikte, tarımsal üretimde su ayak izinin değerlendirilmesi konusunda önemli bir yere sahiptir.

4.2. Dolaylı Ölçüm Yöntemlerinin Avantajları ve Dezavantajları

Dolaylı ölçüm yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında oldukça önemli roller üstlenmektedir. Bu yöntemlerin temel avantajları arasında, zaman ve kaynak açısından sağladıkları verimlilik öne çıkmaktadır. Geleneksel ölçüm tekniklerinin aksine, dolaylı ölçüm yöntemleri, bitkisel su kullanımı ve toprak nemi gibi unsurları uzaktan algılama veya modelleme gibi modern teknolojilerle birleştirerek etkili sonuçlar elde edilmesini sağlar. Örneğin, uydu görüntüleri ve lokal meteorolojik tahmin modelleri, tarımsal alanlardaki su gerekliğini belirlemek için geniş ve kapsayıcı veriler sunar; bu durum, hem maliyetlerin düşürülmesine hem de tarımsal verimliliğin artırılmasına katkıda bulunur.

Öte yandan, dolaylı ölçüm yöntemlerinin bazı dezavantajları da mevcuttur. Bu yöntemlerin doğruluğu, ölçüm parametrelerine ve kullanılan teknolojik altyapıya bağlı olarak değişkenlik gösterebilir; bu durum, sonuçların güvenilirliğini sorgulatabilir. Ayrıca, bazı dolaylı ölçüm teknikleri, karmaşık algoritmalar ve modelleme süreçleri gerektirdiğinden, uzmanlaşmış bilgi birikimi ve yeterli kaynakları talep edebilir. Söz konusu yöntemlerin uygulanması sürecinde, belirli verilerin kaynaktan alınması ve uygun kalibrasyon parametrelerinin belirlenmesi gerekliliği, uygulayıcılar için ek zorluklar oluşturabilir. Dolayısıyla, bu yöntemlerin pratikteki kullanımı, bazı durumlarda ek maliyet ve iş gücü gereksinimleri doğurabilir.

Sonuç olarak, dolaylı ölçüm yöntemleri, su ayak izinin belirlenmesi sürecinde hem avantajlar hem de dezavantajlar içermektedir. Uygulayıcıların, bu yöntemlerin etkinliğini artırmak için sağlanan olanaklar ve karşılaşılabilecek zorlukları dikkatlice değerlendirmeleri gerekmektedir. Böylece, hem tarımsal üretimde su yönetiminin iyileştirilmesine hem de sürdürülebilir kaynak kullanımı hedeflerine ulaşılmasına hizmet edecek çözümler geliştirilebilir. Bu dengeli yaklaşım, dolaylı ölçüm yöntemlerinin potansiyelinden en iyi şekilde yararlanmayı mümkün kılacaktır.

4.3. Modelleme Yöntemlerinin Avantajları ve Dezavantajları

Modelleme yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında önemli bir rol oynamaktadır. Bu yöntemler, karmaşık ekosistem süreçlerini anlamada ve su kullanımının verimliliğini artırma çabalarında kritik bir araç olarak öne çıkmaktadır. Ancak, bu yöntemlerin uygulanması, hem avantajlar hem de dezavantajlar içermektedir. Avantajları arasında, tarımsal faaliyetlerin su kaynakları üzerindeki etkilerini tahmin etme yeteneği ve karar verme süreçlerini destekleme potansiyeli bulunmaktadır. Modelleme, çeşitli senaryoların simülasyonuna olanak tanıyarak, farklı su yönetimi stratejilerinin potansiyel etkilerini analiz etmeye yardımcı olur. Ayrıca, sulama tekniklerinin ve tarım politikalarının optimize edilmesini sağlayarak, su tasarrufu ve sürdürülebilirlik açısından önemli katkılar sağlar.

Bununla birlikte, modelleme yöntemleri belirli dezavantajlarla da yüz yüze kalmaktadır. Bu dezavantajlar arasında, modellerin herhangi bir gerçekliği tam olarak yansıtma kapasitesinin sınırlı olması ve veri gereksinimlerinin yüksekliği yer almaktadır. Doğru ve güvenilir çıktılar elde edebilmek için, detaylı ve kapsamlı verilere ihtiyaç vardır; bu, çoğu zaman zorlu ve maliyetli olabilir. Ayrıca, modellerin karmaşıklığı, kullanıcıların onları etkin bir biçimde değerlendirme ve uygulama yeteneklerini sınırlayabilir. Bu durum, yanlış kararların alınmasına ve kaynakların yanlış yönetilmesine neden olabilecek bir risk taşımaktadır.

Sonuç olarak, modelleme yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında avantajlı bir araç sunarken, kendi bünyesinde çeşitli zorluklar da barındırmaktadır. Tarım sektörünün, su kullanımına ilişkin doğru verilere dayanan modeller geliştirmesi ve uygulaması, su kaynaklarının yönetiminin ve korunmasının etkinliğini artırma yanında, tarımsal sürdürülebilirliği sağlamada kritik bir unsur olarak karşımıza çıkmaktadır. Bu nedenle, modelleme yöntemlerinin dikkatli bir şekilde değerlendirilmesi ve sürekli olarak güncellenmesi, su ayak izinin hesaplanmasında başarılı bir yaklaşım geliştirilmesi için elzemdir.

4.4. Anket Yöntemlerinin Avantajları ve Dezavantajları

Anket yöntemleri, tarımsal üretimde su ayak izinin hesaplanmasında geniş bir uygulama yelpazesine sahip olup, çeşitli avantajlar ve dezavantajlar içermektedir. Bu yöntemlerin en belirgin avantajlarından biri, büyük ve çeşitli bir nüfusa ulaşma yeteneği olmaktadır. Bu sayede, araştırmacılar çok sayıda veri toplayarak genel eğilimler ve kalıplar oluşturabilirler. Ayrıca, anketler, katılımcıların kendi görüşlerini ve deneyimlerini doğrudan ifade etmelerine olanak tanırken, birçok durum ve koşulu kapsayacak şekilde tasarlanabilir. Örnekleme çerçevesinin genişliği, tarımsal su kullanımında yer alan farklı faktörlerin daha iyi analiz edilmesine yardımcı olabilmektedir. Bu bağlamda, anketlerin uygulanabilirliği, zaman ve maliyet açısından da önemli bir avantaj sunmaktadır; çünkü diğer veri toplama yöntemlerine kıyasla, akıllıca tasarlanmış bir anket, hızlıca geniş bir veri seti toplayabilme potansiyeline sahiptir.

Ancak, anket yöntemlerinin dezavantajları da göz ardı edilmemelidir. Öncelikle, anketlerin yanıtlayıcıları üzerinde etkili olabilmesi için dikkatli bir biçimde hazırlanması gerekir. Eğer anket soruları belirsiz veya yanıltıcı ise, bu durum toplanan verinin güvenilirliğini olumsuz etkileyebilir. Ayrıca, anketlerin yanıt oranları, çeşitli faktörlerden etkilenerek düşebilir, bu da örneklemin temsil ediciliğini sorgulamak zorunda bırakır. Katılımcıların, su ayak izi gibi karmaşık bir konudaki bilgi seviyeleri değişkenlik gösterebileceği için, anketler zaman zaman yanıltıcı sonuçlar verebilir. Bu nedenle, anketler ile elde edilen verilerin titizlikle analiz edilmesi ve diğer veri toplama yöntemleriyle birleştirilmesi, elde edilen bulguların doğruluğunu artırmak açısından kritik öneme sahiptir. Sonuç

olarak, anket yöntemleri, su ayak izinin hesaplanmasında değerli bir araç olarak öne çıkarken, dikkatli bir planlama ve uygulama gerektirmektedir.

5. Uygulama Alanları

Uygulama alanları, tarımsal üretimde su ayak izinin hesaplanması süreçlerinin pratikte nasıl gerçekleştirildiğine dair geniş bir perspektif sunar. Su ayak izi, tarımsal ürünlerin yaşam döngüsü boyunca tüketilen su miktarını belirleyen önemli bir değerlendirme aracıdır. Bu hesaplamalar, su kaynaklarının verimli kullanımı ve sürdürülebilir tarım uygulamalarının geliştirilmesi açısından kritik öneme sahiptir. Özellikle, sulama yöntemlerinin etkinliği, ürün seçiminde suya dayalı karar verme süreçleri ve iklim değişikliğinin etkilerine karşı adaptasyon stratejileri üzerinde önemli bir etki yaratmaktadır. (Karaman, 2024; Kahriman, 2023; Dindar, 2021)

Su ayak izinin hesaplanması, farklı tarım uygulama alanlarında çeşitli biçimlerde yer bulmaktadır. Örneğin, sulama yönetimi, konvansiyonel ve organik tarım uygulamalarında su kullanımını optimize ederek, su kaynaklarının sürdürülebilir bir şekilde kullanılmasına imkan tanır. Ayrıca, ürün çeşitliliği ve yetiştirme yöntemleri, su ayak izinin minimize edilmesinde önemli bir rol oynamaktadır. Tarım işletmeleri, ürün bazında su tüketimlerini izleyerek, en az su kullanımı gerektiren türleri yetiştirmeye yönelmektedirler. Bunun yanı sıra, su ayak izi hesaplamaları sayesinde, tarımsal üretim süreçleri sürekli olarak değerlendirilmekte ve iyileştirme fırsatları ortaya konulabilmektedir. (Bulut ve Canbaz, 2022; Yımam, 2023; Muratoğlu, 2024; Demirel, 2023; Ceylan, 2024; Kalender, 2023)

Diğer yandan, su ayak izi verileri, tarımsal üretimden elde edilen ekonomik getiri ile ilişkilendirilerek, çiftçilere ekonomik sürdürülebilirlik sağlamaktadır. Çiftçiler, su ayak izini göz önünde bulundurarak, girdi maliyetlerini azaltma ve verimliliği artırma stratejileri geliştirebilirler. Ayrıca, bu ölçümler, gıda güvenliği ve tarımsal politikalara yönelik kamu politikalarının oluşturulmasında da önemli verilere zemin hazırlamaktadır. Dolayısıyla, tarımsal üretimde su ayak izinin hesaplanması, hem çevresel sürdürülebilirliğin sağlanmasında hem de ekonomik kazançların arttırılmasında kritik bir rol oynamaktadır. (Demirci, 2024; Turgut, 2024; Sak, 2024; Çakır et al.2022; Sezer ve Önder, 2024; Çetintaş, 2024; Karaman, 2024)

5.1. Tarım Sektöründe Uygulama ve Geliştirilen Yeni Yöntemler

Tarım sektörü, su ayak izinin hesaplanması uygulamalı yöntemlerinin gelişimine son derece açıktır. Su ayak izi, belirli bir ürün veya hizmetin yaşam döngüsü boyunca toplam su tüketimini belirlemeye yönelik bir kavramdır ve bu, hem üretim süreçlerinin etkinliğini artırmak hem de çevre üzerindeki olumsuz etkileri azaltmak açısından büyük önem taşımaktadır. Bu bağlamda, tarımsal üretim süreçleri, su kaynaklarının verimli, etkili ve en önemlisi sürdürülebilir bir şekilde yönetilmesinde kritik bir rol oynamaktadır. Uygulama aşamasında, çeşitli hesaplama yöntemleri ve araçları, su ayak izini belirlemek için kullanılmakta ve bu sayede hem su kullanımının optimize edilmesi sağlanmakta hem de çevresel etki analizleri daha doğru bir şekilde yapılmaktadır. Su ayak izinin hesaplanması, sürdürülebilir tarım uygulamalarının benimsenmesine ve çevresel bilincin artırılmasına yardımcı olurken, tarımsal üretim süreçlerinin genel olarak daha sürdürülebilir hale gelmesine olanak tanımaktadır. Bu nedenle, tarım sektöründe su ayak izinin doğru bir şekilde hesaplanması, gelecekteki su yönetimi stratejileri için oldukça önemli bir adım olmaktadır. (Karaman, 2024; Turgut, 2024; Karlı & Artar, 2021; Karlı et al.; İşler, 2022; Sak, 2024)

Tarım sektöründe uygulanan yöntemler arasında en yaygın olanları, su ayak izinin hesaplanmasında kullanılan çeşitli sistem dinamik modelleridir. Bu dinamik modeller, tarımsal üretim süreçlerini simüle ederek, su kullanımının farklı aşamalarını detaylı bir şekilde izleme ve analiz etme imkanı sunar. Örneğin, sulama sistemleri, toprak özellikleri, iklim koşulları ve bitki türleri gibi çeşitli faktörler, su ayak izinin hesaplanmasında kritik ve önemli bir role sahiptir. Bu faktörlerin her biri, su kaynaklarının etkin ve verimli kullanımı açısından büyük önem taşımaktadır. Ayrıca, LCA (Yaşam Döngüsü Değerlendirmesi) gibi yöntemler, ürünlerin çevresel etkilerini değerlendirirken, su ayak izinin tarımsal üretim döngüsündeki yerini daha kapsamlı ve derinlemesine anlamak için önemli bir çerçeve sunar. Bu çerçeve, çiftçilerin daha bilinçli ve sürdürülebilir su yönetimi stratejileri geliştirmelerine yardımcı olur ve böylece kaynakların daha etkin kullanımını teşvik eder. Çiftçiler, bu tür yöntemleri kullanarak, hem ekonomik hem de çevresel açıdan daha faydalı üretim metotları belirleyebilirler. (Karakoç, 2022; Sezer ve Önder, 2024; Özbek, 2023; Yavuz, 2021)

İleri düzeyde uygulamalar, su ayak izinin hesaplanmasında kablosuz sensörler ve uzaktan algılama teknolojilerinin entegrasyonunu içermektedir. Bu modern teknolojiler, su kullanımının gerçek zamanlı izlenmesine olanak tanıyarak tarım alanlarındaki su stresini daha doğru bir şekilde belirlemeye ve suyun verimliliğini artırmaya yönelik anlık veriler sunmaktadır. Bu sayede, tarım işletmeleri su kaynaklarını daha etkin bir biçimde kullanma fırsatına sahip olmanın yanı sıra, kaynakları daha verimli değerlendirmenin yollarını keşfetmekte ve uygulamaktadır. Tüm bu yöntem ve araçlar, tarım sektöründe su ayak izinin etkin bir şekilde hesaplanmasını sağlarken, aynı zamanda su kaynaklarının korunmasına yönelik önemli bir katkı sunarak gelecekteki sürdürülebilirlik hedeflerine ulaşmada yardımcı olmaktadır. Bu durum, sürdürülebilir tarımsal uygulamaların teşvik edilmesine ve bu uygulamaların yaygınlaşmasına önemli bir katkı sağlamaktadır. Dolayısıyla, tarım sektöründeki uygulamalar, su yönetimi ile çevresel sürdürülebilirliğin entegrasyonunu teşvik eden birçok fırsatı barındırmaktadır ve tüm bu süreçler, daha geniş bir perspektifte tarımsal üretkenliğin artırılmasına yardımcı

olmaktadır. Su verimliliği artırıldıkça, hem çevre hem de ekonomik açıdan önemli kazanımlar elde edilmesi mümkün olacaktır, bu da çiftçilerin ve toplumun genel yararına hizmet edecek, sürdürülebilir bir tarımsal kalkınmanın önünü açacaktır. (Çakır et al.2022; Yılmaz, 2022; Hakkı et al.2022)

5.2. Su Yönetimi Politikaları

Su yönetimi politikaları, sürdürülebilir tarımsal üretim ve su kaynaklarının etkin kullanımı için hayati öneme sahiptir. Bu politikalar, sulama sistemlerinin geliştirilmesi, su tasarrufu yöntemlerinin teşvik edilmesi ve su kalitesinin korunması gibi çeşitli boyutları içermektedir. Tarımsal üretim süreçlerinde suyun değerlendirilmesi, ürün verimliliğini artırmanın yanı sıra, potansiyel su kaynaklarını koruma açısından da kritik bir rol oynamaktadır. Su yönetimi politikaları, yerel ve ulusal düzeyde gerçekleştirilen planlama ve uygulamalarla şekillenirken, yukarıdan aşağıya ve aşağıdan yukarıya yaklaşımlar arasında bir denge sağlanmalıdır.

Su yönetiminde en iyi uygulamaların benimsenmesi, paydaşların etkin bir şekilde katılımını gerektirir. Bu bağlamda, çiftçiler, su yöneticileri ve yerel topluluklar poliçe oluşturma süreçlerine dahil edilmelidir. Eğitim programları ve farkındalık artırıcı kampanyalar, su tasarrufunun önemini vurgulamakla kalmayıp, doğru sulama tekniklerinin uygulanmasını teşvik edebilir. Ayrıca, modern teknolojilerin entegrasyonu, veri toplama ve analiz yöntemlerinin geliştirilmesi, daha bilinçli karar alma süreçlerini destekleyerek, su kaynaklarının yönetiminde önemli bir yenilikçi unsurdur. Özellikle uzaktan algılama ve veri analitiği, su tüketimini izleme ve yönetiminde önemli olanaklar sunmaktadır.

Su yönetimi politikalarının etkili bir biçimde uygulanması, sadece tarımsal üretimde su ayak izinin azaltılmasına değil, aynı zamanda ekosistem dengelerinin korunmasına da katkı sağlar. Ekonomik faktörlerin, iklim değişikliğinin ve artan nüfusun beraberinde getirdiği su stresi, bu politikaların geliştirilmesi için bir aciliyet yaratmaktadır. Uygulayıcıların, bu karmaşık dinamikleri göz önünde bulundurarak, hem yerel çözümleri hem de geniş ölçekli stratejileri dikkate alması gerekmektedir. Sonuç olarak, su yönetimi politikaları, tarımsal üretimde sürdürülebilirliği sağlamak adına kritik bir çerçeve sunmakta ve gelecekte su kaynaklarının korunması için belirleyici bir rol oynamaktadır.

5.3. Çevresel Etki Değerlendirmeleri Hakkında Ayrıntılı Bilgiler ve Analizler

Çevresel etki değerlendirmeleri, tarımsal üretimde su ayak izinin hesaplanmasında kritik bir rol oynamaktadır. Bu değerlendirmelerin temel amacı, tarımsal faaliyetlerin çevre üzerindeki potansiyel etkilerini belirlemek ve bu etkileri minimize etmek için stratejiler geliştirmektir. Su kaynakları, tarımsal üretim süreçlerinde hayati öneme sahip olduğundan, su ayak izi analizi, bu kaynakların sürdürülebilir yönetimi açısından oldukça önemlidir. Bu süreçler, çeşitli aşamalarda çevresel etki değerlendirmelerinin entegrasyonunu gerektirmeektedir. Bu bağlamda, öncelikle su tüketiminin izlenmesi, tarımsal üretim sistemlerindeki su kullanım verimliliğine dair bilgiler sağlamaktadır.

Çevresel etki değerlendirmeleri, hem nicel hem de nitel verilerin sistematik bir şekilde toplanmasını ve analiz edilmesini içermektedir. Bu değerlendirmelerin gerçekleştirilmesi, çeşitli yöntemlerin ve yaklaşımların entegrasyonunu gerektirmektedir. Örneğin, su ayak izi hesaplama yöntemleri, yaşam döngüsü analizi (LCA) ile birlikte kullanılabilmekte, böylece tarımsal ürünlerin tüm yaşam döngüsü boyunca su kullanımını değerlendirebilmektedir. Ayrıca, bu süreç içinde ekosistem hizmetleri, toprak sağlığı ve biyolojik çeşitliliğin korunması gibi faktörlerin dikkate alınması, çevresel etkilerin daha kapsamlı bir şekilde değerlendirilmesini sağlamaktadır. (Demirci, 2024; Başkılıç, 2023; Duru & Koç, 2021; Sabır et al.2023; Koç et al.2022; Karadağ, 2022)

Bu tür kapsamlı değerlendirmeler, tarımsal üretimde sürdürülebilirlik uygulamalarının geliştirilmesine olanak tanımaktadır. Dinamik bir veri toplama ve analiz süreci, tarım sektörünün su yönetimi konusunda daha bilinçli kararlar almasına rehberlik etmektedir. Çevresel etki değerlendirmeleri, sadece su kaynaklarının korunmasında değil, aynı zamanda tarımsal üretim süreçlerinin iklim değişikliğiyle adaptasyonunda da önemli bir araç olarak öne çıkmaktadır. Bu sayede, tarımsal üretim sistemleri hem verimlilik hem de çevre koruma açısından uyumlu hale getirilmektedir. Dolayısıyla, çevresel etki değerlendirmeleri, su ayak izinin doğru hesaplanmasının yanı sıra, tarımsal sürekliliğin sağlanmasında da zaruri bir unsur olarak değerlendirilmektedir.

5.4. Sürdürülebilir Tarım Uygulamaları

Sürdürülebilir tarım uygulamaları, tarımsal üretimin çevresel, sosyal ve ekonomik sürdürülebilirliğini sağlamak amacıyla geliştirilmiş yöntem ve yaklaşımlardır. Bu uygulamalar, su kaynaklarının verimli kullanılması, toprak kalitesinin korunması, biyoçeşitliliğin artırılması ve tarımsal ürünlerin sistematik bir şekilde yönetilmesi üzerine odaklanmaktadır. Su ayak izinin azaltılması, bu uygulamaların merkezinde yer alırken, tarımsal üretimde su tasarrufu sağlayan tekniklerin ve stratejilerin entegrasyonu büyük önem taşımaktadır. Örneğin, damla sulama sistemleri gibi hedefe yönelik sulama yöntemleri, su tüketimini minimize ederken, bitkilerin ihtiyaç duyduğu suyu doğrudan kök bölgesine ulaştırarak verimliliği artırmaktadır.

Sürdürülebilir tarım uygulamaları ayrıca, entegre mücadele yöntemleri kullanarak zararlılarla olan mücadelede kimyasal pestisitlerin kullanımını azaltmayı amaçlamaktadır. Doğal düşmanlar ile birlikte çalışarak ekosistem dengesini korumak, çevresel etkileri en aza indirmek ve insan sağlığını korumak yönünde önemli bir adım oluşturmaktadır. Bunun yanı sıra, organik tarım uygulamaları, kimyasal gübre ve pestisit kullanımını azaltarak,

gıda güvenliğine katkı sağlarken, doğanın döngüsel yapısına saygı gösterir. Biyodiverse tarım sistemlerinin oluşturulması, yerel bitki türlerinin teşvik edilmesi ve agroekolojik prensiplerin benimsenmesi de biyoçeşitliliği artırarak ekosistem hizmetlerinin sürdürülebilirliğine katkıda bulunur.

Sonuç olarak, sürdürülebilir tarım uygulamaları, su ayak izinin hesaplanması ve yönetilmesinde kritik bir rol oynamaktadır. Bu bağlamda, tarımsal üretim sistemlerinde çevresel ve kaynakların yönetimi açısından entegre bir yaklaşım benimsemek, tarımsal üretkenliği artırarak hem çevre hem de toplum açısından olumlu sonuçlar doğurmaktadır. Dolayısıyla, sürdürülebilir tarım uygulamaları, yalnızca mevcut kaynakların etkili kullanımıyla sınırlı kalmayıp, gelecekteki nesillerin ihtiyaçlarını da gözeten bir tarım anlayışını temsil etmektedir. Bu anlayış, hem ulusal hem de uluslararası düzeyde tarım politikalarının geliştirilmesinde önemli bir etkendir.

6. Uluslararası Uygulama Örnekleri

Uluslararası düzeyde, tarımsal üretimde su ayak izinin hesaplanmasında uygulanan çeşitli yöntemler ve örnekler, sektördeki sürdürülebilirlik standartlarının yükseltilmesi açısından önemli bir yere sahiptir. Birçok ülke, su kaynaklarının yönetimini iyileştirmek ve tarımsal üretkenliğin artışını sağlamak amacıyla su ayak izi hesaplama yöntemlerini benimsemektedir. Bu kapsamda, Hollanda, su yönetimi konusundaki yenilikçi yaklaşımlarıyla dikkat çekmektedir. Hollanda hükümeti, su ayak izinin azaltılmasına yönelik güçlendirilmiş yasa ve düzenlemeleri yürürlüğe koyarak, hem yerel hem de uluslararası düzeyde bu konuda örnek oluşturmaktadır. Ülke genelindeki tarım işletmeleri, su tüketimini izlemek ve optimize etmek için akıllı sulama sistemleri ve veri analitiği yöntemlerini kullanarak, su ayak izlerini etkili bir Biçimde Azaltma Çabası Içindedir. (Kaya ve Mazlum, 2025; Karakoç, 2022; Çakır et al.2022; Sezer ve Önder, 2024; Aydın, 2023; Demirci, 2024; Sak, 2024; Karaman, 2024; Ceylan, 2024)

Yine, Avustralya, su ayak izi hesaplama ve yönetiminde dikkat çeken bir başka örnek teşkil etmektedir. Avustralya Cumhuriyeti, tarımsal faaliyetlerde kullanılan su kaynaklarının sürdürülebilir yönetimi için kapsamlı bir üst düzey strateji geliştirmiştir. Bu strateji çerçevesinde, tarımsal su ayak izi analizleri, belirli üretim süreçleri ve su kullanımı ile ilgili verilerin toplanması ve değerlendirilmesi üzerine yoğunlaşmaktadır. Örneğin, bu ülkede uygulanan "Water Footprint Assessment" (Su Ayak İzi Değerlendirmesi) yöntemi, bireylerin, toplulukların ve işletmelerin su tüketimini belirlemekte ve kaynakların daha verimli bir şekilde kullanılmasını sağlamaktadır. Dolayısıyla, Avustralya'nın uyguladığı bu yöntemler, hem ekonomik hem de çevresel sürdürülebilirlik hedefleriyle uyumlu bir çerçevede yürütülmektedir. (Durmuşlar et al., 2023; Akçayır & Akın, 2024; Kadıoğlu, 2024; Örtlek, 2024)

Son olarak, Birleşmiş Milletler tarafından desteklenen çeşitli uluslararası projeler de tarımsal üretimde su ayak izinin hesaplanmasında küresel bir düzlemde iş birliğini teşvik etmekte ve bilgi paylaşımını kolaylaştırmaktadır. Bu projelerin amacı, gelişmekte olan ülkelerde su yönetimini güçlendirerek, su kaynaklarının etkin kullanımını sağlamaktır. Bu bağlamda, yerel tarımsal uygulamaların iyileştirilmesi ve su ayak izinin azaltılması konusunda atılan adımlar, yalnızca çevresel etkileri azaltmakla kalmayıp, aynı zamanda gıda güvenliğini artırma yönünde de somut katkılarda bulunmaktadır. Bu tür uygulamalar, envanter hazırlama, hedef belirleme ve strateji geliştirme aşamalarında diğer ülkelere örnek teşkil etmiştir. (Sak, 2024; Başoğlu, 2024; Javidroozi et al.; Karadeniz, 2024; Zahariev et al., 2024)

7. Geçmiş Çalışmaların İncelenmesi

Geçmiş çalışmalar, tarımsal üretimde su ayak izinin hesaplanmasıyla ilgili süreçlerin ve yöntemlerin evrimine dair önemli ve detaylı bilgiler sunmaktadır. Bu alandaki ilk araştırmalar, su ayak izinin tanımını netleştirmek ve ölçüm tekniklerini ve yöntemlerini daha da geliştirmek amacıyla gerçekleştirilmiştir. Özellikle, Allen ve ark. (1998), sütun su indeksinin ilk sistematik değerlendirmesini yaparak, bitki su tüketimini ve iklimsel etmenleri göz önüne alarak su ayak izi kavramını daha geniş bir çerçevede tanıtmıştır. Bu önemli çalışmalar, tarımsal verim ile su kullanımı arasındaki ilişkiyi anlamak için gerekli bir çerçeve ve temel bilgiler sunmuş ve daha sonra geliştirilen metodolojilere yönelik olarak temel bir referans noktası oluşturmuştur. Bu süreçler, günümüzdeki tarımsal uygulamaların çevresel sürdürülebilirlik açısından gelişimini de etkilemiştir. (Demirci, 2024; Yımam, 2023; Karakoç, 2022; Sak, 2024; Sandallar, 2024; Örtlek, 2024; Karaman, 2024)

Daha sonraki araştırmalarda, tarımsal ürünlerin su ayak izinin belirlenmesinde daha sofistike ve gelişmiş hesaplama yöntemleri geliştirilmiştir. Özellikle, Hoekstra ve Mekonnen (2012) tarafından yapılan çalışmalarda, su ayak izi hesaplamalarının kapsamı genişletilerek, çeşitli iklim koşullarında ve farklı ham madde türleri ile birlikte bu tür hesaplamaların nasıl yapıldığına dair detaylı bilgiler sunulmuştur. Kullanılan yöntemler, su tüketimi ve verimlilik açılarından ricat eden karmaşık bir sistem sunmakta ve bu sistemin dinamikleri, oluşan veriler üzerinden incelenmektedir. Bu bağlamda, uzaktan algılama tekniklerinin ve coğrafi bilgi sistemlerinin (CBS) entegrasyonu, daha hassas ve kapsamlı su ayak izi analizlerine olanak tanımış ve bu sayede daha doğru veriler elde edilmiştir. Böylelikle, hem tarımsal sürdürülebilirlik hem de su yönetimi stratejileri konusunda anlamlı çıkarımlar yapılmasına olanak sağlayan kapsamlı veri tabanları oluşturulmuştur. Bu veri tabanları, aynı zamanda gelecekteki analizler ve araştırmalar için de önemli bir kaynak teşkil etmektedir.

Ayrıca, çeşitli bölgelerdeki tarımsal uygulamaları inceleyen çalışmalar, farklı alanlardaki tarım uygulamalarının yerel su ayak izi hesaplamalarının çeşitli farklılıklarını ve bu farklılıkların getirdiği etkileri detaylı bir biçimde analiz etmeye yönelik önemli bulgular ortaya koymuştur. Bu tür araştırmalar, yerel su kaynaklarının mevcut

durumu, iklim iletişim değişkenlikleri ve tarımsal yöntemlerin bölgesel etkileri hakkında daha kapsamlı bir anlayış sağlamaktadır. Bu çalışmalar, yerel su kaynaklarının sürdürülebilir yönetimi için gereken yöntem ve stratejilerin geliştirilmesine de önemli bir katkı sunmaktadır. Sonuç olarak, geçmiş yıllara ait çalışmaların titizlikle incelenmesi, tarımsal üretimde su ayak izinin hesaplanmasının metodolojik verimliliğini artırmakta ve su kaynaklarının yönetimi konusundaki stratejiler ile uygulamaların geliştirilmesine büyük katkı sağlamaktadır. Geçmişe dayalı bu bilgiler, hem bilim insanlarına hem de uygulayıcılara daha etkili ve verimli su yönetimi çözümleri geliştirme hedefinde yardımcı olmakta, bu bilgiler daha iyi bir tarımsal uygulama ve sürdürülebilir bir çevre için son derece önemlidir. (Kayadibi, 2024; Fakıoğlu & Seçkin, 2023)

8. Gelecek Araştırma Alanları

Gelecek araştırma alanları, tarımsal üretimde su ayak izinin hesaplanması sürecinde önemli bir paya sahip olan çok boyutlu dinamiklerin daha kapsamlı bir şekilde incelenmesine yönelik fırsatlar sunmaktadır. Mevcut literatür, su ayak izinin belirlenmesine yönelik çeşitli yöntemler geliştirmiş olsa da, bu yöntemlerin doğruluğu ve genel geçerliliği hâlâ sorgulanmaktadır. Bu bağlamda, su ayak izi hesaplama süreçlerinde kullanılan modellerin daha yenilikçi ve parametrik yaklaşımlarla zenginleştirilmesi, ilerleyen dönemde araştırma ve uygulama alanlarının genişlemesine katkıda bulunabilir. Özellikle, iklim değişikliği ve su kaynaklarının kıtlığı gibi küresel sorunların tarımsal üretim üzerindeki etkilerinin belirlenmesi, gelecekteki araştırmaların odak noktalarından biri olmalıdır. Bu etkileşimlerin çözümlemesi, su yönetimi stratejilerinin yeniden değerlendirilmesine ve yeşil tarım uygulamalarının entegrasyonuna olanak tanıyabilir.

Aynı zamanda, su ayak izinin hesaplanmasında yerel ve bölgesel verilerin entegrasyonu da ilerleyen araştırmalar için elzemdir. Farklı coğrafi bölgelerdeki tarımsal uygulamaların su kullanımı üzerinde farklı etkileri olduğundan, bu farklılıkların göz önüne alınması gerekmektedir. Örneğin, sulama teknikleri, arazinin topografyası ve iklim koşulları gibi faktörler, su ayak izinin hesaplanmasını doğrudan etkileyen unsurlardır. Bu unsurların etkileşimlerinin detaylı bir şekilde incelenmesi, bölgesel bazda daha doğrulanmış ve uygulanabilir su yönetim stratejilerinin geliştirilmesine olanak sağlayacaktır. Ayrıca, çok disiplinli yaklaşımlar benimseyen araştırmalar, su ayak izinin sosyal, ekonomik ve çevresel etkilerini analiz ederken daha kapsamlı bir perspektif sunabilir.

Son olarak, dijital teknolojilerin ve veri analitiğinin tarımsal üretimde su ayak izinin hesaplanmasında kullanımı, gelecekteki araştırmalar için umut verici bir trend olarak öne çıkmaktadır. Uzaktan algılama, coğrafi bilgi sistemleri ve büyük veri analizi, su ayak izinin daha hassas ve gerçek zamanlı hesaplanmasını mümkün kılarak, tarımsal üretim süreçlerinin optimize edilmesine katkıda bulunabilir. Bu bağlamda, bilim ve teknoloji sinerjisinin sağlanması, su kaynaklarının daha verimli kullanılmasına ve sürdürülebilir tarım uygulamalarının teşvik edilmesine yönelik yenilikçi çözümler sunma potansiyeli taşımaktadır. Bu araştırma alanları, tarım sektörünün gelecekteki sürdürülebilirliğini güvence altına almak amacıyla hayati öneme sahiptir.

9. Sonuç

Sonuç bölümünde, tarımsal üretimde su ayak izinin hesaplanması konusundaki mevcut yöntemlerin etkinliğini ve önemini özetlemek amacıyla, başlıca bulgulara ve bu bulguların tarımsal sürdürülebilirlik üzerindeki etkilerine odaklanmak gereklidir. Su ayak izi, tarım sektöründe su tüketiminin izlenebilirliğini sağlayarak, ürün bazındaki su kullanım verimliliğini değerlendirmeye olanak tanımaktadır. Bu bağlamda, aquifer düzeyinde su tüketimi, toprak yapısı ve hava durumu gibi değişkenlerin dikkate alınması, tarımsal faaliyetlerin çevresel etkilerini anlamaya yönelik önemli bir adım teşkil etmektedir. Bu önemli ölçüm, yalnızca su kaynaklarının yönetimi açısından değil, aynı zamanda sera gazı emisyonları ve genel ekosistem üzerindeki baskılar açısından da kritik bir rol oynamaktadır.

Hesaplama yöntemlerinin çeşitliliği, her bir tarımsal ürün için spesifik koşullar ve bölgesel iklim farklılıkları göz önünde bulundurulduğunda büyük bir önem taşımaktadır. Modelleme yaklaşımı, su ayak izinin hesaplanmasında sıklıkla kullanılan bir teknik olmasına karşın, bu yöntemlerin doğruluğu ve geçerliliği yerel verilerin kalitesine bağlıdır. Matematiksel ve istatistiksel modellerin yanı sıra, saha ölçümleri ve uzaktan algılama teknolojileri de, su ayak izinin hesaplanmasında bütünleyici araçlar olarak değerlendirilmektedir. Bu çerçevede, farklı hesaplama yöntemleri arasında yapılan karşılaştırmalar, hem gelecekteki araştırmalar hem de politikaların şekillendirilmesi açısından parmak izi kimliğidir.

Sonuç olarak, tarımsal üretimde su ayak izinin hesaplanması, yalnızca su kaynaklarının korunmasını sağlamakla kalmayıp, aynı zamanda tarımsal üretkenliğin teşvik edilmesi ve iklim değişikliği ile mücadele gibi daha geniş çevresel hedeflerle de doğrudan ilişkilidir. Tarım politikalarının ve yönetim stratejilerinin, bu tür hesaplamalara dayanan verilerle desteklenmesi, su kıtlığı ile mücadele eden bölgelerde tarımsal sistemlerin sürdürülebilirliğinin artırılmasına katkı sağlayacaktır. Dolayısıyla, su ayak izi hesaplaması, tarımsal uygulamaların ekolojik ayak izini azaltmak ve gelecekteki nesillere yaşanabilir bir çevre bırakmak amacıyla kritik bir araç olarak karşımıza çıkmaktadır. (Çetintaş, 2024; Dikel ve Demirkale 2023; Aktürk ve Gültekin, 2023; Bulut ve Özer, 2024; Baysal, 2023; Dündar ve Kolay, 2021)

[2]Division of Food Science & Post Harvest Technology, ICAR-IARI, New Delhi
[3]Crop Sciences Department, University of Rwanda-College of Agriculture Animal Sciences and Veterinary Medicine,
*Corresponding author E-mail: uwisizeg@gmail.com

Abstract

Gibberellic acid, a bio-regulator commercially used for berry elongation in seedless grapes. The European grape species (*Vitis vinifera* L.) is characterized by easily breakable flesh and prone to cracking in high rainfall areas. The firmness of flesh is the major determinant factor for eating quality of table grapes and firmer flesh is usually preferred by the consumers. As the grape production sector under subtropical plains is handicapped by berry cracking due to pre-monsoon showers, the present investigation was carried at Division of Fruits and Horticultural Technology, IARI, New Delhi in 2017-18 for improving the textural properties of seedless grapes through pre-harvest application of gibberellic acid (GA_3). Four different concentrations of GA_3 (20, 30, 40, 60 ppm) were applied at 20 days after full bloom stage. Five seedless grape varieties viz., Pusa Seedless, Perlette, Beauty Seedless, Pusa Trishar, and Pusa Aditi were taken for this study. The highest firmness value was obtained at 40 ppm GA_3 concentration in Pusa Aditi (5.35 N), Beauty Seedless (4.78 N), Perlette (4.13 N), Pusa Trishar (3.81 N) and Pusa Seedless (3.76 N). In cv. Pusa Seedless, the highest bunch weight (447.73 g), bunch length (21.13 cm), berry weight (1.78 g), berry length (1.58 cm) and berry diameter (1.28 cm) was obtained with 60 ppm GA_3. In cv. Perlette, the highest bunch weight (447.23 g), bunch length (19.23 cm), berry weight (2.75 g), obtained with 40 ppm GA_3, whereas maximum berry length (17.4 mm), and berry diameter (16.48 mm) was obtained with 60 ppm GA_3. In cv. Beauty Seedless, the highest bunch weight (312.76 g), bunch length (16.22 cm), berry weight (3.47 g), berry length (17.49 mm), and berry diameter (14.04 mm) was obtained with 40 ppm GA_3. In Pusa Trishar, the highest bunch weight (661.23 g), bunch length (27.34 cm), berry weight (3.45 g), berry length (17.68 mm), and berry diameter (16.33 mm) was obtained with 40 ppm GA_3. In Pusa Aditi, the highest bunch weight (520.41 g), bunch length (24.62 cm), berry weight (4.31 g), berry length (21.95 mm), and berry diameter (19.14 mm) was obtained with 40 ppm GA_3.

Impact of zinc fertilizer on zinc content rice varieties to curve the disease status at farmer's field in Bangladesh

Mohammad Abul Monsur

Bangladesh Rice Research Institute, Bangladesh

Abstract

Zinc (Zn) is an essential micronutrient, that play a positive role in plant defense system to exclude the development and enzymatic reaction of different phytopathogens. Zn is responsible for sustainable plant growth by focusing the nutrient signaling and disease resistance mechanism. Zinc is also a crucial micronutrient for human health. In Asia, more than one billion peoples, specifically children and pregnant women are suffering to Zn deficiency problem. So, by producing zinc content rice variety we can reduce rice disease pressure and can fill-up our zinc requirements in human health. We did an experiment to observe the Sheath blight, Brown spot and Bacterial leaf blight disease status in farmer's field under Shirajgonj district in Bangladesh, where soil content minimum zinc level. Two zinc content rice variety BRRI dhan62 (19.8 milligram/kg), BRRI dhan72 (22.8 milligram/kg) and as a control check two non-zinc rice variety BRRI dhan52 and BRRI dhan87 were transplanted in rain fed season. Three doses of zinc fertilizer were used i) Zn present in soil 0.93 ppm (control) ii) soil test based recommended dose iii) soil test base double of recommended dose. Split-splot design and three replications were followed, where zinc fertilizer were applied in main plot and variety in subplot. We found that disease incidence (DI and Disease severity (DS) in all three diseases like Sheath blight, Brown spot and Bacterial leaf blight disease significantly lower where applied zinc double of recommended doses in rice variety BRRI dhan62 and BRRIdhan72. Disease incidence were 4% (sheath blight), 3% (Brown spot) and 5.7% (Bacterial leaf blight) in BRRI dhan72, where in BRRI dhan87 DI were 12.3% (Sheath blight), 11.7% (Brown spot) and 14% (Bacterial leaf blight) in double of recommended doses zinc treatment. Double doses recommended zinc decrease nitrogen content in all four rice varieties, but Potassium content increase in Zinc rice variety (BRRI dhan72, and BRRI dhan62) and decrease in non-zinc variety (BRRI dhan52 and BRRI dhan87) at booting stage. Zinc content were found 44.95 ppm, 50.17ppm, 52.09 ppm and 62.59ppm at BRRI dhan52, BRRI dhan87, BRRI dhan62 and BRRI dhan72, respectively at booting stage. Disease incidence and severity were minimum in BRRI dhan 72, because it contents higher zinc. Thus, it is important to cultivate zinc content rice variety and apply soil test base zinc fertilizer to reduce disease pressure for better yield and ensure sound health status.

Key wards: *Zinc, Disease severity, Disease incidence, Nitrogen, Potassium.*

Recent Applications in Computer Vision-based Lameness Detection of Dairy Cattles

Furkan Aksoy[1]

[1]Nigde Omer Halisdemir University, Faculty of Agricultural Sciences and Technologies, Department of Animal Production and Technologies, 51240, Nigde, Turkey

Abstract

Lameness is one of the three widespread disorders leads economic losses due to reduced milk and early culling in dairy industry. It affects herd productivity and animal welfare and requires effective management strategies in order to minimize its impact. Therefore, it is essential to have precise and applicability detection of lameness in dairy farming, with a focus on environmental sustainability. The visual locomotion score approach to identification of lameness in lame cows based on qualitative analysis, involving the evaluation of different combinations of bodily abnormalities, it requires observation skills and specialization used in field. The use of computer vision (CV) technology in monitoring gait and posture of dairy cattle the collection of video data on timeline is particularly suitable for rapidly diagnostics. The processes involved in determining locomotion score in CV described as follows: data collection, preprocessing, identification of body regions, extraction of features and training of classifier. This research includes, the latest developments based on computer vision in the literature which used in research and application for the detection of lameness in dairy cattle.

Key Words: *lameness, computer vision, visual locomotion score, dairy cattle, pose-estimation*

Süt Sığırlarında Topallık Tespitinde Bilgisayar Görüsü Tabanlı Güncel Uygulamalar

Özet

Topallık, süt endüstrisinde süt azalması ve erken itlaf nedeniyle ekonomik kayıplara yol açan üç yaygın bozukluktan biridir. Sürü verimliliğini ve hayvan refahını etkilemektedir ve etkisini en aza indirmek için etkili yönetim stratejileri gerektirmektedir. Bu nedenle, çevresel sürdürülebilirliğe odaklanarak süt hayvancılığında topallığın kesin ve uygulanabilir bir şekilde tespit edilmesi çok önemlidir. Topal ineklerde topallığın tespitine yönelik görsel hareket skoru yaklaşımı, bedensel anormalliklerin farklı kombinasyonların değerlendirilmesini içeren kalitatif analize dayanır, gözlem becerisi ve uzmanlık gerektirir. Süt sığırlarının yürüyüş ve duruşlarının izlenmesinde bilgisayarla görme (CV) teknolojisinin kullanılması, zaman çizelgesi üzerinde video verilerinin toplanması, hızlı teşhis için özellikle uygundur. CV'de hareket skorunun belirlenmesinde yer alan süreçler şu şekilde tanımlanmaktadır: veri toplama, ön işleme, vücut bölgelerinin tanımlanması, özelliklerin çıkarılması ve sınıflandırıcının eğitimi. Bu araştırma, süt sığırlarında topallığın tespiti için araştırma ve uygulamada kullanılan literatürdeki bilgisayarlı görmeye dayalı en son gelişmeleri içermektedir.

Anahtar Kelimeler: *topallık, bilgisayarlı görü, görsel hareket skoru, süt sığırı, duruş tahmini*

The Role of Biomimicry in Interior Architecture Education and Structural Forms

Ali Akçaova[1]

[1]Department of Interior Architecture, Faculty of Architecture and Design, Selcuk University, Konya, Turkey

Abstract

Biomimicry is an approach that aims to develop man-made systems by imitating the design principles and processes of nature. The application of biomimicry in interior architecture education allows students to develop creative thinking skills and create sustainable design solutions. This approach aims to integrate the aesthetically and functionally inspiring features of natural systems into interior design. In this context, the study examines the course content applied within the scope of Structural Knowledge, which is a compulsory course in the 3rd semester curriculum of Selçuk University Faculty of Architecture and Design, Department of Interior Architecture. Within the scope of the course, information about the structural system elements of the building, columns, beams, slabs, foundations, and the contribution of the biomimicry design approach to the design process, the structural system and the stages of shell formation are examined. The aim of the study is for students to use the principles of biomimicry to analyze the structural characteristics of structures and organisms in nature and to outline the design process in their own projects. The concept of biomimicry contributes to the development of innovative and sustainable structural forms in interior architecture education, helping them to adopt a design approach in harmony with nature. Within the scope of the study, 2nd year interior architecture students were asked to create a shell and carrier system for the interior architecture projects they worked on in the project studio within the scope of the Structural Knowledge course. As a result of the study, different shell formations and the effect of nature on the design process were emphasized. This study is expected to provide an example of the effect of the concept of biomimicry on the design process and contribute to the literature.

Keywords: *Interior Architecture, Biomimicry, Structural Forms*

İç Mimarlık Eğitiminde Biyomimikrinin Rolü ve Strüktürel Biçimler

Özet

Biyomimikri, doğanın tasarım prensiplerini ve süreçlerini taklit ederek insan yapımı sistemlerin geliştirilmesini amaçlayan bir yaklaşımdır. İç mimarlık eğitiminde, biyomimikrinin uygulanması, öğrencilerin yaratıcı düşünme becerilerini geliştirmelerine ve sürdürülebilir tasarım çözümleri oluşturmalarına olanak tanımaktadır. Bu yaklaşım, doğal sistemlerin estetik ve işlevsellik açısından ilham verici özelliklerini iç mekân tasarımına entegre etmeyi hedefler. Bu kapsamda çalışma Selçuk Üniversitesi Mimarlık ve Tasarım Fakültesi İç Mimarlık bölümü 3. Dönem müfredatında zorunlu ders olarak yer alan Strüktür Bilgisi kapsamında uygulanan ders içeriğini incelemektedir. Ders kapsamında yapının taşıyıcı sistem elemanları kolon, kiriş, döşeme, temel çeşitleri hakkında bilgileri verilmiş ve biyomimikri tasarım yaklaşımının tasarım sürecine katkısı, strüktürel sistem ve kabuk oluşumunun safhaları incelenmiştir. Çalışmada amaç öğrenciler biyomimikri prensiplerini kullanarak, doğadaki yapılar ve organizmaların strüktürel özelliklerini analiz edip, kendi projelerinde tasarım sürecnin ana hatlarını oluşturmasıdır. Biyomimikri kavramı, iç mimarlık eğitiminde yenilikçi ve sürdürülebilir strüktürel biçimlerin geliştirilmesine katkıda bulunarak, doğa ile uyumlu tasarım anlayışını benimsemelerine yardımcı olmaktadır. Çalışma kapsamına İç mimarlık 2. Sınıf öğrencilerinin, Strüktür Bilgisi dersi kapsamında proje stüdyosunda çalıştıkları iç mimari projelerine kabuk ve taşıyıcı sistem oluşturulması istenmiştir. Çalışma sonucunda ortaya çıkan farklı kabuk oluşumları ve doğanın tasarım sürecine olan etkisi öne çıkarılmıştır. Bu çalışma biyomimikri kavramının tasarım sürecinde etkisine yönelik bir örnek oluşturması ve literatüre katkı sağlaması beklenmektedir.

Anahtar Kelimeler: *İç Mimarlık, Biyomimikri, Strüktürel Biçimler*

Numidian fir tree (*Abies numidica*) role in the restoration of high mountain areas in Algerian forests

Kebaili Hakima[a,*], Nouioua Wafa[a], Dahamna Saliha[a], Khennouf Seddik[a], Baghiani Abderrahmane [b]

[a]Laboratory of Phytotherapy applied to chronic diseases, University of Setif 1-Ferhat Abbas, Setif 19000;Algeria
[b] Applied Biochemistry Laboratory, University of Setif 1-Ferhat Abbas, Setif 19000;Algeria
* Corresponding author. *E-mail: hakima.kebaili@univ_setif.dz address: University of Setif1 Ferhat Abbas complex El Baz Setif, Algeria*

Abstract

The Numidian fir tree (*Abies numidica*) can play a significant role in the restoration of high mountain areas and the colonization of limestone terrains, as well as in environmental protection. The aim of this work is to study the plant and forests of the Numidian fir tree and to explore its cultivation methods and conditions, including the propagation of this plant *in situ* (Djebel Babor) and *ex situ* (Tiner Wlad Saber Nursery in Sétif). It is important to note that micropropagation is a specialized technique that requires specific skills and adequate facilities, including a well-equipped tissue culture laboratory. We have learned from individuals involved in the project that approximately 1500 Numidian fir tree seeds were planted, and among them, 800 trees have survived and grown successfully in the Setif region. This represents an estimated success rate of 53.33%.

Keys words: Sapin Numidie, ,*Abies numidica*, Propagation, Djebel Babor.

Comparative Analysis of Tropical Butterfly Garden and Kalehan Ecdat Park in Konya Selçuklu District in Terms of User Preferences

Murat Seyhan[1], Sertaç Güngör[2]

[1]Landscape Architecture Department, Institute of Natural and Applied Sciences, Selçuk University, Konya, Türkiye
[2]Landscape Architecture Department, Architecture and Design Faculty, Selçuk University, Konya, Türkiye

Abstract

The users of Tropical Butterfly Garden and Kalehan Ecdat Park located in Selçuklu district of Konya province were selected as the research material. Existing data on the use of urban parks were examined through a detailed literature review and survey questions were prepared to determine the demographic characteristics and park usage habits of park users in the light of the data obtained from the literature. The survey questions included demographic characteristics of users (gender, age, education level, income level and occupation). In addition, parameters such as users' preferences for park visits, the purpose of using the parks, the units and equipment required in the parks, the benefits and activities provided by the parks were also included in the evaluation. In order to examine park usage, a face-to-face survey was conducted with park users according to the Snowball technique on random weekdays and weekends, based on the law on the protection of personal data and voluntary participation. The survey was conducted with the approval of the Ethics Committee of Selçuk University, Faculty of Architecture and Design. According to Güngör 2024, the population size was calculated to obtain reliable results from the survey. Considering the population of Konya province, Selçuklu district in 2024, a survey was conducted with a 95% confidence interval and a 5% margin of error, and a total of 220 people were surveyed. The collected data were determined by Chi-Square analysis using the SPSS program. Frequency distributions, cross tabulations and statistical analysis were carried out for the survey results. The data obtained from the survey were evaluated using quantitative and qualitative analysis techniques. Quantitative data were analyzed as frequencies and percentages and the relationships between demographic characteristics and park use were examined. Qualitative data were evaluated by content analysis method and the relationships between the expectations and needs of park users and park characteristics were determined and recommendations were developed.

Key Words: *Landscape architecture, Comparative analysis, User preferences, SPSS, Konya*

Safety Factor in Children's Playground Design: A Research in the Case of Seydişehir National Garden

Hatice Ballan[1], Sertaç Güngör[2]

[1]Landscape Architecture Department, Institute of Natural and Applied Sciences, Selçuk University, Konya, Türkiye
[2]Landscape Architecture Department, Architecture and Design Faculty, Selçuk University, Konya, Türkiye

Abstract

Children's playgrounds should be spaces that support children's interests, imagination and the development of large muscle motor skills, and are designed to allow children to move freely. There is a very special relationship between children and play; children learn, socialize, grow and develop by playing. Safety in children's playgrounds is the most important issue to be considered when designing these areas. The material of the research is the children's playground located in the National Garden in Seydişehir district of Konya province. In order to determine the problems related to security in the park, according to the Snowball technique, a face-to-face survey was conducted with the children and their parents on the basis of the law on the protection of personal data and the principle of volunteerism by going to the area on random days on weekdays and weekends. The survey was conducted with the approval of the Ethics Committee of Selçuk University, Faculty of Architecture and Design. 330 children or parents were interviewed, security problems related to the park were revealed and solutions were proposed.

Key Words: *Children playgrounds, Safety factor, Landscape design, National garden, Konya*

Value Added Analysis of Grape Production in Dulkadiroğlu District of Kahramanmaraş Province

Fatma Nur YILMAZ[1], Zeki BAYRAMOĞLU[2]

[1,2]Tarım Ekonomisi, Ziraat Fakültesi, Selçuk Üniversitesi, Konya, Türkiye (ingilizce)

Abstract

Grapevine (*Vitis vinifera* L.), one of the oldest cultivated plants, is an economically important temperate climate plant grown in the world and in our country. Developing value-added products from grape production is a topic that needs to be brought to the agenda. However, adding value to a product or developing a new product requires a certain process. The aim of the study is to test the value-added analysis in grape production by taking the Dulkadiroğlu district of Kahramanmaraş province as an example. The primary data of the study consists of data obtained from surveys conducted in October-November 2024 with producers producing grapes in the Dulkadiroğlu district of Kahramanmaraş province. The number of sample enterprises in the study was determined according to the stratified random sampling method and the sample size was determined as 111 enterprises. According to the results of this research; it is seen that farmers are mostly members of organizations related to agricultural production. Farmers consider that agricultural organizations will be useful in benefiting from state support and aid. The Kabarcık variety, which is generally cultivated in the Dulkadiroğlu district, is mostly consumed as table grape juice, walnut sausage and bastık, as well as being consumed as table grapes. The reason for the intensive cultivation of this variety is its resistance to diseases and its ease of cultivation. In addition, Mahrabaşı, Antep Karası, Azezi, Yıldız Üzümü are among the varieties produced and evaluated as drying. A training system called serpene is used in the region at a rate of 75% and a modern high-cordon training system at a rate of 25%. The biggest problem in production is the distance to the market and transportation problems in addition to disease control. Drug dealers are mostly used in the fight against diseases and pests. In the Bertiz region, the most valuable added products produced from grapes are pekmez, walnut sausage and bastık. There are disruptions in the marketing phase of the produced products. Producers usually leave the grape pulp obtained during production and which has the potential to provide added value in an empty place in the garden. Low product prices are one of the important factors in the marketing of value-added products. Farmers believe that by ensuring branding, value-added production and demand among the public will increase. It is important to introduce high value-added products such as pekmez, walnut sausage, bastık to the world and our country and to ensure branding.

Key Words: *Viticulture, Added value, Production, Kahramanmaraş, Sustainability*

Kahramanmaraş İli Dulkadiroğlu İlçesinde Üzüm Üretiminin Katma Değer Analizi

Özet

Kültüre alınan en eski bitkilerden biri olan asma (*Vitis vinifera L.*) dünyada ve ülkemizde yetiştirilen ekonomik açıdan önemli bir ılıman iklim bitkisidir. Üzümden üretilen ürünlerden katma değerli ürün geliştirme gündeme gelmesi gereken bir konudur. Fakat bir ürüne katma değer katmak ya da yeni bir ürün geliştirmek belirli bir süreç gerektirmektedir. Bu çalışmanın amacı, üzüm üretiminde katma değer analizini Kahramanmaraş ili Dulkadiroğlu ilçesi örnek alınarak test etmektir. Çalışmanın birincil verilerini Kahramanmaraş ili Dulkadiroğlu ilçesinde üzüm üretimi yapan üreticiler ile 2024 yılı Ekim – Kasım aylarında yapılan anketlerden elde edilen veriler oluşturmaktadır. Araştırmada örnek işletmelerin sayısı tabakalı tesadüfi örnekleme yöntemine göre belirlenmiş olup örnek hacmi 111 işletme olarak belirlenmiştir. Bu araştırma sonuçlarına göre; çoğunluklu olarak çiftçilerin tarımsal üretimle ilgili organizasyonlara üye olduğu görülmektedir. Çiftçiler tarımsal örgütlerin devlet destek ve yardımlardan faydalanmada yararlı olacağını düşünmektedir. Dulkadiroğlu ilçesinde genel olarak yetiştiriciliği yapılan Kabarcık çeşidi çoğunlukla şıralık olarak değerlendirilmesinin yanı sıra sofralık, cevizli sucuk ve bastık olarak da tüketilmektedir. Bu çeşidin yoğun olarak yetiştirilmesindeki sebep hastalıklara dayanıklılığı ve yetiştiriciliğinin kolay olmasıdır. Ayrıca Mahrabaşı, Antep Karası, Azezi, Yıldız Üzümü de üretimi yapılan ve kurutmalık olarak değerlendirilen çeşitlerdendir. Bölgede %75 oranında serpene olarak adlandırılan bir terbiye sistemi, %25 oranında ise modern telli terbiye sistemi kullanılmaktadır. Üretimdeki en büyük sorun hastalık mücadelesinin yanı sıra pazara uzaklık ve ulaşım problemleri gelmektedir. Hastalık ve zararlılarla mücadele konusunda çoğunlukla ilaç bayilerinden yararlanılmaktadır. Bertiz bölgesinde üzümden üretilen katma değerli ürünlerin başında pekmez, cevizli sucuk ve bastık gelmektedir. Üretilen ürünlerin pazarlanma aşamasında aksamalar yaşanmaktadır. Üreticiler üretim sırasında elde edilen ve katma değer sağlama potansiyeli olan üzüm poslarını genellikle bahçede boş bir yere bırakmaktadır. Ürün fiyatlarının düşük olması katma değerli ürünlerin pazarlanmasındaki önemli etkenlerden bir tanesidir. Çiftçiler markalaşmanın sağlanmasıyla, katma değerli üretimin ve halk arasında talebin artacağına inanmaktadırlar. Pekmez, cevizli sucuk, bastık gibi katma değeri yüksek ürünlerin dünya ve ülkemize tanıtılması ve markalaşmanın sağlanması önem taşımaktadır.

Anahtar Kelimeler: *Bağcılık, Katma değer, Üretim, Kahramanmaraş, Sürdürülebilirlik*

Impact of Climate Change on Harmful Crop Insects Population

Srishti Chauhan[1], Prodipto Bishnu Angon[1]

[1]Institute of Agronomy, Hungarian University of Agriculture and Life Science (MATE), Gödöllő 2100, Hungary

Abstract

Climate change, resulting from environmental fluctuations and human activities, has a significant impact on agricultural pests by altering their life cycles and infestation trends. Increasing levels of greenhouse gases, high temperatures, unpredictable rainfall, and droughts affect both crops and pests. As temperatures rise, pests can develop more quickly because they receive the necessary amount of heat exposure required for their development. These weather variations influence pest growth, virulence, multiplication, persistence, and range expansion favourably, leading to more severe infestations. Crop yields depend on effective pest and disease management, which can be improved by adopting methods that consider the impact of climate change on plants and pests. In this article, we attempt to present information addressing the issues related to the impact of climate change on crop pests. The influence of basic climatic factors like greenhouse gas emission and temperature on insects are discussed, specifically about the possible effects of climate change, i.e., the gradual increase in the average temperature. The analysis reveals that pests have caused significant crop damage, leading to yield losses and posing a threat to food security. However, strategies such as proper monitoring of insect populations and their invasion patterns can help to adapt to crop health crises caused by climate change.

Key Words: *Climate change, Crop production, Pest population, Greenhouse gas, Environment*

Effect Of Global Alliance for Improved Nutrition (Gain) Technology Transfer on Nutritional Status of Sweet Potatoes Farmers in Oyo State Nigeria

[1]Oyetoro, John Oyewole., [1]Tiamiyu Abdullah Oyediran, [1]Adebayo, Rasheedat Adeola. and [2]Sotola, Abiodun Emmanuel

[1]Department of Agricultural Extension and Rural Development, Ladoke Akintola University of Technology, Ogbomoso, Nigeria
[2]Union Bank PLC, Ondo Branch, Ondo State, Nigeria

Abstract

The integration of new technologies by GAIN (Global Alliance for Improved Nutrition) on sweet potatoes in Nigeria is cardinal to boost the bioavailability of micronutrients, increase crop yields, promote sustainable agriculture practices, ultimately improving the nutritional status and livelihoods of farmers and their families. This study evaluates the effect of the GAIN technology transfer initiatives on the nutritional status of sweet potato farmers in Oyo State, Nigeria. A multi-stage sampling technique was used to select 234 farmers from the catchment areas of Ido, Iseyin, and Oyo West Local Government Areas. Data were collected through structured interviews and analyzed using descriptive statistics and Pearson's Product Moment Correlation. Results indicated that 71.8% of farmers were male, with a mean age of 41.5 years. Most respondents (87.2%) were married, 53.8% had at least seven years of formal education, and sweet potato farm sizes averaged 1.7 hectares. Access to extension services was high (92.3%), with frequent interactions (85.9%). Pearson's correlation revealed significant relationships between household size ($r = 0.727^*$, $p = 0.000$), frequency of contact with extension agents ($r = 0.727^*$, $p = 0.000$), and nutritional status of respondents. The study concluded that while GAIN interventions have improved production and nutrition, challenges such as high input costs and market constraints persist. The study recommended that additional agronomic practices addressing pest infestations on potato tubers should be promoted to improve post-harvest management and storage facilities.

Keywords: *Technology transfer, Orange-Fleshed Sweet Potato, food security, Biofortification, smallholder farmers, GAIN, Oyo State.*

Introduction

Agricultural development plays a fundamental role in ensuring food security, improving livelihoods, and enhancing economic stability, particularly in sub-Saharan Africa. The integration of new technologies by GAIN (Global Alliance for Improved Nutrition) on sweet potatoes in Nigeria is cardinal to boost the bioavailability of micronutrients, increase crop yields, promote sustainable agriculture practices, ultimately improving the nutritional status and livelihoods of farmers and their families. Despite Nigeria's position as one of the largest producers of sweet potatoes in Africa, smallholder farmers in Oyo State face persistent challenges that hinder productivity, market access, and income generation (Food and Agricultural Organization FAO, 2021). These challenges are compounded by limited access to improved sweet potato varieties, inadequate farming technologies, and weak value chain integration, all of which contribute to low yields and economic vulnerability (Ekanem and Nwosu, 2020).

Beyond productivity concerns, malnutrition remains a critical public health issue in Nigeria, with vitamin A deficiency (VAD) affecting approximately 30% of children under the age of five (United Nations Children's Fund UNICEF, 2022). This micronutrient deficiency leads to weakened immunity, impaired vision, and increased child mortality rates. To address this issue, the Global Alliance for Improved Nutrition (GAIN) has facilitated the introduction of the Orange-Fleshed Sweet Potato (OFSP), a biofortified crop with high levels of vitamin A, as part of broader nutrition and agricultural interventions (Bouis *et al.*, 2021). While OFSP presents a viable solution to combat both malnutrition and food insecurity, its adoption among farmers in Oyo State remains limited due to insufficient awareness, inadequate extension services, and lack of financial and infrastructural support (Agbede *et al*., 2023).

Although GAIN's technology transfer initiatives aim to improve agricultural outcomes through the provision of improved OFSP vines, training on best agronomic practices, and strengthening market linkages, there is limited empirical evidence assessing the actual impact of these interventions on farming communities in Oyo State (Global Alliance for Improved Nutrition, GAIN, 2022). The extent to which these efforts have led to increased crop yields, improved household incomes, and enhanced dietary intake of vitamin A-rich foods remains inadequately documented. Moreover, existing studies indicated that market challenges, high production costs, and a lack of policy incentives continue to undermine farmers' ability to benefit fully from biofortified crop adoption (Eze *et al*., 2020 and HarvestPlus, 2022).

Furthermore, structural barriers such as poor transportation networks, post-harvest losses, and consumer preferences for traditional sweet potato varieties have constrained the market demand for OFSP, raising concerns about the long-term sustainability of the initiative (Adepoju *et al*., 2024). Without addressing these constraints, the expected benefits of GAIN's agricultural technology transfer may not be fully realized, thereby limiting its contribution to agricultural development, rural livelihoods, and public health improvements in Nigeria.

This study, therefore, assessed the effect of the Global Alliance for Improved Nutrition (GAIN) technology transfer initiatives on the nutritional status of sweet potato farmers in Oyo State, Nigeria. Specifically, the study described the socioeconomic characteristics of the respondents. identified the technology transferred to the sweet potato farmers ,determine the effect of GAIN technology transfer on nutritional status, identified the reasons for the use of technology transferred to the respondents and investigated the constraints encountered in the use of technologies transferred to the respondents.

Methodology

The study was carried out in Oyo state Nigeria. It is bounded by the states of Kwara on the north, Osun on the east, and Ogun on the south and by the Republic of Benin on the west. Oyo state is traversed by the Yoruba Hills in the north. The state has some tropical rain forest in the south around Ibadan, the state capital, but is covered mostly by a "derived" savanna that is largely the result of clearing and burning the former forest cover to provide land for cultivation. It is inhabited mainly by the Yoruba people. The study focused on sweet potato farmers in Oyo state.The sampling procedure adopted a multi-stage approach. In the first stage, purposive sampling was used to select the three participating local government areas in Oyo State: Ido, Iseyin, and Oyo West. In the second stage, all sweet potato farmers involved in the GAIN project for potato production were purposively selected. A total of 234 sweet potato farmers participated in the study. Data collection was carried out using a well-structured interview schedule designed in alignment with the research objectives. The study measured both dependent and independent variables. The dependent variable, was the effect of GAIN technology transfer on nutritional status of sweet potato farmers. Statements related to effects generated were scored using a four-point rating scale: high effect (3), moderate effect (2), low effect (1), and no effect (0).The independent variables included the respondents' age, years spent in school and so on. Descriptive statistics, including frequency counts, percentages, mean, and weighted mean scores, were used to summarize and interpret the data. To test the research hypothesis and determine the relationship between variables, Pearson Product Moment Correlation was applied as the inferential statistical tool.

Results And Discussion

In Table 1, a majority (71.8%) of the respondents were male, while 28.2% were female, indicating significant male involvement in sweet potato production on GAIN project. This aligns with findings from Aboajah and Ekeledo (2024), who reported that 70.8% of males participated in land preparation activities for sweet potato farming in Anambra State. The predominance of male participation may be attributed to the labor-intensive nature of certain farming activities

Regarding age distribution, nearly 60.0% of respondents were between 31 and 50 years old, with a mean age of 41.5 years, suggesting that the farmers were in their economically active years. This is consistent with Egwuonwu and Ozor (2020), who found an average age of 35.5 years among sweet potato farmers in Imo State, indicating that sweet potato farming is predominantly undertaken by individuals in their productive age bracket. Marital status analysis revealed that 87.2% of the respondents were married, implying a high level of social responsibility among the farmers. This finding is in line with Egwuonwu and Ozor (2020), who reported that 65.0% of sweet potato farmers in Imo State were married, suggesting that marital status may influence farmers' commitment to agricultural activities.

In terms of education, more than half (53.8%) of the respondents had between 7 and 12 years of schooling, while 33.3% had more than 12 years of formal education. This suggests a relatively high literacy level among the farmers, which can facilitate the adoption of improved agricultural technologies. Egwuonwu and Ozor (2020) found that 51.6% of sweet potato farmers in Imo State were literate, highlighting the role of education in enhancing farmers' ability to adopt new technologies.

The average household size among respondents was six members, with 60.3% having between 5 and 8 members. Larger household sizes may provide additional labor for farming activities, potentially influencing the scale of sweet potato cultivation. This observation is supported by Aboajah and Ekeledo (2024), who noted that household size significantly affects gender participation in sweet potato farming activities.

Farm size analysis indicated that 46.2% and 41.0% of respondents cultivated 1 and 2 hectares, respectively, with a mean farm size of 1.7 hectares. This suggests a moderate scale of sweet potato production among the farmers. Egwuonwu and Ozor (2020) reported an average farm size of 1.1 hectares among sweet potato farmers in Imo State, indicating that small to medium-scale farming is common in sweet potato production. Regarding farming experience, 75.6% of respondents had more than two years of experience in sweet potato production, with a mean of 3.2 years. This level of experience may be beneficial in adopting and implementing improved farming practices. Kolawole et al. (2017) emphasized that farming experience is a significant determinant of adopting improved sweet potato technologies in Kwara State.

Table1: Distribution of respondents according to socio-economic characteristics of the respondents n=234

Socioeconomic characteristics	Frequency	Percentage	Mean	
Sex				
Male	168	71.8		
Female	66	28.2		
Age (Years)				
≤ 30	48	20.5		41.6
31-50	135	57.7		
Above 50	51	21.8

Weekly	6	2.6		
Fortnightly	201	85.9		
Monthly	3	1.3		
Yearly	24	10.3		

Source: Field survey, 2024

Access to extension services was reported by 92.3% of respondents, highlighting the importance of extension agents in disseminating agricultural innovations. Egwuonwu and Ozor (2020) found that 61.7% of sweet potato farmers in Imo State had contact with extension officers, underscoring the role of extension services in facilitating technology adoption. The frequency of contact with extension agents varied, with 85.9% of respondents reporting fortnightly interactions. Regular engagement with extension services can enhance farmers' knowledge and adoption of improved practices. Aboajah and Ekeledo (2024) recommended that research and extension should focus on both male and female sweet potato farmers with appropriate techniques to improve participation and enhance income and standard of living.

Effect of GAIN Technologies Transferred to Sweet Potato Farmers

Table 2 presents the effects of GAIN technologies on the nutritional status of sweet potato farmers. The results indicated that the increased consumption of nutrient-rich "Solo Gold" potatoes and the perceived improvement in overall health due to the consumption of nutritious "King J" potatoes were ranked highest, both with a WMS of 2.7. This finding aligns with Low *et al*. (2017), who reported that biofortified sweet potato varieties significantly enhance household nutrition and vitamin A intake, particularly in rural farming communities.

A notable increase in income from "Solo Gold" production, which enabled farmers to purchase a wider variety of nutritious foods, and the production of vitamin- and mineral-rich potatoes were ranked third, each with a WMS of 2.6. This is consistent with the findings of Thiele *et al*. (2020), who highlighted that improved sweet potato varieties contribute to higher yields and better market opportunities, thereby increasing farm incomes.

Training provided by GAIN improved farmers' knowledge of the nutritional value of the "Mother's Delight" variety, with a positive impact on household nutrition. This, along with farmers' willingness to recommend the variety to others, was ranked fifth (WMS = 2.5). Studies by Andrade et al. (2016) suggest that farmer training programs on biofortified crops enhance knowledge adoption, leading to better agronomic practices and higher acceptance of new varieties. Additionally, the production of high-yield, nutrient-dense potatoes was ranked seventh (WMS = 2.2), supporting evidence from Mwanga *et al.* (2017) that improved sweet potato varieties have superior agronomic and nutritional benefits.

Farmers acknowledged that the technology transfer improved their ability to cultivate a diverse range of potatoes and enhanced their understanding of essential micronutrients, both ranking eighth with a WMS of 2.0. However, post-harvest loss reduction ranked the lowest (WMS = 1.8), suggesting that this aspect of production still requires improvement. This finding aligns with Tumwegamire *et al.* (2018), who noted that post-harvest losses remain a major challenge for sweet potato farmers despite the adoption of improved varieties.

Reasons for the usage of GAIN Technologies on sweet potatoes

Table 3 presents the factors influencing the adoption of GAIN technology among sweet potato farmers. The findings indicate that all respondents (100%) identified high tuber yield, early maturity, tuber color, high vine yield, ease of access to the introduced technology, and access to extension agents as key determinants of adoption. These results suggest that the perceived agronomic and economic benefits of GAIN technology play a crucial role in its uptake. This aligns with Rogers' (2003) Diffusion of Innovation Theory, which posits that the relative advantage of a technology significantly influences its adoption.

Moreover, 84.6% of respondents highlighted the provision of market access as a critical factor, reinforcing the argument by Omonona *et al.* (2019) that reliable market opportunities enhance farmers' willingness to adopt improved agricultural technologies. Additionally, 66.7% and 60.3% of respondents identified good culinary quality and pest and disease resistance, respectively, as motivations for adoption. This is consistent with Abdoulaye *et al.* (2014), who emphasized that consumer preferences and resistance to biotic stress are key determinants of technology uptake in smallholder farming systems. Furthermore, 41.0% of farmers indicated that drought resistance was an important factor, while 26.9% considered high dry matter content significant. These findings are in agreement with Simtowe et al. (2021), who established that the environmental adaptability and nutritional attributes of improved crop varieties influence farmers' usage decisions.

GAIN Agricultural Technologies Transferred to Sweet Potato Farmers

Table 4 presents the GAIN agricultural technologies transferred to sweet potato farmers in the study area. The findings indicated that all respondents (100%) reported receiving improved sweet potato varieties, including Mother Delights (yellow), Solo Gold (pink), and King J (pink), alongside recommended agronomic practices such as correct spacing (30 cm × 30 cm) and the use of 2–3 node cuttings. These results suggest that GAIN extension services prioritize both varietal improvement and best agronomic practices, aligning with findings by Low et al. (2017), which highlight the role of improved crop varieties in enhancing smallholder productivity.

Furthermore, 84.6% and 73.1% of respondents indicated receiving training on the application of liquid fertilizer and the use of vines from vine multipliers, respectively, reflecting the importance of soil fertility management and quality planting materials in sweet potato production. This aligns with Abidin et al. (2015), who emphasized that the availability of certified planting materials significantly enhances yield and disease resistance.

In addition, 39.7% of farmers reported adopting the 75 cm × 75 cm ridge planting method, and 37.2% utilized insecticides, fungicides, and tractors for cultivation. The relatively lower adoption rates for mechanized farming and chemical pest control may indicate financial or infrastructural constraints, consistent with studies by Gurmu et al. (2020), which found that resource limitations often hinder smallholder farmers from fully integrating modern agricultural technologies.

Table 2: Distribution of respondents according to effect of GAIN technologies transferred to the sweet potato farmers

*Effect of the GAIN technologies transferred on sweet potato farmers nutritional status	WMS	Rank
There is increase in consumption of nutrient-rich "solo gold" potatoes since adopting the GAIN technology	2.7	1st
GAIN technology transfer has helped me to produce a more diverse range of potatoes, improving my family's access to essential micronutrients	2.0	8th
My family noticed an improvement in my overall health and wellbeing, which attributed to the increased consumption of nutritious "king J" potatoes	2.7	1st
The training received from GAIN enabled me to make informed decisions about the nutritional value of "mothers delight" sweet potato variety	2.5	5th
Through GAIN technologies, there is considerable production of potatoes with higher yields and better nutritional content, which has improved my family's nutrition status	2.2	7th
The technology transfer project has helped to reduce post-harvest losses, resulting in more potatoes available for consumption and improved nutrition for the family	1.8	10th
There is significant increase in income since adopting the production of "Solo gold", which has enabled me to purchase a more diverse range of nutritious foods for the family	2.6	3rd
The technology transfer project has empowered me to take control of my nutrition and make informed decisions about the food I grow and consume	2.0	8th
There is production of the new potatoes that are rich in essential vitamins and minerals, improving family's overall nutrition status	2.6	3rd
Production of "mothers delight" has had a positive impact on family's nutrition status, and I would recommend it to other farmers	2.5	5th

Severity of constraints encountered in the use of GAIN agricultural technology transferred to sweet potato farmers

Table 5 presents the severity of constraints affecting the adoption of GAIN agricultural technologies among sweet potato farmers in the study area. The results indicate that poor storage facilities and millipede and centipede infestations were the most significant challenges, each with a weighted mean score (WMS) of 3.0. This suggests that post-harvest loss management remains a critical issue despite the introduction of GAIN technologies. Tuber rot disease ranked third, with a WMS of 2.7, while the high cost of recommended liquid fertilizer and excessive water content in potato tubers followed, both with a WMS of 2.6. These findings highlight financial constraints as a major impediment to the full implementation of GAIN technologies. Furthermore, inadequate market access (WMS = 2.3) and low income from sweet potato cultivation (WMS = 2.1) were identified as additional constraints. Poor extension education on sweet potato production ranked the lowest, with a WMS of 1.1, indicating a potential gap in knowledge dissemination.

Table 5. Distribution of respondents according to severity of constraints encountered in the use of GAIN agricultural technology transferred in the study area

Severity of constraints encountered in the use of GAIN technology transferred	WMS	Rank
High cost of recommended liquid fertilizer	2.6	4th
Tuber rot disease	2.7	3rd
Inadequate access to market	2.3	6th
Millipede and Centipede infestation (pest)	3.0	1st
Poor income from sweet potato cultivation	2.1	7th
Poor extension education on sweet potato production	1.1	8th
High water content in the potato tuber	2.6	4th
Poor storage facilities	3.0	1st

Source: Field survey, 2024
F: Frequency
%: Percentage
WMS: Weighted Mean Score

The result in table 5 revealed that that household size (r = -0.727*, p = 0.000) and frequency of contact with extension agents (r = 0.727*, p = 0.000) were significantly related to the effect of GAIN technologies. These findings suggested that larger household sizes attracted lower nutritional status of farmers. Additionally, frequent interactions with GAIN extension agents enhance farmers' ability to utilize the technologies effectively, leading to improved production and nutritional status.

Table 5: PPMC showing significant relationship between the selected socioeconomic characteristics of respondents and effect of GAIN technology transferred on sweet potato farmer's nutritional status

Socioeconomic characteristics	Correlation Coefficient	P-value	Remark
Age	0.039	0.735	Not Significant
Years spent in school	0.094	0.413	Not Significant
Household size	0.764*	0.000	Significant
Frequency of contact with GAIN extension agents	0.348*	0.000	Significant
Years of farming experience	0.004	0.974	Not Significant

Source: Computed data, (2024)

Conclusion And Recommendations

This study concluded that GAIN technologies transferred on sweet potatoes have significantly benefited sweet potato farmers by enhancing their nutritional status. The usage of GAIN technologies was influenced by reasons such as high tuber yield, early maturity, and ease of access to improved varieties. Key technologies received and utilized included the Mother Delights, Solo Gold, and King J sweet potato varieties, along with recommended agronomic practices. However, farmers faced challenges such as poor storage facilities and pest infestations. The study recommended that additional agronomic practices addressing pest infestations on potato tubers should be promoted to improve post-harvest management and storage facilities.

AI and IoT-Based Smart Irrigation: A Review of Challenges and Future Trends

Yusuff Lawal[1], Oluwadere Adebisi[2]

[1]Mechanical and Mechatronics Engineering, Faculty of Engineering and Technology, Abiola Ajimobi Technical University, Ibadan, Nigeria. Email: yusuff.lawal@tech-u.edu.ng
[2]Mechanical and Mechatronics Engineering, Faculty of Engineering and Technology, Abiola Ajimobi Technical University, Ibadan, Nigeria.

Abstract

Artificial Intelligence (AI) and Internet of Things (IoT) integration has established a new generation of intelligent irrigation systems that deliver sustainable water management solutions to address world water scarcity problems and agricultural requirements. This literature review presents an analysis of the present situation and obstacles alongside emerging trends of AI and IoT-based smart irrigation systems supported by international examples and technological milestones. Physical water conservation through AI-driven irrigation systems combined with IoT sensor surveillance and drone monitoring results in 20-35% water savings at the same time as improved yield outcomes across Australian regions together with Indian and Spanish territories. The wide use of smart irrigation systems is limited by technical difficulties that prevent rural Africa from connecting by economic pressures on poor farmers and by ethical challenges with European data security. The deployment become challenging because of scalability issues and maintenance problems that affect different farming ecosystems. The development of emerging technologies like edge computing, blockchain, and 5G, together with solar-powered IoT systems, provides solutions alongside research efforts toward energy-efficient climate-friendly designs. A comprehensive review combines current evidence into two major parts to evaluate its impacts on farmers, policymakers, and researchers. The review also shows where scalability and accessibility remain limited. The success of AI and IoT precision farming technology relies on cooperative work between multiple fields of study together with equal policies that support their implementation. Time must be dedicated to resolving these problems because smart irrigation systems need to fulfill worldwide food security along with sustainable development targets.

Key words: AI-driven irrigation, IoT sensors, smart agriculture, precision irrigation, water management, blockchain in agriculture, edge computing, renewable energy irrigation

1.1 Introduction

Agriculture stands as the foundational element of worldwide food security, although its operation suffers from major problems because of growing populations joined with climate shifts and evaporating freshwater availability. A 40% water deficit exists in the global water supply estimation for 2050, while irrigation utilizes about 70% of worldwide freshwater withdrawals. The standard irrigation techniques present difficulties because they neither successfully optimize agricultural production nor protect the environment efficiently. The combination of Artificial Intelligence (AI) systems operating with Internet of Things (IoT) devices makes up a revolutionary irrigation solution under the name of smart irrigation. Having IoT devices monitor environmental parameters gives AI systems the ability to manage water consumption efficiently and determine irrigation requirements and guide decision-making processes. This combined technology approach will direct farming operations into a new exacting direction which brings sustainable water management practices alongside higher agricultural output.

1.2 Objectives of the Review

The review examines existing knowledge about AI and IoT-based smart irrigation systems which focuses on their applications together with their limitations as well as future potential. This paper examines three essential aspects regarding AI and IoT applications in irrigation practices: (1) describes current integration methods, (2) describes key barriers affecting adoption, and (3) investigates emerging models for future smart irrigation systems. Through this combined technical and practical approach, this study provides essential information for researchers, practitioners and officials who work in agriculture technology fields.

1.3 Scope and Methodology

This review investigates AI and IoT applications in irrigation management while not addressing broader agricultural applications except when they directly touch irrigation systems. The review examines recent research from peer-reviewed journals, conference materials, and technical reports that originate mainly from IEEE Xplore, Scopus, and Google Scholar databases during the previous ten years. The search for relevant literature relied on the selected keywords “AI in irrigation,” “IoT smart irrigation,” “precision agriculture,” and “water management technologies.” The study included research papers about AI-IoT integration challenges and innovations and future direction works that maintained a focused relevant analysis. The analysis focuses on worldwide ideas that

additionally respect geographical differences between various agricultural tech acceptance and farming requirements.

2. Overview of AI and IoT in Smart Irrigation

2.1 Core Concepts

Two major functions guide smart irrigation technology through the integration of Artificial Intelligence (AI) and the Internet of Things (IoT). These functions include the acquisition of data and the implementation of intelligent decision systems. IoT consists of networked objects including sensors that monitor ground moisture and weather monitoring systems and controllers which share information through wireless communication networks (Selvam & Al-Humairi, 2023). The established monitoring infrastructure tracks vital measurements including soil water levels together with environmental humidity and prediction of rain events. AI-operated algorithms consisting of ML and DL generate insights from the processed data (Rane, *et al.,* 2024). AI analyzes weather data in combination with plant water needs to establish ideal irrigation timing which leads to better water use efficiency and reduced wastage. The combination of these technologies operates in a self-contained system which dynamically responds to environmental changes thus making smart irrigation differ from conventional approaches.

2.2 Evolution of Smart Irrigation Systems

The techniques of irrigation have experienced drastic changes as human-operated flood irrigation systems evolved to technology-powered automated irrigation systems. The early development of irrigation technology integrated timer-based sprinklers and drip irrigation yet did not offer adjustable controls (Tripathi, 2022). The early development of IoT in the 2000s enabled farmers to use mobile device connectivity for monitoring sensors which helped them modify irrigation routines. Prediction technology and automation have brought AI systems into the current irrigation development. AI-IoT combines to minimize water consumption by 30% better than traditional techniques yet produces equal or better production results (Senoo *et al.,* 2024). Precision agriculture represents the dominant movement in which resource management becomes the most critical aspect.

2.3 Key Components

The functionality of AI and IoT-based smart irrigation systems depends on various hardware and software collaborative elements. Low-power IoT devices like capacitive soil moisture sensors and weather stations together with solenoid valves constitute hardware components (Shamsudeen, 2021). These devices operate on solar-powered batteries to maintain sustainability for distant locations. Cloud platforms collect IoT network data through software components where AI algorithms execute data analysis to create irrigation strategies beginning with basic regression models and ending with neural networks (Preite & Vignali, 2024). The components of an irrigation system use ZigBee and LoRaWAN and Wi-Fi communication protocols to transfer data effectively (Dhatterwal, *et al.,* 2024). The system's scalable design operates well due to reliable connections between its parts while ensuring software interoperability.

3. Current State of Research

3.1 Applications of AI and IoT in Irrigation

AI and IoT applications for smart irrigation systems are widely adopted by international agricultural sectors to suit various needs within different climate zones and economic ranges. The precision irrigation system serves as a primary use case that uses IoT devices with Artificial Intelligence algorithms for delivering precise water dispensations to targeted plant areas at correct times. This prevents irrigation water from going to waste. The adoption of these systems within Middle Eastern arid regions enables optimal date palm management through decreased water requirements by 25% according to (Alnaim *et al.,* 2022). The combination of IoT data from meteorological measurements with AI forecasting models enables water scheduling through weather-based methods which yields good results in Asian regions dependent on monsoons (Indira *et al.,* 2023). Soil and crop monitoring uses IoT multispectral sensors to collect data which machine learning processes for agricultural evaluation in both large-scale North American maize fields and Southeast Asian rice paddies (Solano Correa, 2025). The range of agricultural settings which proves the flexibility of AI-IoT solutions includes high-tech European commercial operations in addition to Sub-Saharan African areas with limited resources.

3.2 Notable Case Studies

Zone irrigation and collective irrigation programs benefit from real-world practices of AI and IoT technologies in irrigation management. The Murray-Darling Basin conducted an IoT and AI decision support system pilot project that cut water usage by 35% without affecting cotton production rates (Parr *et al.,* 2022). The Tamil Nadu Agricultural University in India built a low-cost IoT-AI system for drip irrigation and this technology enhanced rice production by 20% while attracting use from small farmer community (Ahmad & Nabi, 2021). AI enabled Spanish vineyards to increase their water efficiency rate by 30% through European Union backing for IoT data analysis (Linaza, et al., 2021). A Kenyan research study demonstrated limited water savings of 15% because of connectivity issues despite conducting the study in the region (Karuku, 2018). This showed discrepancies in local infrastructure development. The implementation examples demonstrate the capacity for and inconsistent advancement rates of smart irrigation systems worldwide.

3.3 Technological Advancements

AI together with IoT functionalities have received major enhancements in recent times. The development of sensor technology now includes affordable yet precise devices such as capacitive soil moisture sensors made by China which are currently deployed across Asia and Africa (Aarif KO *et al.,* 2024)]. Deep learning models enable artificial intelligence to predict irrigation requirements precisely which is apparent through studies that used neural networks in Brazilian soybean fields (Baio *et al.,* 202)]. Large-scale monitoring became possible through the data fusion of IoT information and satellite images and drones particularly in Canada's prairie farming region (Sishodia *et al.,* 2020). Cloud-based platforms operating in Japan and Germany use mobile apps to allow real-time processing and connect farmers to database resources (Zhang, 2024). Smart irrigation technologies continue to advance worldwide due to local research communities who work across multiple continents.

4. Challenges in AI and IoT-Based Smart Irrigation

4.1 Technical Challenges

The implementation of AI and IoT technologies for smart irrigation systems encounters substantial technological challenges in different areas and infrastructure networks. Sensor-driven data accuracy represents a crucial problem because environmental elements including dust in North African deserts and tropical Southeast Asian moisture can compromise sensor performance (Gualtieri, *et al.,* 2024). The connectivity issue is a major problem in regions with limited internet access like Sub-Saharan Africa since the area suffers from poor cellular network coverage that disrupts IoT data transmission (Onsomu, *et al.,* 2024). The high demands for data processing capacity from AI models create operational problems for developing countries because they do not have strong computing infrastructure or cloud access (Rehan, 2024). Research conducted in India showed real-time processing delays decreased irrigation efficiency by 15% in regions restricted by limited resources according to available findings (Nsoh, *et al.,* 2024). The technical obstacles serve as evidence that flexible systems that work well for different worldwide environments need to be developed.

4.2 Economic and Adoption Barriers

The integration of AI-IoT irrigation systems faces scalability limitations because of economic obstacles and challenges with adoption mainly affecting low-income agricultural economic settings. Poorest communities especially struggle to afford investment costs in IoT hardware coupled with AI software that can reach thousands of dollars per unit of cultivated land (Hambye & Desmet, 2021). Government aid programs in Latin American regions struggle to promote AI-IoT irrigation systems adoption because both maintenance costs and technical illiteracy prevent rural area adoption (McCarthy, *et al.,* 2024). The survey conducted in Eastern Europe revealed that 60% of farmers showed ignorance regarding smart irrigation advantages as they maintained a preference for traditional irrigation practices (Ricart & Rico-Amorós, 2021). Wealthier regions with technical proficiency such as North America as well as Western Europe receive the majority of digital technology uptake because of economic and social factors that create a divide between communities.

4.3 Environmental and Ethical Concerns

AI and IoT irrigation systems produce environmental as well as ethical concerns in addition to technical and economic challenges. The energy usage of IoT devices and AI computing requires significant power consumption that leads to carbon emission problems identified as main sustainability concerns in Scandinavia (Ruilova Alfaro, 2024). Data privacy poses an ethical problem for EU farmers since they are worried IoT devices transmit their information to external organizations under GDPR (Ryan *et al.,* 2024). The implementation of technology has encroached upon traditional farming wisdom in indigenous areas across Australia and South America, causing concern about cultural heritage maintenance (Bellwood, 2022). A fair balance needs to be established that connects smart irrigation systems to worldwide sustainability and fairness goals.

4.4 Scalability and System Maintenance Challenges

The deployment of AI and IoT irrigation systems on a large scale after successful tests faces logistical obstacles that become more difficult due to required maintenance work. Scalability is restricted because agricultural systems with different landscape variations prevent systems from successfully being implemented across multiple agricultural areas (Salpina, 2020). The Chinese national smart irrigation program encountered interoperability problems between different provinces because its IoT protocols remained unstandardized (Zeng *et al.,* 2025). Adoption becomes more difficult because remote areas like rural Mongolia and the Andean highlands lack technical support, while sensors and devices need regular maintenance procedures (Orlove *et al.,* 2024). A South African examination uncovered that 40% of IoT irrigation systems stopped functioning after two years because of poor maintenance practices, which underlines the requirement for such systems to have durable life cycles and low-maintenance provisions (Alharbi *et al.,* 2024). Smart irrigation faces sustainability threats throughout its extended application because of various obstacles that specifically affect resource-constrained and diverse agricultural regions.

5. Future Trends and Innovations

5.1 Emerging Technologies and Innovations

Smart irrigation with AI and IoT deployed by the following technological advancements will increase the efficiency and global adaptation of this system. Implementing AI predictive models equipped with deep learning

and machine learning functions enables precise water need forecasting to control irrigation timings. Brazilian soybean automation through neural networks cut water consumption by 20% in a solution suitable for Southern African rural areas (Silva *et al.,* 2024). The use of UAVs (drones) in crop monitoring leads to better real-time detection, which helped Canadian prairie farmers increase their wheat production by 15% (Al-Mallahi, 2024) and Kenyan small-scale farmers map maize fields at a reasonable cost (Wanyama *et al.,* 2021). The Dutch track water use by blockchain technology, while edge computing reduces response time at remote agricultural locations in Central Asia. Technology developments in South Korea advance 5G for quick irrigation control (Watts *et al.,* 2019). The Netherlands, along with the U.S., participates in blockchain and edge computing for data processing efficiency and security (Ahmed *et al.,* 2024). Smart irrigation technology is moving toward worldwide adoption due to recent innovative developments.

5.2 Research Directions

Scientists will tackle existing issues in research by building upon these emerging trends. The implementation of solar-powered IoT systems with renewable energy systems stands as a primary research priority because they helped Spanish olive farms conserve 40 percent of their energy costs and Ethiopian smallholder farmers received an additional 50 percent irrigation capacity (Mérida García, 2020; Tesfaye *et al.,* 2021). Solar IoT implementations in Sub-Saharan Africa help to decrease the carbon emissions of these systems (Mukisa *et al.,* 2022). Research teams in Bangladesh are developing affordable AI-Internet of Things kits that aim to give small farmers the power they need (Satapathy *et al.,* 2022), and AI software from Brazil predicts drought timing patterns compatible with Southern Africa (Chivangulula *et al.,* 2024). Through collaboration between agronomists and data scientists in Japan and Canada, researchers have found comprehensive answers (Suresh *et al.,* 2024). The established directions work to establish both sustainability and access to smart irrigation throughout agricultural locations with varied environments.

5.3 Policy and Industry Implications

The complete implementation of these innovations depends on strong support from both government policies and industrial organizations. Governments should provide financial support for solar-IoT systems. The German public-private partnerships build farmer-friendly platforms that serve as a model for European territories (Sjaf *et al.,* 2022). The adoption rate of drones and blockchain in industries continues to grow because Mexico established farmer training programs for UAV operation and IEEE developed universal IoT standards for Southeast Asia (Tiwari *et al.,* 2021; Wangere, 2024). International joint investments in AI and renewable energy research development are speeding up deployment worldwide through Chinese edge-blockchain pilot programs (Yang *et al.,* 2025). These initiatives guarantee that technology breakthroughs become practical benefits that reach all farmers justly across the board.

6. Discussion

6.1 Synthesis of Findings

Smart irrigation has experienced a revolutionary change because of AI and IoT implementation that has been proven through multiple case studies and research developments. Through the combination of IoT sensors with AI analytics systems and precision irrigation methods, water savings reached between 20-35% in Australian, Indian, and Spanish locations (Wei *et al.,* 2024) while drone-based farming and predictive analysis techniques improved agricultural productivity in North American and African territories (Guebsi & El Wai 2025). Several roadblocks, mainly stemming from technical difficulties regarding rural African internet connectivity combined with economic factors influencing Asian smallholders and European privacy rights, are preventing the widespread adoption of the proposals. The integration of solar-powered systems in Ethiopia, combined with blockchain solutions in the Netherlands, provides a solution for existing barriers, but China faces difficulties in achieving standardization following their deployment (Abiri *et al.,* 2023; Polymeni *et al.,* 2024). This work highlights two conflicting trends that show major potential restricted by continuing obstacles that affect different regions and resource amounts.

6.2 Implications for Stakeholders

The results deliver significant ramifications that affect stakeholders all over the world. The implementation of AI-IoT technology provides efficiency improvements to farmers yet necessitates affordable user-friendly solutions, which are vital for South Asian and Latin American small-scale farmers (Muhammed *et al.,* 2024). Water-scarce nations such as Morocco need policymakers to establish both training programs and financial aid schemes, which have proven successful in Israel (Tinazzi, 2024). The refinement of scalable and energy-efficient technologies requires research collaboration across different fields of study similar to Canadian research institutions (Neethirajan, 2024). The adoption of new agricultural technologies, such as edge computing in remote Central Asian regions, can be achieved through industry collaborations led by drone manufacturers and IoT developers, much like in Germany and by extending to Central Asian farms. The stakeholders must work together toward producing effective transformational outcomes from research through efforts that suit different agricultural settings.

6.3 Limitations of the Review

The review aims to be comprehensive; however, some restrictions need to be acknowledged. The majority of studies in English-language publications bias researchers against evaluating important research conducted in Spanish or Chinese, which could hide valuable innovations from Latin America and East Asia. The examination of recent research during the last decade fails to include fundamental studies that established the framework for smart irrigation development. Successful case studies dominate the research due to published limitations since resource-limited areas, particularly Sub-Saharan Africa, often fail to report their unsuccessful implementations (Higginbottom et al., 2021). Further research should expand linguistic and geographical bounds in reviews to achieve full global representation of research.

Conclusion

Artificial Intelligence (AI) integration with the Internet of Things (IoT) brings substantial opportunities for global water shortage management and increased agricultural crop outputs. Predictive AI models and IoT monitoring, along with drone application, blockchain technology, and solar-powered systems, prove effective in water utilization optimization and increased yield production throughout Australia to Ethiopia. The extensive implementation faces multiple obstacles that include technical obstacles as well as financial hurdles and scalability problems and ethical issues which predominantly impact regions such as Sub-Saharan Africa and South Asia which have limited resources. The implementation of edge computing with 5G technology and renewable energy integration requires major combined work to achieve their future applications.

Technology in precision agriculture earns its value because it generates sustainable farming systems through precise management capabilities. Implementing these methodologies demands the elimination of the digital gap through affordable technology systems that support robust policies across the board. The authors propose that researchers should conduct more studies about energy-efficient, affordable agricultural system designs while improving collaborative work between agronomists and engineers along with policymakers. People across the world in agricultural roles alongside governmental organizations, scientific researchers, and industrial experts should join forces to lead this technology adoption. AI and IoT-based smart irrigation represent a vital opportunity in the present climate to protect both our food supply and environmental systems because water availability continues to decrease.

Acknowledgements

The authors express gratitude towards academic advisors and colleagues for contributing their knowledge to the development of this literature review. I express my gratitude to the research community, which gave us access to important studies and IoT and AI data regarding smart irrigation systems. The authors achieved their goal to submit this conference paper because of assistance and facility access from Abiola Ajimobi Technical University, Ibadan Oyo State, Nigeria. The authors accept responsibility for all potential mistakes or oversights within the document.

Characterization of Dried Orange Waste as a Valuable Ingredient in Broiler Chicken Diets

CHAIB EDDOUR Ahmed Readh[1*], LITIM Miloud[1], LARBAOUI Abdelkarim[2], BELHOCINE Chaimaa[1], BOUDEROUA Kaddour[1]

[1]Laboratory of "Applied Biotechnology for Agriculture and Environmental Preservation," Higher School of Agronomy, Mostaganem, Algeria
[2] Laboratory of Food Technology and Nutrition, Abdelhamid Ibn Badis University, Mostaganem, Algeria

Abstract

Several valorization strategies have been explored as alternatives to mitigate the disposal of orange waste in landfills. In the orange juice industry, over 50% of the raw material is converted into by-products that are rich in bioactive compounds and possess high nutritional value. Enhancing the utilization of these by-products could serve as a crucial strategy for advancing a circular economy. Orange waste represents a potential source of revenue or cost savings for juice production facilities, given its potential as a source of value-added products and energy vectors. To produce a flour from orange juice by-product and characterize it, in order to incorporate it in broiler chicken feed. The sun-dried and grounded (particle size < 1mm) orange by-products were characterized in terms of its chemical composition, dietary cellulose, phenolic compounds, and antioxidant potential. Dried orange pulp presented a moderate high content of dietary cellulose (89.19% dry matter (DM)), minerals (ash = 3.81% DM), and total phenolic compounds (202.59 mg gallic acid equivalent (GAE)/100 g of DM). In general, orange by-products showed total cellulose content, flavonoids content, and antioxidant activity with the following values, 22.03 %, 430.70 mg QE/100g, and 1158.8 FRAP mg/g FRAP mg/g, respectively. The qualification of phenolics compounds in dried orange pulp demonstrated that flavonones were the most presents with a high content of hesperidin 61.29 mg/g of orange juice powder by-product. Furthermore, the most elevated concentration in hydro cinnamic acids content was the ferulic acid with (27.1 mg/g). These findings make dried orange pulp a valuable product for broiler chicken, contributing not only to animal welfare but also to more cost-effective and eco-friendly poultry production practices.

Keywords: *Orange waste, Hydro cinnamic acids, Hesperidin, Ferulic acid.*

Introduction

Fruits and vegetables have the highest waste rates of any food, i.e., 45% (Caldeira et al., 2019). Citrus is one of the most important fruit crops in the world with an annual production exceeding 122.5 million tons and one-third of the crop is processed (Jiang et al., 2014). Peel (flavedo) and rag (albedo) by-products are generated from the production of citrus juice, and represent about 45%–60% of the fruit (Berk et al., 2016). These by-products contain nutrients and bioactive compounds; they are considered a problem. Therefore, the need for more sustainable practices, with reduced environmental impacts towards the application of a circular economy in the food system, represents a key strategy for the future. Fruit is widely known for its functional potential and, more recently, fruit by-products have gained attention due to their higher nutritional contents in comparison to their respective edible portion (Can-Cauich et al., 2017). It is noteworthy that the use of by-products also contributes to reduce the economic and environmental problems caused by the discard of waste by fruit processing industries (O'Shea et al., 2012).

Valorizing co-products offers both environmental and economic benefits for the food sector, contributing to the development of sustainable value chains in agriculture and processing. There is currently high demand for transforming co-products into new ingredients through sustainable processes. This involves reducing disposal costs and improving environmental impact by transforming these co-products into useful products for various industries such as food, dietary, pharmaceutical, cosmetic, and others. As previously detailed, orange juice by-product is mostly destined for animal feed (Bampidis et al., 2006), or for essential oils (Sahraoui et al., 2011). For this, an adequate process for developing the by-product and its complete characterization, in terms of composition, and also in relation to functional properties, is necessary before its application in real and easily manufactured animal feed, which are the objectives of this study.

Turkish Science and Technology Publishing (TURSTEP)

Materials and Methods

Preparation and obtaining the powdered orange juice co-product

The orange juice waste, obtained from an Algerian processing company in January 2021, was transported to the Biotechnology Laboratory at the Higher School of Agronomy in Mostaganem, Algeria. It was dried in a glass greenhouse for four days, then ground into a fine powder with particle size <1 mm for easier incorporation into broiler chicken feed (Readh et al., 2023).

Proximate composition analysis

Determination of dry matter

The sample is dehydrated in an oven at 105°C for 24 hours (Özcan et al., 2021; Ebouel et al., 2023).
The dry matter of the samples are calculated by the following expression :

DM (%) = Mass (DM)(g)/Mass (sample) (g) × 100 (1)

Determination of Ash

The dehydrated samples will be heated to 550°C for 3 hours in a muffle furnace until white ashes are obtained. The specimens are weighed for the calculation and expression of results (Lagha-Benamrouche et al., 2018; Ebouel et al., 2023). The following formula (equation 3) were utilized to calculate the mineral matter content (MM):

Mineral Matter (MM %) = (M2 - M0) / (M1 - M2) × 10 (3)

M0: Mass of the empty crucible (in grams)
M1: Mass of the crucible containing the test sample (in grams)
M2: Mass of the crucible and the raw minerals (in grams)
The content of MM is expressed in g/100g of the sample.

Proteins

The aliquot is ground with 25ml of physiological saline solution on ice and the mixture is filtered using filter paper. From this filtrate, 1ml is taken and added to 100 ml of distilled water. Then, from this mixture, 1ml is transferred into a test tube, and Lowry reagent is added and allowed to stand for 10 minutes. Afterward, half-diluted *Folin-Ciocalteau* reagent is added to each tube. The tubes are then agitated using an electric homogenizer for 2 minutes and left to stand for 30 minutes at 4°C in the dark. The readings are taken with a spectrophotometer at a wavelength of 700nm. The optical densities obtained are converted into protein percentages using a calibration curve prepared under the same conditions (Satpathy et al., 2020).

Orange By-Product Extraction

The solvent for the production of the extracts utilized was the absolute methanol. Briefly, 20 g of sample 200 mL of absolute methanol was added, the mixture was agitated on a compact shaker (Edmund Bühler GmbH model KS-15, Hechingen, Germany) at 450 rpm for 24 h at room temperature (23 ± 1 °C), protected from the light. After that, the extrait sample was stored to an amber pear-shaped flask. To evaluate the antioxidant capacities of the dried orange pulp extract, free radical DPPH inhibition and ABTS assays were performed. In addition, the Total Phenolic Compounds (TPC), the Total Flavonoid Content (TFC) and condensed tannins were determined.

The quantification of phenolic compounds

Total phenolic content

The polyphenols were quantified using spectrophotometry following the method described by (Jaradat et al., 2015). One milliliter of the methanolic extract (20 g of powder in 200 mL of methanol-water (8v/2v)) was mixed with 5 mL of *Folin-Ciocalteu* reagent. This solution was diluted tenfold and 4 mL of 75 g/L Na2CO3 was added. A standard curve was prepared using a 1 g/L gallic acid solution with dilutions of 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 µg/mL. Absorbance was measured at 765 nm after a 1-hour incubation at room temperature. The color intensity is proportional to the level of oxidized phenolic compounds capable of reducing *Folin-Ciocalteu* reagent. The results are expressed as milligrams of gallic acid equivalent per gram of dry extract.

Flavonoids

The flavonoids in dried orange pulp were quantified using spectrophotometry according to the method described by (Pertiwi et al., 2020). A volume of 0.75 mL of AlCl3·6H2O (2%) was mixed with an equal volume of the extract. After a 10-minute incubation, the optical densities were read at 430 nm in the UV-Visible range. Flavonoid concentrations were determined against a standard curve generated using quercetin (0_60 mg/L). The results are expressed as milligrams of quercetin equivalent (EQ) per gram of dry extract.

Condensed Tannins

According to Agbo et al. (2015), the modified vanillin assay was used to determine the total tannin content. For this purpose, 1.5 ml of concentrated sulfuric acid was combined with three milliliters of a 4% vanillin solution in methanol, which was then added to 50 ml of a diluted sample. The absorbance relative to methanol as a blank was measured at 500 nm, and the mixture was left to stand for 15 minutes. A calibration curve with catechin was used to express the total amount of condensed tannins in milligrams of catechin equivalent per 100 grams of dry matter (mg CE/100g DM). The calibration curve ranged from 0 to 400 µg/ml (R^2 = 0.999).

Antioxidant Activity

Free Radical DPPH Inhibition Assay

For the free radical DPPH inhibition assay, the method described by (Gargouri et al., 2013) and modified by (Mohammedi et al., 2023), was applied. Briefly, a volume of 0.1 mL of each extract was transferred into a test tube. The reaction was carried out for 30 min in the dark. Then, absorbance was measured at 517 nm. An aliquot of 2 mL of DPPH (2,2-diphenyl-1-picrylhydrazyl) solution (0.4%) in ethanol and 0.1 mL of phenolic extract at different concentrations ranging from 31.25 µg/mL to 500 µg/mL was mixed and shaken vigorously. After 30-min incubation at 30°C in the dark, the absorbance was measured at 517 nm against a blank sample. A control assay was performed with the solvent in which the sample was dissolved. The inhibition percentage (IP) of DPPH was calculated according to the following equation (5):

$$\textbf{IP (\%)} = (Ac - As)/Ac \times 100 \quad (5)$$

Where:

(Ac) is the absorbance of the control and **(As)** is the absorbance of the sample.

ABTS radical scavenging activity

As reported by Gargouri et al. (2013), a modified approach was employed by (Mohammedi et al., 2023), to assess ABTS radical scavenging activity. The ABTS radical cation was generated by combining an aqueous solution of ABTS (7 mM) with potassium persulfate (2.45 mM, final concentration) and incubating it in darkness at 25°C for 12–16 hours. The resulting solution was diluted with ethanol to attain an absorbance of 0.70 (± 0.02) at 734 nm. Subsequently, 20 µl of trolox or the test sample in water were introduced into 2.0 mL of this diluted solution, and absorbance readings were taken at 734 nm at 30 °C following 6 minutes of initial mixing. Blank samples for each assay were prepared using appropriate solvents. The antioxidant's efficacy was evaluated by measuring its capacity to reduce the concentration of the ABTS radical cation, with results expressed relative to the trolox antioxidant equivalent concentration. This assessment of antioxidant activity was conducted at three distinct concentrations.

Quantification of the Polyphenolic Compounds by HPLC-DAD/UV

Phenolic compounds were identified using high-performance liquid chromatography (HPLC). This characterization was performed by comparing the retention times of the chromatographic peaks of the sample, in accordance with the methodology specified by Maalej et al. (2022). The concentration of phenolic compounds present in the ethyl acetate extracts was quantified using an HPLC-DAD system (1260-Agilent, Germany). An Eclipse DB C18 column, with a particle size of 5 µm and dimensions of 4.6 x 25.0 mm, was used for compound separation in this study. Two distinct mobile phases were used for this purpose: solvent A, consisting of a 0.1% acetic acid aqueous solution, and solvent B, composed of 100% acetonitrile. The separation was carried out following an acetonitrile gradient with the following conditions: from 0 to 22 minutes (10 % B) and from 22 to 32 minutes (50 % B). The conditions were then modified as follows: (100 % B) from 32 to 40 minutes, (100 % B) from 40 to 44 minutes, and (10 % acetonitrile) from 44 to 50 minutes. The total analysis cycle duration was 50 minutes. Samples were injected at a flow rate of 0.5 ml/min, with an injection volume of 5 µl, maintained at a temperature of 40°C. The ultraviolet-visible (UV_VIS) spectra of the phenols were recorded over a range of 190 to 400 nm, and the samples were detected at wavelengths of 254, 280, and 330 nm, according to the protocol described by Mohamadi et al. (2023).

Statistical Analysis

The characterization of orange pulp was conducted using five replicates. Data were analyzed using appropriate statistical methods to assess variability and ensure reliability. Descriptive statistics were computed, and results are expressed as mean.

Results

Biochemical Composition of Dried Orange Pulp

The chemical composition of the orange juice by-products is presented in Table 1.

Total Content of Polyphenols and Flavonoids

The quantified levels of polyphenols, flavonoids, tannins, and the measured antioxidant activities (DPPH and FRAP) are presented in Table 2.

Table 1. Chemical composition of dried orange by-products obtained from the orange juice extraction ($g.100g^{-1}DM$)

Parameter	Dried Orange Pulp (DOP)
Dry Matter	89.19
Ash	3.81
Crude Proteins	5.50

Each value is the mean of (n=5). The results are expressed as means ± standard deviations

Table 2. Phenolic Compounds and Antioxidant Activity of the studied by-products (*Citrus Siensis*)

Parameter	Dried Orange Pulp (DOP)
Phenolic compounds mg GAE/g	202.59
Flavonoids mg QE/g	430.70
Tannins mg CE/g	150.00
FRAP mg/g	1158.8
DPPH mg/g	270.68

Each value is the mean of (n=5). The results are expressed as means ± standard deviations

The analysis of dried orange pulp revealed that it contained significant quantities of bioactive compounds, contributing to its antioxidant potential. The phenolic compounds and flavonoids present in DOP reflect its high nutritional value and potential health benefits. Additionally, the notable levels of tannins further indicated its bioactive richness. The antioxidant capacity, as measured by FRAP and DPPH values, confirmed the strong antioxidant properties of DOP.

High-Performance Liquid Chromatography with Diode Array Detection (HPLC-DAD) Polyphenolic Profile of Orange Pulp

The phenolic profile and polyphenol content of orange by-products were analyzed using HPLC-DAD, enabling routine screening and quantification of polyphenols.

The study identified 19 phenolic compounds, including four flavonoids, across three groups: phenolic acids, flavanone glycosides, and flavanol glycosides (Table 3).

Table 3. Phenolic Compounds in Orange Pulp

	RT	Component	mg/g	Λ nm	Subclasses of Compounds
1	8.92	Caffeic acid	1.00	330	Hydrocinnamic acids
2	17.12	Ferulic acid	27.1	280	
3	19.83	p-Coumaric acid	0.3	280	
4	7.03	p-Hydroxybenzoic acid	1.31	254	Hydrobenzoic acids
5	14.45	Vanillic acid	0.1	254	
6	23.86	Dydimine	0.61	330	Flavonones
7	20.91	Naringenin	0.2	280	
8	23.09	Naritunine	1.76	280	
9	32.77	Hesperidin	61.29	330	
10	42.72	Hesperetin	0.3	280	
11	22.74	Luteolin	0.8	330	Flavones
12	25.96	Apigenin	0.8	254	
13	15.15	Rutin	0.4	330	Flavanols
14	22.92	Quercetin	10.6	254	
15	13.66	Epicatechin	7	280	
16	22.51	Quercitrin	4.2	254	
17	10.40	Protocatechuic acid	Trace	280	Phenolic acids
18	7.89	Chlorogenic acid	2.7	254	
19	4.48	Ascorbic acid	3.2	280	
T			123.67		

RT: retention time; C: concentration (mg/mL); λ nm: wavelength; T: Total

Each compound was characterized by its retention time (Rt), maximum absorption wavelengths (λmax), structural class, and main MS/MS fragments. The most abundant compound is hesperidin, a flavonone, which stands out with a concentration of 61.29 mg/g. This dominance is followed by ferulic acid, a hydro cinnamic acid, at 27.1 mg/g, highlighting the significant presence of phenolic acids. Additionally, quercetin, rutin, and epicatechin, belonging to the flavanols, contribute substantially to the overall antioxidant capacity of the orange pulp. The variety of compounds, including both flavonoids and phenolic acids, suggests a strong potential for antioxidant activity, further underlining the nutritional value and functional properties of the pulp.

Discussion

The orange pulp used in our study showed higher levels of dry matter and proteins compared to those reported by El-Beltagi et al. (2022). It also exhibited significantly elevated ash content, surpassing Castro et al. (2020), while

maintaining a similar protein content. The dry matter content of our oven-dried orange peel powder was closely similar to Özcan et al. (2021) result. However, our results differ from García-Rodríguez et al. (2019), who reported a broad protein range in orange pulp by-products, from 7.3 g/kg dry matter in clementines to 110 g/kg in orange pulp. Additionally, Pourhossein et al. (2019) highlighted compositional differences between our orange pulp and the orange peel in their study, which had 88.00% dry matter, 5.46% protein, 1.10% calcium, 0.05% phosphorus, and 7.00% ash. In contrast, Akpe et al. (2019) found biodegraded sweet orange peel containing 7.18% crude protein and 7.50% ash.

Phenolic compounds in citrus peels have been reported in the range of 131.0 to 223.2 mg of gallic acid equivalent (GAE) per 100 g (Ghasemi and Ebrahimzadeh, 2009). The orange pulp used in our investigation exhibited a higher total phenolic content compared to the results reported by Al-Juhaimi et al. (2014). In their study, they extracted phenolic compounds from orange peel, obtaining 178.90 mg GAE/100 g, and from mandarin peel, yielding 169.54 mg GAE/100 g.

Furthermore, their analysis revealed phenolic concentrations in orange pulp of 123.02 and 104.98 mg GAE/100 g, respectively. Our findings revealed lower levels of phenolic compounds compared to the content reported in the study conducted by (Castro et al., 2020), with a content of 534 mg gallic acid equivalent (GAE)/100 g dry matter. Furthermore, our experiment revealed that the average flavonoid content of the orange pulp showed moderate similarity to the findings of Abou-Arab et al. (2016).

Specifically, the microwave-dried orange pulp exhibited flavonoid variations ranging from 437.50 mg quercetin equivalent (QE)/100 g in mandarins to 453.33 mg QE/100 g in *C. Valencia* and *C. Balady* oranges. Additionally, the flavonoid concentrations in oven-dried orange peels varied from 150.83 mg QE/100 g in *Citrus Balady* oranges to 327.50 mg QE/100 g in *Citrus Valencia* oranges.

In contrast, the study by Lagha-Benamrouche and Madani (2013) in Algeria found that the peels of six orange varieties had lower flavonoid concentrations than those observed in our investigation. The total flavonoid content in sweet orange peel varies with drying and grinding methods (Garau et al., 2007). Fresh orange peel initially contained 506.82 mg QE/g, decreasing to 309.9 mg QE/g after microwave drying and to 365.40 mg QE/g after oven drying (Abd-El Ghfar et al., 2016). The correlations between antioxidant activity (ABTS and DPPH) and phenolic compounds align with Barreca et al. (2014) and Papoutsis et al. (2016). Additionally, Abd-El Ghfar et al. (2016) found higher flavonoid content in oven-dried lemon peel than in microwave-dried peel. Our study's orange pulp flavonoid content exceeded that of oven-dried orange peels reported by Abou-Arab et al. (2016).

The dehydrated orange pulp in our study showed higher levels of caffeic, ferulic, and hydrobenzoic acids compared to kinnow peel (Rafig et al., 2019) but lower levels of quercetin, caffeic acid, naringin, and rutin than those reported by Omoba et al. (2015). Additionally, hydroxycinnamic acids like caffeic, ferulic, and p-coumaric acids were also detected, confirming findings by De Ancos et al. (2017), Cheong et al. (2012), and Ferreira et al. (2018) in orange pulp, methanolic extracts of *Citrus microcarpa* bark, and extracts from mandarin peels.

The presence of naringenin, hesperidin, narirutin, and didymin in the orange pulp aligns with De Ancos et al. (2017), with didymin unique to orange by-products, whereas narirutin and hesperidin were detected in citrus by-products derived from both oranges and lemons (Gómez-Mejía et al., 2019). Moreover, the hesperidin concentration in the analyzed orange pulp exceeded that found in two orange peel varieties, recorded at 26.81 mg/g and 20.99 mg/g, as reported by Chen et al. (2017). This hesperidin level was comparable to those in lemon peels after methanol extraction (Huang and Ho, 2010). Additionally, our findings align with hesperidin and naringin levels in C. reticulata peel (50.13–100.52 mg/g) (Liu et al., 2013). Low luteolin levels (0.08–0.21 mg/g) matched those identified by Wang et al. (2008), and the presence of rutin, quercitrin, quercetin, and epicatechin aligns with Molina-Calle et al. (2015). The examined orange pulp showed higher levels of rutin and quercetin than those found in the peels of eight citrus fruits (Wang et al., 2008). Our analysis focused on flavanone glycosides, revealing that hesperidin was the predominant compound, surpassing levels reported by Molina-Calle et al. (2015). Additionally, hesperidin and naringenin content in our study was higher than those found by De Ancos et al. (2017) in various orange pulps and juices (49-434 µg/g).

Conclusion

The chemical composition of orange waste supports various applications, with methanol and acetic acid yielding higher bioactive compound extraction than other solvents. High phenolic content and glucose adsorption capacity make it a potent source of natural antioxidants, particularly hesperidin, for food additives, enhancing shelf life and developing functional foods within a circular economy.

Abstract

This study evaluated the influence of NPK fertilizer and cow dung manure (CDM) on okra (*Abelmoschus esculentus*) yield and its components under the Sudan Savanna conditions of Nigeria. A 4 × 4 factorial experiment in a randomized complete block design with four replications was conducted at Teaching and Research farm, Bayero University, Kano. Treatments included four levels each of NPK fertilizer (0, 200, 300, and 400 kg ha^{-1}) and CDM (0, 2.5, 5.0, and 7.5 t ha^{-1}). Results indicated that NPK and CDM significantly ($P < 0.001$) influenced pod yield, with the highest yields obtained at 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM (4367.00 kg ha^{-1} in 2019 and 9148.00 kg ha^{-1} in 2020), representing a 391% and 384% increase, respectively, over the control (888.00 kg ha^{-1} in 2019 and 1889.00 kg ha^{-1} in 2020). Pod length increased significantly ($P < 0.001$) with 100–200 kg ha^{-1} NPK in 2019 but was not significantly affected in 2020, suggesting seasonal variability. CDM at 7.5 t ha^{-1} produced the highest pod count (18.47 in 2019 and 24.73 in 2020), outperforming lower rates. The findings underscore the benefits of integrated nutrient management, as the combination of NPK and CDM enhanced soil fertility, increased pod number, and improved total yield. These results confirm that organic and inorganic fertilizers complement each other in optimizing okra productivity. Thus, integrated nutrient management using 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM could be adopted by the farmers for sustainable okra production in nutrient-deficient soils of the Sudan Savanna region.

Keywords: *Fertilization strategy, okra, yield optimization, soil fertility, Sudan savanna*

Introductıon

Okra (*Abelmoschus esculentus* L. Moench) is an economically important vegetable crop widely cultivated in tropical and subtropical regions, including Nigeria. It is rich in vitamins, minerals, and antioxidants, making it an essential part of human nutrition (Ibitoye and Kolawole, 2022). However, the yield of okra in the Sudan Savanna ecology of Nigeria remains low due to poor soil fertility and inadequate nutrient management practices (Hamisu *et al.,* 2021). Integrated Nutrient Management (INM), incorporating the principles of Integrated Soil Fertility Management (ISFM), is a sustainable approach to enhancing soil health, crop productivity, and long-term agricultural viability (Pathan *et al.,* 2024). By combining organic and inorganic fertilizers, this approach optimizes nutrient availability, where organic amendments improve soil structure and microbial activity, while inorganic fertilizers provide essential nutrients for plant growth (Liu *et al.,* 2024). Additionally, Justus von Liebig's law of the minimum states that plant growth is limited by the most deficient nutrient, reinforcing the need for balanced fertilization to maximize okra yield (Bimpe *et al.,* 2023).

Despite the importance of okra in Nigeria, its yield remains suboptimal due to nutrient depletion, poor soil fertility, and over-reliance on synthetic fertilizers (Badu Brempong and Addo-Danso, 2022). Conventional fertilization methods often lead to soil degradation, nutrient imbalances, and declining crop productivity (Akter *et al*., 2020; Ayodele *et al*., 2020). Additionally, excessive use of inorganic fertilizers contributes to environmental pollution and increased production costs (Abdalla *et al*., 2024). The limited adoption of integrated nutrient management strategies in the Sudan Savanna region exacerbates the problem, necessitating research on the most effective nutrient management approach to enhance okra yield while maintaining soil health.

Previous studies indicate that INM enhances soil structure, microbial activity, and nutrient availability, leading to higher crop productivity (Yusuf *et al*., 2020; Gupta *et al.,* 2022). However, in the Sudan Savanna region, erratic rainfall, high temperatures, and nutrient-deficient soils pose significant challenges to crop production (Olowolafe and Dibal, 2019), highlighting the need to assess INM's impact on okra yield and its components to optimize nutrient management for sustainable agriculture in Nigeria. This study aims to evaluate the impact of different rates of NPK fertilizer and CDM on the yield and yield components of okra under Sudan Savanna conditions.

Materials And Methods

The trials were conducted at the Teaching and Research Farm of Bayero University, Kano (Latitude 11° 58.861'N and Longitude 08° 31.177'E, with altitude of 476m above sea level). The experimental field was properly cleared of debris ad stumps. The land was then ploughed, harrowed to fine tilt and ridged. The field was demarcated into three replicates consisting of sixteen plots of gross plot size of 3 m x 3 m (9 m^2) and a net plot of 3 m x 1.5 m (4.5 m^2) which consists of the two inner rows. A pathway of 0.5 m and 1.0 m was between plots and replication was maintained to provide ease of movement and prevent nutrient drift. The experiment was a 4 x 4 factorial combination laid out in a randomized complete block design with four replications. The treatments comprised of varied rates of NPK fertilizer (0, 200, 300, and 400 kg ha^{-1}) and cow dung manure (CDM) (0, 2.5, 5.0, and 7.5 t ha^{-1}), resulting in 16 treatment combinations.

The okra seeds variety NHB-AI-13 was sourced from the National Horticultural Research (NIHORT) substation, Bagauda, Kano state. The cow dung was sourced from the livestock unit of the department of Animal Science of Bayero University Kano while the NPK fertilizer was from the department of Agronomy, BUK. The cow dung manure was applied as a basal application by broadcasting and incorporating it into the soil two weeks prior to sowing for ease of decomposition and to allow CO_2 escape, thus preventing scorching of the tender okra seedlings. NPK fertilizer (15-15-15) was applied according to the designated rates at 2 WAS about 10 cm radius away from the plant stand using ring method. For the treatments without CDM and NPK, no manure was applied throughout the growing season.

Three to four seed s of okra (NBH-AI-13) were sown directly into the soil at a depth of 2 cm with a spacing of 30 cm x 30 cm. the seedlings were later thinned to one plant per stand at 2 WAS. The crops were managed using standard agronomic practices for okra cultivation, including weeding, and pest control. Weeding was done manually as at when due using hoe. The defoliating insect pest were managed using Lampda (Cyhalothrin 2.5 EC) a contact insecticide applied at 2 L ha^{-1} using Cp3 knapsack sprayer set at a pressure of 2.1 kg m^{-2}.

Data were collected using standard agronomic procedure on the following yield component and yield of okra: Number of pods per plant, Individual pod weight, pod length, pod diameter and total pod yield (kg ha^{-1}). All data collected was subjected to analysis of variance (ANOVA) using SAS (Version 9.1) and significant means were separated using Duncan Multiple Range Test (DMRT) at 5% probability level.

Results And Dıscussıon

Effects of NPK Fertilizers and Cow dung manure on pods count per plant and pod weight per plant

Table 1 presents the effect of NPK fertilizer and cow dung manure (CDM) on the pods count per plant and individual pod weight of okra during the 2019 and 2020 wet seasons. The results show that while both inputs significantly ($P < 0.001$) influenced pod number, they had no significant ($P > 0.05$) effect on individual pod weight. Higher pods count were recorded with NPK application (100-300 kg ha^{-1}), whereas the control resulted in the lowest values across both seasons. Similarly, CDM at 7.5 t ha^{-1} produced the highest pod count, followed by 5.0 t ha^{-1}, outperforming lower rates in both years. The effectiveness of high-rate NPK in enhancing pods count highlights its role in promoting reproductive growth, while CDM's success at 7.5 t ha^{-1} suggests that organic fertilization is a viable alternative to synthetic fertilizers for increasing okra yield. This underscores the importance of balanced nutrient management, particularly in nutrient-deficient soils. These findings align with Muhammad and Sanda (2019), who reported that applying 800 kg ha^{-1} of NPK or a 50:50 combination of NPK and poultry manure significantly increased the number of pods per plant and overall yield. Similarly, Adekiya *et al*. (2020) found that poultry manure application improved okra pod production in comparison to sole NPK fertilizer.

The interaction between NPK and CDM on the pods count per plant was significant across both seasons, as shown in Table 2. The combined application of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM produced the highest pods count per plant in 2019 (18.47) and 2020 (24.73), outperforming other treatment combinations. This suggests that integrating organic and inorganic fertilizers creates a more balanced nutrient supply, enhancing pod formation and overall productivity. These findings align with those of Meena (2024), who reported that combining organic and inorganic fertilizers improved fruit set and pod production in okra. Similarly, Karim *et al.* (2024) found that integrating mineral fertilizers with organic amendments significantly enhanced crop yield by improving soil nutrient availability and plant growth. These results reinforce the benefits of integrated nutrient management in optimizing okra production through improved soil fertility and plant performance.

Effects of NPK Fertilizers and Cow dung manure on Pod length, Pod diameter, and Total pod yield per hectare.

The effects of NPK and CDM rates on pod length, pod diameter, and total pod yield of okra in the 2019 and 2020 seasons are presented in Table 3. Results show that applying 100 and 200 kg/ha NPK significantly ($P < 0.001$) increased pod length in 2019 but had no significant ($P > 0.05$) effect in 2020, suggesting seasonal variability in nutrient response. Similarly, pod diameter was not significantly affected in either season, indicating that factors such as genetics, soil conditions, and environmental variables may play a more dominant role than nutrient application alone. However, the significant increase in total pod yield (3011.14 & 3011.14 kg ha^{-1}) with 200 kg ha^{-1} NPK application across both seasons highlights the importance of adequate nutrient supply in enhancing

productivity. This suggests that while pod size may not be directly influenced, optimizing NPK application can significantly boost total yield, making it essential for maximizing okra production. These findings align with Esmond *et al*. (2023), who reported a significant increase in okra pod weight and yield with higher NPK rates, while Sabo and Zubairu (2021) and Sababa *et al.* (2024), who found that optimal NPK and NPS fertilizer rates improved pod length and yield, reinforcing the role of proper nutrient management in enhancing okra productivity, respectively.

On the other hand, CDM application had no significant ($P > 0.05$) effect on pod length across both seasons or pod diameter in 2019 but significantly increased pod thickness compared to the control in 2020, indicating improved pod quality. Additionally, the significant rise in pod yield with CDM application underscores its role in enhancing productivity. The highest yield recorded with 7.5 t ha^{-1} CDM in both seasons (3066.10 kg ha^{-1} in 2019 and 955.17 kg ha^{-1} in 2020) suggests this rate provides optimal nutrient availability for okra growth. However, seasonal yield variations indicate possible environmental influences on nutrient efficiency. These findings highlight the benefits of organic fertilization in improving okra yield and pod quality, positioning CDM as a viable alternative or supplement to synthetic fertilizers for sustainable production. This study aligns with Kamunyu *et al*. (2023), who found that applying 5-7 t ha^{-1} of poultry, cattle, or goat manure significantly increased okra yield and pod quality by enhancing soil nutrients and microbial activity. Similarly, Olowokere *et al.* (2021) reported that composted cow dung at 10-30 t/ha improved pod thickness, length, and overall yield, reinforcing the role of organic amendments in sustainable okra production.

The interaction between NPK and CDM on total pod yield was highly significant ($P < 0.001$), as shown in Table 4, where the combined application of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM resulted in the highest yields (4367.00 kg ha^{-1} in 2019 and 9148.00 kg ha^{-1} in 2020). This suggests that integrating organic and inorganic fertilizers provides a balanced and efficient nutrient supply, enhancing crop productivity. In contrast, the lowest yields recorded with the 0 × 0 combination (888.00 kg ha^{-1} in 2019 and 1889.00 kg ha^{-1} in 2020) highlight the detrimental impact of nutrient deficiency on okra production. The variation in yield between seasons also indicates potential environmental influences on nutrient uptake and efficiency. These findings align with Akinmutimi *et al.* (2023), who reported that combining poultry manure and NPK fertilizer significantly improved okra growth and yield compared to sole applications or control treatments. Similarly, Adekiya *et al*. (2020) and Mondai *et al*. (2022) in their separate studies found that organic manure sources outperformed NPK fertilizer in enhancing soil properties and okra productivity, reinforcing the importance of integrating organic and inorganic fertilizers. This confirms that the synergistic use of organic and synthetic fertilizers optimizes nutrient availability, leading to higher okra yields and sustainable agricultural production.

Conclusıon And Recommendatıon

This study demonstrated that the combined application of NPK fertilizer and cow dung manure significantly improves okra yield and yield components. The highest pod yield was obtained with the interaction of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM, highlighting the effectiveness of integrated nutrient management. While pod size showed seasonal variability, pod yield consistently increased with appropriate fertilization. The results suggest that balanced nutrient supply from organic and inorganic fertilizers enhances soil fertility and maximizes crop productivity. The findings emphasize the need for sustainable soil fertility management to ensure long-term agricultural productivity in the Sudan Savanna region of Nigeria. Therefore, to maximize okra yield, farmers in the study region should adopt integrated nutrient management by applying 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM.

Abstract

This study evaluated the influence of NPK fertilizer and cow dung manure (CDM) on okra (*Abelmoschus esculentus*) yield and its components under the Sudan Savanna conditions of Nigeria. A 4 × 4 factorial experiment in a randomized complete block design with four replications was conducted at Teaching and Research farm, Bayero University, Kano. Treatments included four levels each of NPK fertilizer (0, 200, 300, and 400 kg ha^{-1}) and CDM (0, 2.5, 5.0, and 7.5 t ha^{-1}). Results indicated that NPK and CDM significantly ($P < 0.001$) influenced pod yield, with the highest yields obtained at 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM (4367.00 kg ha^{-1} in 2019 and 9148.00 kg ha^{-1} in 2020), representing a 391% and 384% increase, respectively, over the control (888.00 kg ha^{-1} in 2019 and 1889.00 kg ha^{-1} in 2020). Pod length increased significantly ($P < 0.001$) with 100–200 kg ha^{-1} NPK in 2019 but was not significantly affected in 2020, suggesting seasonal variability. CDM at 7.5 t ha^{-1} produced the highest pod count (18.47 in 2019 and 24.73 in 2020), outperforming lower rates. The findings underscore the benefits of integrated nutrient management, as the combination of NPK and CDM enhanced soil fertility, increased pod number, and improved total yield. These results confirm that organic and inorganic fertilizers complement each other in optimizing okra productivity. Thus, integrated nutrient management using 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM could be adopted by the farmers for sustainable okra production in nutrient-deficient soils of the Sudan Savanna region.

Keywords: *Fertilization strategy, okra, yield optimization, soil fertility, Sudan savanna*

Introductıon

Okra (*Abelmoschus esculentus* L. Moench) is an economically important vegetable crop widely cultivated in tropical and subtropical regions, including Nigeria. It is rich in vitamins, minerals, and antioxidants, making it an essential part of human nutrition (Ibitoye and Kolawole, 2022). However, the yield of okra in the Sudan Savanna ecology of Nigeria remains low due to poor soil fertility and inadequate nutrient management practices (Hamisu *et al.,* 2021). Integrated Nutrient Management (INM), incorporating the principles of Integrated Soil Fertility Management (ISFM), is a sustainable approach to enhancing soil health, crop productivity, and long-term agricultural viability (Pathan *et al.,* 2024). By combining organic and inorganic fertilizers, this approach optimizes nutrient availability, where organic amendments improve soil structure and microbial activity, while inorganic fertilizers provide essential nutrients for plant growth (Liu *et al.,* 2024). Additionally, Justus von Liebig's law of the minimum states that plant growth is limited by the most deficient nutrient, reinforcing the need for balanced fertilization to maximize okra yield (Bimpe *et al.,* 2023).

Despite the importance of okra in Nigeria, its yield remains suboptimal due to nutrient depletion, poor soil fertility, and over-reliance on synthetic fertilizers (Badu Brempong and Addo-Danso, 2022). Conventional fertilization methods often lead to soil degradation, nutrient imbalances, and declining crop productivity (Akter *et al*., 2020; Ayodele *et al*., 2020). Additionally, excessive use of inorganic fertilizers contributes to environmental pollution and increased production costs (Abdalla *et al*., 2024). The limited adoption of integrated nutrient management strategies in the Sudan Savanna region exacerbates the problem, necessitating research on the most effective nutrient management approach to enhance okra yield while maintaining soil health.

Previous studies indicate that INM enhances soil structure, microbial activity, and nutrient availability, leading to higher crop productivity (Yusuf *et al*., 2020; Gupta *et al.,* 2022). However, in the Sudan Savanna region, erratic rainfall, high temperatures, and nutrient-deficient soils pose significant challenges to crop production (Olowolafe and Dibal, 2019), highlighting the need to assess INM's impact on okra yield and its components to optimize nutrient management for sustainable agriculture in Nigeria. This study aims to evaluate the impact of different rates of NPK fertilizer and CDM on the yield and yield components of okra under Sudan Savanna conditions.

Materials And Methods

The trials were conducted at the Teaching and Research Farm of Bayero University, Kano (Latitude 11° 58.861'N and Longitude 08° 31.177'E, with altitude of 476m above sea level). The experimental field was properly cleared of debris ad stumps. The land was then ploughed, harrowed to fine tilt and ridged. The field was demarcated into three replicates consisting of sixteen plots of gross plot size of 3 m x 3 m (9 m^2) and a net plot of 3 m x 1.5 m (4.5 m^2) which consists of the two inner rows. A pathway of 0.5 m and 1.0 m was between plots and replication was maintained to provide ease of movement and prevent nutrient drift. The experiment was a 4 x 4 factorial combination laid out in a randomized complete block design with four replications. The treatments comprised of varied rates of NPK fertilizer (0, 200, 300, and 400 kg ha^{-1}) and cow dung manure (CDM) (0, 2.5, 5.0, and 7.5 t ha^{-1}), resulting in 16 treatment combinations.

The okra seeds variety NHB-AI-13 was sourced from the National Horticultural Research (NIHORT) substation, Bagauda, Kano state. The cow dung was sourced from the livestock unit of the department of Animal Science of Bayero University Kano while the NPK fertilizer was from the department of Agronomy, BUK. The cow dung manure was applied as a basal application by broadcasting and incorporating it into the soil two weeks prior to sowing for ease of decomposition and to allow CO_2 escape, thus preventing scorching of the tender okra seedlings. NPK fertilizer (15-15-15) was applied according to the designated rates at 2 WAS about 10 cm radius away from the plant stand using ring method. For the treatments without CDM and NPK, no manure was applied throughout the growing season.

Three to four seed s of okra (NBH-AI-13) were sown directly into the soil at a depth of 2 cm with a spacing of 30 cm x 30 cm. the seedlings were later thinned to one plant per stand at 2 WAS. The crops were managed using standard agronomic practices for okra cultivation, including weeding, and pest control. Weeding was done manually as at when due using hoe. The defoliating insect pest were managed using Lampda (Cyhalothrin 2.5 EC) a contact insecticide applied at 2 L ha^{-1} using Cp3 knapsack sprayer set at a pressure of 2.1 kg m^{-2}.
Data were collected using standard agronomic procedure on the following yield component and yield of okra: Number of pods per plant, Individual pod weight, pod length, pod diameter and total pod yield (kg ha^{-1}). All data collected was subjected to analysis of variance (ANOVA) using SAS (Version 9.1) and significant means were separated using Duncan Multiple Range Test (DMRT) at 5% probability level.

Results And Dıscussıon

Effects of NPK Fertilizers and Cow dung manure on pods count per plant and pod weight per plant
Table 1 presents the effect of NPK fertilizer and cow dung manure (CDM) on the pods count per plant and individual pod weight of okra during the 2019 and 2020 wet seasons. The results show that while both inputs significantly ($P < 0.001$) influenced pod number, they had no significant ($P > 0.05$) effect on individual pod weight. Higher pods count were recorded with NPK application (100-300 kg ha^{-1}), whereas the control resulted in the lowest values across both seasons. Similarly, CDM at 7.5 t ha^{-1} produced the highest pod count, followed by 5.0 t ha^{-1}, outperforming lower rates in both years. The effectiveness of high-rate NPK in enhancing pods count highlights its role in promoting reproductive growth, while CDM's success at 7.5 t ha^{-1} suggests that organic fertilization is a viable alternative to synthetic fertilizers for increasing okra yield. This underscores the importance of balanced nutrient management, particularly in nutrient-deficient soils. These findings align with Muhammad and Sanda (2019), who reported that applying 800 kg ha^{-1} of NPK or a 50:50 combination of NPK and poultry manure significantly increased the number of pods per plant and overall yield. Similarly, Adekiya *et al*. (2020) found that poultry manure application improved okra pod production in comparison to sole NPK fertilizer.

The interaction between NPK and CDM on the pods count per plant was significant across both seasons, as shown in Table 2. The combined application of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM produced the highest pods count per plant in 2019 (18.47) and 2020 (24.73), outperforming other treatment combinations. This suggests that integrating organic and inorganic fertilizers creates a more balanced nutrient supply, enhancing pod formation and overall productivity. These findings align with those of Meena (2024), who reported that combining organic and inorganic fertilizers improved fruit set and pod production in okra. Similarly, Karim *et al.* (2024) found that integrating mineral fertilizers with organic amendments significantly enhanced crop yield by improving soil nutrient availability and plant growth. These results reinforce the benefits of integrated nutrient management in optimizing okra production through improved soil fertility and plant performance.

Effects of NPK Fertilizers and Cow dung manure on Pod length, Pod diameter, and Total pod yield per hectare. The effects of NPK and CDM rates on pod length, pod diameter, and total pod yield of okra in the 2019 and 2020 seasons are presented in Table 3. Results show that applying 100 and 200 kg/ha NPK significantly ($P < 0.001$) increased pod length in 2019 but had no significant ($P > 0.05$) effect in 2020, suggesting seasonal variability in nutrient response. Similarly, pod diameter was not significantly affected in either season, indicating that factors such as genetics, soil conditions, and environmental variables may play a more dominant role than nutrient application alone. However, the significant increase in total pod yield (3011.14 & 3011.14 kg ha^{-1}) with 200 kg ha^{-1} NPK application across both seasons highlights the importance of adequate nutrient supply in enhancing productivity. This suggests that while pod size may not be directly influenced, optimizing NPK application can significantly boost total yield, making it essential for maximizing okra production. These findings align with Esmond *et al*. (2023), who reported a significant increase in okra pod weight and yield with higher NPK rates, while Sabo and Zubairu (2021) and Sababa *et al.* (2024), who found that optimal NPK and NPS fertilizer rates

improved pod length and yield, reinforcing the role of proper nutrient management in enhancing okra productivity, respectively.

On the other hand, CDM application had no significant ($P > 0.05$) effect on pod length across both seasons or pod diameter in 2019 but significantly increased pod thickness compared to the control in 2020, indicating improved pod quality. Additionally, the significant rise in pod yield with CDM application underscores its role in enhancing productivity. The highest yield recorded with 7.5 t ha^{-1} CDM in both seasons (3066.10 kg ha^{-1} in 2019 and 955.17 kg ha^{-1} in 2020) suggests this rate provides optimal nutrient availability for okra growth. However, seasonal yield variations indicate possible environmental influences on nutrient efficiency. These findings highlight the benefits of organic fertilization in improving okra yield and pod quality, positioning CDM as a viable alternative or supplement to synthetic fertilizers for sustainable production. This study aligns with Kamunyu *et al*. (2023), who found that applying 5-7 t ha^{-1} of poultry, cattle, or goat manure significantly increased okra yield and pod quality by enhancing soil nutrients and microbial activity. Similarly, Olowokere *et al.* (2021) reported that composted cow dung at 10-30 t/ha improved pod thickness, length, and overall yield, reinforcing the role of organic amendments in sustainable okra production.

The interaction between NPK and CDM on total pod yield was highly significant ($P < 0.001$), as shown in Table 4, where the combined application of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM resulted in the highest yields (4367.00 kg ha^{-1} in 2019 and 9148.00 kg ha^{-1} in 2020). This suggests that integrating organic and inorganic fertilizers provides a balanced and efficient nutrient supply, enhancing crop productivity. In contrast, the lowest yields recorded with the 0 × 0 combination (888.00 kg ha^{-1} in 2019 and 1889.00 kg ha^{-1} in 2020) highlight the detrimental impact of nutrient deficiency on okra production. The variation in yield between seasons also indicates potential environmental influences on nutrient uptake and efficiency. These findings align with Akinmutimi *et al.* (2023), who reported that combining poultry manure and NPK fertilizer significantly improved okra growth and yield compared to sole applications or control treatments. Similarly, Adekiya *et al*. (2020) and Mondai *et al*. (2022) in their separate studies found that organic manure sources outperformed NPK fertilizer in enhancing soil properties and okra productivity, reinforcing the importance of integrating organic and inorganic fertilizers. This confirms that the synergistic use of organic and synthetic fertilizers optimizes nutrient availability, leading to higher okra yields and sustainable agricultural production.

Conclusıon And Recommendatıon

This study demonstrated that the combined application of NPK fertilizer and cow dung manure significantly improves okra yield and yield components. The highest pod yield was obtained with the interaction of 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM, highlighting the effectiveness of integrated nutrient management. While pod size showed seasonal variability, pod yield consistently increased with appropriate fertilization. The results suggest that balanced nutrient supply from organic and inorganic fertilizers enhances soil fertility and maximizes crop productivity. The findings emphasize the need for sustainable soil fertility management to ensure long-term agricultural productivity in the Sudan Savanna region of Nigeria. Therefore, to maximize okra yield, farmers in the study region should adopt integrated nutrient management by applying 200 kg ha^{-1} NPK and 7.5 t ha^{-1} CDM.

Abstract

Adoption of sustainable agriculture through agroforestry systems presents a viable solution to address declining soil fertility, land degradation, and food insecurity in Bangladesh. This review focuses on intensive agroforestry systems characterized by high density, multispecies cropping and their potential to improve crop yield, restore soil health, and enhance ecosystem services. Agroforestry practices such as homestead gardening, multi-storey cropping, orchard based systems, and boundary plantations contribute to nutrient cycling, biodiversity conservation, and climate resilience. However, widespread use of chemical fertilizers continues to degrade soil quality and diminish productivity. Integrating organic and bio fertilizers within an integrated nutrient management (INM) framework offers a sustainable alternative that improves soil structure, increases nutrient availability, and supports long term agricultural productivity. The review also emphasizes the importance of policy interventions to promote balanced fertilizer use, incentivize sustainable practices, and enhance extension services. Furthermore, regionally informed strategies and insights from global models can guide the effective adoption of agroforestry in Bangladesh. This review highlights intensive agroforestry and diversified fertilizer management as practical pathways to achieving sustainable food production, ecological balance, and rural livelihood improvement.

Keywords: *Agroforestry, Intensive Cropping, Fertilizer Types, Food Production, Soil Health*

Introduction

The current global food crisis highlights the urgent need for sustainable development strategies that enhance food production and ensure food security particularly in densely populated countries like Bangladesh (Talucder et al., 2024). Rising demand for food, however, has accelerated soil degradation and environmental decline, posing significant threats to long term agricultural productivity (Ray & Ray, 2011). Bangladesh, with a population exceeding 165 million and a land area of only 147,570 km², has among the world's lowest per capita availability of arable (0.06 ha) and forest land (0.02 ha) (Hasan et al., 2013; BBS, 2019). Furthermore, 21.8% of the population lives in poverty, with over 87% of the poor residing in rural areas where livelihoods are heavily reliant on tree and cropbased farming systems (Islam et al., 2015). Land degradation presents a major threat to sustainable food systems. Each year, more than 23,000 hectares of cultivable land are lost to infrastructure expansion, urban sprawl, and rural settlement growth extremely affecting smallholder farmers and intensifying pressure on remaining agricultural land (Hasan et al., 2013). Between 1989 and 2020, the share of arable land fell from 73.4% to 61.5% (Ahsan et al., 2023), and projections suggest that rapid urbanization and industrial growth could result in an annual loss of approximately 69,000 hectares of farmland (Khan, 2023). These trends exacerbate land scarcity and threaten Bangladesh's capacity to meet the growing demand for food and nutrition.

Soil, a finite and non-renewable resource crucial to food production, is increasingly being depleted due to unsustainable land management practices. Healthy soils are essential for poverty alleviation and food security, as they enhance crop yields and reduce vulnerability to pests and diseases (FAO, 2017; Hou et al., 2020). Over the past five decades, global food production has declined by 11.9–13.4% due to soil degradation (Jie et al., 2002). In South Asia, including Bangladesh, soil degradation is particularly severe 140 million hectares of land are impacted by groundwater depletion, erosion, waterlogging, and nutrient loss (Jahan & Gurung, 2017), resulting in an estimated annual GDP loss of 2% (USD 10 billion) due to land degradation (Niino, 2011). The situation is especially dire in south eastern Bangladesh, where land degradation is compounded by steep topography (Chowdhury et al., 2023). However, the Green Revolution initially boosted yields through high yield crop varieties, intensive tillage, and chemical inputs, these practices have also led to long term soil fatigue and nutrient depletion.

Continuous monoculture and input intensive methods have rendered 74.2% of Bangladesh's soils deficient in key nutrients, undermining productivity and climate resilience (Sharna et al., 2022; Barbier & Hochard, 2018).
Agroforestry integrating trees with crops and/or livestock on the same land unit offers a promising and sustainable alternative. It has been recognized for enhancing livelihoods, improving climate resilience, and supporting food and nutritional security (Islam et al., 2013). Research by Allen et al. (2004) and Mukhlis et al. (2022) has shown that agroforestry can rehabilitate degraded land and enhance ecosystem services by improving the physical, chemical, and biological properties of soil through mechanisms such as litter deposition and root activity. Nevertheless, much of the existing research focuses primarily on biophysical outcomes, with limited attention to the socioeconomic dimensions of agroforestry particularly within the Bangladeshi context (Atangana et al., 2013). Recently, orchard based systems particularly in districts like Dinajpur have gained popularity due to their economic returns and potential to enhance soil health. However, many of these orchards lack integrated management practices, such as intensive understory cropping, that could maximize land use efficiency. Sustainable orchard management through multispecies understory cropping and improved nutrient practices could significantly enhance productivity, stabilize income, and rehabilitate soil health for smallholder farmers.
This review aims to fill the knowledge gap surrounding sustainable, orchard based agroforestry systems in north western Bangladesh. Specifically, it evaluates the potential of intensive understory cropping to improve soil health, examines current fertilizer management practices, and proposes sustainable strategies to enhance productivity within agroforestry frameworks. Addressing these factors is essential for improving the long term sustainability of agroforestry, ensuring food security, promoting ecological restoration, and supporting resilient rural livelihoods.

Food Production Patterns in Bangladesh

Bangladesh's fertile soils and favourable agro climatic conditions support the production of over 70 million tonnes of agricultural output annually, with more than 70% of the country's land area devoted to agricultural use (BIDA, 2021). The primary crops cultivated include rice, jute, wheat, potatoes, fruits, vegetables, legumes, and oilseeds. Among these, rice is the most dominant, occupying approximately 71% of the total cultivated land and contributing 59% to the overall crop value. Potatoes follow as the second most valuable crop, accounting for 9.5% of total crop value (Barois et al., 2024). Moreover, in the livestock and aquaculture sectors, fish and crayfish dominate animal production, comprising 73% of total output, with aquaculture alone contributing 68% of fish production. Goat farming ranks second in meat production value at around 6% (FAO, 2023a). The agriculture sector including crops, fisheries, and forestry employs approximately 40.6% of the labor force aged 15 and older. Smallholder farmers represent the backbone of the agricultural economy, with about 12 million farms supporting 60 million people and producing roughly 60% of the nation's food. The average farm size is just 0.24 hectares, and most households engage in integrated farming systems that combine rice cultivation with one to two additional crops and livestock rearing (Barois et al., 2024).

Status of Food Security in Bangladesh
Bangladesh has made measurable progress in food and nutrition security over recent years. The prevalence of moderate and severe food insecurity declined slightly from an average of 32.2% during 2014–2016 to 31% in 2020–2022, even as food insecurity increased significantly across South Asia, rising from 27.6% to 41.3% during the same period (Barois et al., 2024). Despite this progress, the country remains heavily reliant on food imports to meet the nutritional needs of its growing population. As of 2015, food imports constituted approximately 17% of total merchandise imports, whereas food exports accounted for just 3%, underscoring a considerable trade imbalance (World Bank, 2015). This reliance on traditional, subsistence based agriculture limits opportunities for commercialisation and poses risks to long term food sovereignty. These challenges highlight the urgent need for sustainable, resource efficient agricultural practices that can reduce import dependence and bolster national food security.

Soil Fertility and Soil Health Status in Bangladesh
To sustain crop productivity, farmers in Bangladesh have increasingly depended on chemical fertilisers urea alone accounting for approximately 75% of total fertiliser use (Shil et al., 2016). However, this intensive use of synthetic inputs has contributed to declining soil quality. Organic matter levels in most agricultural soils remain critically low, with values below the recommended 1.5%, and saw a 5–36% decline between 1967 and 1995. Furthermore, recent assessments indicate that nearly 47% of farmers misuse fertilisers, which not only compromises soil health but also poses environmental and human health risks (Barois et al., 2024).Therefore, soil fertility remains poor across much of the country, with the exception of a few Agro Ecological Zones (AEZs 10, 12, 13, and parts of 11), which exhibit comparatively better conditions. This widespread degradation necessitates immediate and strategic intervention. Promoting sustainable land management practices such as the use of organic and biofertilisers, crop rotation, and ecologically integrated approaches like intensive agroforestry can help restore soil

fertility, enhance soil structure, and reduce dependence on synthetic inputs. Strengthening farmer awareness, along with institutional and policy support, will be essential for ensuring long term soil health and agricultural sustainability (Barois et al., 2024).

Contributions of Agroforestry Practices to Soil Health Improvement

Agroforestry has emerged as a vital land use strategy in many developing countries, including Bangladesh, offering smallholder farmers a means to enhance ecological resilience, farm productivity, and biodiversity. By integrating trees with crops, agroforestry systems play a critical role in preventing soil degradation while simultaneously boosting agricultural yields. These systems enrich soil organic matter, increase soil carbon content, and improve the availability and cycling of key nutrients such as nitrogen (N), phosphorus (P), and potassium (K) (Islam et al., 2024). As such, agroforestry offers a promising and sustainable pathway for restoring soil fertility and supporting broader environmental conservation efforts.

Traditional or extensive agroforestry systems have long been practiced across diverse ecological zones in Bangladesh. As noted by Nair (1990), these systems are well adapted to the rural livelihood needs and local environmental conditions of the country. Practices such as homestead gardening, boundary planting, alley cropping, and silvopasture have developed organically, shaped by local variations in soil type, rainfall, topography, and socioeconomic context. According to Islam et al. (2024), these low input systems provide multiple ecosystem services, including food, fodder, fuelwood, and timber, while enhancing climate resilience and conserving natural resources at the community level. In contrast, intensive agroforestry systems are designed to optimise land productivity by employing multistory canopy structures and increasing both tree and crop density. These systems often incorporate fast growing, multifunctional species such as *Grevillea robusta* and are structured to promote vertical layering, year round output, and ecological synergy (Keerthika et al., 2024). Unlike traditional systems that emphasize subsistence and minimal management, intensive agroforestry is driven by goals of yield maximisation, ecological sustainability, and revenue diversification, often employing precision agriculture and "smart" farming techniques (Leakey, 1999). This approach is particularly relevant for land scarce countries like Bangladesh, where efficient land use is paramount.

Despite its advantages, the adoption of intensive agroforestry remains limited in Bangladesh, particularly concerning its long term impact on soil health under the country's subtropical monsoon climate. However, ecosystem services such as enhanced biodiversity, regulated soil moisture, and biomass recycling suggest that even low input intensive systems can deliver significant environmental benefits. Expanding research and field implementation of these systems could unlock their full potential in sustainable land management and agricultural productivity enhancement.

Table 1: Key differences between traditional and intensive agroforestry systems

Futures	**Traditional Agroforestry systems**	**Intensive agroforestry systems**
Input level	Low to moderate	High
Purpose	Farmer food security, income and ecological balance	Industrial production such as tea and cocoa
Management	Traditional	Precision or smart practice
Scale	subsistence	Commercial
Output	Moderately diversified	Highly diversified
Examples	Homestead, cropland, silvopasture, alley cropping etc.	Fodder bank, tea garden, bioenergy, timber, food chain processing etc.

Trends and Challenges of Agroforestry in Bangladesh

Agroforestry has deep historical roots in rural Bangladesh, particularly within smallholder and homestead systems. Traditionally, these practices have supported household food security, biodiversity conservation, and cultural continuity while providing essential resources such as fuel, timber, and supplementary income (Ahsan & Begum, 2023). Common forms such as boundary planting and scattered tree cultivation within croplands continue to enhance local climate resilience and diversify livelihoods (Hanif et al., 2018). Studies on agroforestry have received growing attention from the government and development partners as a viable strategy to meet socioeconomic and environmental objectives. Nevertheless, most institutional efforts and policy initiatives have focused on promoting conventional agroforestry models, with limited emphasis on research, extension, or promotion of intensive approaches. Although there is considerable potential for diverse, site specific systems across agroecological zones including the Chittagong Hill Tracts, floodplains, and coastal regions systematic

adoption of high density, intercropped agroforestry remains limited (Bari et al., 2024). Several structural challenges constrain the widespread adoption of intensive agroforestry in Bangladesh. These include the absence of integrated policy frameworks and scientific validation tailored to the complex, multispecies nature of such systems. Extension services are often inadequate, limiting farmers' access to high quality planting materials, technical support, and training. Furthermore, weak market linkages, poor knowledge dissemination mechanisms, and insufficient farmer engagement hinder the replication of successful models. A critical gap also persists in interdisciplinary research that integrates ecological, agronomic, and socioeconomic dimensions particularly studies involving long term soil monitoring. Addressing these gaps is essential for advancing a nuanced understanding of how intensive agroforestry systems affect soil fertility, resource use efficiency, and rural livelihoods, thereby enabling the development of scalable and sustainable land use strategies.

Role of Intensive Agroforestry Systems in Food Security and Sustainability

Intensive agroforestry systems significantly contribute to food security and sustainable agriculture by promoting dynamic interactions among crops, trees, and soil organisms. As Bhaduri et al. (2017) note, these interactions enhance biological, chemical, and physical soil processes, leading to increased agricultural productivity and improved soil health. Trees incorporated into farmland contribute organic matter through leaf litter and root biomass, stimulating soil organic carbon (SOC) accumulation. Higher SOC levels, in turn, improve microbial activity, enhance soil structure, and increase water holding capacity all vital attributes for long term agricultural sustainability. One of the hallmark features of agroforestry is the use of nitrogen fixing leguminous tree species, which naturally enrich the soil and reduce dependence on synthetic fertilisers (Sileshi et al., 2014). Additionally, the deep rooted nature of many agroforestry species facilitates a process known as “nutrient pumping,” whereby nutrients are absorbed from subsoil layers and redistributed to the surface through litter fall and root turnover (Garrity & Lefroy, 1994). This nutrient recycling enhances topsoil fertility and promotes higher crop yields over time.

Agroforestry also confers significant physical protection to the soil. Tree canopies reduce the erosive impact of rainfall, while their extensive root systems help stabilise soil, thereby mitigating erosion an especially critical service in Bangladesh’s flood and cyclone prone regions (Zuazo & Pleguezuelo, 2009). Furthermore, shaded microclimates created by tree cover help moderate soil temperature, retain moisture, and foster beneficial microbial communities such as mycorrhizal fungi, which facilitate nutrient mineralisation and suppress soil pathogens (Sileshi et al., 2014). This intensive system indicate that root density and biomass turnover are high thereby improve the ecological functions significantly. The synergy between woody perennials and annual crops not only rejuvenates degraded soils and reduces chemical input requirements but also builds resilient agroecosystems. In the context of Bangladesh, such systems represent a vital pathway for enhancing food security, improving soil sustainability, and supporting climate adaptation.

Table 2: Comparative impact of cropping systems on key sustainability parameters

Parameters	**Mono cropping**	**Traditional Agroforestry**	**Intensive Agroforestry**
Soil fertility	Decline over time	Regulators	Significantly improves
Carbon sequestration	Minimal(0.51 t c/ha/yr)	Moderate (2.4 t c/ha/yr)	High (48 t C/ha/yr)
Biodiversity conservation	Very low	Medium	High
Climate resilience	Poor (vulnerable)	Moderate	High
Water retention	Low	Moderate	High
Overall Sustainability	Low	Medium to high	Very high

Yield Productivity Index under Different Cropping Systems

The comparative analysis of yield productivity indices across cropping systems reveals distinct differences in agricultural efficiency and sustainability. Among the systems, monocropping consistently demonstrates the lowest productivity index. This underperformance is primarily due to its inherent limitations dependence on a single crop species per season leads to rapid nutrient depletion, increased vulnerability to pest infestations, and accelerated soil degradation. Such systems also lack ecological redundancy, making them highly susceptible to climatic and market shocks. Traditional agroforestry systems show marginal improvements in productivity over monocropping. These systems involve limited integration of trees with crops, contributing to modest gains in soil health, biodiversity, and microclimate regulation. However, their productivity remains suboptimal due to low species diversity, inadequate spatial design, and limited management intensity. While they provide subsistence benefits and ecological services, their potential to enhance output is constrained by their extensive, low input nature. Comparatively, intensive agroforestry systems achieve the highest yield productivity index. These systems strategically combine high density, multispecies planting arrangements that utilise vertical stratification and

complementarity among species to maximise land use efficiency. Through mechanisms such as nutrient cycling, nitrogen fixation, and organic matter enrichment, intensive agroforestry significantly enhances soil fertility and resilience. It also supports year round production and greater economic returns through diversified outputs, including food, fodder, timber, and biomass. The superiority of intensive agroforestry in yield productivity underscores its potential as a climate adaptive, resource efficient, and sustainable agricultural model. This is particularly relevant for densely populated, resource constrained regions such as Bangladesh, where land scarcity, soil degradation, and food insecurity are persistent challenges. By integrating ecological principles with modern agronomic practices, intensive agroforestry can play a transformative role in ensuring long term productivity and rural livelihood resilience.

Food Production Potential under Different Cropping Systems

Intensive agroforestry systems have demonstrated significant potential for enhancing food production in Bangladesh, particularly among smallholder farmers operating on limited land resources. By integrating multiple crop species with perennial trees in spatially and temporally optimized arrangements, these systems consistently outperform conventional monoculture practices in terms of productivity per unit area (Rahman et al., 2015). Strategic pairings such as banana with vegetables or mango with pulses enable efficient vertical stratification and staggered harvesting cycles, thereby ensuring dietary diversity and more effective land use (Awasthi, 2018).

The synergistic relationships between trees and crops in intensive agroforestry systems result in higher aggregate caloric and protein yields compared to monocropping or traditional agroforestry (Mulugeta, 2014). These systems offer a year round food supply, mitigate seasonal food shortages, and enhance resilience to climate induced stresses such as droughts and floods. Moreover, the incorporation of fruit bearing and nitrogen fixing leguminous trees contributes to improved household nutrition while also generating supplementary income through the sale of marketable produce. Economic evaluations indicate that intensive agroforestry can deliver greater long term returns on investment than conventional cropping systems, despite moderately higher initial establishment costs (Van et al., 2016). Benefits such as enhanced soil fertility, reduced dependency on synthetic fertilisers, diversified income streams, and climate adaptability collectively contribute to the economic viability and sustainability of these systems. Their effectiveness is particularly evident in ecologically sensitive regions such as the coastal belts and the Chittagong Hill Tracts where they contribute to landscape rehabilitation and sustainable livelihoods (Saha et al., 2022).

The integration of sustainable management techniques including mulching, composting, and integrated pest management (IPM) further amplifies the productivity and ecological value of intensive agroforestry. These practices thrive in diverse cropping environments, reinforcing system resilience while reducing input costs and environmental risks. In the context of Bangladesh's land constraints and environmental challenges, intensive agroforestry presents a scalable and sustainable **model** for food security, soil restoration, and agricultural intensification.

Table 3: Food Production Potential under Different Cropping Systems

System type	Production output	Source
Mono cropping	Single crop	Islam et al 2021
Traditional Agroforestry	Tree, crops, fruits, fuel wood	Rasul and Thapa, 2006
Intensive agroforestry	Homestead Gardening, Integrated Mangrove Aquaculture	Ahmed et al 2018

Conceptual Framework of Intensive Agroforestry Systems

Agroforestry is increasingly recognised as a sustainable land use approach that synergistically integrates trees and shrubs with crops and/or livestock to form ecologically resilient and economically productive landscapes (Dahal et al., 2025; Tennakoon & Tharindi, 2025). These multifunctional systems promote biodiversity, enhance soil fertility, support water conservation, and strengthen climate resilience attributes that are particularly valuable in regions vulnerable to environmental degradation and food insecurity. Agroforestry systems display considerable structural and functional diversity, ranging from simple boundary plantations and scattered onfarm trees to more complex multistory home gardens and alley cropping configurations. In tropical regions, especially South and Southeast Asia, home garden agroforestry systems are a widely adopted traditional model. These systems are typically arranged around homesteads, incorporating a variety of perennial trees, shrubs, herbaceous crops, and sometimes livestock in a vertically stratified and spatially integrated manner (Kumar, 2015).

In Bangladesh, traditional agroforestry practices such as mixed cropping, farmhouse gardening, and homestead forestry are deeply embedded in rural culture and livelihoods. These systems have long contributed to food, fuel, and fodder security while maintaining ecological balance. Contemporary efforts now aim to intensify and modernise these practices by incorporating scientific design, improved species selection, and enhanced management techniques to optimise land productivity, improve soil health, and ensure agricultural sustainability. At the core of intensive agroforestry systems lies the principle of soil health regeneration, which is fundamental to the sustainability and productivity of any agricultural system. Soil health is governed by the dynamic interaction of physical, chemical, and biological components (Rajput et al., 2024). Key indicators include the availability of essential nutrients nitrogen (N), phosphorus (P), and potassium (K) as well as pH stability, microbial biomass, resistance to erosion, and soil organic carbon (SOC). Maintaining and enhancing these indicators are critical not only for sustaining yields but also for safeguarding broader ecosystem services that underpin food security. Sal forest regions indicate that intensive agroforestry practices can significantly improve soil fertility parameters. These improvements are visually represented in Figure 4, which highlights trends in SOC build up, nutrient availability, and other soil quality markers following the adoption of intensive agroforestry interventions.

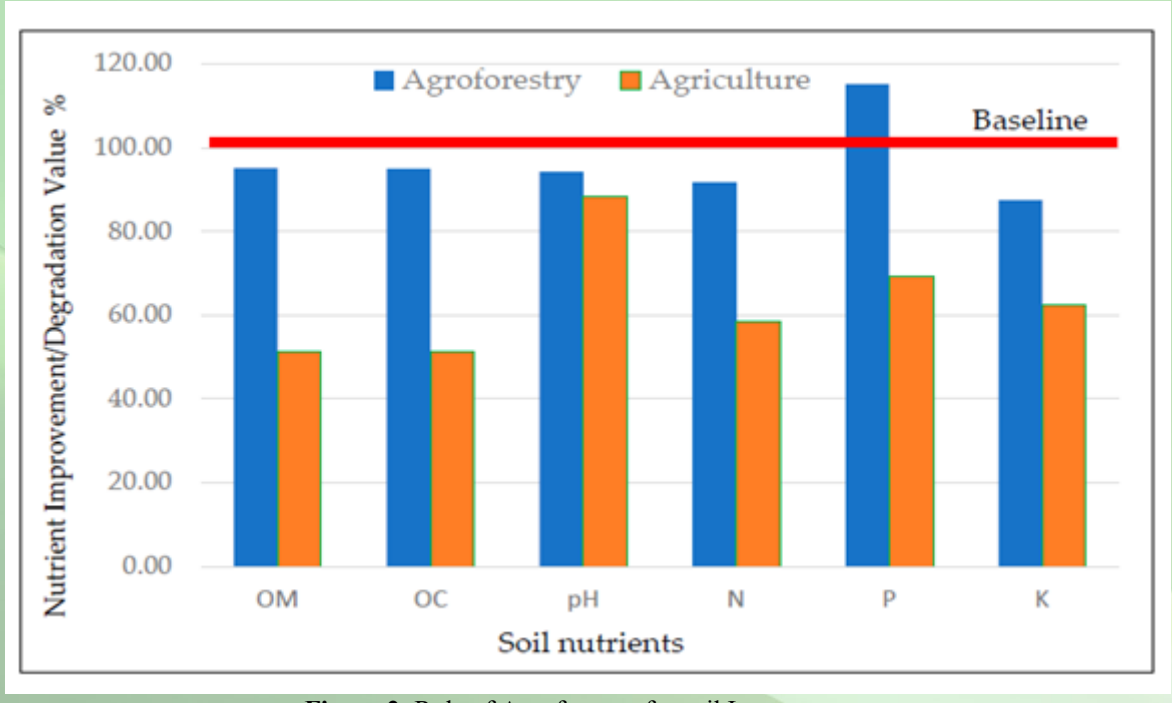

Figure 2: Role of Agroforestry for soil Improvement
Source: Islam, K.K., et al. (2024)

Intensive agroforestry systems contribute to soil enhancement through several ecological mechanisms. These include the deposition of organic matter via litter fall, biological nitrogen fixation through leguminous tree species, stimulation of soil microbial activity, and improved water retention capacity (Kaur et al., 2023). Together, these processes foster long term soil fertility, reduce vulnerability to erosion, and build resilient agro ecosystems supporting the broader transition toward sustainable and climate adaptive farming systems.

Model Success Stories and Adoption of Intensive Agroforestry Systems

Bangladesh has numerous successful agroforestry projects that have demonstrated the viability and benefits of intensive agroforestry systems (Rahman et al., 2011). In the northern districts of Rangpur and Dinajpur, farmer led innovations that integrate fruit trees with vegetables and legumes have notably enhanced both crop yields and soil stability (Chaki et al., 2023). Such combinations like maize intercropped with lentil improve nutrient cycling and reinforce soil structure, particularly in regions prone to both drought and flooding. In coastal regions such as Khulna and Barisal, mixed cropping models have been implemented that combine rice and leafy vegetables with saline tolerant trees, including mangrove species (Rahman et al., 2021). These models address soil salinity issues while enhancing food production and providing environmental services like saline intrusion control. These climate resilient strategies contribute to land rehabilitation and increased food security in ecologically vulnerable coastal areas. Similarly, in the Chittagong Hill Tracts, agroforestry combinations involving bamboo, banana, and turmeric in multistrata arrangements have yielded significant ecological and economic returns (Hossain et al., 2020). These systems well suited to steep, erosion prone terrain have reduced soil loss, enhanced land stability, and raised household incomes. Notably, these models are accessible to smallholder and indigenous communities, offering low input yet high impact solutions

Regional Background and adaptation strategies

Replicable models from neighbouring countries offer strategic insights. For instance, India's Greening India Programme has promoted drip irrigation alongside high density agroforestry (Kumar et al., 2023), while community managed agroforestry in Nepal has bolstered food security and soil retention on steep slopes (Maharjan et al., 2024). These examples underscore the importance of community engagement, cooperative marketing, and topography sensitive practices like contour planting, which could be adapted to Bangladesh's context. Modern technologies are increasingly instrumental in supporting agroforestry optimisation. The use of remote sensing, GIS based monitoring, and systems modelling allows for spatial analysis of soil variability, prediction of yields, and tracking of land use changes (Nuwarapaksha & Udumann, 2025; Toromade & Chiekezie, 2024). These tools promote evidencebased planning and strengthen the evaluation of agroforestry interventions.

Limitations and Prospects for Adoption

Several barriers hinder the widespread adoption of intensive agroforestry systems in Bangladesh, despite their promising potential. A primary limitation is the continued dependence on chemical fertilizers. When not properly integrated with biologically active systems, synthetic inputs can disrupt natural nutrient cycling and degrade soil health (Nair et al., 1999). Over application, especially when inconsistent with agroecological principles, may undermine the nutrient recycling mechanisms essential for long term sustainability. Another major challenge is the high labor intensity required for managing these systems. Unlike monoculture farming, high density and multispecies agroforestry setups demand more time, specialized skills, and technical knowledge (Raj et al., 2022). Poorly designed systems can also lead to interspecies competition for sunlight, water, and nutrients, reducing overall productivity (Ong et al., 2007). As noted by Sima and Shemelis (2025), nutrient management remains a technical obstacle, particularly in regions with limited resources and variable soil conditions. Moreover, smallholder and subsistence farmers may be reluctant to adopt agroforestry practices due to the delayed economic returns, which do not align with their immediate income needs (Rahman et al., 2017). Despite these constraints, promising strategies are emerging to overcome them. Integrated Nutrient Management (INM), which blends organic fertilizers, biofertilizers, and limited chemical inputs, has shown to significantly enhance soil health while reducing dependence on synthetic products (Prakash et al., 2024). INM approaches have been particularly effective in increasing soil organic carbon, improving pH levels, and enhancing nutrient availability in mountainous and resource scarce areas. Furthermore, agroforestry practices such as orchards, boundary plantings, homestead gardens, and multistory systems offer a range of additional ecological benefits. These include improved microclimate regulation, enhanced carbon sequestration, and greater biodiversity preservation (Kumar, 2016). Such benefits reinforce agroforestry's value as a tool for sustainable land use planning. To facilitate wider adoption, targeted extension services and farmer education programs are critical. Additionally, policy support is essential. The formal recognition of agroforestry within national land use frameworks could improve institutional backing and resource allocation, accelerating the transition toward large scale implementation.

Research Gaps and Future Directions

Although agroforestry is gaining recognition in Bangladesh, long term studies assessing its impacts on soil health, agricultural productivity, and ecosystem services remain insufficient. Most existing research is either short term or fragmented, which limits comprehensive understanding especially in the context of socioeconomic and climatic variability.To ensure meaningful adoption, future efforts must integrate regional knowledge with global scientific advancements. Lessons from countries with similar agroecological conditions should be tailored to local realities, fostering systems that enhance both livelihood security and environmental resilience. A systems based approach is vital to embed agroforestry within broader development agendas targeting poverty reduction, climate adaptation, and food security. However, key research priorities include quantifying the biophysical and economic trade offs of various agroforestry models, creating decision support tools for species and system selection, and using spatial technologies like GIS and remote sensing to inform land use planning. Moreover, policy frameworks must institutionalize agroforestry within national strategies for climate resilience and sustainable agriculture. With adequate policy backing, research investment, and extension infrastructure, agroforestry in Bangladesh has the potential to evolve from a soil rehabilitation technique into a driver of sustainable development and equitable rural transformation.

Conclusion

This review highlights the transformative potential of intensive agroforestry systems in enhancing Bangladesh's food security, soil health, and climate resilience. By integrating trees with crops in strategic and ecologically sensitive ways, these systems offer a viable alternative to conventional monoculture farming, particularly in land constrained and environmentally vulnerable regions. Case studies at both national and regional levels illustrate that well designed agroforestry systems can enhance biodiversity, boost soil fertility, and increase overall agricultural output. Nevertheless, challenges such as labor intensity, insufficient technical support, and the lack of long term studies continue to hamper broader adoption. Looking ahead, scaling up agroforestry will require a coordinated approach that blends scientific innovation, farmer education, supportive policy frameworks, and modern technological tools. Only through such an integrated effort can agroforestry fulfil its promise as a cornerstone of sustainable agriculture and rural development in Bangladesh.

Novelty of the Present Review

This review uniquely focuses on high density, multispecies agroforestry systems, distinguishing them from traditional models by highlighting their enhanced ecological and agronomic functions. It explicitly explores the link between soil health improvement and tangible food production benefits for smallholder farmers. Grounded in evidence from the Bangladeshi context, the review addresses a critical gap in localized assessments of intensive agroforestry. It underscores agroforestry as a comprehensive, systems based strategy that integrates agroecological principles with food security and climate resilience, offering a pathway toward sustainable rural livelihoods.

Declarations: This review study was presented via online oral presentation at the 4th International Congress of the Turkish Journal of Agriculture Food Science and Technology (Turjaf_2025) April 2830, 2025,

Acknowledgments: The author highly acknowledges the invaluable guidance, time, and support provided by his supervisor and co-supervisor in reviewing and conceptualizing this manuscript. Sincere appreciation to his teacher and faculty member for proofreading and offering constructive suggestions. The author is also thankful to a Ph.D. fellow and one Master's student from the faculty and department respectively, for their assistance in writing and editing portions of this manuscript.

Conflicts of Interest: The authors declare that no conflicts of interest exist.

Abstract

Molecular hydrogen, a gas that is abundantly present in the atmosphere, is light, colorless, odorless, and non-toxic. Its ability to rapidly penetrate tissues, along with its antioxidant, anti-inflammatory, and gene-regulatory biological effects, has been predominantly applied in the medical field. These biological effects of hydrogen may also yield beneficial outcomes in agricultural practices. The agricultural sector faces numerous challenges, including population growth, air pollution, climate change, and declining soil fertility. Hydrogen's reducibility, as well as its characteristics as a plant growth regulator, and its safe, environmentally friendly, and sustainable properties, make it a promising approach for both addressing these challenges and advancing agricultural development. Hydrogen farming refers to the application of hydrogen biology in agriculture. Hydrogen-rich water (HRW) treatments can regulate plant hormones, enhance resistance to stress conditions, support growth and development, increase nutritional value, and influence protein modifications through the regulation of mRNA and DNA expression. Furthermore, it may help reduce nitrite accumulation during storage, thus contributing to food safety. This study aims to investigate the effects of hydrogen farming by reviewing research involving hydrogen-rich water (HRW) applied to various pre-harvest vegetables and fruits.

Keywords: *Hydrogen; plants; Agriculture; Quality characteristics*

Hidrojen Tarımcılığı

Özet

Havada yaygın olarak bulunan moleküler hidrojen hafif, renksiz, kokusuz ve toksik olmayan bir gazdır. Dokulara hızlı nüfuz etmesi, antioksidan, anti-inflamatuar ve gen düzenleyici gibi biyolojik etkileriyle daha çok tıp alanındaki uygulamalarla karşımıza çıkmaktadır. Hidrojenin bu biyolojik etkileri tarım alanında da olumlu sonuçlar sağlayabilir. Tarım sektörü, nüfus artışı, hava kirliliği, iklimsel faktörler, toprak verimliliğinin azalması gibi birçok sorunla karşı karşıyadır. Hidrojenin İndirgenebilme özelliği, bitki büyüme düzenleyicisi, güvenli, yeşil ve çevre dostu olma gibi özellikleriyle, tarım alanında hem bu sorunların çözümü hem de tarımın gelişmesi için iyi bir uygulama alanı olabilir. Hidrojen tarımı, hidrojen biyolojisinin tarıma uygulanmasıdır. Hidrojen açısından zengin su (HRW) uygulamaları, bitki hormonlarını düzenleyerek; bitkilerin stres koşullarına karşı direncini artırabilir, büyüme ve gelişmesini destekleyebilir, besin değerini artırabilir, mRNA ve DNA ekspresyonunu düzenleyerek protein modifikasyonunu etkileyebilir. Aynı zamanda depolama sırasında nitrit birikimini azaltarak gıda güvenliğinin korunmasına yardımcı olabilir. Bu çalışma, hidrojen tarımının etkilerini araştırmak için hasat öncesi bazı sebze ve meyveler üzerinde hidrojen açısından zengin su (HRW) ile yapılan bazı araştırmaları ele almayı amaçlamaktadır.

Anahtar kelime*: Hidrojen; Bitki; Tarım; Kalite özellikleri*

Giriş

Hidrojen gazı evrende en çok bulunan elementtir (Alwazeer et al., 2021; Wen-biao Shen et al., 2018). Hidrojen, başka bir hidrojen atomu ile birleşerek kimyasal formülü H_2 olan moleküler hidrojeni oluşturur. Moleküler hidrojen, standart sıcaklık ve basınçta (STP) 0,08988 g/L yoğunluğa sahip (Alwazeer et al., 2021) renksiz, kokusuz, tatsız, metalik olmayan (Alwazeer & Çiçek, 2022) en küçük ve en hafif moleküldür (Alwazeer et al., 2021). Düşük yoğunluk ve boyut ile yüksek ayrışma enerjisine sahip olması nedeniyle gıdalarda ve çevrede kalıntı bırakmaz ve toksik değildir (Alwazeer, Elnasanelkasim, Çiçek, et al., 2023)(Alwazeer, Elnasanelkasim, Engin, et al., 2023). Moleküler hidrojen (H_2) sıfır karbon emisyonu, yüksek enerji değeri nedeniyle son yıllarda potansiyel enerji kaynağı olarak değerlendirilmektedir. Hayvanlar üzerinde H_2 gazıyla yapılan laboratuvar çalışmalarında, H_2 gazının biyolojik etkileri aşamalı olarak keşfedilmiştir (Liu et al., 2024). Ohsawa ve ark. (2007), sıçanların %2-4 (h/h) H_2 solunması sonrasında iskemik beyin hasarında iyileşmeler gözlemlemesiyle, H_2 gazının klinik uygulamalardaki potansiyeli fark edilmiştir (L. Li et al., 2022a). H_2 gazının etkili sitoprotektif ajan, antioksidan

(Russell et al., 2024), çeşitli gen ifadelerini düzenleyerek, antiapoptik, anti-inflamatuar ve anti-alerjik etkiler gösteren bir terapi gazı olduğu ortaya konmuştur (Liu et al., 2024)(Alwazeer & Çiçek, 2022)(Bulut et al., 2023) .Yüksek difüzyon hızına sahip moleküler hidrojen (H_2) biyolojik doku ve hücrelere hızlı bir şekilde yayılıp, hücre zarına kolaylıkla nüfuz etmektedir. Aynı zamanda vücudun redoks reaksiyonlarını değiştirmeyerek, hiçbir yan etkiye sahip değildir. Moleküler hidrojenin biyolojik ve tıbbi etkileri üzerine birçok çalışma yapılmakla birlikte bu araştırmalar devam etmektedir (Alwazeer & Çiçek, 2022). Bu çalışmalarla, moleküler hidrojen (H_2), metabolik, sindirim, solunum ve kardiyovasküler hastalıklar, nörodejeneratif bozukluklar ve kanser gibi hastalıkların tedavisi için umut verici olmaktadır (L. Li et al., 2022b; M. Li et al., 2024).

Hidrojen biyolojisinin etkileri tıp alanında olduğu gibi tarım alanında da olumlu sonuçlar sağlayabilir. Tarım, iklim değişikliği, doğal afetler, çevre kirliliği ve gıda güvenliği sorunlarının sebep olduğu birçok problemle karşı karşıyadır (L. Li, Lou, et al., 2021). Kimyasal kirlilik, biyolojik çeşitliliğin azalması gibi çağdaş sorunlar, kaliteli gıdaların üretilmesini, korunmasını ve dağıtımını giderek zorlaştırmaktadır (Russell et al., 2024).

Hidrojen tarımı, bu zorlukların çözümüne katkı sağlayacak hidrojen biyolojisinin pratik bir uygulamasıdır (L. Li, Lou, et al., 2021). Yapılan çalışmalar, moleküler hidrojenin (H_2) bazı botanik etkilere sahip olduğunu göstermiştir. Moleküler ağı, miRNA ve gen ekspresyonunun, hormon düzeylerinin kontrolü ve protein modifikasyonlarının düzenlenmesi süreçlerini kapsar (Wen-biao Shen et al., 2018). Bitkilerde, çevresel zorluklar, doğal bozulma ve oksidatif strese bağlı hücresel ve doku hasarı gibi faktörler gıdanın büyümesini, verimini ve kalitesini olumsuz etkileyebilir. Oksidatif hasar, gıdada lipit oksidasyonuna, renk bozulmasına ve lezzet değişimlerine neden olabilir (Dong et al., 2023). Buna karşılık moleküler hidrojen (H_2), bitkinin oksidatif strese karşı toleransını artırabilir, bitki büyüme ve gelişimini destekleyebilir (M. Li et al., 2024), besin değerini artırabilir, raf ömrünü uzatabilir ve sebzelerin depolanması sırasında nitrit birikimini azaltabilir (L. Li, Lou, et al., 2021). Son yıllarda moleküler hidrojen (H_2) çalışmaları bitkilere doğru kaymıştır (L. Li et al., 2022) ve birçok akademik çalışmada, bitkilerin ekilme ve büyüme evrelerinde H_2 'ye maruz bırakılması sonucunda bitki kök oluşumunun iyileştiği, bitkinin hastalık direncinin arttığı ve tohum, yaprak, meyve büyüme ve gelişmesini desteklediği gözlemlenmiştir (Russell et al., 2024). Bitki köklerindeki iyileşmenin, kök iyileşmesini destekleyen kök bakterilerinin çoğalmasıyla ilişkili olup (Alwazeer et al., 2024a); bu da kimyasal gübrelere karşılık H_2 'nin alternatif bir gübre olma potansiyeline ortaya koymuştur (L. Li et al., 2022),(Alwazeer et al., 2024b). Bu sonuçlara göre H_2'nin tarım alanı uygulamaları, tarımsal faydalar açısından önemli bir rolü olabilir (L. Li, Zeng, et al., 2021).

Hidrojen Açısından Zengin Su (HRW) Uygulamaları

Gaz formundaki moleküler hidrojen H_2, ayrışma hızının yüksek olması ve yüksek konsantrasyonlarda yanıcı özelliği saha uygulaması için pratik değildir (M. Li et al., 2024). Bu yüzden moleküler hidrojen (H_2) açısından zengin su (HRW) daha uygulanabilir alternatiftir. HRW uygulamalarında, turp filizleri ve yonca fidelerinin antosiyaninler ve flovonoidler gibi ikincil metobolitleri ile filizlenmiş arpanın besin bileşiklerini artırdığı gözlemlenmiştir. Pirinç ile yapılan başka bir çalışmada ise verim ve kalitesinin arttığı gözlemlenmiştir (Liu et al., 2024). (H_2) açısından zengin su (HRW), salatalık (*Cucumis sativus*) ve domates (*Lycopersicon esculentum*) bitkilerinin kök gelişimini teşvik ettiği gözlemlenirken, yoncada (*Medicago sativa*) ağır metal toksisitesinin hafiflediği keşfedilmiştir (L. Li, Zeng, et al., 2021).

Farklı bitki türlerinde HRW'nin etkileri üzerine yapılan bazı araştırmaların analizi

Çin lahanası (*Brassica chinensis* L. 'Qingshan') hem verimi hemde kalitesi üzerine yapılan araştırmada, Çin lahanası, hidrojen nanokabarcık suyu (HNW) formunda olan hidrojen bazlı sulama ile sulanmıştır. Hidrojen bazlı sulama, Çin lahanasının büyüme ve verimle ilgili sonuçlarını belirgin şekilde iyileştirirken, besin kalitesini artırıp nitrat içeriğini azaltmıştır. Denemeler sonrası hidrojen bazlı sulama ile kontrol grupları karşılaştırıldığında, hidrojen bazlı sulama ile elde edilen Çin lahanasının şeker oranı, çözünür protein oranı ve klorofil oranı önemli ölçüde artmıştır. Sonraki denemelerde, HNW demir (Fe), çinko (Zn) ve bakır (Cu) gibi eser elementlerin yanı sıra fosfor (P), potasyum (K) ve magnezyum (Mg) gibi makro elementlerin içeriklerinin karşılaştırılmasını sağlanmıştır. Fe, Zn ve Cu içerikleri önemli ölçüde artarken; K ve Mg içeriklerindeki önemsiz değişikler karşısında P içeriği önemli ölçüde artmıştır. HNW ile antioksidan bileşiklerinin ve antioksidan aktivitesinin arttığı gözlemlenmiştir. Aynı zamanda hidrojen bazlı sulamanın, Askorbik asit (AsA) içeriğini önemli ölçüde artırdığı tespit edilirken buna PMM1 (fosfomannomutaz), GMP2 (GDPR-mannoz pirofosforilaz), GME1 (GDPR-mannoz-3',5'-epimeraz), GGP3 (GDPR -l -galaktoz fosforilaz), GPP (l -galaktoz-1-fosfat fosfatazı) ve MDHAR2 (monodehidroaskorbat redüktaz dahil olmak üzere AsA biyosenteziyle ilişkili genlerin önemli ölçüde yukarı düzenlenmesinin eşlik ettiği gözlemlenmiştir (Liu et al., 2024). Pirinç ile yapılan başka bir çalışmada, HNW ile yapılan sulamanın, pirincin tarla ve tane kalite özelliklerini etkileyip etkilemediği incelenmiştir. Elde edilen verilere göre HNW ile sulanan pirinçlerin uzunluk, genişlik ve kalınlık farkının belirgin olduğu görülmüştür. Pirinç bitkilerinde azot (N), fosfor (P) ve potasyum (K) emilimiyle ilgili temsili genlerin transkriptlerinin, N asimilasyonu

ve taşınmasının yanı sıra P ve K emiliminin kontrolü de dahil olmak üzere Nitrat taşıyıcıları 2.3 (NRT2.3), Nitrit redüktaz (NiR), ABC1 baskılayıcı 1 (ARE1), Nin benzeri protein 4 (NLP4) ve Potasyum taşıyıcısı 1 (AKT1), HNW ile sulanan pirinç köklerinde belirgin şekilde arttığı görülmüştür. Beyaz pirincin HNW'nin jel kıvamını arttığı, pirincin tebeşirlilik oranını azalttığı keşfedilmiştir. Sonraki sonuçlar, HNW sulama işleminin, pirincin endospermindeki önemli ve ana depolama proteini olan glutelinde önemli değişiklik olmadan toplam protein seviyesini %19,8 oranında; toplam nişasta içeriğini değiştirmeden amiloz içeriğini %31,6 oranında azalttığı görülmüştür. Bu bulguların mekanizmasını araştırmak için, beyaz pirinçteki amiloz oluşumunu kontrol eden ilgili bazı genler, granüle bağlı nişasta sentaz1 (GBSS1), nişasta izomeraz1 (ISA1) ve nişasta dallanma enzimi1 / 2 (SBE1 / 2) dahil olmak üzere analizler yapılmış ve hedef genlerin transkripsiyonel ifadesindeki değişiklikler, amiloz içeriğindeki azalmayla ilişkili olduğu saptanmıştır. HNW ile sulamanın beyaz pirinç element içeriği ile ilişkisini saptamak için daha fazla çalışma yapılmıştır. Yapılan deneyler sonucunda Cd (kadminyum) ve Sn (kalay) içeriklerinde önemli azalma görülmüştür. HNW'nin beyaz pirinçteki P (fosfor), K (potasyum), Mg (magnezyum) ve Fe (demir) dahil birçok besin elementinin içeriğini artırdığı tespit edilmiştir (Cheng et al., 2021). Çilek meyvesi ile yapılan (Fragaria × ananassa 'Benihoppe') bir çalışmada, çileklerin tarlaya ekiminden hemen sonra HNW'li su uygulanmaya başlanmıştır. Hasat sonrası çileklerde, çilek meyvesinin lezzetini artırmakla beraber en önemlisi de lignin, selüloz ve hemiselüloz sentezini düzenleyerek çilek meyvesinin raf ömrünü olumlu yönde etkilediği keşfedilmiştir (Jin et al., 2023). Çilek meyvesi ile yapılan başka bir çalışmada ise HNW uygulaması aldehitler, ketonlar, esterler ve asitler gibi toplam uçucu bileşiklerin konsantrasyonlarını farklı şekilde artırdığı gözlemlenmiştir. HNW uygulaması çilekteki çözünür şeker (glukoz, sakaroz, fruktoz) miktarını artırarak, meyvedeki şeker-asit oranı değişmiştir. Bu durumunun ise tüketici beğenisini olumlu yönde etkileyeceği vurgulanmıştır (L. Li et al., 2022).

Sonuç

Doğal afetler, çevre kirliliği, hızlı nüfus artışı gibi birçok faktör tarım sektörünü olumsuz etkilemekte; tarımsal üretimde azalmaya ve kalite problemlerine sebep olmaktadır. Sağlık, enerji alanlarında olduğu gibi Moleküler hidrojen (H_2), tarım alanında da yeşil bir çözüm olabilir (Alwazeer et al., 2024a). Son yıllarda yapılan araştırmalar incelendiğinde, hidrojen tarımı, bu yaklaşım için umut verici olmuştur. Daha fazla araştırma ve geliştirme çalışmalarıyla hidrojen tarımı, güvenli, lezzetli, sağlıklı ve yüksek verimli tarım ürünleri sağlamayı destekleyebilir (L. Li, Lou, et al., 2021).

Abstract

Nowadays, aquaculture sector is one of the fastest developing sectors in the food industry. Increasing production quantities and changing climatic conditions cause some problems. In this sense, in the recent years, in addition to probiotics, the use of some additives and growth promoters are commonly used in the aquaculture sector. In this study, the combined effects of feeding probiotics (*Bacillus* sp.) and growth promoters (Viusid®) supplemented to the feed under culture conditions on growth parameters and morphological development of sea bream (*Sparus aurata*) larvae, which are intensively produced in our country, were investigated. For this purpose, within the scope of the experiments lasting between 0-40 days after hatching, in the study designed with 4 different experimental groups and 3 replicates, the experimental group in which no supplementation was made was accepted as the control group (C), and probiotic (P), growth promoter (V) and probiotic+growth promoter (P+V) were applied in the other 3 experimental groups, respectively. When the data obtained at the end of the experiment were analysed, the best growth performance and survival rate were observed in P+V group, followed by V, P and C groups, and C group showed significant differences with the other experimental groups ($p<0,05$). Similarly, when the deformation rates were analysed, the highest deformation rate was found in the C group and significant differences were found with the other experimental groups (P+V, V and P) ($p<0,05$). In conclusion, although probiotic and growth promoters provided significant increases in growth performance, survival rate and morphological aspects when used separately, it was determined that the combined effects gave better results on these parameters when used together.

Key Words: *Sea bream, Sparus aurata, Probiotics, Growth promoters, Growth performance.*

Çipura (*Sparus aurata*, L.) Larva Kültüründe Probiyotik ve Büyüme Hızlandırıcıların Kullanımı: Büyüme Performansı ve Morfolojik Gelişim Üzerine Bileşik Etkisi

Özet

Günümüzde akuakültür sektörü gıda endüstrisi içinde en hızlı gelişen sektörlerin başında gelmektedir. Artan üretim miktarları ve değişen iklim koşulları beraberinde bazı sorunlara da neden olmaktadır. Bu bağlamda son yıllarda probiyotiklerin yanında bazı katkı maddelerinin ve büyüme hızlandırıcıların akuakültür sektöründeki kullanımları yaygın hale gelmiştir. Bu çalışmada, ülkemizde yoğun olarak üretimi yapılan çipura (*Sparus aurata*) larvalarının kültür koşullarında yemlere eklenen probiyotik (*Bacillus* sp.) ve büyüme hızlandırıcılar (Viusid®) ile beslenmesinin büyüme parametrelerinin yanında ve morfolojik gelişim üzerine bileşik etkileri incelenmiştir. Bu amaçla 0-40. günler arasında süren denemeler kapsamında 4 farklı deneme grubu ve 3 tekrarlı olarak tasarlanan çalışmada herhangi bir uygulamanın yapılmadığı deneme grubu kontrol grubu (C) olarak kabul edilmiş, diğer 3 deneme grubunda ise sırasıyla probiyotik (P), büyüme hızlandırıcı (V) ve probiyotik+büyüme hızlandırıcı (P+V) uygulanmıştır. Deneme sonunda elde edilen veriler değerlendirildiğinde en iyi büyüme performansı ve yaşama oranı P+V grubunda gözlenirken bu grubu V, P ve C grubu izlemiş, C grubu diğer deneme grupları ile farklılık göstermiştir ($p<0,05$). Benzer şekilde, defromasyon oranları incelendiğinde de en yüksek deformasyon oranı C grubunda tespit edilmiş ve diğer deneme grupları (P+V, V ve P) ile önemli farklılılar bulunmuştur ($p<0,05$). Sonuç olarak probiyotik ve büyüme hızlandırıcılar ayrı ayrı kullanıldıklarında büyüme performansı, yaşama oranı ve morfolojik açıdan önemli artışlar sağlasa da birlikte kullanıldığında bileşik etkisinin bu paratmereler üzerinde daha iyi sonuçlar verdiği tespit edilmiştir.

Fenolik Bileşikler ile Mineraller Arasındaki Etkileşim Mekanizmaları Ve Besinsel Etkileri

Duried Alwazeer[1], Şafak Yılmaz[2]

Iğdır Üniversitesi, Sağlık Bilimleri Fakültesi, Beslenme ve Diyetetik Bölümü, Iğdır, Türkiye, ORCID ID: https://orcid.org/0000-0002-2291-1628, alwazeerd@gmail.com
Iğdır Üniversitesi, Sağlık Bilimleri Fakültesi, Beslenme ve Diyetetik Bölümü, Iğdır, Türkiye, ORCID ID: https://orcid.org/0009-0005-2696-1162, dyt.safakyilmazz4@gmail.com

Özet

Fenolik bileşikler, bitkisel kaynaklarda yaygın olarak bulunan ve insan sağlığı üzerinde çeşitli olumlu etkiler gösteren biyoaktif bileşiklerdir. Antioksidan, antiinflamatuvar ve antimikrobiyal özellikleri sayesinde fenolik bileşikler, kronik hastalıkların önlenmesi ve genel sağlık durumunun iyileştirilmesi açısından büyük önem taşımaktadır. Ancak bu bileşiklerin vücutta nasıl kullanıldığı, yani biyoyararlanımı, çeşitli faktörlerden etkilenmektedir. Bu faktörlerden biri de fenolik bileşiklerin minerallerle olan etkileşimidir. Fenolik bileşikler, başta demir, çinko ve kalsiyum olmak üzere çeşitli minerallerle kompleksler oluşturarak mineral emilimini artırabilir veya engelleyebilir. Örneğin, fenolik bileşiklerin demir ile şelat oluşturma yeteneği nedeniyle, bitkisel gıdalardaki non-hem demirin biyoyararlanımı önemli ölçüde azalabilir. Bu durum özellikle demir eksikliği riski taşıyan bireyler açısından önemlidir. Benzer şekilde, çinko ile fenolik bileşiklerin etkileşimi sonucunda çözünmeyen kompleksler oluşabilir ve çinko emilimi engellenebilir. Kalsiyum ise fenolik bileşiklerle çözünmeyen tuzlar oluşturabilir, bu da kalsiyumun biyoyararlanımını düşürebilir. Ancak bu etkileşimlerin her zaman olumsuz olmadığı da bilinmektedir. Örneğin, bazı fenolik bileşiklerin minerallerle etkileşimi sonucu, mineral emilimini artıran çözünebilir kompleksler oluşabilir. Ayrıca, fenolik bileşiklerin antioksidan özellikleri sayesinde oksidatif stresin azaltılması, mineral metabolizmasını dolaylı olarak destekleyebilir. Örneğin, polifenollerin demirin serbest radikal üretimini engelleyerek vücutta demir dengesini korumaya yardımcı olabileceği gösterilmiştir. Beslenme açısından değerlendirildiğinde, fenolik bileşikler ve mineraller arasındaki bu etkileşimler, özellikle bitkisel bazlı diyetler açısından önem arz etmektedir. Fenolik bileşiklerin aşırı alımı, bazı minerallerin emilimini azaltarak eksiklik riskini artırabilirken, dengeli bir beslenme planı ile bu etkileşimlerin olumsuz etkileri en aza indirilebilir. Bu nedenle, minerallerin optimal emilimini sağlamak için fenolik bileşiklerden zengin gıdalarla mineral kaynaklarının birlikte tüketim zamanlaması dikkatle planlanmalıdır. Örneğin, çay ve kahve gibi polifenol içeriği yüksek içeceklerin demir açısından zengin öğünlerle birlikte tüketimi sınırlanmalı, C vitamini gibi emilimi artırıcı faktörlerle desteklenmelidir. Bu çalışma, fenolik bileşikler ve mineraller arasındaki etkileşim mekanizmalarını inceleyerek, bu etkileşimlerin beslenme üzerindeki etkilerini değerlendirmektedir. Elde edilen bulgular, beslenme stratejilerinin daha bilinçli bir şekilde planlanması gerektiğini ortaya koymakta ve bu etkileşimlerin sağlık üzerindeki uzun vadeli etkilerine yönelik daha fazla araştırmaya ihtiyaç olduğunu vurgulamaktadır.

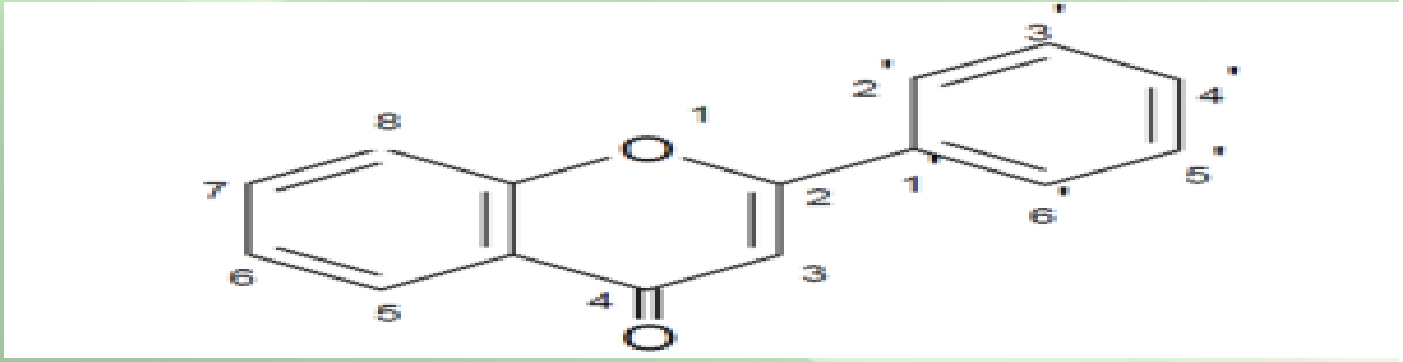
Interaction Mechanisms And Nutritional Effects Between Phenolic Compounds And Minerals

Abstract

Phenolic compounds are bioactive compounds that are widely found in plant sources and have various positive effects on human health. Thanks to their antioxidant, anti-inflammatory, and antimicrobial properties, phenolic compounds are important in preventing chronic diseases and improving general health. However, how these compounds are used in the body, i.e., their bioavailability, is affected by various factors. One of these factors is the interaction of phenolic compounds with minerals. Phenolic compounds can increase or inhibit mineral absorption by forming complexes with various minerals, especially iron, zinc, and calcium. For example, due to the ability of phenolic compounds to chelate with iron, the bioavailability of non-heme iron in plant foods can be significantly reduced. This is especially important for individuals at risk of iron deficiency. Similarly, insoluble complexes can form due to the interaction of zinc with phenolic compounds, and zinc absorption can be inhibited. Calcium can form insoluble salts with phenolic compounds, which can reduce the bioavailability of calcium. However, it is also known that these interactions are not always negative. For example, due to the interaction of some phenolic compounds with minerals, soluble complexes that increase mineral absorption can be formed. In addition, the reduction of oxidative stress, thanks to the antioxidant properties of phenolic compounds, can indirectly support mineral metabolism. For example, it has been shown that polyphenols can help maintain iron balance in the body by preventing the free radical production of iron. When evaluated in terms of nutrition, these interactions between phenolic compounds and minerals are especially important for plant-based diets. While

excessive intake of phenolic compounds can reduce the absorption of some minerals and increase the risk of deficiency, the negative effects of these interactions can be minimized with a balanced nutrition plan. Therefore, the timing of consuming mineral sources and foods rich in phenolic compounds should be carefully planned to ensure optimal absorption of minerals. For example, the consumption of polyphenol-rich beverages such as tea and coffee should be limited to iron-rich meals and should be supported by absorption-enhancing factors such as vitamin C. This study examines the interaction mechanisms between phenolic compounds and minerals and evaluates the effects of these interactions on nutrition. The findings reveal that nutritional strategies should be planned more consciously and emphasize the need for more research on the long-term effects of these interactions on health.



Keywords: *Phenolic compounds; Minerals; Bioavailability; Nutrition*

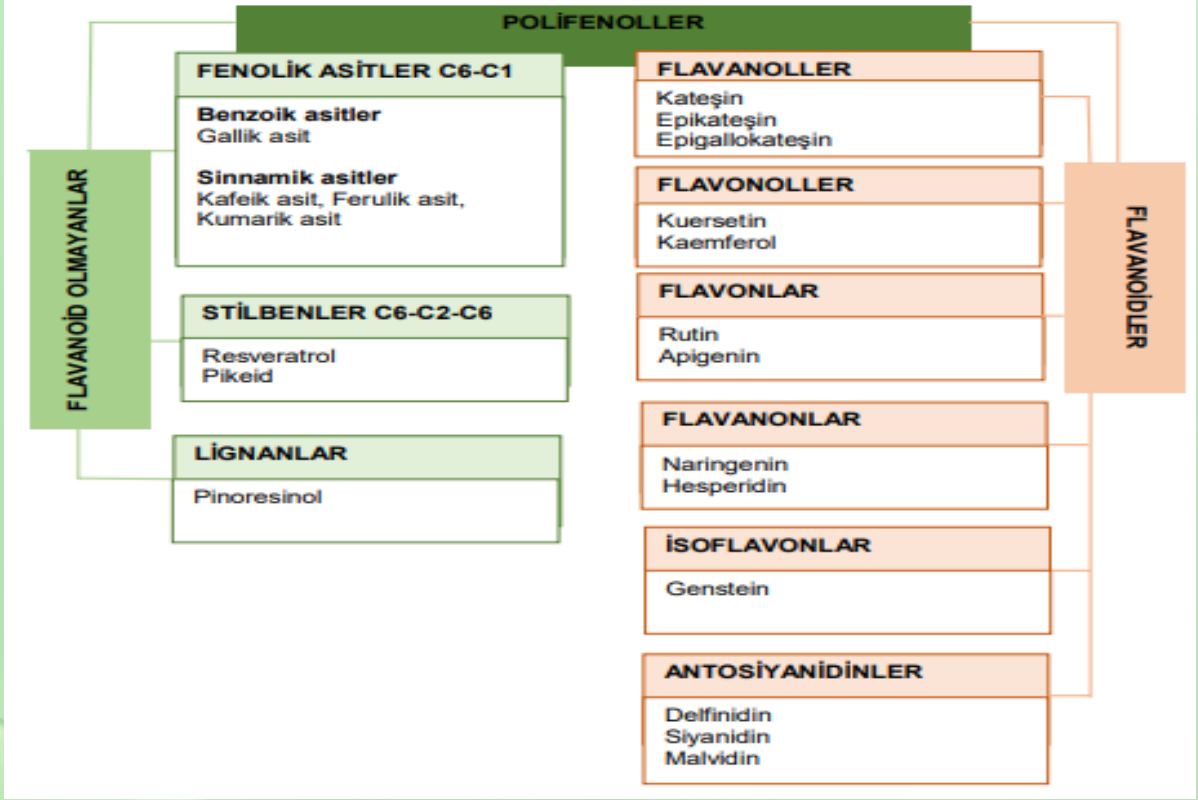
1. Giriş

Fenolik bileşikler, bitkisel kaynaklı gıdalarda yaygın olarak bulunan, biyolojik olarak aktif olan ve çeşitli sağlık yararları ile ilişkilendirilen bileşiklerdir. Fenolik bileşikler, özellikle antioksidan, anti-inflamatuvar, antimikrobiyal, antikanserojen ve kardiyovasküler sağlık üzerinde koruyucu etkiler göstermesiyle tanınmaktadır (Scalbert vd., 2005). Bu bileşikler, bitkilerde genellikle sekonder metabolitler olarak bulunurlar ve besinlerde genellikle flavonoidler, fenolik asitler, lignanlar, stilbenler gibi sınıflarda yer alırlar. Fenolik bileşiklerin sağlık üzerine olan etkileri, biyoyararlanımları ve vücutta nasıl metabolize oldukları ile doğrudan ilişkilidir. Bununla birlikte, fenolik bileşiklerin biyoyararlanımı ve vücutta gösterdikleri biyolojik aktiviteler, vücutta bulunan diğer besin bileşenleri ve minerallerle olan etkileşimleriyle şekillenir. Bu etkileşimler, beslenme ve sağlık üzerine etkilerini belirleyebilir. Fenolik bileşikler, mineraller ile etkileşime girerek, bu minerallerin emilimini, biyoyararlanımını ve vücutta ne şekilde kullanıldığını değiştirebilir. Mineraller, vücudun düzgün çalışabilmesi için kritik öneme sahip olup, kemik sağlığı, bağışıklık sistemi, enzim aktivasyonları ve elektrolit dengesinin sağlanması gibi birçok biyolojik fonksiyonu yerine getirirler. Demir, çinko, kalsiyum, magnezyum gibi minerallerin vücutta yeterli seviyede bulunması, optimal sağlık için gereklidir. Bununla birlikte, fenolik bileşiklerin bu minerallerle olan etkileşimleri, mineral emiliminde ve biyoyararlanımında olumlu ya da olumsuz değişikliklere yol açabilir (Shahidi & Peng, 2018). Özellikle, fenolik bileşikler genellikle minerallerle çözünmeyen kompleksler oluşturarak, bu minerallerin emilimini engelleyebilirler. Örneğin, çayda bulunan tanenler veya baklagillerdeki fitatlar, demir ve çinko gibi minerallerle bağlanarak, bu minerallerin biyoyararlanımını önemli ölçüde azaltabilirler. Bununla birlikte, bazı fenolik bileşiklerin antioksidan özellikleri ve minerallerle etkileşimleri, serbest radikallerin ve oksidatif stresin azaltılmasında faydalı olabilir. Fenolik bileşiklerin bu etkileşimleri, yalnızca minerallerin biyoyararlanımını etkilemekle kalmaz, aynı zamanda genel vücut fonksiyonlarını da modüle edebilir (Emirhüseyinoğlu vd., 2025). Bu derleme, fenolik bileşiklerin minerallerle olan etkileşimlerini incelemeyi amaçlamaktadır. Demir, çinko, kalsiyum, magnezyum ve diğer mineraller ile fenolik bileşiklerin etkileşim mekanizmaları ve bu etkileşimlerin besinsel etkileri üzerinde durulacaktır. Ayrıca, fenolik bileşiklerin bu minerallerle olan etkileşimlerinin sağlık üzerine olan etkileri tartışılacak ve uygun beslenme stratejileri ile bu etkileşimlerin nasıl yönetilebileceği üzerine önerilerde bulunulacaktır.

2. Fenolik Bileşiklerin Genel Özellikleri

Fenolik bileşikler, bitkilerde bulunan ve biyolojik olarak aktif olan organik bileşiklerdir. Bu bileşiklerin yapısal özellikleri genellikle bir veya daha fazla fenol grubu içeren bir karbon halkasından oluşur (Şekil 1). Fenolik bileşikler, bitkilerin metabolik süreçlerinde önemli bir rol oynar ve bitkiler için savunma mekanizmaları, renk, tat ve aroma gibi özellikler sağlar. İnsan sağlığı açısından fenolik bileşikler, antioksidan, antimikrobiyal, anti-inflamatuvar ve anti-kanserojenik etkiler gibi çok çeşitli biyolojik etkilere sahiptir (Karabulut & Yemiş, 2019).

Şekil 1. Flavonoidlerin kimyasal yapısı



Fenolik bileşikler, bitkisel kaynaklardan elde edilen gıdalarda yaygın olarak bulunur ve bu gıdaların besinsel değerini artırabilir. Çoğu fenolik bileşik, bitkilerde sekonder metabolitler olarak sentezlenir, bu da onların doğrudan bitkilerin büyümesi için gerekli olmayan, ancak organizmanın çevresel streslere karşı savunmasına yardımcı olan bileşikler oldukları anlamına gelir. Fenolik bileşiklerin kimyasal yapıları oldukça çeşitlidir ve başlıca sınıfları şunlardır (Şekil 2):

2.1. Fenolik Asitler: Bunlar, fenol halkasına bağlı bir karboksil grubuna sahip bileşiklerdir ve en yaygın olarak bulunan fenolik bileşik sınıfıdır. Örnekler arasında gallik asit, ferulik asit, kafeik asit ve klorojenik asit yer alır.

2.2. Flavonoidler: Flavonoidler, genellikle 15 karbon atomu içeren ve iki fenol halkası ile bağlanan bir yapıya sahip bileşiklerdir. Bu sınıf, antosiyaninler, kateşinler, kuersetin, epikateşin, ve luteolin gibi birçok bileşiği içerir. Flavonoidler, genellikle meyve ve sebzelerde bulunur ve sağlık üzerinde olumlu etkiler gösterir.

2.3. Lignanlar: Lignanlar, bitkilerde bulunan, bir fenolik yapıyı içerip ayrıca karbon-karbon bağlarıyla birbirine bağlı aromatik halkalar oluşturan bileşiklerdir. Lignanlar, özellikle tohumlar, tam tahıllar ve sebzelerde bulunur ve antioksidan özellikler gösterirler.

2.4. Stilbenler: Stilbenler, resveratrol gibi bileşikleri içeren, genellikle üzüm kabuğu, kırmızı şarap ve bazı meyvelerde bulunan bir fenolik bileşik sınıfıdır. Stilbenler, kanserle savaşma ve kalp sağlığını destekleme özellikleriyle tanınır.

Şekil 2. Fenolik bileşiklerin sınıflandırılması (Karabulut & Yemiş, 2019)

Fenolik bileşiklerin vücuda alınması sonrasında, birçok biyolojik etkiye sahip olmaları nedeniyle sağlık üzerinde çeşitli yararlar sağlar. Bu yararlar, büyük ölçüde onların antioksidan kapasitesi ile ilişkilidir. Antioksidan etkiler, serbest radikallerin nötralize edilmesine yardımcı olur, böylece oksidatif stresin önüne geçilerek hücresel hasar engellenir. Bunun yanı sıra, fenolik bileşiklerin anti-inflamatuvar ve antimikrobiyal etkileri de bulunmaktadır, bu da onların bağışıklık sistemini destekleyerek çeşitli hastalıklara karşı koruyucu bir rol oynamasını sağlar.

3. Fenolik Bileşikler ve Mineraller Arasındaki Etkileşim Mekanizmaları

Fenolik bileşikler, bitkisel kaynaklı gıdalarda bulunan, kimyasal olarak fenol halkaları içeren ve biyolojik açıdan oldukça aktif olan organik bileşiklerdir. Bu bileşiklerin başlıca sınıfları flavonoidler, fenolik asitler, stilbenler ve lignanlar gibi gruplarda toplanmaktadır. Fenolik bileşiklerin sağlık üzerindeki olumlu etkileri uzun yıllardır araştırılmaktadır ve bu etkiler büyük oranda onların antioksidan, antimikrobiyal, anti-inflamatuvar ve kardiyovasküler hastalıklarla mücadele etme potansiyellerine dayanmaktadır. Ancak, bu bileşiklerin beslenme ve metabolizma üzerindeki etkileri, yalnızca biyolojik aktiviteleri ile sınırlı değildir; fenolik bileşikler aynı zamanda vücutta bulunan minerallerle etkileşime girerek bu minerallerin biyoyararlanımını ve metabolik etkinliğini

etkileyebilirler. Mineraller, vücudun temel fonksiyonlarını düzenleyen mikronutrientlerdir (Eylem Atak & Mehmet Emin Uslu, 2018). Özellikle demir, çinko, kalsiyum ve magnezyum gibi mineraller, vücutta enzim fonksiyonları, kemik sağlığı, bağışıklık yanıtları ve oksijen taşınımı gibi kritik süreçlerin düzenlenmesinde rol oynar. Bununla birlikte, fenolik bileşiklerin bu minerallerle olan etkileşimleri, özellikle mineral emiliminde ve biyoyararlanımında önemli değişikliklere yol açabilir. Fenolik bileşiklerin, minerallerle etkileşimlerinin genellikle çözünmeyen kompleksler oluşturarak minerallerin biyoyararlanımını sınırladığı bilinmektedir.

3.1. Demir ile Etkileşim

Demir, vücutta oksijen taşıma fonksiyonu gibi birçok önemli biyolojik süreçte yer alan bir mineraldir. Demir, hem ve non-hem olmak üzere iki ana formda bulunur. Hem demir, hayvansal kaynaklardan elde edilirken, non-hem demir bitkisel kaynaklardan alınır ve emilimi hem demire göre daha zordur. Fenolik bileşikler, özellikle bitkisel kaynaklardan alınan non-hem demir ile etkileşime girerek bu mineralin biyoyararlanımını engelleyebilir. Fenolik asitler ve flavonoidler, demir ile şelat yaparak çözünmeyen kompleksler oluştururlar ve bu da demirin bağırsakta emilim kapasitesini önemli ölçüde azaltabilir özellikle çay, kahve, kakao ve kırmızı şarap gibi içeceklerde bulunan polifenoller, demirin emiliminde önemli bir engel oluşturur (Çizelge 1). Bu içecekler, bağırsakta tanen ve diğer fenolik bileşiklerle reaksiyona girerek, demir iyonlarını bağlar ve bu komplekslerin çözünürlüğünü azaltır. Böylece, demirin bağırsaktan geçişi ve kan dolaşımına geçişi engellenmiş olur. Ayrıca, bazı gıdalar ve içecekler, demirin emilimini azaltırken, C vitamini gibi bileşikler bu etkileşimi tersine çevirerek emilimi artırabilir. C vitamini, demir ile reaksiyona girerek demir iyonlarının indirgenmesine ve biyoyararlanımının artmasına yardımcı olur (Eylem Atak & Mehmet Emin Uslu, 2018).

Çizelge 1. Demir biyoyararlılığında etkili başlıca ana artırıcı ve azaltıcı etki sağlayan gıda ve bileşenler (Çağındı, 2020a).

Etki	Gıda	Bileşen	Mekanizma	Açıklama
Artırıcı etki	Narenciye meyveleri, meyve suları, sebzeler	Askorbik asit	Bağırsakta çözünür kalan ve Fe^{3+}'in Fe^{2+}'ya indirgenen çözünür demir-askorbat komplekslerinin oluşumunda her ikisi de emilimi destekler	Askorbik asidin demir emiliminde güçlü bir artırıcı etkisi bulunmaktadır. Ancak ortamda ısı varlığında kolayca bozunabilmektedir.
	Et, balık, kümes hayvanları	Hayvansal bileşenler	Demirin sindirim ürünlerine bağlanması sonucu proteinlerin çözünen bileşikler oluşturması	Termal proseslerden etkilenmemektedir.
Azaltıcı etki	Tam taneli tahıl, kuruyemiş, baklagiller	Fitik asit	Bağırsakta çözünmeyen demir fitat komplekslerinin oluşumu	Yüksek diyet lifi içeren gıdalar en önemli inhibitördür.
	Çay, kahve, kakao	Polifenoller	Bağırsakta demir ile çözünmeyen komplekslerin oluşumu	Çay polifenolleri en güçlü inhibitör olarak bilinmektedir
	İnek sütü, süt ürünleri	Süt Proteini Kalsiyum	Tüm kazein ve α-kazein fosfo peptitleri, demire bağlanarak emilimini güçlü bir şekilde engellemektedir. Hem ve hem olmayan demirlerin emilimi azalır.	Peynir altı suyu proteinleri inhibitör değildir. *In vitro* testlerden ve insanlarda epidemiyolojik çalışmalardan elde edilen sonuçlar dahilinde gözlemlenmiştir.

3.2. Çinko ile Etkileşim

Çinko, hücresel işlevler, bağışıklık fonksiyonu, DNA sentezi ve protein sentezi gibi kritik biyolojik süreçlerde önemli bir mineraldir. Fenolik bileşiklerin çinko emilimi üzerinde etkisi genellikle olumsuzdur. Özellikle fitat içeren gıdalar (örneğin, tam tahıllar, baklagiller), çinko ile çözünmeyen kompleksler oluşturarak bu mineralin biyoyararlanımını sınırlayabilir. Ayrıca, flavonoidler ve bazı fenolik asitler de çinko ile bağlanarak onun emilimini

engelleyebilir. Örneğin, kuersetin ve gallik asit, çinko ile bağlanabilme kapasitesine sahip olup, bu bağlanma çinkonun emilimini azaltır. Çinko emiliminde olumsuz etkileri azaltmak için, diyetinize dikkat edilmesi gerekmektedir. Çinko emilimini artırıcı faktörler arasında, çinko içeren gıdaların daha iyi emilmesini sağlayacak stratejiler yer alır. Örneğin, çinko emilimini artıran bir diğer bileşik olan vitamin A ve D'nin de vücutta çinko metabolizmasında önemli rol oynadığı bilinmektedir. (Akdeniz V.D. 2016)

3.3. Kalsiyum ile Etkileşim

Kalsiyum, kemik sağlığı ve kas fonksiyonları açısından son derece önemli bir mineraldir. Kalsiyum emilimi, bazı fenolik bileşiklerin etkisi altında olumsuz şekilde değişebilir. Örneğin, oksalik asit içeren gıdalar, kalsiyum ile birleşerek çözünmeyen kalsiyum oksalat kompleksleri oluştururlar ve bu da kalsiyumun bağırsaktan emilimini engeller (Weaver & Plawecki, 1994). Ispanak, pazı ve diğer yeşil yapraklı sebzelerde yüksek oksalat içeriği bulunur ve bu da kalsiyumun biyoyararlanımını düşürür. Ayrıca, çay ve kahve gibi içeceklerde bulunan polifenoller, kalsiyumun bağırsaklardan emilimini engelleyebilir. Kalsiyumun emilimini artırıcı stratejiler de mevcuttur (Yılmaz, S.E. & Yılmaz, D.A 2024). Özellikle, kalsiyum içeren gıdaların C vitamini ve magnezyum gibi besin öğeleriyle birlikte tüketilmesi kalsiyumun emilimini artırabilir. Bununla birlikte, kalsiyum emilimini etkileyen faktörlerin dengeli bir şekilde yönetilmesi gerekmektedir. Örneğin, oksalat içeriği yüksek gıdaların aşırı tüketiminden kaçınılması ve kalsiyum içeren besinlerin uygun kombinasyonlarla tüketilmesi önerilmektedir (Guéguen & Pointillart, 2000).

3.4. Magnezyum ile Etkileşim

Magnezyum, hücresel enerji üretimi, sinir iletimi ve kas fonksiyonları gibi birçok biyolojik süreçte yer alır. Fenolik bileşiklerin magnezyum emilimi üzerindeki etkisi henüz tam olarak anlaşılmamış olsa da, bazı çalışmalarda fenolik bileşiklerin magnezyumun biyoyararlanımını artırabileceği belirtilmiştir. Özellikle flavonoidler ve bazı fenolik asitlerin magnezyum ile etkileşimde bulunarak bu mineralin emilimini kolaylaştırdığı gözlemlenmiştir. Ancak, bazı gıdalarda bulunan yüksek miktarda fitat ve oksalatlar, magnezyumun biyoyararlanımını sınırlayabilir (Ergün, 2019).

4. Besinsel ve Sağlık Üzerindeki Etkileri

Fenolik bileşiklerin sağlık üzerindeki etkileri oldukça çeşitlidir ve bu etkiler genellikle fenolik bileşiklerin yapısal özellikleriyle ilişkilidir. Yapıları, farklı biyolojik yolları etkileyecek şekilde tasarlanmış olan fenolik bileşikler, bağışıklık sistemi, kardiyovasküler sağlık, kanserle mücadele ve metabolik hastalıklar gibi bir dizi sağlık sorunu üzerinde doğrudan etki gösterebilir.

4.1. Antioksidan Etkiler ve Oksidatif Stres

Fenolik bileşiklerin en belirgin özelliklerinden biri, güçlü antioksidan etkinlikleridir. Antioksidanlar, serbest radikalleri ve reaktif oksijen türlerini (ROS) nötralize ederek oksidatif stresin zararlı etkilerini azaltır. Oksidatif stres, hücresel bileşenlerin (özellikle DNA, lipitler ve proteinler) oksijen radikalleriyle hasar görmesine yol açabilir ve bu da yaşlanma, kanser, kardiyovasküler hastalıklar, nörolojik hastalıklar gibi bir dizi hastalığın gelişmesine neden olabilir. Fenolik bileşikler, bu serbest radikalleri etkili bir şekilde temizleyerek hücresel düzeyde korunmayı sağlar. Örneğin, flavonoidler ve fenolik asitler, biyolojik sistemlerde güçlü antioksidan özellikler göstererek lipid peroksidasyonunu inhibe eder ve DNA hasarını azaltır. Bu bileşiklerin antioksidan etkileri, kanser hücrelerinin büyümesini engellemeye, kardiyovasküler hastalıkların riskini azaltmaya ve sinir hücrelerini oksidatif hasardan korumaya yardımcı olabilir (Yılmaz, 2010).

4.2. Anti-inflamatuvar Etkiler

Fenolik bileşiklerin anti-inflamatuvar özellikleri, inflamasyonla ilişkili hastalıkların önlenmesinde kritik bir rol oynar. Kronik inflamasyon, Alzheimer hastalığı, artrit, kalp hastalıkları ve bazı kanser türleri gibi bir dizi hastalığın gelişiminde önemli bir faktördür. (Baradaran vd., 2014). Fenolik bileşikler, inflamasyonu modüle eden biyokimyasal yolları etkileyerek bu hastalıkların riskini azaltabilir. Flavonoidler ve stilbenler gibi fenolik bileşiklerin, bazı inflamasyonla ilişkili proteinlerin aktivitesini inhibe ederek inflamasyonu azaltabildiği gösterilmiştir. Ayrıca, fenolik bileşiklerin, iltihaplanmayı kontrol eden sitokinlerin üretimini düzenleyerek bağışıklık sistemini dengeleyebileceği de araştırmalarla desteklenmektedir (Rafieian-Kopaei et al., 2014).

3. Kanserle Mücadele

Fenolik bileşiklerin kanserle mücadeledeki potansiyel etkileri, onların hücre döngüsünü düzenleyebilme, apoptoz (programlanmış hücre ölümü) indükleyebilme ve kanser hücrelerinin metastazını engelleyebilme yeteneklerinden kaynaklanmaktadır. Özellikle antosiyaninler, flavonoidler ve stilbenler, kanser hücrelerinin çoğalmasını engelleyerek tümör büyümesini yavaşlatabilir. Resveratrol gibi stilbenler, kanser hücrelerinin çoğalmasını engelleyebilen ve kanserin yayılmasını önleyebilen bileşikler arasında yer alır. Yapılan çalışmalar, resveratrolün çeşitli kanser türlerine karşı etkili olduğunu, özellikle meme, kolon ve prostat kanserinde potansiyel bir tedavi aracı olabileceğini göstermektedir (Neuhouser, 2004).

4. Kardiyovasküler Sağlık

Fenolik bileşikler, kardiyovasküler hastalıkların risk faktörlerini azaltabilir. Özellikle, flavonoidlerin, kan basıncını düşürme, damar sağlığını iyileştirme, kolesterol seviyelerini dengeleme ve kan pıhtılaşmasını engelleme gibi etkileri bulunur. Bu etkiler, kalp hastalıkları ve inme riskini önemli ölçüde azaltabilir. Örneğin, yeşil çayda

bulunan kateşinler, arter duvarlarında oksidatif stresi azaltarak damar tıkanıklığını engeller. Ayrıca, flavonoidler ve antosiyaninler, kolesterol düzeylerini düşürerek aterosklerozun önlenmesinde yardımcı olabilir. Yapılan epidemiyolojik çalışmalar, flavonoid açısından zengin gıda tüketiminin kalp hastalıkları üzerindeki etkilerini olumlu yönde göstermektedir (Muhsiroğlu, 2017).

5. Metabolik Hastalıklar ve Obezite

Fenolik bileşiklerin metabolik hastalıklar üzerindeki etkileri, şeker metabolizması, insülin duyarlılığı ve yağ depolanması gibi süreçlere müdahale edebilme yeteneklerinden kaynaklanmaktadır. Özellikle fenolik bileşikler, insülin direncini azaltabilir, kan şekeri seviyelerini düzenleyebilir ve obeziteyi önleyebilir. Örneğin, yeşil çayda bulunan kateşinler, yağ oksidasyonunu artırarak ve karaciğerdeki yağ birikimini azaltarak obeziteyi kontrol altına alabilir. Bunun yanı sıra, fenolik bileşiklerin bağırsak mikrobiyotasını olumlu yönde etkileyerek, metabolik hastalıkların gelişim riskini azaltabileceği de gösterilmiştir (Yurt, t.y.).

5. Sonuç ve Öneriler

Fenolik bileşikler ve mineraller arasındaki etkileşimler, hem beslenme bilimlerinde hem de klinik beslenme alanında önemli bir araştırma konusudur. Bu etkileşimlerin, vücudun mineral emilimi ve biyoyararlanımını etkileyebilmesi, özellikle mineral eksiklikleri veya dengesiz beslenme ile ilişkili sağlık sorunları açısından kritik sonuçlar doğurabilir. Fenolik bileşiklerin aşırı alımı, demir, çinko, kalsiyum ve diğer minerallerin biyoyararlanımını sınırlayarak, beslenme dengesizliğine yol açabilir. Bu nedenle, fenolik bileşiklerin içeriği yüksek olan gıdaların tüketimi, belirli minerallerin emiliminden olumsuz etkilenmemek için dikkatlice izlenmelidir (Yılmaz, S.E. & Yılmaz, D.A 2024). Özellikle demir eksikliği ve anemi gibi durumlar, fenolik bileşiklerin aşırı tüketimiyle ilişkili olabilir. Özellikle bitkisel kaynaklardan beslenen bireylerde, çay, kahve ve kakao gibi fenolik bileşiklerce zengin gıdaların fazla tüketimi, demir emilimini önemli ölçüde azaltabilir. Bu durum, demir eksikliği riski taşıyan bireylerde beslenme stratejilerinin gözden geçirilmesini gerektirir. Demir, kalsiyum ve çinko gibi minerallerin emilimi, C vitamini, organik asitler gibi emilimi artırıcı faktörlerle desteklenebilir. Örneğin, demir emiliminin artırılması amacıyla C vitamini içeren gıdaların, demir içeren gıdalarla birlikte tüketilmesi önerilmektedir. Ayrıca, minerallerin emilimi üzerinde olumsuz etkileri azaltmak için bazı stratejiler kullanılabilir. Fenolik bileşiklerin emilimi sınırlayan etkilerini dengelemek adına, bu bileşenlerin emilim zamanlarının ve besinlerin tüketilme sırasının optimize edilmesi önemlidir. Örneğin, demir ve çinko emilimini artırıcı C vitamini içeren gıdaların fenolik bileşiklerle zenginleşmiş gıdalarla aynı öğünde tüketilmesi önerilebilir (Çağındı, 2020b). Fenolik bileşiklerin minerallerle etkileşimleri, sadece minerallerin emilimini değil, aynı zamanda vücutta bu minerallerin biyolojik aktivitelerinin düzenlenmesini de etkileyebilir. Örneğin, fenolik bileşiklerin antioksidan özellikleri, serbest radikallerin nötralize edilmesinde önemli bir rol oynar. Bu da, özellikle oksidatif stresle ilişkili hastalıkların önlenmesinde faydalı olabilir. Ancak, fenolik bileşiklerin aşırı tüketimi ve minerallerin emilimi üzerindeki olumsuz etkiler göz önünde bulundurularak, dengeli ve çeşitli bir diyetin önemi vurgulanmalıdır. Sonuç olarak, fenolik bileşikler ve mineraller arasındaki etkileşimlerin beslenme üzerinde önemli etkileri vardır. Bu etkileşimlerin daha iyi anlaşılması, beslenme ve sağlık alanında daha etkili stratejiler geliştirilmesine yardımcı olabilir. Beslenme planlaması yapılırken, bu etkileşimlerin dikkate alınması ve dengeli bir diyetin oluşturulması, mineral eksikliklerinin önlenmesi ve optimal sağlık durumunun korunması için gereklidir. Ayrıca, bu alandaki gelecekteki araştırmalar, fenolik bileşiklerin minerallerle olan etkileşimlerini daha da netleştirerek, daha etkili beslenme rehberleri ve müdahaleleri geliştirilmesine olanak sağlayacaktır.

Öneriler:

1. **Fenolik Bileşiklerin Tüketimi ve Mineral Emilimi:** Fenolik bileşiklerin yanlış tüketimi mineral emilimini engelleyebilir. Bu nedenle, fenolik bileşiklerce zengin gıdalarla birlikte mineral emilimini artırıcı gıdaların (örneğin, C vitamini) tüketilmesi önerilir.
2. **Bilinçli Diyet Planlaması:** Minerallerin emiliminde olumsuz etkileri azaltmak için diyetlerin dengeli ve çeşitlendirilmiş olması gerekmektedir. Özellikle bitkisel kaynaklardan beslenen bireyler, demir ve çinko emilimini artırıcı gıdalara yönlendirilmelidir.
3. **Bireysel İhtiyaçlar:** Her bireyin beslenme ihtiyaçları farklıdır, bu nedenle fenolik bileşiklerin ve minerallerin etkileşimleri, kişiye özel beslenme planlamalarıyla yönetilmelidir. Özellikle demir, çinko ve kalsiyum eksikliği riski taşıyan bireyler için uygun stratejiler belirlenmelidir.

Effects of GA_3 and PLGA-Controlled Release of GA_3 on the Germination of Caraway (*Carum carvi* L.)

Münüre TANUR ERKOYUNCU[1]

[1]Department of Field Crop, Faculty of Agriculture, Selcuk University, Konya, Türkiye, mtanur@selcuk.edu.tr

Abstract

This study was conducted to evaluate the effects of gibberellic acid (GA_3) applied at different concentrations and its combination with PLGA (poly(lactic-co-glycolic acid)) controlled-release systems on the germination of *Carum carvi* L. seeds. The experiment was designed as a factorial trial in a completely randomized plot design using five treatments: control (distilled water), GA_3 at 150 and 300 mg/L, and GA_3 + PLGA combinations at 150 and 300 mg/L concentrations. Germination percentage (%), mean germination time (days), and germination index (speed) were analyzed. The results showed that GA_3 applied alone resulted in poor or no germination. In contrast, the combination of GA_3 with PLGA significantly improved both the germination rate and speed, providing more stable germination compared to the control group ($P \leq 0.05$). Notably, the PLGA + 300 mg/L GA_3 treatment exhibited the highest performance, achieving a germination rate of 42.86% and a germination index of 5.01. No significant differences were observed between the control and PLGA + GA_3 treatments in terms of mean germination time. Moreover, while growth regression was observed in the control group after the 14th day, the PLGA + GA_3 treatments resulted in healthier and more sustained seedling development. These findings suggest that PLGA is an effective carrier for the controlled release of growth regulators such as GA_3 and can positively influence germination and early seedling development in medicinal and aromatic plants like *Carum carvi* L.

Keywords: Carum carvi *L., GA_3, PLGA, Germination*

Introduction

Carum carvi L. (commonly known as caraway) is an annual or biennial aromatic and medicinal plant belonging to the Apiaceae (Umbelliferae) family. Its natural distribution spans Western Asia, Europe, and North Africa, and it is also an integral part of the Turkish flora (Goyal et al., 2018). The seeds of *Carum carvi* L. are particularly notable for their high essential oil content, with carvone (55–60%) and limonene (30–40%) being the primary constituents (Öztürk et al., 2018). Pharmacologically, this species exhibits a wide spectrum of bioactivities, including antioxidant, antimicrobial, anticancer, hepatoprotective, anticholinergic, analgesic, and antidiabetic properties (Agnihotri et al., 2024). Consequently, *C. carvi* L. continues to be widely used in traditional medicine and has found increasing applications in modern pharmaceutical formulations.

As is common in many aromatic and medicinal plants, the germination rate of *C. carvi* L. seeds can be adversely affected by factors such as genetic variation, seed dormancy, and environmental conditions (Galambosi & Peura, 1996). In particular, low and delayed germination rates constitute major limiting factors for the commercial cultivation of this species. Seed germination represents a critical stage in the plant life cycle and directly influences agricultural productivity. Accordingly, various chemical and biological treatments have been developed to improve germination success. Among these treatments, gibberellic acid (GA_3) plays a pivotal role in breaking physiological dormancy and stimulating metabolic activation in the embryo (Miransari & Smith, 2014).

Despite the high essential oil content and medicinal value of *C. carvi* L., research focused on improving its germination through biostimulants and growth regulators remains limited. A study by Mirmazloum et al. (2020) demonstrated that osmopriming treatments using various chemical solutions (PEG, KNO_3, KCl) positively affected germination and early seedling development in *C. carvi* L. seeds. In contrast, the germination-promoting effects of GA_3 have been well-documented in numerous plant species. For example, GA_3 application significantly increased the germination rate of *Capsicum chinense* seeds (Mendoza-Gómez et al., 2021) and both improved the germination rate and reduced the germination period in *Sorghum bicolor* (Kamal et al., 2025).

Recent advancements in agricultural biotechnology have highlighted the potential use of biodegradable polymers, particularly poly(lactic-co-glycolic acid) (PLGA), in controlled-release delivery systems. PLGA is a biologically degradable polymer widely used in sustained-release nanosystems (Yang et al., 2024). Studies have shown that PLGA nanoparticles can be absorbed by plant roots and translocated within plant tissues, allowing active compounds such as GA_3 to be protected from environmental stressors and delivered to the seed surface in a more prolonged and effective manner (Vishwakarma et al., 2023). Experiments with *Arabidopsis thaliana* have demonstrated the effectiveness of PLGA in substance transport and its potential to enhance root development post-germination (De Angelis et al., 2023).

The present study aims to investigate the effects of different doses of GA_3 and GA_3 + PLGA combinations on germination rate, germination speed, and mean germination time in *C. carvi* L. seeds. Furthermore, this research will evaluate whether the controlled-release system provided by PLGA enables the physiological effects of GA_3 to be sustained in a more prolonged and balanced manner.

Materials and Methods

This study was conducted at the Plant Biotechnology Laboratory of the Department of Field Crops, Faculty of Agriculture, Selçuk University. The plant material used in this research was *Carum carvi* L. (caraway), an annual aromatic and medicinal species. The seeds were obtained from the Zeytinburnu Medicinal Plants Garden. For the experimental treatments, Resomer RG 503H-type poly(lactic-co-glycolic acid) (PLGA) (Sigma-Aldrich, 719870) and gibberellic acid (GA_3) (Sigma-Aldrich, 77065) were employed.

To evaluate seed germination performance, five different treatments were established: (1) a control treatment with distilled water, (2) GA_3 applied at two concentrations (150 mg/L and 300 mg/L), and (3) GA_3 + PLGA combinations prepared at the same two concentrations (150 mg/L and 300 mg/L). The experiment was arranged in a factorial design within a completely randomized block design (CRBD) with three replications per treatment. In each petri dish, 35 seeds were placed. Prior to germination, seeds were surface-sterilized using a 5% (v/v) sodium hypochlorite (NaClO) solution for 10 minutes, followed by three rinses with distilled water (Tanur & Yorgancılar, 2020). Subsequently, seeds were dried for 24 hours on filter paper at room temperature to restore their original moisture content. The dried seeds were uniformly arranged in sterile petri dishes lined with double layers of Whatman filter paper. Throughout the germination period, treatment solutions (GA_3 and GA_3 + PLGA) were applied at a volume of 10 mL every other day. Petri dishes were incubated under dark conditions at 25 ± 2 °C in a climate chamber for 14 days or until no further germination was observed. Daily observations were performed, and seeds were considered germinated when radicle emergence reached 5 mm (Demir & Mavi, 2008). At the end of the experiment, germination performance was assessed based on germination percentage, germination index, and mean germination time, calculated using the following formulas:

- **Germination Percentage (%)** = $(G / T) \times 100$

  G: Number of germinated seeds, T: Total number of seeds
- **Germination Index (GI)** = $N_1/T_1 + N_2/T_2 + ... + N_n/T_n$

N: Number of seeds germinated on a given day, T: Number of days (Kader & Jutzi, 2004)

- **Mean Germination Time (MGT)** = $\sum(f \times x) / \sum f$

f: Number of seeds germinated on a given day, x: Number of days (Ellis & Roberts, 1981)

The obtained data were subjected to analysis of variance (ANOVA) using the JUMP statistical software, and differences among treatment means were determined by Tukey's multiple comparison test at the $P<0.05$ significance level.

Results and Discussion

Effects of GA_3 and PLGA-Controlled Release Treatments on Germination Dynamics of *Carum carvi* L.

An evaluation of the germination dynamics of *Carum carvi* L. seeds revealed that germination commenced on the 7th day and no additional germination was observed beyond the 14th day. Notably, in the control treatment (distilled water), some seeds exhibited inhibited or regressed radicle and shoot development after the 14th day. In contrast, the PLGA + GA_3 combinations promoted post-germination development, resulting in healthier and more sustainable seedling growth. According to the findings, on the 7th day, the highest germination rate (26.67%) was recorded in the control group, while the PLGA + GA_3 treatments at 150 mg/L and 300 mg/L concentrations exhibited similar germination rates of 22.86% and 21.90%, respectively. In the groups treated solely with GA_3, germination rates remained below 1%, and in some cases, no germination was observed at all (Table 1).

Table 1. Effects of GA_3 and PLGA-Controlled Release GA_3 Treatments on Germination Percentage (%) of *Carum carvi* L. Seeds Over Time

Days	Control	150 mg/L GA_3	300 mg/L GA_3	PLGA +150 mg/L GA_3	PLGA +300 mg/L GA_3	Mean
7	26.67bd	0.95e	0.00e	22.86cd	21.90d	**14.48B**
9	34.29ac	1.90e	0.00e	37.14ab	40.95a	**22.86A**
12	38.10ab	3.81e	0.00e	40.95a	42.86a	**25.14A**
14	38.10ab	4.76e	0.00e	40.95a	42.86a	**25.33A**

Day:**, Treatment:**, Dayxtreatment:* (**$P \leq 0.01$, *$P \leq 0.05$)						

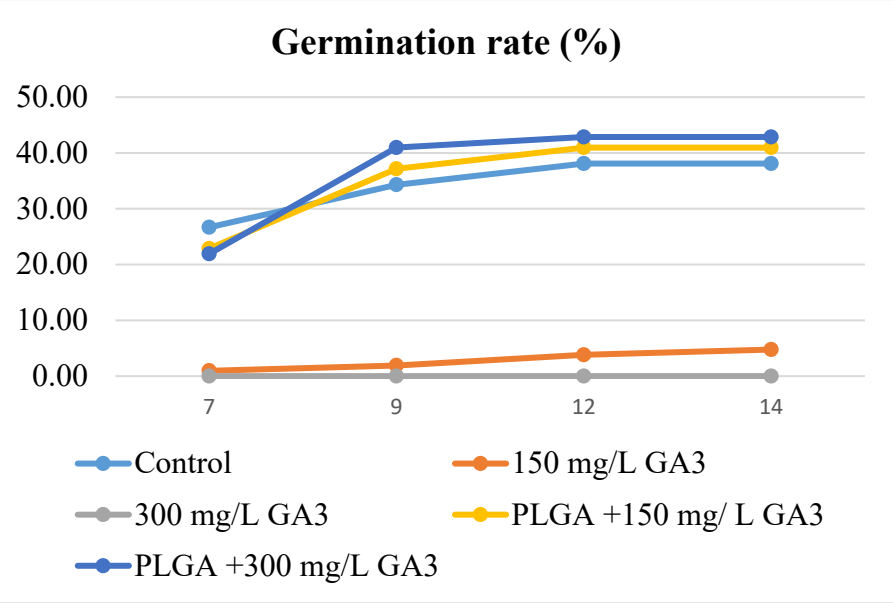

Figure 1. Time-Dependent Changes in Germination Rate (%) of *Carum carvi* L. Under GA_3 and PLGA-Controlled Release Treatments

During the subsequent days of the experiment, particularly on the 9th, 12th, and 14th days, the germination rate of the PLGA + GA_3 combinations increased sharply, exceeding 40%. On the 14th day, the highest germination rate (42.86%) was achieved with the PLGA + 300 mg/L GA_3 treatment, while the control group reached a maximum of 38.10%. In contrast, the GA_3-only treatments consistently showed germination rates below 5%, indicating the ineffectiveness of GA_3 alone in stimulating germination (Figure 1).

In general, the control and PLGA + GA_3 treatments were statistically grouped together, exhibiting similar germination rates, while the GA_3-only groups displayed significantly lower germination performance ($P \leq 0.01$). Additionally, it was observed that germinated seeds in the control group exhibited growth cessation or even regression after the 14th day. However, the PLGA + GA_3 treatments supported post-germination seedling development and ensured continued growth.

Analysis of variance (ANOVA) revealed that the main effects of day, treatment, and their interaction (day × treatment) were all statistically significant ($P \leq 0.01$, $P \leq 0.05$). These results indicate that both treatment type and temporal variation were critical determinants of the germination process.

Effects of GA_3 and PLGA-Controlled Release Treatments on Germination Index (GI) and Mean Germination Time (MGT) of *Carum carvi* L.

The effects of different treatments on the germination index (GI) and mean germination time (MGT) of *Carum carvi* L. seeds were investigated, and the results were found to be statistically significant ($P \leq 0.05$), with distinct differences detected among the treatments (Table 2).

In terms of germination speed, the highest GI value (5.01) was recorded in the PLGA + 300 mg/L GA_3 treatment, followed by the PLGA + 150 mg/L GA_3 (4.81) and the control (4.73) treatments. In contrast, the groups treated solely with GA_3 exhibited extremely low germination speeds, with a GI of 0.35 in the 150 mg/L GA_3 group and 0.00 in the 300 mg/L GA_3 group due to the absence of germination. These findings indicate that GA_3 applied alone negatively affected germination speed in *C. carvi* L., while its combination with PLGA mitigated this inhibitory effect and significantly improved germination performance.

Table 2. Effects of GA_3 and PLGA-Controlled Release GA_3 Treatments on Germination Index (GI) and Mean Germination Time (MGT) of *Carum carvi* L.

	GI	MGT (day)
Control	4.73a	10.83a
150 mg/L GA_3	0.35b	8.13ab
300 mg/L GA_3	0.00b	0.00b
PLGA +150 mg/ L GA_3	4.81a	10.99a
PLGA +300 mg/L GA_3	5.01a	11.01a
	*$P \leq 0.05$	*$P \leq 0.05$

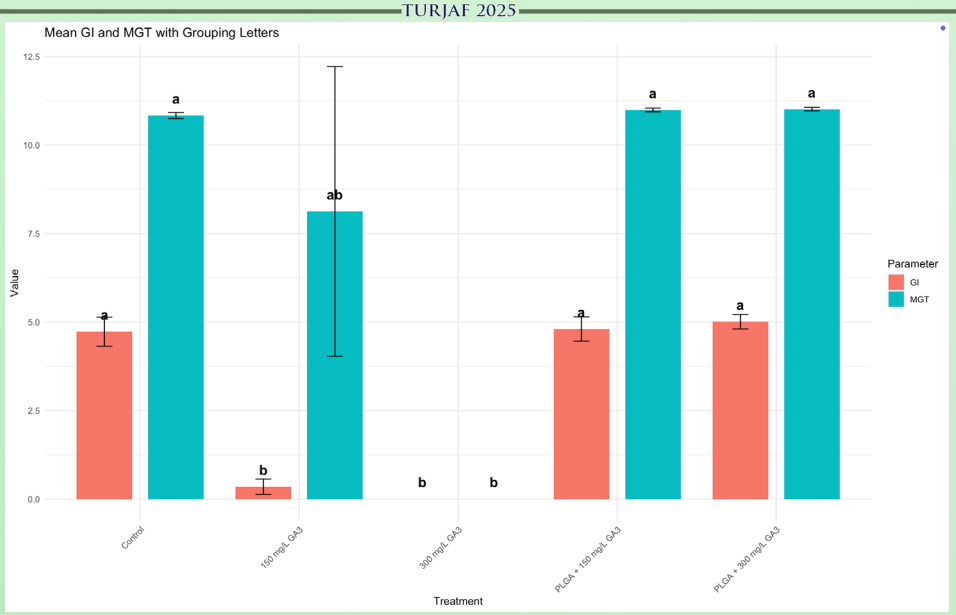

Figure 2. Comparison of GI and MGT Among Different GA_3 and PLGA-Controlled Release Treatments in *Carum carvi* L.

Regarding mean germination time (MGT), similar and statistically comparable values were observed among the control (10.83 days), PLGA + 150 mg/L GA_3 (10.99 days), and PLGA + 300 mg/L GA_3 (11.01 days) treatments. However, the 150 mg/L GA_3 treatment showed a shorter MGT of 8.13 days, although its biological relevance was limited due to the low germination speed and poor overall germination performance. In the 300 mg/L GA_3 group, no MGT value could be calculated due to the absence of germination (Figure 2).

Overall, the results revealed that GA_3, when combined with PLGA, enhanced the germination speed while maintaining a mean germination time comparable to the control group. In contrast, GA_3 applied alone resulted in reduced germination speed and poor germination performance. Statistical analysis confirmed significant differences among treatments for both germination index and mean germination time ($P \leq 0.05$).

The findings of this study clearly demonstrate that the direct application of GA_3 was insufficient to effectively promote germination and seedling development in Carum carvi L. However, when GA_3 was applied via a controlled-release system using PLGA, both germination rate and seedling development were significantly improved. This result is particularly noteworthy considering the presence of morphophysiological dormancy, which is common among species within the Apiaceae family. Similar patterns have been reported in the literature. For example, studies on *Ferula assa-foetida* (Rajabian et al., 2007), *Kelussia odoratissima* (Etemadi et al., 2010) and *Ducrosia anethifolia* (Ashtari et al., 2013) have shown that GA_3 alone had a limited effect on promoting germination, but its effectiveness improved when combined with additional environmental cues such as cold stratification.

In the present study, the combination of GA_3 with PLGA notably enhanced the germination rate (~42%) and germination speed (GI = 5.01) while supporting sustained seedling development. This improvement can be attributed to the controlled-release capabilities of PLGA. Biodegradable polymers like PLGA have gained attention in recent years for their potential use in seed coating and as carriers for plant growth regulators (Shakiba et al., 2020). PLGA adheres to the seed surface, creating a localized environment that retains the hormone near the root and shoot zones, thereby minimizing rapid degradation caused by environmental factors and enabling the gradual and balanced release of the hormone (Bonser et al., 2023).

Consistent with these findings, other studies have reported similar benefits of polymer-based delivery systems. For instance, GA_3 encapsulated within alginate/chitosan polymer matrices improved germination and yield in *Solanum lycopersicum* (Pereira et al., 2019). Likewise, the slow release of metolachlor using mPEG-PLGA nanocarriers was successfully achieved in plants (Gao et al., 2018).These findings highlight that polymer-based carriers are not only effective for pesticide delivery but also for the controlled release of plant growth regulators.

In this study, the slow-release effect provided by PLGA appears to have reduced the potential phytotoxicity of GA_3 in *C. carvi* L., a species characterized by strong seed dormancy, and allowed for the sustained delivery of physiologically tolerable doses of the hormone. This resulted in a significant improvement in both germination performance and early seedling development.

Conclusion

Controlled release systems present an effective strategy to overcome common challenges such as low germination rates and poor seedling development, especially in species belonging to the Apiaceae family. Our findings demonstrated that the use of GA_3 through controlled release formulations, rather than direct application, significantly optimizes both germination and seedling growth. Specifically, in *Carum carvi* L. seeds, GA_3 alone had limited and low impact on germination, whereas its combination with PLGA notably enhanced both germination and seedling vigor. These results are largely consistent with previous reports on various Apiaceae species, highlighting the potential of controlled release systems to improve propagation efficiency in this important plant family.

Evaluation of the Antifungal Effects of *Datura stramonium* Extracts on *Sclerotinia sclerotiorum* and *Rhizoctonia solani* under *In Vitro* Conditions

Raziye Koçak[1], Özden Salman[2], Bahadır Şin[3]

[1]Animal and Plant Production Department, Çumra Vocational School, Selçuk University, Konya, Türkiye
[2]Department of Plant Protection, Faculty of Agriculture,Selçuk University, Konya, Türkiye
[3]Department of Plant Protection, Faculty of Agriculture, Sakarya Universty of Aplied Science, Sakarya, Türkiye

Abstract

In this study, the antifungal effects of methanol and ethanol extracts obtained from the aerial green parts of *Datura stramonium* were investigated under *in vitro* conditions against the significant plant pathogens *Sclerotinia sclerotiorum* and *Rhizoctonia solani*. These pathogens cause severe losses in the production and yield of many plant species. Different concentrations (1.0%, 2.0%, and 4.0%) of *Datura stramonium* extracts were applied to both pathogens, and the obtained data were compared. The results revealed that the methanolic extract exhibited higher antifungal activity compared to the ethanolic extract. Accordingly, the methanol extract provided 12% greater inhibition against *S. sclerotiorum* and 22% greater inhibition against *R. solani* than the ethanol extract. It was observed that the antifungal effect increased in a dose-dependent manner, and at a 4.0% concentration in both solvents, mycelial growth of *S. sclerotiorum* and *R. solani* was completely inhibited. The highest inhibition effect was observed in the 2% concentration of the methanolic extract, where *R. solani* mycelial growth was suppressed by 77.77%, and *S. sclerotiorum* by 72.22%. In contrast, the antifungal activity of ethanolic extracts at the same concentration was found to be lower. In conclusion, extracts obtained from the aerial green parts of *Datura stramonium* have been shown to possess antifungal potential against plant pathogens when dissolved in different solvents. This suggests that they could be evaluated as a natural biofungicide source for controlling phytopathogenic fungi.

Key Words: *Datura stramonium, Plant pathogens, Organic solvents, Antifungal activity, Biological control.*

Datura stramonium Ekstraktlarının *In Vitro* Koşullarda *Sclerotinia sclerotiorum* ve *Rhizoctonia solani* Üzerine Antifungal Etkilerinin Değerlendirilmesi

Özet

Bu çalışmada, *Datura stramonium*'un toprak üzeri yeşil aksamından elde edilen metanol ve etanol ekstraktlarının önemli bitki patojenlerinden *Sclerotinia sclerotiorum* ve *Rhizoctonia solani*'ye karşı antifungal etkileri *in vitro* koşullarda araştırılmıştır. Bu patojenler, birçok bitki türünün üretim ve veriminde ciddi kayıplara neden olmaktadır. Çalışmada, her iki patojen üzerine farklı konsantrasyonlarda (%1,0, %2,0 ve %4,0) *Datura stramonium* ekstraktları uygulanmış ve elde edilen veriler karşılaştırılmıştır. Sonuçlar, metanolik ekstraktın antifungal etkinliğinin etanolik ekstrakta kıyasla daha yüksek olduğunu ortaya koymuştur. Buna göre metanol ekstraktının *S. sclerotiorum* üzerinde %12, *R. solani* üzerinde ise %22 oranında daha fazla inhibisyon sağladığı belirlenmiştir. Antifungal etkinin doza bağlı olarak arttığı gözlemlenmiş olup, her iki çözücüde de %4,0 konsantrasyonda *S. sclerotiorum* ve *R. solani*'nin misel gelişimi tamamen inhibe edilmiştir. En yüksek inhibisyon etkisi, metanolde çözündürülmüş %2 konsantrasyondaki ekstraktlarda tespit edilmiş olup, *R. solani*'nin misel gelişimi %77,77, *S. sclerotiorum*'un misel gelişimi ise %72,22 oranında baskılanmıştır. Aynı konsantrasyonda etanolik ekstraktların antifungal aktivitesinin daha düşük olduğu belirlenmiştir. Sonuç olarak, *Datura stramonium* toprak üzeri yeşil aksamından elde edilen ekstraktlarının farklı çözücülerde çözündürülerek bitki patojenlerine karşı antifungal potansiyele sahip olduğu ortaya konmuş ve fitopatojenik fungusların kontrolünde doğal bir biyofungisit kaynağı olarak değerlendirilebileceğini göstermektedir.

Abstract

The study examines food security among Cocoa Farming Household in Osun State, Nigeria. Multistage sampling technique was used to select the 120 respondents used in this study. Analytical techniques used were the descriptive and inferential (Food security index and Logistic regression) statistics. The result revealed that 49.17% of the respondents were female, while male were 50.83%. The mean age for cocoa farming households' head was 61.1 years. Majority (83.3%) of the respondents were married. Most of the household heads in the study area had formal education. The result of the food security indices that the proportion of the food insecure households was 70% while the proportion of the food secure households was 30%. Logit result revealed that age ($p< 0.1$), sex ($p< 0.05$), household size ($p< 0.01$) and number of meal per day ($p< 0.01$) were variables significantly responsible for food security of cocoa farming households in the study area. The study therefore recommends that reduction in food insecurity should involve collaborated efforts by both the government and private sectors through regular orientation that encourages education among farm households on the need to expand their sources of income from agriculture to off-farm income generating business. In addition, farmers groups and government should provide agricultural inputs to farming households during farming seasons at affordable prices.

Keywords: *Cocoa, Food Security, Logit Regression*

Introduction

The 2023 removal of the fuel subsidy in Nigeria marks a pivotal moment in the nation's economic, social, and environmental trajectory. This decisive policy shift carries with it a multitude of implications that warrant rigorous investigation to comprehend its far-reaching consequences. The core problem at the heart of this study lies in uncovering the intricate web of impacts – positive, negative, direct, and indirect – that arise from the subsidy removal and examining their ramifications for both the Nigerian economy and society. The subsidy removal, while driven by the intent to align with global trends of fossil fuel subsidy reduction and enhance fiscal sustainability (Al Jazeera, 2023), presents a host of challenges. Foremost among these challenges is the potential exacerbation of socio-economic inequality, given that subsidy removal can lead to increased fuel prices and a subsequent rise in the cost of living, thereby leading to food insecurity. This predicament echoes the concern raised by Ude (2023), emphasizing that while subsidy elimination might hold long-term benefits, it can strain the financial resources of households, particularly those already marginalized.

Food is a vital need for all humans which must be satisfied for a healthy and productive living. Issues related to food security vis-à-vis availability, accessibility/affordability, and sustainable utilization remain pertinent for policymakers and academics. This may have stemmed from the fact that malnutrition may result in dire health and physical consequences. Arising from the 1996 World Food Summit was a holistic definition of food security which incorporates the four domains of food security namely; availability, access, utilization and stability. Food security was defined as ability of all people to have physical and economic access, at all times, to safe nutritious food to maintain a healthy and active life (Ogunniyi *et al.* 2020; Omotayo 2020). Conversely, a household becomes food insecure when such a household is unable to afford, or have access at all times to such quantity and quality of food that makes for healthy living (Obayelu and Orosile 2015). Food insecurity can be viewed as an extreme form of poverty, a state of deprivation of basic human needs to which a person, household, community, or nation can be subjected (Brimah *et al.,* 2015). Lack of resources to acquire enough food for individual or household results in insufficient nutrition, poor calorie intake and poor nutrition; a low income household may not be immune to hunger and the concomitant health challenges since constrained economic access to food would result in poor nutrition (malnutrition) which may either be chronic or transitory in natural (Mutisya *et al.,* 2015). In Nigeria, per capita calorie intake over the past two decades has fallen below the

recommended level. Evidence from the Global Food Security Index (GFSI), Nigeria ranked 91 in 109 countries and had a 37.1 weighted score out of 100 (GFSI, 2015).

Recently, in Nigeria as a whole there is a high rate of inflation which directly affects food security on the Country, (World Bank, 2018). Additionally, Nigeria is among the large exporters of agricultural products. Tree crops such as cocoa, oil palm, rubber among others has largely led agricultural exports in Nigeria. The production and export of cocoa (*Theobroma cacao*) has served as a major source of foreign exchange for many developing countries particularly in Sub-Saharan Africa (SSA). Since its discovery in the 18th century at the Amazon basin, cocoa cultivation has spread to other tropical areas of south and central, and indeed West Africa, which became the major producer from the mid-1960s. The dominance in world cocoa production shifted from America to Africa in the second half of the nineteenth century and remains so to date. Cocoa was introduced to West Africa from Brazil (South America) precisely from Fernando Po into Nigeria in 1874 and Ghana in 1879 by one Squiss Bamengo, a chief of the Niger Delta, (Eduardo and Philippe 2013). West Africa has been the centre of cocoa cultivation for many decades, as two-thirds of the world's cocoa is produced in West Africa. Currently, the main producers of cocoa are Cote D'Ivoire, Ghana, Indonesia and Nigeria. Nigeria remains the third largest producer of cocoa and sixth globally, (International Cocoa Organization, ICO, 2012). Before the emergence of black gold (crude oil) in Nigeria, cocoa was the major leading cash and export crop in Nigeria especially in southern part of Nigeria. The top growing States Ondo, Ogun, Osun Oyo and Ekiti account for about 60% of the cocoa production and make up at least 30% of the total cocoa export in Nigeria. Others are Cross River, Edo, Abia, Kwara, Kogi, Adamawa, and Akwa Ibom. But Nigerian Bureau of Statistic (2013) identified eighteen cocoa producing States in Nigeria. Therefore in addition to the aforementioned State, others are Taraba, Delta, Lagos, Bayelsa, River and Imo States. Although there have been several studies on food insecurity, some of which were Antwi and Lyford (2018), Fawole, Ozkan and Ayanrinde (2016), Awoyemi, *et al.,* (2022) but research on food insecurity among cocoa farming households most especially in Osun State, Nigeria is very terse in literature. This study therefore assesses the food insecurity among Cocoa Farming Household in Osun State Nigeria. Specifically, the study described the Socio-economic characteristic of cocoa famer in the study area, estimate the food security status of cocoa faming household in the study area, determined the factor that influencing the food security among cocoa faming household in the study area and describe the constraint associated with cocoa faming in the study area.

Methodology

This study was conducted in Osun State Nigeria. Osun State (Ìpínlẹ̀ Ọ̀ṣun), occasionally known as the State of Osun by the state government, is a State in Southwestern Nigeria; bounded to the east by Ekiti and Ondo states, to the north by Kwara State, to the south by Ogun State and the west by Oyo State. The State is known for its rich cultural heritage, historical sites, and diverse economic activities. Multistage sampling technique was used to select respondents for the study. The first stage involves population selection of Ife-east Local Government Area (LGA) because of high population of cocoa farmer compared to other LGA in the State. At the second stage, five [5] villages were randomly selected based on their involving in cocoa production. Finally, twenty five [25] cocoa farmers were randomly selected in the villages/communities earlier chosen. Making a total of 125 respondents [cocoa farmer], meanwhile, five responses were discarded due to incomplete information. The research used descriptive statistics such as the mean, frequency, percentage variance to describe the socio-economic characteristic of the respondents in the study area and Logit regression to estimate the factors responsible for food insecurity among cocoa farmers in the study area, Awoyemi, *et al.,* (2022).

Food Security Index (FSI) was adopted for this Study

Method 1

In food security index, food security line was estimated from household monthly expenditure on food items. Any households spending above 2/3 of this line are classified as food insecure while those below it are considered food secure. The food security is calculated based on the total expenditure of food items consumed by a household over the past seven days. The food security index is given as:

$$F_i = \frac{percapitafoodexpenditureforthehouseholds}{{}^{2}/_{3}\, meanpercapitafoodexpenditureinallhouseholds}$$

Where

$$per\ capita\ food\ expenditure\ (PCE) = \frac{Total\ food\ Expenditure}{Household\ Size}$$

$$mean\ per\ capita\ household\ food\ expenditure\ (MPCFHE) = \frac{Total\ household\ PCE}{Total\ number\ of\ Households}$$

$$F_i = Foodsecurityindex$$

When$F_i \geq 1 \ = foodsecureithhousehold$

$$F_i \leq 1 = foodinsecureithhousehold.$$

Method 2

In order to compute the mean per capita household expenditure index, the following equations were adopted:

$$meanpercapitahouseholdexpenditure(MPHE) = \frac{\sum_i^n K_i}{\sum_i^n H_i}$$

Where: $K_i$is the monetary value of all food items that were consumed per day by the household, $H_i$is sum of members in the household. Therefore, the proportion of households that were food secured index (FSI) was computed as:

$$FSI = \frac{m}{N}, m$$

m is the number of food secured households, N is sample population. When this is multiplied by 100, it gives the percentage of households that were food secured.

The Logit Regression (LR) Model

The LR gives each predictor a coefficient which measures its independent contribution to variation in the dependent variable. The dependent variable Y takes the value 1 if the response is "food secure" and takes a value 0 if the response is "food insecure".

The Logit equation is written as (Green, 1993).

$$P_i = \frac{e^{\beta x}}{1 + e^{\beta x}}$$

Where P_i = 1(For food secure) and 0 for food insecure. Since Logistic regression calculates the probability of success (p) over the probability of failure (q), the results of the analysis are in the form of an odds ratio (p/q).

Y = (1 if food secured and 0 otherwise)

X_1= Sex, X_2= Age, X_3= Marital Status, X_4=Schooling, X_5= Household Size, X_6= Experience, X_7= Member of Association, X_8= Extension Agent, X_9= Number of Meal per day, X_{10}= Enough Food, X_{11}= Protein Rich, X_{12}= Meal Skip, ε = error term

Results and Discussion

Socioeconomic variables of the respondents are presented in Table 1. According to the Table, 50.83% of the respondents were male, while female were 49.17%. The result shows that both male and female constituted the rural households in the study area and male forms the majority probably because many of the nature of cocoa farming activities, thus agreeing with the finding of Ndaghu et. al., (2009) and Robert *et al.,* (2013) who reported that males are the most household heads who are responsible for major production decision. This finding however disagrees with Zubairu and Maurice (2014) and Hadebe and Mpofu (2013) who found that women are mostly involved in food crop production which ensures food security. The result further shows that the mean age for cocoa farming households' head was 61 years. About 38.33% of the total respondent households' head had their age below the mean age, while about 61.67% of the respondents had their age above it. Hence, there were older households' head than their younger counterparts in the study area. However this result is similar to the result obtained by Oluyole *et al.,* (2015) who found out that the older the household head, the lower the probability that the household would be food secure. Majority (83.3%) of the respondents were married. Given the very low rate of single (25.00%), widowed (10.0%) and divorced (2.5%). This implies that majority of the respondents will have additional responsibilities to their spouses and children. This implies that there is the likelihood that there could be more family labor available to farming households (Oluyole *et al.,* 2015). Gotten from the Table, majority (85.3%) of the respondents had between 3 and 16 children with mean size of 7. This could be regarded as large family size. However it is likely that these children will be used as source of manual labor in the household, also the age at marriage will have an impact on family size. The implication of this finding is that the quantity of food intake will be affected and dependency ratio will be affected. The larger the family size the lesser food availability to each person within the household and also nutritional status is affected. The result is in agreement with Babatunde *et al.,* (2007), which depicted that as the household size increases, the probability of food security decreases. This could mean that as the household size increases, there is larger number of people to be taken care of by the same source of income. Table 1 also shows that 35.83% of the respondent spent up to 7-12 years in school. This shows that the respondent with the more years of education will find it easy to assimilate new innovation that will aid their farming activities at a faster rate, which will lead them to be more food secured. While 28.33% of the responded spend up to 6 years in school will also understand the new innovation but at a slower rate. Result from Table one shows that 46.67% of the respondent are into farming activities as their major

occupation,11.67% are into Trading, 17.50% are Civil servant ,20% are artisan, 1.67% are Medical practitioner and 1.67% are also Driver and 0.83% are retired civil servant. The results in the Table also revealed that 69.11% of the respondents belonged to associations, while 30.83% did not belong to any associations. The implication of this result is that most of the farmers in the study area will likely enjoy the benefits accruable to the farming association society's membership through pooling of resources together for a better expansion and effective management of resources.

Estimate the Factor that is Influencing the Food Security among Cocoa Farming Household

A binary logistic regression analysis was conducted to estimate the factor that influencing the food security among cocoa farming household in the study area (Table 3). The dependent variable (Food Security) was captured as food insecure = 0 and food secured = 1 based on the food security line. The model is statistically significant, indicating that the explanatory variables estimated reliably distinguished between the food insecure and food secure (Chi-

square (χ^2) = 56.33, p = 0.000). Pseudo R-square value is 0.3842 indicating that 38.42% of the variation to be observed in the food insecurity situations of the cocoa farmers were explained by the combined effects of all the independent variables in the model specified. Binary logistic regression is based on four crucial assumptions that need to be addressed. First, the dependent variable should be ordinal. In this study, the dependent variable was captured as a binary variable. Secondly is the linearity assumption. Linearity in the binary logistic model assumes that independent variables have a linear relationship with the dependent variable. This assumption can be verified by checking the model fit statistics and pseudo-R-Squared (R^2). In this study, the model fit statistics and pseudo R^2 in Table 3 indicate that the model well fits data. Also, binary logistic regression does not need a linear relationship between the dependent and independent variables because it applies a non-linear log transformation to the predicted odds ratio. Thirdly is the assumption of independent errors. The assumption of independent errors states that errors should not be correlated for two observations. That is, data should be drawn from independent samples and not dependent samples such as before and after or matched pairings.

Household size variable is highly significant (p = 0.000) with a positive coefficient (β = 0.268). The results revealed that an increase in household size increases farmer's chances of becoming food insecure. The odds ratio value of 0.268 indicates that ceteris paribus, an increase in household size by one adult equivalent increases household log odds of becoming food insecure by 0.268 times. An increase in household size constraints existing income. Reduction in income reduces household consumption expenditure and hence an increase in household food insecurity. Previous studies such as Achieng (2014) and Macho (2015) found that an increase in household size, directly and indirectly, increases household poverty through reduction in income per adult equivalent which eventually impairs standard of living. Variable indicating number of meal per day is statistically significant (p = 0.003) with a positive coefficient (β = 6.198). The results revealed that number of meal per day reduces household food insecurity of cocoa farmers. The odds ratio = 6.198 means that ceteris paribus, access to number of meal per day reduces household log odds of becoming food insecure by 6.198 times and vice versa (Igbalajobi *et al.,* 2013). Variable indicating the age of household head is statistically significant (p = 0.084) with a coefficient (β = -2.009). The results means that an increase in the age of household head increases his/her chance of becoming food insecure and vice versa. The odds ratio = 1.078 shows that ceteris paribus, an increase in the age of household head one year, increases log odds of a household becoming food insecure by 1.078 times and vice versa. As the age increases, the productivity of household head decreases due to poor health associated with old age. The findings agrees with Khamaldin *et al.,* (2015). The studies revealed that the aging of the household head tends to increase the household probability of falling into food insecurity. Contrary results are reported in Akona (2014), who found that an increase in the age of household head significantly reduces household observed poverty. The study argued that as the household head grows older, he/she should accumulate more income that is sufficient to move their households out of poverty.

Constraint to Cocoa Production

The constraints encountered by the respondents as revealed in the study indicated that higher percentage of the respondents which is 99.17% has access to land for Cocoa production. While 0.83% claimed to have no access to land for the production of cocoa as shown in Table 5. About 71.67% do not have access to good farm road and only the few 28.33% have access to good road. In Table the results also shows that 57.50% of the respondents are very much affected by pest and disease, while 40.50% are not that affected. Pest and disease of cocoa are the major challenges faced by cocoa farmer and it reduces their level of production. This shares a relationship with the research carried out by Andrew *et al.,* (2022).Which revealed that Pest and diseases represent a challenge to production to a greater or lesser extent in most Cocoa-growing regions. From the Table, 100% indicated that they are sure that there is no rituals associated with cocoa farming in the study area. The study revealed that 36.67% of the respondents had no access to credit while 63.33% have access to production credit from both formal and informal sources in terms of acquired for farm. This access to production credit by some of the respondents may not be unconnected with the fact that many of the respondents belonged to a cooperative society which is the major means of obtaining assistance either from Government or Non-Governmental Organizations (NGO). From the Table, the result of the respondent show that 36.67% faced pest and disease challenges, 25.00% faces too much rainfall, 20.83% faces monkeys infestation, 5.00% faces high prices of Agrochemicals, 4.17% faces mistletoe infestation, 5.00% faces financial problems, 1.67% faces pest and diseases and too much of rainfall and also 1.67% faces weather as major challenges.

Table 4: Constraints to cocoa production

	Frequency	Percentage
Do you have access to farm land for cocoa farming?		
No	1	0.83
Yes	119	99.17
Do you have access to good road for transportation to bring cocoa input into your farm?	Frequency	Percentage
No	86	71.67
Yes	34	28.33
How do pest and disease affect cocoa production on your farm	Frequency	Percentage
Very much	69	57.50
Not much	51	42.50
Are there cultural or rituals associated with cocoa production		
No	120	100.00
Have you had to finance cocoa farming activities		
No	44	36..67
Yes	76	63.33
What are the major challenges faced in cocoa farming		
Pest and disease	44	36.67
Too much rainfall	30	25.00
Monkey infestation	25	20.83
High price of agrochemicals	6	5.00
Mistle-toe infestation	5	4.17
Financial problem	6	5.00
Pest and disease and too much rainfall	2	1.67
Weather	2	1.67

Source: Field Survey, 2024

Conclusion

The study was necessitated due to the significance role cocoa exports play in the development of the Nigeria economy. Results from the study showed high level of food insecurity among cocoa producing households in the study area. The study therefore recommends that reduction in food insecurity should involve an integrated approach by both the government and private sectors through regular orientation that promotes education among farm households on the need to diversify their sources of income from agriculture to off-farm income generating business. In addition, Government and farmers groups should provide agricultural inputs to farming households during farming seasons at affordable prices in order to increase their farms size and food production capacity since

farm size was one of the factors that influenced farm household food security.

Assessing Contamination Risks in Sultanköy and Altınyazı Reservoirs (Türkiye) Using Modified Organic Pollution Indices

Said Muhammed[1], Cem Tokatlı[2]

[1]University of Peshawar, National Centre of Excellence in Geology, Peshawar / Pakistan
[2]Trakya University, Evrenos Gazi Campus, Edirne / Türkiye
e-mail: saidmuhammad1@gmail.com

Abstract

Due to their lentic and enclosed nature, lakes are more susceptible to organic pollution and eutrophication. Sultanköy and Altınyazı reservoirs are located in the Edirne Province of Türkiye, where is classified as "Agricultural Land" because of its abundant freshwater resources and fertile soils. The reservoirs are exposed to organic pollution from surrounding agricultural activities and domestic wastewater. This study evaluated and compared the contamination threats for the Sultanköy and Altınyazı dam lakes by means of some modified organic contamination indices using Turkish Standards. For this purpose, nutrient pollution index (NPI) and water quality index (WQI) were selected as the organic pollution risk assessment indicators. Water samples were collected in the autumn season of 2024 and measured for 5 limnological parameters (SO_4, NO_3-N, NO_2-N, NH_4-N and PO_4-P) that are used to calculate the indices. The results revealed that although the Altınyazı Reservoir exhibits a lower potential eutrophication risk compared to Sultanköy Reservoir, the waters of both dam lakes were highly polluted.

Keywords: *Sultanköy Reservoir, Altınyazı Reservoir, Organic pollution indicators*

Introduction

Organic contaminants, particularly nutrients derived from agricultural runoff and wastewater, are critical drivers of algal bloom formation in lacustrine ecosystems (Atıcı et al., 2018; Haq et al., 2023; Din et al., 2023; Muhammad et al., 2025). These blooms, characterized by excessive algal proliferation, disrupt aquatic ecosystems by depleting dissolved oxygen, obstructing light penetration, and altering trophic dynamics. Furthermore, organic contamination contributes to the development of hypoxic zones, where oxygen concentrations decline to critically low levels (Howarth et al., 2011; Borrell et al., 2019; Mia et al., 2023). The assessment of organic contaminants is crucial for understanding their cumulative effects on aquatic biodiversity, water quality, and overall ecosystem integrity (Çiçek et al., 2014; Köse et al., 2020; Varol et al., 2022; Ustaoğlu et al., 2022; Yüksel et al., 2024). A comprehensive approach is required to effectively evaluate aquatic ecosystem health and formulate sustainable management strategies. Notably, key indicators such as the Nutrient Pollution Index (NPI) and the Water Quality Index (WQI) are widely utilized to assess the synergistic impacts of organic contamination (Tokatlı and Varol, 2021; Varol et al., 2022; Muhammad et al., 2024; Tokatlı et al., 2025).

Sultanköy and Altınyazı Dam Lakes are among the most significant reservoirs in Edirne Province, Türkiye, serving as essential water sources for both irrigation and drinking water supply. Constructed by the General Directorate of State Hydraulic Works (DSİ) to enhance agricultural productivity and fulfil the water demands of local communities, these reservoirs play a crucial role in maintaining both economic stability and ecological balance (http://www2.dsi.gov.tr/). However, similar to many freshwater ecosystems, they are increasingly subjected to anthropogenic pressures, particularly from agricultural runoff and domestic wastewater discharge. These activities introduce excessive nutrients, pesticides, suspended solids, and organic pollutants into the water bodies, posing significant risks to water quality and aquatic ecosystem health (Tokatlı et al., 2017; Tokatlı, 2019; 2020a; 2020b). This study aims to assess and compare the contamination threats affecting Sultanköy and Altınyazı Dam Lakes by employing a set of modified organic contamination indices. The evaluation is conducted in accordance with Turkish Standards, providing a comprehensive framework for analysing the extent and impact of organic pollution in these freshwater ecosystems. By utilizing standardized assessment methods, the study seeks to offer valuable insights into water quality dynamics and potential environmental risks, thereby contributing to the development of effective management and conservation strategies.

Materials and Methods

Research area and sample collection

Sultanköy and Altınyazı Dam Lakes, along with the selected sampling stations on these reservoirs, are presented in Figure 1, providing a visual representation of the study area. To evaluate the current water quality status, water

Turkish Science and Technology Publishing (TURSTEP)
www.turstep.com.tr

samples were systematically collected from the designated stations during the autumn season of 2024, ensuring that potential pollutant influxes were accurately represented in the analysis.

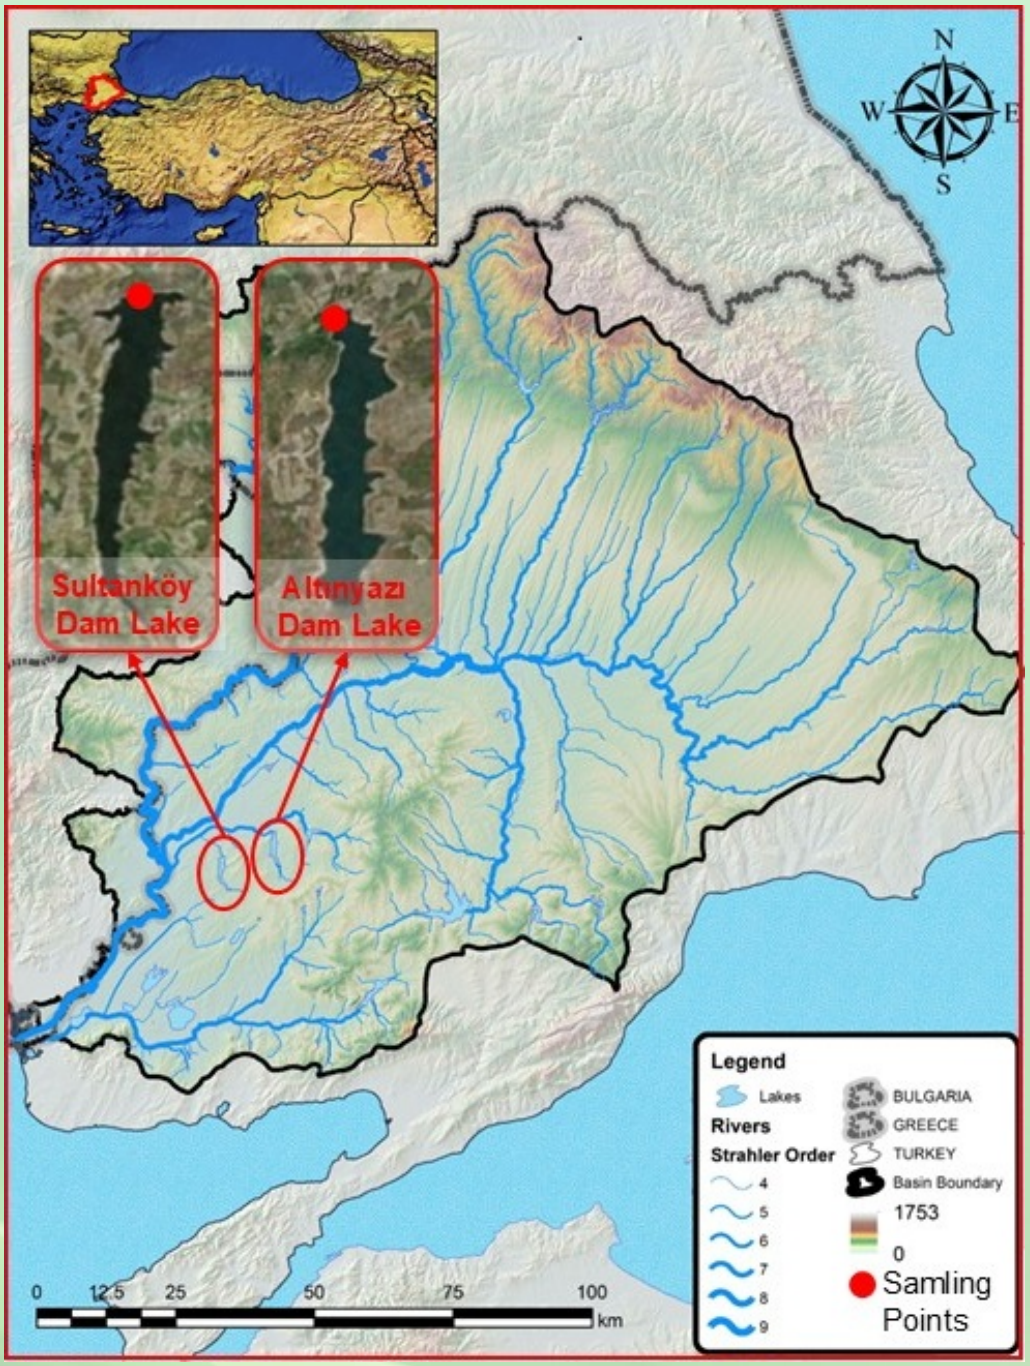

Figure 1. Meriç – Ergene Basin, investigated reservoirs and selected sampling stations

Physicochemical analysis and ecological indices

The concentrations of phosphate-phosphorus, nitrite-nitrogen, nitrate-nitrogen, ammonium-nitrogen and sulphate were analysed in the laboratory following APHA protocols (1998, 2017) using a Hach spectrophotometer and a Hach colorimeter.

The details of the formulas and computation techniques for the modified organic contamination indices applied in this study, based on the Turkish Standards (TSWQR, 2021), are provided in Table 1 (Tokatlı et al., 2025). These indices were carefully selected to assess the level of contamination and biodegradability in the water samples, ensuring an accurate representation of the environmental conditions.

Table 1. Methods of applied modified organic pollution risk assessment indices

Index	Calculation	Formula Explanations	Rating of Water Quality
NPI	$NPI = (C_N/MAC_N) + (C_P/MAC_P)$	C_N: The levels of NO_2-N in water sample C_P: The levels of PO_4-P in water sample MAC_N: The maximum limit of NO_2-N MAC_P: The maximum limit of PO_4-P	<1: No polluted 1-3: Moderate polluted 3-6: Considerable polluted >6: Very high polluted
WQI	$WQI = \sum_{i=1}^{n} Wi\ x\ (\frac{Ci}{Si})\ x\ 100$ $Wi = \frac{W_i}{\sum_{i=1}^{n} W_i}$	WI: The relative weight Wi: The values assigned to i (1-5) Ci: The values of measured parameters Si: The standard values	<50: Excellent water quality 50–100: Good water quality 100–200: Poor water quality 200–300: Very poor water quality >300: Unsuitable

Results and Discussion

The data for the calculated modified organic contamination indices for the waters of the Sultanköy and Altınyazı reservoirs are presented in Figure 2. The results indicate that although the Altınyazı Reservoir exhibits a lower potential eutrophication risk compared to Sultanköy Reservoir, the waters of both dam lakes were highly polluted. According to the applied ecological indices, it was determined that the water qualities of both reservoirs are considerably degraded, exhibiting high levels of pollution. Specifically, the Nutrient Pollution Index (NPI) were recorded as 8.10 for Sultanköy Reservoir and 6.50 for Altnyazı Reservoir, both falling into the "very high pollution" category. Similarly, the Water Quality Index (WQI) values were recorded as 284 for for Sultanköy Reservoir and 198 for Altnyazı Reservoir, classifying as "very poor water quality" and " poor water quality", respectively.

The application of chemical fertilizers, which contain considerable amounts of nitrogenous and phosphorus compounds, is a prevalent agricultural practice in the areas surrounding the reservoirs. These fertilizers, along with organic pollutants from agricultural runoff, can be transported into adjacent water bodies through multiple pathways, including irrigation, precipitation, and soil erosion (Mutlu et al., 2021a; 2021b; Jannat et al., 2022; Tokatlı et al., 2023; 2024). The accumulation of these pollutants within the reservoirs leads to excessive nutrient enrichment, thereby exacerbating the risk of eutrophication. Furthermore, domestic wastewater discharges from nearby settlements are considered a major contributing factor to the elevated ecological risk index values identified in this study, highlighting the significant anthropogenic pressures impacting these freshwater ecosystems.

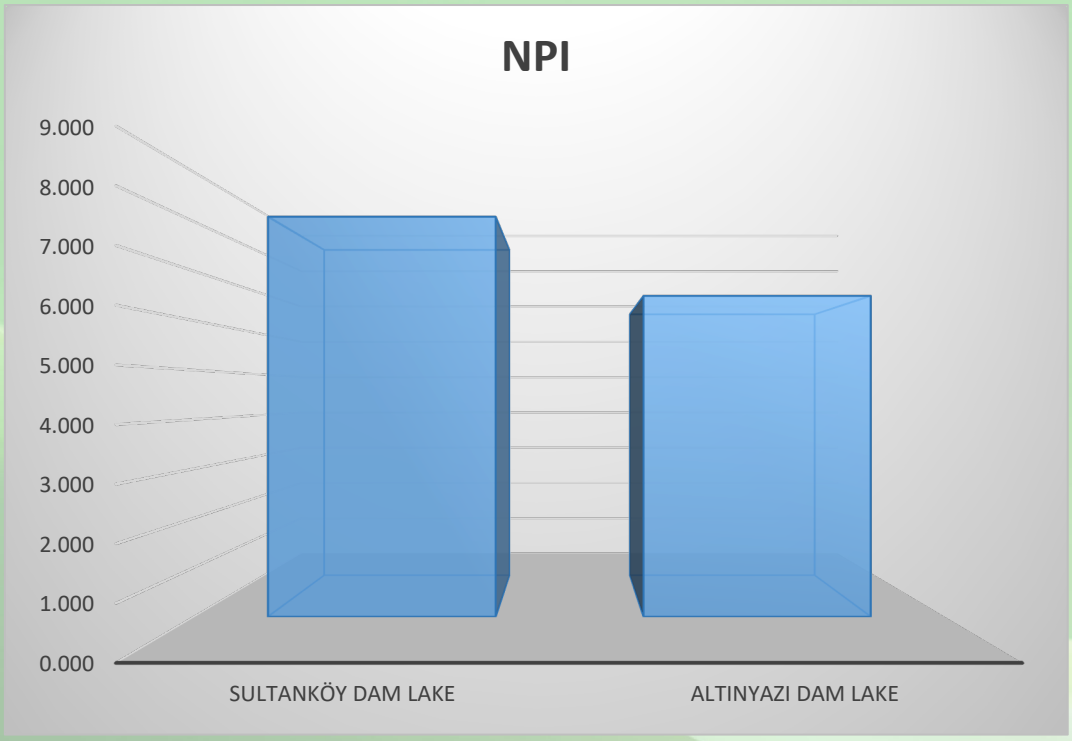

Figure 2. Results of applied NPI (up) and WQI (down) in waters of investigated dam lakes

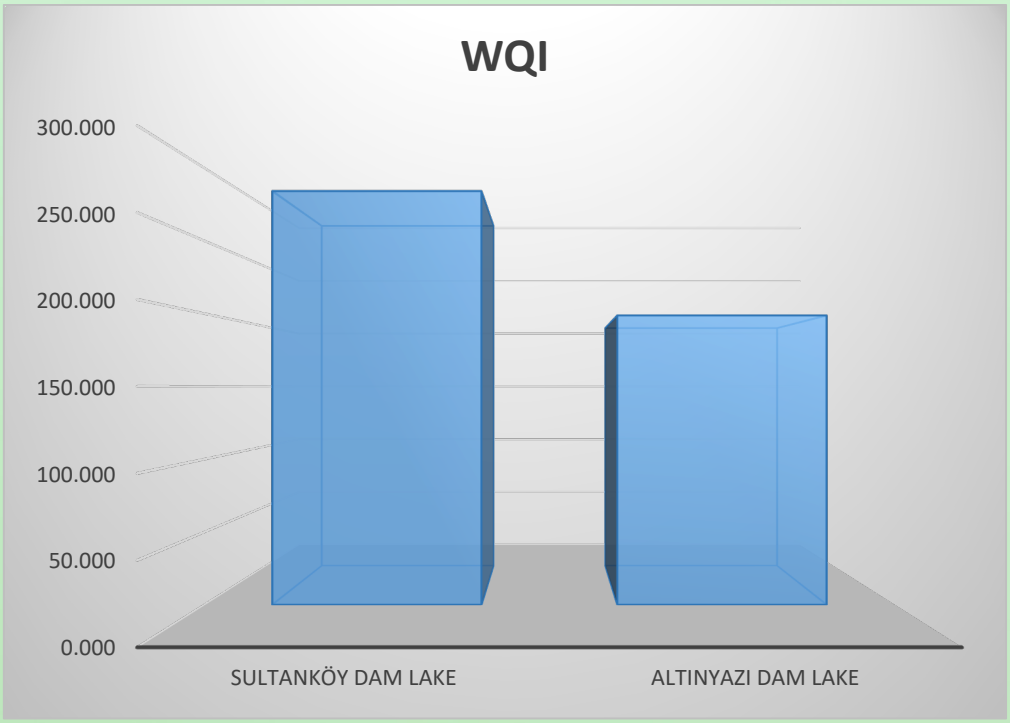

Figure 2. Results of applied NPI (up) and WQI (down) in waters of investigated dam lakes (continued)

Conclusions

The findings of this study reveal significant organic contamination in both Sultanköy and Altınyazı Reservoirs, highlighting severe water quality degradation. Although Altınyazı Reservoir exhibited a relatively lower risk of eutrophication compared to Sultanköy Reservoir, the overall pollution levels in both water bodies were alarmingly high. The calculated Nutrient Pollution Index (NPI) values of 8.10 for Sultanköy Reservoir and 6.50 for Altınyazı Reservoir indicate that both reservoirs fall within the "very high pollution" category. Similarly, the Water Quality Index (WQI) values of 284 for Sultanköy Reservoir and 198 for Altınyazı Reservoir classify the water quality as "very poor" and "poor," respectively. These results underscore the urgent need for comprehensive water management strategies to mitigate further degradation and restore ecological balance in these critical freshwater ecosystems.

Comparative Aluminum Stress Tolerance in Red (Fırat-87) and Black-Seeded (Beluga) Lentils

Muhammad Sameeullah[1]
[1]Departmentn of field crops, Faculty of agriculture, Bolu Abant Izzet Baysal University, Bolu, Türkiye

Abstract

Aluminum (Al) is a significant toxicant that restricts root growth in plants, even at low concentrations found in acidic soils. This study aimed to investigate the comparative Al stress tolerance of a red lentil cultivar (Fırat-87) and a black-seeded lentil cultivar (Black Beluga). Five-day-old seedlings of both cultivars were exposed to 100 µM $CaCl_2$ (control) or 100 µM $CaCl_2$ supplemented with 50 µM Al (Al treatment) under hydroponic conditions at pH 4.5 for 24 hours. Histochemical staining of Fırat-87 roots with hematoxylin demonstrated clear cracks and intense dark staining in the root apex and elongation zone, indicating a greater accumulation of Al compared to Black Beluga. Similarly, Evan's blue staining revealed cracks and dark blue staining in the root elongation zone of Fırat-87, whereas Black Beluga showed no visible cracks or dark staining. Lipid peroxidation, assessed using Schiff's reagent, exhibited pronounced dark pink staining in the root apex of Fırat-87, but only minimal staining in Black Beluga. These histochemical analyses suggest that Fırat-87 is more susceptible to Al toxicity than Black Beluga. Consistent with these findings, Black Beluga exhibited significantly higher relative root elongation (77.27%) compared to Fırat-87 (55.32%), reinforcing its Al tolerance. Quantitative real-time PCR analysis of the *LcALMT1* gene revealed significantly higher expression levels in Al-treated roots of Black Beluga compared to Fırat-87, implying that *LcALMT1* may play a crucial role in the enhanced Al tolerance observed in Black Beluga. In conclusion, these results demonstrate that Black Beluga is an Al-tolerant lentil cultivar, making it a promising candidate for cultivation in acidic soils without compromising seedling establishment and subsequent growth.

Key Words: *Aluminum toxicity, Lentil tolerance, Histochemical staining, Root elongation, LcALMT1 gene expression*

[2]Department of Agricultural Economics, School of Agriculture and Industrial Technology, Babcock University, Ilishan-Remo, Ogun State, Nigeria

Abstract

The rising awareness of functional foods and their health benefits has influenced consumer preferences and purchasing behavior globally. However, limited research exists on the consumption patterns of functional foods in Nigeria. This study examines the determinants of functional food consumption in Ifo Local Government Area, Ogun State, using primary data collected through structured questionnaires administered physically and virtually via the KoboToolbox platform. A multistage sampling technique was employed, selecting 10 Community Development Committees (CDCs), 30 Community Development Associations (CDAs), and 300 households, with 240 valid responses for analysis. Descriptive statistics were used to assess the socio-economic characteristics, awareness levels, and purchasing behavior of respondents. A Poisson regression model was applied to identify key factors influencing functional food consumption. Findings indicate that age, marital status, and income significantly determine purchasing behavior. Family, friends, and health professionals were the primary sources of nutrition information, while local markets and roadside vendors served as major suppliers. Price and availability emerged as the most crucial factors affecting consumer choices. To enhance functional food consumption, policies should focus on improving accessibility, regulating prices, and increasing consumer awareness. Additionally, future research should expand to larger and more diverse populations to strengthen the generalizability of findings. Insights from this study provide valuable information for policymakers, food producers, and marketers to promote functional foods and support sustainable nutrition practices in Nigeria.

Key Words: *Preference, Purchasing behaviour, Functional Foods, Households, Nigeria.*

Introduction

Recently, there has been growing concern about the healthiness of diets globally, and consumers are revealing increasing interest in foods that minimise the risk of diseases for optimal health promotion, boost mental health and improve quality of life beyond foods with the traditional aim of hunger satisfaction or correction of nutrient deficiency (Green, 2014; Amoah et al., 2023). This is because poor-quality diets are highly correlated to chronic diseases like cancer, diabetes, heart disease, stroke, obesity and hypertension (Drewnowski et al., 2021), and have been identified as a phenomenon with the greatest threat to public health worldwide and changing lifestyles like poor nutrition and inadequate physical activity caused the epidemic of non-infectious diseases which lead to several health problems and even death (Plasek *et al*., 2020). According to Goetzke *et al*. (2014), it is important to prevent diseases considering the high costs of curative medicine. Therefore, it is pertinent to advocate for increasing the intake of foods with additional health benefits among households, which includes functional foods. The public interest in the concept of functional foods came into the limelight during the global awareness of the role foods could play in improving the health of human beings and was first established by the Japanese to introduce a legal category of foods with potential health benefits as part of national efforts to curbing the increasing cost of health care (Ohama *et al*., 2006). Functional food was invented in 1980 in Japan and was defined as enhanced food products that give a positive physiological action (Stanton *et al*., 2005). Functional foods could be natural or altered food products by adding or removing one or more components, reducing the risk of disease (Roberfroid, 1999). In 2012, a more consensus and acceptable definition was developed at the Functional Food Centre (FFC)'s 10th International Conference in Santa Barbara, CA. Functional foods were defined as ''Natural or processed foods that contain known or unknown biologically-active compounds; which in defined amounts provide a clinically proven and documented health benefit for the prevention, management, or treatment of chronic disease" (Martirosyan & Singh, 2015). Having noticed a deficiency in this definition, in 2014, at the 17th international conference jointly organised by the United States Department of Agriculture (USDA) and Agriculture Research Service (ARS). The definition of functional food was revisited in a Panel Discussion entitled "The Definition of Functional Foods and Bioactive Compounds". Functional foods were defined as "Natural or processed foods that contain known or unknown biologically-active compounds; which, in defined, effective, non-

toxic amounts, provide a clinically proven and documented health benefit for the prevention, management, or treatment of chronic disease" (Functional Food Centre, 2018). The amendment to this definition was in the amount of bioactive compound previously stated to be ´´defined amount´´ but changed to ´´defined effective non-toxic amount´´. This was necessary as the latter gave a more precise description for future use. Hence, the latter definition will be used in this study to select local functional foods established in the literature.

There are many health benefits of functional foods, ranging from their potential to boost the immune system to reduce the risk of cardiovascular problems, osteoporosis, obesity and cancer (some types), as well as to enhancing memory and physical condition (Bekoglu *et al*., 2016; Topolska *et al*., 2020). It generally improves the quality of life, prevents obesity and improves psychophysical and working ability (Jokić *et al*., 2016). It is acknowledged in the food market as a special category. It represents one of the most intense areas of innovation in food products globally (Đurović *et al*., 2020). It is more sought after in the hospitality market because it is essential for improving the quality of life, balancing and maintaining the maximum of body functions, maintaining health and reducing disease risk (Cvetković *et al*., 2016). Fortified products such as non-alcoholic beverages fortified with vitamin A, dairy products containing Lactobacillus fermentum ME-3, enriched products such as eggs enriched in omega-3 and vitamin E, natural foods such as cereals like oats and barley, which can be used as fermentable substrates for the growth of probiotic microorganism are examples of functional foods approved by European Food Safety Authority (Siro *et al*., 2008)

In Nigeria, some local/natural foods have potential as functional food sources. For instance, Acham *et al*. (2018) stated that Nigeria has abundant preservation of its own local functional food resources with massive potential of being a source of revenue to the people who are now becoming more conscious of their lifestyles or health status. In this study, local/natural functional foods are obtained from natural sources such as traditional food, fruits and vegetables. Some of these foods are edible mushrooms, tigernuts, soy milk, melon seed, bitter leaf, moringa, kunun-zaki, zobo, snail, edible insects, fura da nunu and garlic (Chanda *et al*., 2011; Akerele *et al*., 2016; Acham *et al*., 2018; Adenowo & Kazeem, 2020). These foods have been proven to have many health benefits. For instance, garlic has antimicrobial activity, anti-carcinogenic effects, antioxidant activity, ability to reduce cardiovascular diseases, improve immune functions, anti-diabetic activity and contains sulfide (Diallyl-sulfide, Diallyl-thiosulfinate, Allyl-methyl trisulfide) that help in detoxification of undesirable compounds, support the maintenance of heart, immune and digestive health; prebiotics (Inulin, Fructo-oligosaccharides, Polydextrose), that enhance maintenance of digestive health and calcium absorption; as well as selenium, which neutralises free radicals that may damage cells, and aids maintenance of immune and prostate health (Rahman, 2007). Frequent consumption of edible mushrooms can cure diabetes, breast cancer, prostate and high cholesterol levels (Okigbo & Nwatu, 2015). In fact, tigernut was referred to as natural functional food owing to its usefulness in treating indigestion and controlling flatulence, excessive thirst, diarrhoea, and dysentery treatment. It is also used in the prevention and treatment of coronary heart disease, obesity, diabetes, colon cancer and gastrointestinal disorders (Chevallier, 1996; Adejuyitan, 2011). Other local foods like fura (from millet) can prevent the incidence of gallstones in women (Chibuikem, 2015); edible insects like termite (M. nigeriensis) can be added to the diets of people suffering from high blood cholesterol content and probably at risk of cardiovascular disease because of its high desirable unsaturated fatty acid content and low saturated fatty acid (Alamu *et al*., 2013); snail is used in some part of Africa as native medicine to treat hypertension, whooping cough and asthma (Offiong *et al*., 2013). However, most of these foods are yet to be approved as functional food due to legislative or regulatory issues, especially by the European Union, which accepts products as functional foods if they are labelled and if the acclaimed health and nutritional benefits on their labels are guaranteed by law (Chanda *et al*., 2011). Although people are shifting attention to food with functional benefits to their health, studies have shown that preference has been given to natural/local functional food, that is, food whose functional components are inherent in the original products rather than added functional components (Siegrist *et al*., 2008; Kuster-Boluda & Vidal-Capilla, 2017).

Functional food is an emerging concept in Nigerian literature. Little is known empirically about the consumers´ awareness, preference and purchasing behaviour of these functional foods. For instance, some of the studies considered consumers´ attitudes and willingness to pay in Malaysia, Iran, Italy, Germany, China, Turkey, Spain (Salleh *et al*., 2015; Siegrist *et al*., 2015; Bekoglu *et al*., 2016; Küster-Boludaa & Vidal-Capilla, 2017; Mohammad *et al*., 2017; Palmieri *et al*., 2022). However, these studies pay little attention to local/natural functional foods. The available literature in Nigeria mainly selected one of these natural functional foods; for instance, Akerele et al. (2020) and Obayelu et al. (2015), among others, examined the health claim awareness and sources of the awareness for tiger nut and Consumers' willingness to pay for labelled and certified moringa products respectively. Also, Adetunji et al. (2022) focused on mushrooms as functional foods.

It is pertinent to examine consumers' preferences and purchasing behaviour of functional foods to provide information for farmers, food processing industries, and food marketers on the potential of these local foods as a source of income and to develop marketing strategies to capture potential customers in different parts of the world. In the long run, it will increase farmers' income, reduce poverty and promote good health and well-being, which are crucial parts of the sustainable Development Goals (SDGs) for 2030. Several researchers surveyed functional

foods and consumers' attitudes towards them. They observed that people purchase functional foods because they perceive they are healthier, safer and more convenient than other products (Nystrand & Olsen, 2020; Marina & Marija, 2014). Preference and purchasing behaviour of consumers could serve as sources of innovative ideas for novel foods (Grujić, 2024). To formulate and model products, producers must identify food properties that can benefit target consumers (Grujić & Odžaković, 2021). Consumers must widely accept functional foods. Other than its health properties, it must appeal to consumers. A healthy diet is popular when it includes tasty foods with acceptable sensory quality (Grujić et al., 2023). Food producers must improve the attractiveness of healthy food products for consumers' trust and acceptance (Lassale et al., 2019; Springfield et al., 2020). Producers must ensure they produce what consumers want in terms of quality and quantity. Consumer preference and purchase decisions cannot occur without knowledge of their motivations and utility derived. Information on consumer preference and purchasing behaviour of functional foods is essential to identify potential economic opportunities, promote food innovation and promote trade.

Materials and Methods

This research was conducted in the Ifo Local Government Area of Ogun State. Primary data were obtained through a questionnaire, and data collection was accomplished with the aid of a Kobotool box, which enabled us to access respondents physically and virtually. A multistage sampling technique was adopted to select respondents for the study. The first stage randomly selected 10 Community Development Committees (CDCs) in Ifo L.G.A. The second stage was the proportional random sampling of 30 Community Development Associations (CDAs) from the selected CDCs based on the size of the CDC. The third stage randomly selected 10 households from each selected CDA to give 300 households. However, only 240 households' responses were helpful in our analysis, giving an 80% response rate. The reason for this low response rate was that most of the responses gotten virtually did not complete the questionnaire compared to the respondents we interacted with physically.

Analytical Tools

Descriptive Statistics

We used descriptive statistics to describe the socio-economic characteristics of the respondents, the level and sources of awareness of urban households about the nutrition and health benefits of functional foods, and assess consumer preference and purchasing behaviour of selected functional foods.

Poisson Regression Model

The Poisson regression model was used to determine the factors influencing the purchasing behaviour of selected functional foods. The Poisson regression model was specified owing to its appropriateness in estimating count data as it is a non-linear regression model application of Poisson distribution. (Mensah-Bonsu et al., 2017). In this model, a scalar dependent variable is linked to independent variables. Following Chekol et al. (2022), this can be expressed as:

$$P(Y_i = y_{i,}\mu) = \frac{e^{-\mu_i}\mu^y}{y_i!}, \mu_i > 0, i = 1,2,3 \dots \dots$$

The equation can be specified as:

$$\mu = exp(\beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \cdots + \beta_k X_{ki})$$

Where y_i is the value of the count outcome occurring at a time with a mean parameter μ_i; μ is the mean and variance of the Poisson distribution, assumed to be a non-linear function of the explanatory variables; βs are the intercept and the coefficients of the (estimated parameters as maximum likelihood function) regressors; K represents the number of regressors.

The dependent variable (y) is the frequency of purchase of functional foods per week. The analysis was done separately for each selected functional food.

The explanatory variables used in the study are:

X_1 = Awareness of health benefits (Dummy: 1 if yes; 0, otherwise)
X = Age of household head (Years),
X_3 = Sex of household head (Dummy: 1 if male; 0, otherwise),
X_4 = Marital status (Dummy: 1 if married; 0, otherwise), Households size (Number)
X_5 = Education (Years spent in school),
X_6 = Major occupation of spouse (Dummy: 1 if civil service; 0, otherwise),
X_7 = Major occupation of household head (Dummy: 1 if civil service; 0, otherwise),
X_8 = Monthly income of spouse (Naira),
X_9 = Monthly income of household head (Naira),
X_{10} = Monthly garlic expenditure (Naira),
X_{11} = Monthly ginger expenditure (Naira),
X_{12} = Monthly tigernut expenditure (Naira),
X_{13} = Monthly turmeric expenditure (Naira)
X_{14} = Monthly moringa expenditure (Naira)

Results and Discussion

Socioeconomic Characteristics of Households.

The mean age of household heads in the study area was approximately 53 years, which means that the majority (about 57%) were aged above 50 years. The majority (app. 85%) of household heads were male, as expected from typical African culture, where males are expected to head households and provide basic needs for them. Most (about 85%) household heads were married, which may have substantially affected their consumption pattern compared to other types of households. The average household size was 4, and the majority (about 56%) of households had less than 4 members, close to the average size of 5 from Akerele *et al. (2020)*. There was a high level of education among the households in the study area, where the largest share of the respondents (about 44%) had a bachelor's degree or higher national diploma. In comparison, only about 2% had no formal education, which was contrary to the finding of Akerele et al. (2020), where NCE and National Diploma were the highest levels of education. The major occupation of more than half of the household heads was civil service, followed by trading, while the majority (about 54%) of their spouses were traders.

Distribution of Households' Income and Food Expenditure.

The average monthly income of the household head was about 88,000 naira, meaning that the most significant proportion (about 45%) earned between 50,000 and 100,000 naira monthly. On the other hand, the majority (about 69%) of the spouses earned 50,000 naira or less per month. On average, about 47,000 naira was spent on food by the households in the study area, while about 100,000 naira was spent on non-food items. This implies that the majority (about 87%) of the households spent less than 50,000 on food, while more than 50% spent between 50,000 and 100,000 on non-food items.

Level and Sources of Awareness About the Health Benefits of Functional Foods

Most households knew the health benefits of all the selected functional foods (moringa, garlic, ginger, tigernut, and turmeric). This awareness could influence their consumption and dietary choices. The level of awareness varies across functional foods; the highest awareness level was reported for ginger, with about 99% of the respondents, followed by garlic (about 97%), tiger nut (app. 93%), and turmeric (app. 78%). Moringa had the lowest awareness level with about 56% of respondents. This means that almost all the respondents knew the health benefits of ginger, garlic, and tigernut. This is crucial for their preference and consumption among households.

The data also give insights into how individuals in the surveyed population gain awareness about dietary choices. Family and friends (43.75%) and health professionals (35.83%) were the two most common sources of awareness about functional health benefits. This indicates that personal relationships and healthcare experts play significant roles in propagating the healthiness of diets. Books or publications (9.58%), seminars or workshops on nutrition (3.75%), and radio/television (4.59%) were also sources of awareness to some individuals, although to a lesser extent. Only about 2% of the respondents got information on the health benefits of these foods through newspapers. This might be due to low publications on the health benefits of foods in newspapers or that most respondents have not acquainted themselves with the newspaper. In summary, this result showed a high level of awareness about the healthiness of functional foods. It emphasised the significant impact of family, friends and healthcare professionals in achieving such a high level of awareness. The implication is that family, friends, and health workers can be important avenues for shaping urban households' dietary choices and consumption patterns to be healthy and sustainable.

Frequency of Purchase of Functional Foods Per Week

The result of the weekly purchase of functional foods is presented in Table 4. Ginger is the most frequently purchased functional food among the selected foods, and it was purchased on average about 1.48 times per week. This was followed by tigernut and garlic, which were purchased about 1.36 and 1.26 on average, respectively, per week. The high purchase frequency of ginger and garlic might be because most households use them as spices in food and soup. Also, tigernuts require little or no processing compared to others before eating, and most people eat them as snacks, which justifies their higher purchase frequency. Turmeric and moringa were the least purchased

functional foods, with an average purchase frequency of 0.97 and 0.98, respectively. Unlike garlic and ginger, these two functional foods are used primarily for medicinal purposes among those aware of their functionality; consequently, if we assume that purchases equal consumption, this result shows that the most frequently consumed functional foods were ginger, garlic, and tigernuts due to their inclusion as spices in foods and minimum processing requirements.

Attributes Considered When Selecting Functional Foods

When choosing preferred functional foods, consumers consider some attributes that later inhibit or improve their purchasing behaviour. These attributes include taste, flavour, nutrient content, health benefits and price. The respondents were asked to select the most important attribute before selecting functional foods. According to their responses, nutritional value was the most important attribute, with more than 70% of the respondents' affirmation. This was followed by flavour, health benefits and taste, as indicated by about 66%, 58% and 57% of respondents. Price was the least considered attribute, as it was chosen by only about 13% of the respondents. This showed that respondents valued functional nutritional and health attributes over their prices. Consequently, emphasis should be placed on the quality of functional foods when policy regarding their consumption is formulated.

Table 5: Attributes Considered in Selecting Functional Foods

Attributes	% of an affirmative response
Taste	56.67
Flavour	66.25
Nutritional value	70.83
Health benefits	57.92
Price	13.33

Source: Field Survey, 2023

Attributes Considered When Purchasing Functional Foods

We also inquire about the attributes that influence the purchase of functional foods. Some of the factors frequently mentioned in the literature were presented to the respondents, including price, availability, taste, quality, convenience, and security, among others, to rank based on their effects on the purchase. The result showed that price, availability and taste were ranked first, second and third, respectively, as the factors with the most significant impact on purchasing functional foods. This is understandable based on the premise of demand theory. It might also be a result of the economic status of most of the respondents. The implication is that policy on price regulation, increasing production and value addition to functional foods should be a priority to increase the consumption of these foods among consumers.

Table 6: Attributes Considered when Purchasing of Functional Foods

Factors	Score	Rank
Price	1119	1st
Availability	1087	2nd
Taste	1077	3rd

Point of Purchase of Functional Foods

The point of purchase is necessary for targeting policy intervention. Identifying the point of purchase of most respondents would enlighten policymakers on how to improve the marketing of these products and pricing regulation to enhance their consumption. According to this result, the purchase points of the selected functional foods vary slightly. While most of the functional foods (four out of five, that is, garlic, ginger, turmeric and moringa) were purchased at the local markets by the majority (more than 50%) of the respondents, tigernut was purchased from roadside vendors by the most (about 45%) of the respondents. Aside from local markets, some respondents also purchased from supermarkets, making it the second preferred point of purchase for garlic, ginger, turmeric and moringa. The implication is that to facilitate the consumption of functional foods, the government and non-governmental organisations should target local markets when formulating policies regarding demand, supply and price regulation for functional foods to improve their consumption.

Table 7: Point of Purchase of Functional Foods

Tigernut	Frequency	Percentage
Local markets	88	36.67
Roadside vendors	107	44.58

Factors Considered When Choosing Where to Purchase Functional Foods

Most respondents ranked safety, freshness, and brand reputation as the most important factors for choosing the supermarket to purchase functional foods. Purchasing by the roadside was motivated mainly by safety, which ranked first, followed by price and freshness. In contrast, the highest choice factors for local market purchase were safety, variety and price. Based on this, safety was the most important factor consumers considered when choosing where to buy functional products, followed by freshness prices. This implies that to increase the consumption of functional foods, policymakers and stakeholders in agriculture, food system, and health should monitor all purchase points to improve the safety of goods so that consumers can purchase these items at any purchasing point closer to them without worrying about food safety.

Table 8: Factors that Determine the Choice of Point of Purchase

Factors Influencing the Purchasing Behaviour of Selected Functional Foods

Table 9 shows the factors influencing the purchasing behaviour of selected functional foods (moringa, garlic, ginger, tigernut, and turmeric) among households. The frequency of purchase was used as a proxy for purchasing behaviour following Adeoye et al. (2016). The frequency of moringa purchases was significantly affected by the household head's and spouse's monthly income, with negative and positive effects, respectively. This implies that while the monthly income of the household head inhibits its purchase frequency, the spouse's monthly income enhances it. The expenditure on tigernut also positively affected the frequency of purchase of moringa. This means

that the frequency of moringa purchases increases with tigernut expenditure. Also, married household heads had a higher frequency of purchasing moringa than others (single, divorced, and separated).

The major occupation of the household head (using civil service as a reference) and ginger expenditure had negative and positive significant effects on ginger purchasing behaviour, respectively. This means that civil servant households purchased ginger less frequently. Also, ginger purchasing frequency increases with expenditure.

The purchasing behaviour of tigernut is significantly influenced positively by marital status (ρ10%), education (5%) of household heads and tigernut expenditure (1%), and negatively by the occupation of household heads (10%). This implies that married household heads with a high level of education had a higher frequency of tigernut purchases, and the civil servant household had a lower frequency of purchasing tigernut. The frequency of purchase of tigernut increases with tigernut expenditure. This finding is consistent with Akerele et al. (2020), who state that a higher level of education enhances the consumption of tigernuts.

Source: Field Survey, 2023

The purchasing behaviour of turmeric is positively influenced by awareness of its nutrition and health benefits, household size, the income of the spouse, and turmeric expenditure. The implication is that awareness of nutrition and health benefits enhances the purchasing of turmeric. This is similar to the finding of Akerele et al. (2017) that awareness positively influences the consumption of some foods known with specific health claims in Nigeria. Also, larger households with higher spouse income had a higher purchase frequency. However, the age and income of household heads and garlic and ginger expenditure negatively affected its purchasing. The frequency of purchase increases with an increasing level of awareness, household size, the income of the spouse and the amount spent on turmeric per week. At the same time, it decreases as the age and income of household heads increase. The higher the garlic and ginger expenditure, the lower the purchase frequency of turmeric. Contrarily, Ong et al. (2014) affirmed that age positively correlated with the purchase frequency of functional foods. Also, Sekinat et al. (2024) stated that as people's age increases, social factors have more impact on their purchase decisions toward functional foods.

Conclusion

The demographic and socioeconomic characteristics of the surveyed population provide valuable insights into the diversity and occupation patterns within the community. Income and expenditure patterns indicate varying economic conditions, with a substantial portion of the population falling into the average income categories. Sources of awareness highlight the significance of family, friends, and health professionals in disseminating nutrition and health-related information. The roadside vendors and local markets were the major suppliers of functional foods to the households. Price and availability were the most crucial attributes considered when purchasing functional foods. Age, marital status and income were the determinants of purchasing behaviour of functional foods.

Recommendations

To enhance the consumption of functional foods, it is necessary to improve their availability and ensure that they are accessible at lower, regulated prices, especially among local market and roadside vendors. Since age and income were important determinants of purchasing behaviour, increasing the minimum wage will enhance purchasing functional foods since most respondents were civil servants. For effective policy regarding functional foods, there is a need to consider age differences since it is an important determinant of functional food purchasing behaviour. Future research should consider a larger sample size that covers a wider geographical location to enhance the generalizability of the findings. It may also consider diversity in socioeconomic characteristics when analysing data on functional food consumption and purchasing behaviour.

Antimicrobial Potential of Prickly Pear (Opuntia ficus-indica) Seed Oil and Grain Extracts

SAKHRAOUI-Amira Sakhraoui

Characterization and Valorization of Natural Resources, University Mohamed El Bachir El Ibrahimi of Bordj Bou Arreridj, Algeria.

Abstract

The prickly pear (*Opuntia ficus-indica*) is a succulent plant belonging to the cactus family. It is a highly nutritious and refreshing fruit, valued for its seeds and oil. This study aims to evaluate the antibacterial and antifungal activity of oil extracted from prickly pear seeds (from the Bordj Bou Arréridj region) and the acetone extract of spontaneous grains against 15 microbial strains (bacteria and fungi). The samples were extracted separately using distilled water and 70% acetone to obtain a dry extract, which was then stored at 4°C until testing. The antimicrobial activity was assessed using the agar diffusion method (well diffusion technique), measuring the diameters of inhibition zones. The results indicate that four bacterial strains and six fungal strains, including two yeasts, were sensitive to the dry extract. For the oil extract, two bacterial strains and five fungal strains, including two yeasts, exhibited sensitivity. Both extracts demonstrated strong antimicrobial activity, particularly against yeasts and Gram-positive bacteria, confirming the antimicrobial potential of *Opuntia ficus-indica*.

Keywords: *Opuntia ficus-indica*, seed oil, antibacterial activity, antifungal activit

A Comprehensive Study on Heat Balance Analyses in Grain Warehouses During the Winter Season: The Case of Konya Province

Elif Şahin Suci[1], Nuh Uğurlu[1]

[1] Department of Agricultural Structures and Irrigation, Faculty of Agriculture,Selçuk University, Konya, Türkiye

Abstract

The storage of agricultural products such as grains, which are of strategic importance for food security and agricultural sustainability, has become an increasingly critical issue worldwide. In this context, preserving the quality of stored products with minimal loss is only possible by precisely controlling the environmental conditions within the warehouse. This study was conducted to reveal how vary depending the positive or negative flow conditions between heat losses caused by structural elements and ventilation, as well as the heat generated by the metabolic activities of the products, on the building materials used and the type of products in storage structures with different constructions during the winter season. As a result of material-based analyses, it has been determined that the thermal conductivity value of 2.62 kcal/m²h°C measured in steel warehouses is statistically significantly higher than the value of 1.69 kcal/m²h°C in reinforced concrete warehouses. Despite the higher minimum ventilation rate requirements in concrete silos (barley: 19, wheat: 24, corn: 74 $m^3 \cdot h^{-1} \cdot ton^{-1}$), steel silos (barley: 18, wheat: 23, corn: 73 $m^3 \cdot h^{-1} \cdot ton^{-1}$) exhibited higher ventilation efficiency for all products (34%, 22%, 8%). In contrast, the efficiency values in concrete silos (17%, 11%, 4%) remained relatively low. The heat balance analyses conducted during the winter months in different storage materials (concrete/steel) have clearly revealed product-based ventilation differences. These findings clearly demonstrate that when designing grain storage systems, not only structural factors but also parameters such as storage capacity, product type, the presence of ventilation systems, and the thermal conductivity levels of structural elements must be considered. It has been concluded that storing grains with a high respiration rate (such as corn) in steel warehouses, which provide higher ventilation performance, would be more suitable. The results of this study prove that the selection of materials used in storage structures plays a critical role in the energy efficiency of storage systems.

Key Words: *Thermal conductivity, Heat balance, Ventilation efficiency, Concrete and steel warehouses, Grain storage.*

Kış Mevsiminde Hububat Depolarında Isı Dengesi Analizleri Üzerine Kapsamlı Bir Araştırma: Konya İli Örneği

Özet

Gıda güvenliği ve tarımsal sürdürülebilirlik açısından stratejik öneme sahip olan hububat gibi tarımsal ürünlerin depolanması, dünyada giderek kritik bir konu haline gelmiştir. Bu bağlamda, depolanan ürünlerin kalitesinin minimum kayıpla korunabilmesi ancak depo içi çevre koşullarının hassas bir şekilde kontrol edilebilmesiyle mümkündür. Bu çalışma, farklı konstrüksiyona sahip depolama yapılarında, kış mevsimi boyunca yapı elemanları ve havalandırmadan kaynaklı ısı kayıpları ile ürünlerin metabolik faaliyetleri sonucu açığa çıkan ısı miktarları arasındaki pozitif ya da negatif yönlü akış koşullarının; kullanılan yapı malzemeleri ve ürün çeşidine göre nasıl değişkenlik gösterdiğini ortaya koymak amacıyla yürütülmüştür. Malzeme bazlı yapılan analizler sonucunda, çelik depolarda hesaplanan 2.62 kcal/m²h°C'lik ısıl iletkenlik değerinin, betonarme depolardaki 1.69 kcal/m²h°C değerinden istatistiksel olarak anlamlı derecede yüksek olduğu belirlenmiştir. Beton silolardaki yüksek minimum havalandırma debi gereksinimlerine (arpa: 19, buğday: 24, mısır: 74 $m^3 \cdot h^{-1} \cdot ton^{-1}$) karşın, çelik silolar (arpa: 18, buğday: 23, mısır: 73 $m^3 \cdot h^{-1} \cdot ton^{-1}$) tüm ürünlerde daha yüksek havalandırma verimliliği (%34, %22, %8) sergilemiş, beton silolardaki verimlilik değerleri ise (%17, %11, %4) nispeten düşük seviyelerde kalmıştır. Farklı depo malzemelerinde (beton/çelik) kış aylarında yürütülen ısı dengesi analizleri, ürün bazlı havalandırma farklılıklarını net biçimde ortaya koymuştur. Bu bulgular, tahıl depolama sistemleri tasarlanırken sadece yapısal değil, aynı zamanda depolama kapasitesi, ürün çeşidi, havalandırma sistemlerinin varlığı ve yapı elemanlarının termal ısıl iletim düzeyleri gibi parametrelerin de dikkate alınması gerektiğini açıkça göstermektedir. Özellikle yüksek solunum hızına sahip olan tahılların (örneğin mısır) yüksek havalandırma performansı sağlayan çelik depolarda depolanmasının daha uygun olacağı sonucuna varılmıştır. Bu çalışmadan elde edilen sonuçlar, depolama yapılarında kullanılacak malzeme seçiminin depolama sistemlerinin enerji verimliliği üzerinde kritik bir rol oynadığını kanıtlamaktadır.

Anahtar Kelimeler: *Termal iletkenlik, Isı dengesi, Havalandırma verimliliği, Beton ve çelik depolar, Hububat depolama.*

Abstract

The modern global food system is increasingly fragile, a consequence of the sweeping agricultural transformations initiated during the Green Revolution of the 1940s. While the Green Revolution introduced high-yielding crop varieties (HYVs), chemical fertilizers, pesticides, and intensive irrigation, these advancements came at a cost: a significant loss of crop biodiversity, soil degradation, and increased vulnerability of food systems to climate change and disease outbreaks. The Food and Agriculture Organization (FAO) estimates that 75% of global crop diversity was lost between 1900 and 2000. This paper examines the unintended consequences of the Green Revolution on food security and biodiversity while exploring regenerative agriculture as a viable solution to correct these damages. Regenerative farming practices, including crop diversification, organic soil amendments, reduced chemical inputs, and agroecological approaches, have demonstrated potential in restoring soil fertility and increasing ecosystem resilience. By transitioning from an extractive, yield-maximizing agricultural model to a regenerative one, it is possible to address food production challenges in a sustainable manner. This paper also highlights the need for policy shifts, economic incentives, and scientific research to support the widespread adoption of regenerative agriculture, ensuring a resilient global food system for the future.

Keywords: *Green Revolution, regenerative agriculture, crop biodiversity, food security, nutrient density, industrial agriculture, sustainability, malnutrition.*

1.0 Introduction

Biodiversity refers to all species of plants, animals and micro-organisms existing and interacting within an ecosystem (Vandermeer and Perfecto, 1995). Natural biodiversity has provided the foundation for all agricultural plants and animals. The entire range of the domestic crops used in world agriculture is derived from wild species that have been modified through domestication, selective breeding and hybridization. Most remaining world centers of diversity contain populations of variable and adaptable landraces as well as wild and weedy relatives of crops, all of which provide valuable genetic resources for crop improvement (Harlan, 1975).

According to Clergue (2005), biodiversity is a very complex issue. In agroecosystems, it serves three basic functions: genetic, agricultural, and ecological functions. The first function of biodiversity involves maintaining species gene pool, in particular, the endangered ones. The second function, connected with agricultural activity, contains increasing the resistance of agroecosystems to abiotic and biotic stresses, as well as maintaining their productive role. Biodiversity has also ecological functions, for example, creating habitats with different flora and fauna species that have specific significance in agroecosystems. The issue of widespread species decline and ecosystem degradation was formally highlighted in 1992 with the creation of the Convention on Biological Diversity (CBD) during the inaugural Earth Summit held by the United Nations in Rio de Janeiro, Brazil.

The loss of biological diversity is one of the most important problems of the world and a threat to our civilization. The destruction of primary ecosystems, intensive farming, urbanization, and also infrastructure development cause depletion and weakening of the stability of ecosystems. Agroecosystems are the most at risk of losing biological diversity (TEEB, 2008). During the last decades, worldwide losses of biodiversity have occurred at an unprecedented scale and agricultural intensification has been a major driver of this global change (Matson *et al*., 1997).

Since the 1900s, some 75-percent of plant genetic diversity has been lost as farmers worldwide have left their multiple local varieties and landraces for genetically uniform, high-yielding varieties. 30-percent of livestock breeds are at risk of extinction; six breeds are lost each month. Today, 75-percent of the world's food is generated from only 12 plants and five animal species. Of the 4-percent of the 250-000 to 300-000 known edible plant species, only 150 to 200 are used by humans. Only three-rice, maize and wheat - contribute nearly 60-percent of calories and proteins obtained by humans from plants. Animals provide some 30-percent of human requirements

for food and agriculture and 12-percent of the world's population live almost entirely on products from ruminants (FAO, 1999).

The net result of biodiversity simplification for agricultural purposes is an artificial ecosystem that requires constant human intervention, whereas in natural ecosystems the internal regulation of function is a product of plant biodiversity through flows of energy and nutrients, and this form of control is progressively lost under agricultural intensification (Swift and Anderson, 1993). Commercial seed-bed preparation and mechanized planting replace natural methods of seed dispersal; chemical pesticides replace natural controls on populations of weeds, insects, and pathogens; and genetic manipulation replaces natural processes of plant evolution and selection. Even decomposition is altered because plant growth is harvested and soil fertility maintained, not through nutrient recycling, but with fertilizers (Cox and Atkins, 1979).

Thus, modern agricultural systems have become productive but only by being highly dependent on external inputs. A growing number of scientists, farmers and the general public fear for the long-term sustainability of such highly input-dependent and ecologically simplified food production systems. Questions are being raised about the growing dependence of modern farming on non-renewable resources, the loss of biodiversity, the loss of land through soil erosion and the heavy reliance on chemical fertilizers and pesticides. Farm chemicals are questioned on grounds of cost but their widespread use also has implications for human and animal health, food quality and safety and environmental quality. The commercial agricultural sectors of developing countries suffer from similar problems but the greater challenge for them is to determine new ways to increase small farm productivity that not only benefit the rural poor under marginal agricultural conditions (hillsides, rainfed and marginal soils), but also conserve and regenerate the resource base (Altieri, 1995).

The significant decline in agroecosystem biodiversity can be largely attributed to the Green Revolution, which catalyzed the widespread adoption of high-yielding crop varieties and intensive monoculture farming systems. This transformation prioritized productivity and uniformity over ecological diversity, leading to habitat simplification, reduction in genetic variability, and disruption of ecological interactions essential for resilient agroecosystems. Promoting functional biodiversity within agroecosystems represents a fundamental ecological approach to achieving sustainable agricultural production. To illustrate this concept, this paper examines how regenerative farming practices can help counteract the negative impacts caused by monoculture-driven biodiversity loss.

2.0 Monoculture, Ecological Impact and Agroecosystem Decline

Monoculture/solely crop production farms are the farming types by which farmers grow only crops, both annual crops/trees and field crops, such as wheat, corn, rice, rapeseed, sugar cane, and cotton. Monoculture is widely used in industrial farming systems, including conventional and organic farming, and has allowed increased efficiency in planting and harvest. Continuous monoculture, or "monocropping" where the same species is grown year after year, can lead to unsustainable environments such as building up disease pressure and reducing particular nutrients in the soil. Under certain circumstances, monocropping can lead to deforestation. The practice has also been criticized for its environmental impacts, one of the major being soil degradation due to non-rotational cropping. Crop rotation is the practice of changing the types of crops in a farmland from year to year, which improves soil health and quality, whereas monocropping has been implicated in the loss of nutrients from the soil (Bennett *et al*., 2012).

Monoculture is the annual production of the same plant species on a farm, for one or more years (Andres *et al*., 2016; Utomo *et al*., 2016). It is a commercial mode of production that has been predominant in recent decades and has largely integrated food market systems, as it is mass-produced (Woźniak, 2020).

From an economic viewpoint, larger or single-component production with mechanical- or technological-dependent system seems more practical. By cultivating the same species in a huge land area, farmers can maximize their profit by mass production via a single operation through unique growing/farming practices including planting, maintaining (including pest control), and harvesting with similar resources. This helps result in a greater yield at a lower cost. In addition, farmers can pick the best monoculture crops to grow considering the local climate and soil conditions. Further, it is much easier and straightforward to cultivate one kind of crop or breed one type of livestock in terms of the knowledge and experience needed to do it successfully (Salaheen & Biswas, 2019).

Monoculture farming has several disadvantages due to the ability to produce a larger volume of affordable products with less investment. Monoculture farming cultivates a single crop in an intensive manner and on a very large scale, such as current practices in the United States in which corn, wheat, soybeans, cotton, and rice are commonly grown. However, growing the same crops year after year can deplete the soil of appropriate nutrients or humus that play key roles in soil fertility. In some cases, monocultures are more susceptible to certain weeds and pests, which means that farmers will depend vastly on pesticides to save their crops, which may have environmental impacts (Salaheen & Biswas, 2019).

For example, Zhao *et al*. (2018) have currently showed that coffee monoculture, in the long term, decreased soil pH and organic matter content, while it increased soil salinity, which severely inhibited the growth of coffee plants and therefore affected its yield. The richness of soil bacteria and of fungal communities also declined with

continued coffee cultivation (Zhao *et al*., 2018). Similarly, Xiong *et al*. (2015) have demonstrated that continuous and long-term cultivation of black pepper resulted in a significant decrease in organic matter content, soil pH, and enzyme activities. These led to a decline in the abundance of soil bacteria, hence 454 pyrosequencing analyzes of 16S rRNA genes revealed that acidobacteria and proteobacteria were the major phyla that dominated 73% of the soil around black pepper plants. Similarly, the relative abundance of the Bacteroides and firmicutes phyla was depleted with continuous cultivation, and at the genus level, the abundance of Pseudomonas decreased significantly after 21 years of monoculture (Xiong, Li, *et al*., 2015).

Further, Liu *et al*. (2014) also confirmed this finding and have revealed that soil bacterial communities formed by potato monoculture have increased soil incidence of Fusarium wilt disease which impacted the performance of this crop. When a crop is grown as a monoculture, the microbial community is instantly exposed to the roots of that plant, selecting certain groups of microorganisms, namely soil pathogens, which are responsible for debilitating the yield of that crop (Cook, 2006).

Several studies on the monoculture of soybeans (Bai *et al*., 2015), melon (Soriano-Martín *et al*., 2006), bananas (Chen *et al*., 2013), and apples (Mazzola & Manici, 2012). With regard to yield and plant biomass, it turned out that the latter dropped significantly, in monoculture. This was supported by the study conducted by Zhao *et al*. (2018), which showed that shoots and dry weight of coffee decreased significantly with increasing years of monoculture. Similarly, Strom *et al*. (2020) found that soybean did not have a high yield after planting it directly after five years of continuous maize cultivation.

Further, continuous cultivation of black pepper severely inhibits its growth (Xiong *et al*., 2015). Continuous cultivation or monoculture can lead to an unhealthy and unsustainable environment, easily developing diseases and draining the soil from its nutrients, which is responsible for debilitating yields (Salaheen & Biswas, 2019).

The crops grown in the genetically homogeneous monocultures that characterize industrial farming are neither able to feed the world's expanding population nor resilient to the more frequent and destructive climate extremes (Altieri *et al*., 2015; Reza & Sabau, 2022). For instance, Wright *et al*. (2017) found that crop species grown in plots with higher biodiversity were, on average, less adversely affected by flooding, and the plants with higher system leaf area and higher root system performed better.

Furthermore, plots with mixed crops had higher soil porosity, which positively impacted plant performance. The negative impact of flooding on the performance of monocrops is primarily due to limited gas exchange due to slower gas diffusion in water compared to air, and low light intensity in turbid floodwaters, thereby causing an energy and carbohydrate deficit (Sasidharan & Voesenek, 2015), inhibiting plant growth, and eventually its survival (Mommer & Visser, 2005; Nguyen *et al*., 2018; Zhou *et al*., 2020). According to the survey carried out by Reza & Sabau (2022), it has been shown that monocropping has a negative impact on soil depletion and contributed to a decrease in soil nutrient diversity.

Although this cropping system is commercially efficient and profitable, it provides an unbuffered niche for parasitic species, increasing the crop's vulnerability to opportunistic insects, plants, and microorganisms (Blary *et al*., 2021; Dolezal *et al*., 2019; Suarez *et al*., 2023). Because a single crop is more vulnerable to a particular pathogen or pest, it accelerates the spread of diseases and pest outbreaks (Biber-Freudenberger *et al*., 2016; Cui *et al*., 2023; Kaur *et al*., 2021), increasing farmers' intensive reliance on pesticides and fertilizers, which affects water quality, human health, and wildlife population (Rahman, 2023). Increased use of chemical fertilizers and synthetic pesticides will ultimately increase emissions of greenhouse gases such as N2O (Reza & Sabau, 2022).

Compared to monocultures, intercropping contains more water, biomass, root system, and litter and can supply habitat for more organisms and contribute to flood mitigation, soil conservation, habitat quality, and carbon storage (Li *et al*., 2020; Ma *et al*., 2022; Sun *et al*., 2021). Climate change will increase the likelihood and severity of droughts into the future in many worldwide locations (Abdelmajid *et al*., 2021; Altieri *et al*., 2015; Chien *et al*., 2023; Leal Filho *et al*., 2023; Moldavan *et al*., 2023; Mutengwa *et al*., 2023; Shukla *et al*., 2019).

Natarajan & Willey (1986) studied the effect of drought on improved yields with multicropping by manipulating water stress on intercrops of sorghum and peanut, millet and peanut, and sorghum and millet. All the intercrops overyielded consistently at five levels of moisture availability, ranging from 297 to 584 mm of water applied over the growing season. Finn *et al*. (2018) found that grassland monocrop with experimental drought, decreased strongly the yield by 66%, in contrast, mixtures increased yield by 33% compared to the average of monocultures. Altieri *et al*. (2015) attested that multicropping has been shown to have higher yield stability and less productivity loss during drought than monocropping. The effects of drought on yield depend on environmental conditions, including agricultural intensity (Sun *et al*., 2021; Vogel *et al*., 2012; Zwicke *et al*., 2013), as well as pre-drought conditions and soil type, in particular, soil moisture retention properties (Hofer *et al*., 2016). Extreme weather events last longer, droughts become longer, moisture deficits during plant development during vegetation increase, soil moisture declines, and new pests and plant diseases appear (Cui *et al*., 2023; Moldavan *et al*., 2023) that agroecological farms are better able to counteract through the use of genetically diverse varieties of cultivated plants (Chien *et al*., 2023; Cui *et al*., 2023; Ma *et al*., 2022; Moldavan *et al*., 2023). Pathogen development and survival are most likely to be impacted by projected climate changes (Elad & Pertot, 2014). It is projected that a crop will become more vulnerable to numerous pests, diseases, and weeds as a result of changes in an area's climate

or weather pattern. While yields are predicted to decline at lower latitudes, they are forecast to increase in countries with high and middle latitudes (Rosenzweig *et al*., 2001). However, estimates indicate that a one-degree increase in temperature will result in a 10–25% increase in losses from insect pest infestation (Deutsch *et al*., 2018; Shrestha, 2019).

Nowhere are the consequences of biodiversity reduction more evident than in the realm of agricultural pest management. The instability of agroecosystems, which is manifested as the worsening of most insect pest problems, is increasingly linked to the expansion of crop monocultures at the expense of the natural vegetation, thereby decreasing local habitat diversity (Altieri and Letourneau, 1982). Plant communities that are modified to meet the special needs of humans become subject to heavy pest damage and generally the more intensely such communities are modified, the more abundant and serious the pests. The inherent self-regulation characteristics of natural communities are lost when humans modify such communities through the shattering of the fragile thread of community interactions. Agroecologists maintain that this breakdown can be repaired by restoring the shattered elements of community homeostasis through the addition or enhancement of biodiversity (Altieri, 1994).

For years, ecologists have debated the assumption that increased diversity fosters stability. Critical theoretical reviews on this subject are abundant in the literature, as well as reviews that use agricultural examples to bolster the theory (Andow, 1991). Most studies conclude that by mixing certain plant species with the primary host of a specialized herbivore gives a fairly consistent result: specialized species usually exhibit higher abundance in monocultures than in polycultures. In a recent review, Andow (1991) identified 209 published studies that deal with the effects of vegetation diversity in agroecosystems on herbivorus arthropod species. Fifty-two percent of the 287 total herbivore species examined in these studies were found to be less abundant in diversified systems than in monocultures, while only 15.3% (44 species) exhibited higher densities in polycultures.

Monoculture relies heavily on the use of chemical fertilizers and pesticides. The intensive use of chemical fertilizers can also affect soil properties and those of microbial communities and their functions (Pahalvi *et al*., 2021; van der Bom *et al*., 2018). Excessive use of nitrogen fertilizers can leach nitrates into water bodies, causing eutrophication and affecting aquatic life and drinking water quality (Khan *et al*., 2018). Phosphate is adsorbed on soil particles and transported to water bodies by soil erosion. Long-term excessive fertilizer use causes soil acidification, with long-term effects on soil productivity and soil protection (Mandal *et al*., 2020). In recent decades, the use of fertilizers and pesticides has increased the exposure of farmers, farm workers and the general population to these chemicals (Gupta, 2008). Dhankhar & Kumar (2023) attested that when fertilizers are applied to croplands, they are either directly or indirectly distributed into grains and vegetables, harming human health and lowering the nutrient density of the dominant plants. For instance, the nitrates and nitrites in fertilizers have been linked to cancer, birth defects, and other health issues like intoxications (Guo *et al*., 2020; Savci, 2012).

Furthermore, lead and cadmium-based fertilizers can be hazardous to both humans and animals, resulting in health difficulties such organ damage, neurological abnormalities, and developmental problems (Dhankhar & Kumar, (2023). Furthermore, Sharma (2017) reported that according to the U.S Environmental Protection Agency EPA's Office of Pesticide Programs, most of the pesticides contain ingredients that are cancerogenic to humans. The continued use of fertilizers hardens the soil, and can even modify its pH by increasing its acidification. For example, Pan *et al*. (2021) found that P addition slowed the process of nitrification in urea-treated soils, where a high N:P ratio appeared to be a major barrier. Ammonia-oxidizing bacteria's (AOB) response, which was more responsive to P addition than ammonia-oxidizing archaea's (AOA's) response, further corroborated this. The findings of this study indicated that the nitrification process in soil amended with urea was slowed by the application of P fertilizer, indicating that a synergistic feature of N and P nutrient management should be further investigated to slow N losses from agricultural systems.

Furthermore, the most frequently form of nitrogen or sulfur fertilizer in soil is nitrates or sulfate (S) (Brito *et al*., 2007; Vandenberghe *et al*., 2012), which is likely to exacerbate secondary salinization in the soil layer (Lu *et al*., 2019; Shen *et al*., 2016). Increased secondary salinization may lead to a reduction in soil fertilizer availability, which would reduce the productivity of crops, like cotton (Osanai *et al*., 2017; Tian *et al*., 2018), sunflower (Aziz *et al*., 2019), and maize (Lu *et al*., 2019; Rajeshwar & Khan, 2010). These will contribute to a drop in the content of organic matter in the soil, humus and the useful microbial load, relating to the decrease in quality of agricultural land, stunted plant growth, which is responsible for greenhouse gas emissions (Pahalvi *et al*., 2021). On the other hand, the excessive and long-term application of the chemical inputs is confirmed to contaminate the soil by heavy metals, including arsenic, mercury, and cadmium which are present either in the raw materials of the fertilizers (Atafar *et al*., 2010; Pogrzeba *et al*., 2018). Some heavy metals are required for plant development, such as, Fe, Cu, Mn, Mo and Zn, although they can be toxic to plants when present in excess. In addition, there are other Heavy Metals (Cd, Hg, Pb) that are irrelevant to plant development and can damage plants (Pogrzeba *et al*., 2018). The infiltration of these constituents, during the production processes, cannot be fully absorbed by the crops, and penetrates into the groundwater which causes their contamination (Chen *et al*., 2021). Nitrogen (N), phosphorus (P) and potassium (K) are the main macronutrients frequently required by crops to maximize their productivity (Gautam *et al*., 2020; Maathuis, 2009). Global nitrogen use, which is the single most important determinant of crop yield, is expected to increase by 1.6% per year until 2018, while phosphate use is expected to increase by

2.2% and potash 2.6%. In comparison, supplies of these three essentials are expected to grow by 3.7%, 2.7% and 4.2% per year, respectively (Nations, 2015).

The intensive use of nitrogen fertilizers causes emissions of ammonia and nitrogen oxide into the atmosphere and therefore has the effect of harming the ozone layer, its overuse can lead to an accumulation of nitrates in soils, leading to their acidification and salinization (Chen *et al*., 2021). In addition, the phenomenon of acidification accelerates the leaching process of calcium and magnesium, this can contribute to the reduction of the saturation of soils in nutrients and possibly their fertility (Chen *et al*., 2021; Pahalvi *et al*., 2021). These are suggested to influence the biodiversity and sustainability of soil. Consequently, it has become essential to protect and maintain soil productivity in the long term without resorting to destructive and unbalanced practices, in particular the irrational application of chemical inputs which leads to a degradation of soil quality and water (Abebe *et al*., 2022; Gautam *et al*., 2020; NING *et al*., 2017; Wu *et al*., 2021).

The Green Revolution may not be the only reason for biodiversity decline. But it's definitely a major factor. According to the FAO's State of the World's Biodiversity for Food and Agriculture (2019), while more than 6 000 plant species have been cultivated for food, fewer than 200 make substantial contributions to global food output, with only nine accounting for 66 percent of total crop production in 2014. Although it is not possible to make definitive statements about global trends in the erosion of on-farm crop diversity, evidence suggests that, overall, the diversity present in farmers' fields has declined and that threats to diversity are getting stronger (FAO, 2019). Biodiversity serves as a foundational component of natural ecosystems and the global food system. Its ongoing decline poses significant risks to ecological stability and the continuity of life-supporting processes. Without urgent and effective intervention to halt and reverse this trend, the trajectory points toward an uncertain and potentially destabilizing future for human societies and the planet at large.

3.0 Regenerative Agriculture: Principles and Practices

The Green Revolution in the 1950s and 1960s led to a significant increase in productivity through modern machinery, artificial fertilisers and highly bred crop varieties (Evenson & Gollin, 2003). At the same time, the impact on the environment, including on soils, water quality and biodiversity, has often been neglected. As the world's population and the demand for agricultural products is growing further, the environmental impacts are not only becoming more acute, but also have long-term implications for food security itself. Global food systems will remain highly dependent on ecosystem services and abiotic factors, some of which are also changing for the worse, most notably climate (Foley *et al*., 2005; Wheeler & von Braun, 2013).

To overcome the negative consequences of conventional farming, alternative approaches have arisen in recent decades. These are often subsumed under the term sustainable agriculture, defined by the Food and Agriculture Organization (FAO) as " ... the management and conservation of the natural resource base and the orientation of technological and institutional change in such a manner as to ensure the attainment and continued satisfaction of human needs for present and future generations. Such sustainable development ... conserves land, water, plant and animal genetic resources, is environmentally non-degrading, technically appropriate, economically viable and socially acceptable" (FAO, 1989).

Various approaches have been developed and implemented to achieve this transformation (Oberč & Arroyo Schnell, 2020). One established approach is conservation agriculture (CA), which has its roots in conservation tillage as a solution that emerged from the "Dust Bowl" that affected US and Canadian prairies in the 1930s (Hobbs, 2007). In the 1970s and 1980s, this approach was complemented by the practice of intercropping and crop rotations and has been employed widely under the label CA since the 1990s. The FAO highlights three key principles of CA: minimisation of soil disturbances, enhancement or maintenance of a protective organic cover, cultivation of a wide range of plant species (FAO, 2011).

Conservation agriculture is the basis of regenerative agriculture. The concept of a regenerative agriculture can be traced back to the cusp of the 1980s discussions of sustainability (Gabel, 1979; Sampson, 1982; Rodale, 1983). Regenerative agriculture adopts the principles of conservation agriculture that's meant to maintain soil health. Where regenerative agriculture diverges is its broader focus on increasing biodiversity in general and creating a closed nutrient cycle in combination with livestock management at farm level. It includes additional approaches such as manure composting, rotational grazing and silvopasture in grassland management (Smith *et al*., 2021).

In practice, regenerative agriculture and conservation agriculture involve similar cropping systems and the terms are often used interchangeably. Some scholars and practitioners additionally ascribe a social dimension to RA (Müller, 2020). Some of the more holistic regenerative approaches transcend soil regeneration and additionally aim at "regenerating" the social aspects related to agriculture. For example, in terms of good livelihoods, social relationships and stable incomes (LaCanne & Lundgren, 2018), future perspectives, and (re) building human–nature relationships (Gordon *et al*., 2022; Hes & Rose, 2019).

Newton *et al*. (2020), in their comprehensive meta-analysis, are the only researchers to date who have explicitly categorized regenerative agricultural practices based on a thorough review of the literature. Drawing from 229 peer-reviewed journal articles, they identified the five most frequently cited practices. These include: using no or low external inputs while maximizing on-farm inputs (26.4%), integrating livestock into farming systems (19.0%),

avoiding synthetic pesticides (12.4%), avoiding synthetic fertilizers (12.4%), and reducing tillage (11.6%). This list reflects the academic emphasis on minimizing synthetic inputs and enhancing self-sufficiency within farm ecosystems. In contrast, when examining 25 practitioner websites, Newton *et al.* found a slightly different prioritization of regenerative practices. The most commonly mentioned were reducing tillage and integrating livestock, both cited by 40.9% of sources. These were followed by the use of cover crops (36.4%), crop rotations (31.8%), and minimizing external inputs in favor of on-farm resources (31.8%). This practitioner-focused perspective highlights a more operational and practical orientation toward soil health and system resilience, indicating both overlap and divergence between academic and on-the-ground understandings of regenerative agriculture.

Conclusively, regenerative practices contribute significantly to biodiversity by creating diverse, resilient agroecosystems that support a wide range of organisms. Reducing or eliminating synthetic inputs like pesticides and fertilizers helps preserve beneficial insects, soil microbes, and pollinators, which are often harmed by chemical exposure. Integrating livestock and using cover crops and crop rotations introduce a variety of plant and animal species into the farming system, breaking pest and disease cycles and enriching habitat complexity. Additionally, reducing tillage protects soil structure and fosters underground biodiversity, including fungi, earthworms, and microbial communities. Altogether, these practices enhance both above- and below-ground biodiversity, promoting ecosystem balance and long-term sustainability.

4.0 Evidence of Biodiversity Recovery in Regenerative Agriculture

Biodiversity loss is a critical global concern, driven largely by conventional agricultural practices that simplify ecosystems and rely heavily on synthetic inputs. In response, regenerative farming has emerged as a holistic approach aimed at restoring ecological balance through methods that enhance soil health, reduce chemical dependence, and increase biodiversity. A growing body of research suggests that regenerative practices—such as cover cropping, crop rotation, livestock integration, and minimal tillage—not only sustain productivity but also foster the recovery of biodiversity at multiple trophic levels. Regenerative agriculture restores soil biodiversity by reversing the degradative effects of monoculture, which typically depletes soil life through uniform cropping, heavy tillage, and chemical input use. It promotes a heterogeneous and nutrient-rich soil environment that supports diverse microbial communities, fungi, earthworms, and other soil organisms.

Microorganisms, for example, are crucial to soil biodiversity and ecosystem functioning. They decompose organic matter, releasing nutrients essential for plant growth. Bacteria and fungi work in tandem to break down complex organic materials, converting them into forms that plants can readily absorb. For instance, mycorrhizal fungi form symbiotic relationships with plant roots, facilitating the uptake of water and nutrients, especially phosphorus, which is crucial for plant health (Smith & Read, 2008). Fungi, particularly mycorrhizal species, are essential for maintaining soil biodiversity. They create extensive networks that connect plant roots, allowing for nutrient exchange not only between plants but also with soil microorganisms. This network improves the overallhealth of the soil ecosystem, enhances plant resilience, and facilitates the transfer of water and nutrients over long distances (van der Heijden *et al*.,2008). In summary, regenerative systems foster the recovery and proliferation of soil biodiversity that monoculture systems often diminish or destroy.

Plant diversity is a cornerstone of agroecosystem resilience. Increasing cropping diversity in field has been shown to lead to increased crop and forage yield in some contexts (Smith *et al*., 2008). This is achieved through the establishment of diverse plant species that have complementary nutrient requirements and support beneficial interactions (Beillouin *et al*., 2021). Crop diversity can also improve yield stability by reducing the risks associated with monocultures and susceptibility to pests, diseases and climate shocks (Raseduzzaman and Jensen, 2017).

Furthermore, increased on-farm biodiversity can provide a greater range of habitats to support pollinators, crucial for the success of some crops and fruit trees (Nicholls and Altieri, 2013; Pywell *et al*., 2015). Increased biodiversity promotes natural pest suppression, as a diverse range of predators and beneficial organisms helps regulate pest populations (Gurr *et al*., 2003; He *et al*., 2019; Nicholls and Altieri, 2013). Increased crop diversity or the use of cover crops can also suppress weed pressure, as diverse plant communities compete with and inhibit weed growth (Isbell *et al*., 2017). Increased diversity in grassland has been shown to be associated with higher levels of soil carbon and nitrogen, and invertebrate abundance in soils (Norton *et al*., 2022). On-farm diversification of crops is known to enhance biodiversity and a range of ecosystem services such as supporting pollinators, pest control, nutrient cycling, soil fertility and water regulation, without compromising crop yields (Brooker *et al*., 2015; Tamburini *et al*., 2020).

The results of a meta-analysis of 53 individual European studies on the effects of agroforestry on ecosystem services showed a strong positive effect of agroforestry on biodiversity, with the effect size varying depending on the taxa and systems studied; the strongest positive effects were seen for birds and silvo-arable systems (Torralba *et al*., 2016).

RizomaAgro is developing regenerative agriculture in three farms in Brazil, which have a size of over 2,000 hectares. In 2022, it reported a significant improvement in environmental indicators related to carbon

sequestration, biodiversity and water retention. According to the report, it tripled the number of species of pollinators and natural enemies of pests (RizomaAgro, 2022).

Regenerative agriculture can reduce on-farm herbicide and pesticide use. Besides supporting pollinators, cover and companion crops support a broad spectrum of beneficial insects through creation of habitats during the growth and senescence phases of the crop. Furthermore, companion crops can be used to divert insect pests away from the main cash crop and could also act as barriers against fungal pathogen spread throughout the cash crop (Huss *et al*., 2022). There is potential to reduce herbicide and pesticide use if weeds, pests and diseases are successfully suppressed through companion cropping (Osipitan *et al*., 2019). Potential benefits from mixed crops include the maintenance of crop yields with reduced inputs, such as herbicides and pesticides and greater resilience to environmental variability such as summer droughts (Weih *et al*., 2022). By reducing the reliance on chemical pesticides and fostering a diverse insect community, regenerative agriculture creates a more resilient system capable of self-regulation (Benton *et al*., 2003). Studies have shown that farms with higher plant diversity can significantly boost pollinator visitation rates, leading to improved crop yields and ecosystem health (Klein *et al*., 2007).

In conclusion, the evidence presented underscores that regenerative agriculture offers a viable and ecologically sound alternative to conventional practices, with significant benefits for soil health, biodiversity restoration, ecosystem services, and long-term farm productivity, ultimately contributing to a more resilient and sustainable agricultural system.

5.0 Conclusion

The health of an ecosystem is measured by the degree of its diversity. This paper has demonstrated that regenerative agriculture offers a powerful framework for reversing biodiversity loss driven by conventional farming practices. Through practices such as cover cropping, crop rotation, livestock integration, and minimal tillage, regenerative systems foster rich and resilient ecosystems both above and below ground. The restoration of soil microbial communities, enhancement of plant diversity, support for pollinators, and natural pest regulation all contribute to healthier, more self-sustaining agroecosystems.

Despite these promising outcomes, the widespread adoption of regenerative practices faces several challenges—including economic and policy barriers, limited farmer training, and insufficient market incentives. There may also be trade-offs, particularly between yield stability and biodiversity gains, that require context-specific evaluation and management.

To fully realize the potential of regenerative agriculture, long-term biodiversity monitoring must be prioritized, alongside efforts to integrate these practices into national and international agricultural policies. Scaling biodiversity-friendly farming will require coordinated research, cross-sectoral collaboration, and financial frameworks that reward ecological stewardship.

In conclusion, regenerative agriculture stands out as a viable pathway to restore biodiversity while sustaining agricultural productivity. This calls for deeper interdisciplinary research and robust policy support to overcome barriers and ensure its benefits are accessible, scalable, and lasting as the world moves toward sustainability.

Comparison of Secondary Models for Modeling the Growth of *Salmonella* in Leafy Greens

Basri Omac[1]

[1]Department of Food Processing, Tunceli Vocational School, Munzur University, Tunceli, Turkiye

Abstract

An estimated 550 million individuals worldwide suffer from food-related illnesses, which also cost the economy billions of dollars annually and result in 230,000 fatalities. If it were possible to identify and track the growth or survival of pathogen microorganisms, these illnesses and expenses might be decreased. However, monitoring the development or survival of bacteria using traditional microbiological methods is very expensive and labor-intensive, and the knowledge gained is not cumulative. Instead of employing conventional microbiological techniques, predictive microbiology has been created to forecast microbial behavior during food processing using precise and adaptable mathematical models. Primary, secondary, and tertiary models are the three general categories into which mathematical models fall. Secondary models examine how parameters that appear in primary modeling approaches change in response to one or more environmental factors, such as pH, temperature, etc. In order to ascertain which secondary models were most suitable for Salmonella in leafy greens, this study compared the suboptimal Ratkowsky square-root, suboptimal Huang square-root, Cardinal, and Arrhenius-type models. The best model to fit data on the maximum growth rate as a function of temperature, according to the findings of the current study, was the Arrhenius-type model. These findings shed light on predictive microbiology and aid researchers and food microbiologists in selecting the best secondary growth prediction model.

Key Words: *Food safety, Foodborne outbreaks, pathogens, Predictive microbiology, lettuce*

Abstract

Sowing seed treatments have been reported to have influence on the germination percentage and growth performance, which could affect crop yield when transplanted to the field. Replacing chemically expensive and laborious pre-treatment with physically pre-treatment with physically pre-treated seed reduce the cost of producing moringa by resource poor farmers. Therefore a Nursery experiment was conducted at the Department of Agronomy, Bayero University Kano, to examined effect of three pre sowing seed treatment, dry seed with complete coat (DSCC), dry cracked seed with complete coat (DCSC), soaked seed with complete coat (SSCC,) soaked cracked seed coat, (SCSC), on the germination percentage and growth indicator of *moringa* plants. The treatment was replicated three time in a completely randomized design, the result indicated that DCSC had significantly higher (P=0.05) seed germination percentage; than SCSC and SSCC however the highest seed germination percentage was observed under DSCC. By 55.5%, 44.4%, 33.3%, and 88.9% respectively at 1 week after sowing (WAS). The experiment provides information about sowing seed treatment of *moringa oleifera* which could replace the chemically expensive and laborious sowing seed treatment technique for optimal *moringa* production. in term of germination. Percentage sowing seed treatment have no significant effect on *moringa* seed germination percentage, this indicate that the resource- poor farmers there is no need to treat *moringa* seed before sowing into sandy loam soil.

Introduction

Moringa oleifera is among the world's most useful plants. its grown throughout the tropics for human food, like stock forage, medicine, dye and water purification. It is known by names in different countries, but is popularly called the "drumstick tree" for its pod that are used by drummer and the "horse radish tree" for the floor of its roots, it is also one of the world's most nutritious crops. The leave of *Moringa* have more beta carotene than carrots, more protein than peas, more vitamin C than orange, more calcium than Milk, more potassium than banana, and more iron than spinach. Native to south Asia, it is a vital source of nutrition in this region, where most of the poor people live. The multiple uses of *Moringa* have attracted the attention of the researchers, development workers, and farmers, (Igbal et. al, 2006). *Moringa*oleifera belong to the monogenetic family of shrub and trees, Moringaceae. *Moringaoleifera*is cultivated throughout the Middle East and in most of the tropic belt. It was introduce in eastern Africa from India at beginning of the 20th century. *Moringaoleifera* is a medium – sized tree that reaches about 10m in height. It has straight traced about 10 – 30cm thick with bark that is whitish grey, carry with longitudinal cracks. It also has a tuberous tap root to tolerate hash conditions. The umbrella shaped tree comes with a loose crown of feathery foliage. The foliage is over green or decisions depending on the environment. Scented flowers arranged in drooping panicles. Flower are insect pollinated and required a large number of insect visitations, with bees the most common (Fuglie, 2001) Globally, agriculture play a key role on improving livelihood especially in rural communities. Crop production is the main stay of agriculture commodity. It provide up to 50% of the value of agricultural output globally and one third in developing countries (Delgado et. al, 1999). During the past 3 decades, rapid increase and development in the crop production sector has led to "Crop revolution" or "food revolution" due to rapid technology invasion in this sector, and especially crop improvement of crop industry. This increase in crop production has emerged to be more impressive – than animals production (Sanoncy, 1995) to meet the demand for nutritionally balanced food for the worlds increase population and relieve the intense pressure on land used and natural resources, plants spices used as food must be diversified, inclusion of a wide array of indigenous vegetable species in cereal, tubers and livestock – based agriculture will be crucial to contribute to food and nutritional security and diversification for stake holder in the subsistence farming system that predominate in the under developed and developing world, therefore, improving the genetic potential of vegetable like (*MoringaSpp*) is of paramount importance it has considerable area under cultivation in Africa and India with huge socio-economic potential. *Moringa*is called Zogale in Hausa, English *Moringa* tree, ben oil tree, cabbage tree, clarifier tree, horse raddish tree west India ben in Ibgo (OkweOyrbo), Yoruba (Ew)The ultimate importance of nursery establishment is to produce *Moringa* seedling that when planted and managed will improve the living condition of the people in affected area through the provision of basic certain requirement and by

reserving the environment degradation, (Hajji, 2011).Nursery establishment as new technology introduce for former adaptation and subsequent seeding production in improving germination rate particularly in extreme northern Nigeria, however it is said to rate that people's knowledge about seed and their socio- economic benefic have found inadequate, the ultimate important of nursery establishment is to produce seedling that when planted and managed will improve the living condition of the people in affected areas .

Pre sowing seed treatment is the influence on germinate percentage and growth performance which could affect the crop yield when transplanted to the field ,Is the replacing the chemically expenses and laborious pre –treatment with physically pre-treated seed could reduce the cost of reducing *moringa* by resource poor farmers.

Seed treatment method : some of these crop are propagated by seed while some are vegetatively propagated most of these forage crop are perennials, that is why most of the paddocks generate every rainy season and most of the paddocks are maintained for over 70 days Back. The purpose of seed treatment is to break seed dormancy so as to improve seed germination and emergence, some method are hot water method, mechanical method, acid/chemical method, rhizobium inoculation. The seed are said to be dormant if it does not germinate after 15 days.Sandy loam is a types of soil used for gardening. The types of soil are made up of sand along with varying around of soil and clay sand soil are used for gardening because the soil organic matters and moderating water retention.

Given high nutritive value of *Moringa* and its implication as important human food supplement, it become imperative that studies into the most ideal condition for its initial establishment in the nursery are carried out, such study will ensure high established rates of the seeds sown out, as the seed has also proven to be very difficult to acquire, high initial seedling establishment result in increased production levels, thus availing more *moringa* produce to those in need of it as a food source and also identify the most ideal seed priming method for optimum germination and initial seedling establishment and growth because seed priming increase germination percentage and initial seedling establishment.

Moringa is one of the vegetable plant with high nutritive value and it is produced in small quantity by local farmers in Nigeria therefore there is need to encourage the farmer to used specific seed treatment which help in faster germination rate and grow and harvest earlier.

Methodology

Experimental Site

The experiment was conducted in the nursery site, Department of Agronomy faculty of Agriculture, Bayero University, Kano, located within latitude $13^0$53' N – 10^0 25' N and longitude 7^0 40'E – 10^0 53' E situated in Sudan savannah ecological zone of Nigeria (Olofin, 2007). The zone characterized by distinct dry and wet season the rainy season started in May/June and end in September/October. The dry season start from November to April with occurrence of hamattan in November to January. The ambient temperaturerange from 16.7^{0}C – 22 8^{0}C in the month of January to June and 23.9^{0}C to 26.7^{0}C in July to December (Anon, 2010) an Average month rainfall of 0 to 300mm recorded in January to June and 780mm to 1320mm in July to December (KNARDA, 2001). The relative humidity range between 40 to 50% (Olofin, 2007).

Experimental Design

The experiment was laid out in completely randomize design(CRD), the pre-sowing seed treatment are as fallowed (i) dry seed with complete coat (DSCC) (ii) dry cracked seed coat (DSC) seed coat was cracked using pliers before sowing (iii) soaked seed with complete coat (SSCC) – seed was soaked with water in a container for 24 hours prior to sowing. The seed sowing was done in poly-bag, (V) soaked cracked seed coat (SCC) seed were cracked using plier and soaked with water for 24 hours before sown. 2kg soil capacity, the treatment was replicated three times in a nursery. The sowing was done with the aid of a calibrated stick to ensure uniform sowing depth of 2cm for all treatment (Oshunsanya, et,al 2017).

Data Collection:

The data was collected for the following parameters:

Germination percentage, **Plant height** (cm); the height of the plant will be measured weekly from the ground level to the tip of terminated bud, with the aid of meter rule, and this will be carried out for 1,2,3,4,and 8 (WAS). **Stem girth**: the stem girth was measured by tighten a thread round the Circumstance of the plants; meter rule was used to determine the length of the measured Circumstances from the thread. **Number of leaf**: the total number of the leaves was obtained by direct counting of the leaves.

Data Analysis

The data collected was subjected to analysis of variance using Genstat (2018) software version 11. The means were separated using Students Newman Keul Test (SNK).

Results and Discussion

Discussions

Germination percentage at first WAS

The seed germination percentage as affected by the various pre- sowing seed treatment as presented above, the germination percentage per treatment was significantly ($p<0.05$) higher under DCSC (55.5%) then SCSC (44.4%) and SSCC (33.3%) however the highest seed germination percentage (88.9%) was observed under DSCC. This was in lined with finding of (Oshunsanya, 2015) who observed that the *moringa* seed without sowing treatment(DSCC) fastened the seed germination, this confirm that, in spite of the treatment, achieved high germination percentage. This result supports the claim that considers pre germination seed treatment unnecessary.

Effect of pre sowing seed treatment on plant height (cm) of *Moringa oleifera*

The result as presented in (Table 1) shows that there is no significant difference ($p>0.05$) in term of plant height between the treatments in all the weeks. This finding indicates that sowing seed treatment do not have effect in plant height. Although, some scientific results show that soaking is an option for improving the Moringa seed germination, other reports consider it unnecessary (Padilla, C., Fraga, N. and Suarez, M. 2012).

Effect of pre sowing seed treatments on stem diameter (mm) of *Moringaoleifera*

The result as presented in (Table 2) showed that there is no significant differences ($p>0.05$) in term of stem diameter between the treatment in all the weeks, this indicate that sowing treatment do not have effect on stem diameter. The non significance differences were attributed to the genetic constituent of the variety and

environmental condition. This finding indicate pre sowing treatment have no influence in stem diameter of the *moringa* plant Sogbo, (2006).

Effect of pre sowing seed treatment on leave number of *Moringa olifeira*

The significant differences was observed only in week 6 and 7 as presented in (Table 3.) in which at week 6 DSCC has the highest means value followed by DCSC then SSCC. The least mean value was observed in SCSC. But there were no statistical differences between DSCC and DCSC. At week 7 they have shown the same effect. This difference was attributed to managements such as pest attacked and may be attributed to the genetic makeup of the variety. This are in line with the finding of Raja (2013). That pre sowing treatment have influence in determining growth parameters (leaves numbers).

Conclusion

The experiment provides information about pre-sowing seed treatment of *moringa oleifera* which could replace the chemically expensive and laborious pre-sowing seed treatment technique for optimal *moringa* production in term of germination. Percentage pre-sowing seed treatment have no significant effect on *moringa* seed germination percentage, this indicate that the resource- poor farmers there is no need to treat *moringa* seed before sowing into sandy loan soil.

Recommendation

From the studies carried out, dry seed with complete coat which is control (DSCC) have proven to have significant effects on germination percentage of the *moringa* plants. Therefore in addition further research should be conducted to examine more about pre-sowing seed treatment

Abstract

A feeding trial was conducted with four to six-week old rabbits (n=30) to determine their growth and nutrient digestibility on diets in order to evaluate the maize replacement value of sweet orange peel biodegraded with rumen filtrate. Rumen filtrate was obtained from the rumen content and liquor of four randomly selected slaughtered cattle, to which water was added in ratio 1:1, and filtrate manually squeezed out. Freshly collected sweet orange peel was divided to five batches of 5 kg each. Rumen filtrate was added to and mixed with one of 5 kg each in ratio 1:5, 2:5, 3:5, 4:5 and 5:5 and biodegraded for 24 hrs, sundried and milled. Each of replaced 50% maize in the control diet (T1) of rabbits to obtain diets T2, T3, T4, T5 and T6, respectively. Thirty mixed breed exotic rabbit of both sexes were randomly allocated to six diets of five rabbits each. Rabbits were fed ad libitum and provided adequate drinking water in a 77-day feeding trial. Growth indices and coefficient of digestibility of nutrients were determined. Experimental diets had no significant effect ($p>0.05$) on final live body weight, feed intake, body weight gain, feed conversion and protein intake, but protein efficiency ratio differed significantly ($p<0.05$) with higher value of 2.10 in T5. Diets had varied significant effect ($p<0.05$) on the coefficients of digestibility of nutrients and improved crude protein digestibility. Bovine rumen filtrate can be used to treat sweet orange peel in a ratio of 4 litre rumen filtrate : 5kg for its biodegradation to improve its feed value, and as a replacement for dietary maize at 50% level in growing rabbit diet.

Keywords: *Rumen filtrate, biodegradation, peel, rabbit*

Introduction

Food is a necessity in human life as it helps in body growth and sustenance of diverse life activities. However, the world is facing food insecurity which is a threat to human survival most especially in the developing countries. The shortage in animal food production with increase in population growth brings about the current food crisis in many developing countries. In Nigeria, over 70% of the citizens are involved in agriculture and mainly at subsistence level (Babamaaji and Ekwe, 2023). In spite of its contribution to the nation's economy, the sector confronts a myriad of problems which affect productivity, prominent among which are climate change, land degradation which reduces cultivable land mass, inadequate local production of feed ingredients, post-harvest losses and high production cost. These have adverse effect on agricultural productivity, causing increased food importation due to population increase and decreased food sufficiency. Nigeria's population is estimated at 223.8 million with a growth rate of 2.41% (Worldometer, 2024), and dietary protein deficiency is a major problem partly, because the demand for protein of animal origin is greater than supply. The recent average animal protein intake in Nigeria put at 6 – 8 g/day (Have et al., 2020) is dismal. The global average daily total protein intake based on a reference intake value of 0.83 g/kg of body weight is 64 g, and in advanced economies more than 60% of protein intake comes from animal sources whereas, in Africa, India and other food deficient countries it ranges from 20 – 25% of total protein (Capper et al., 2013). Animal production in Nigeria remains underexploited, thus, a dire need for an appreciable step-up in livestock production to mitigate the critical shortage of animal protein using animals like the domestic rabbit which when compared with other livestock is characterized by early sexual maturity, high prolificacy, relatively short gestation period, short generation interval, high productive potential, rapid growth, in addition to its ability to utilize forages and fibrous plant materials and agricultural wastes. Rabbit is thus regarded as an animal at the nexus of food production and bioscience research for sustainable development in developing countries (Sikiru et al., 2020). Sweet orange peels are abundant citrus wastes in most part of Nigeria because of the heavy consumption of the fruit. It is high in metabolisable energy content, and similar to maize in crude protein (Jobo and Oluremi, 2023) and can be an alternative feed ingredient to maize in rabbit nutrition because of its relatively high crude fibre.

The study determined the feed value of sweet orange peels biodegraded with rumen filtrate from bovine species in grower rabbit performance

Materials And Methods

The feeding trial was carried out in the Rabbitary unit at the Teaching and Research Farm, Federal University of Agriculture, Makurdi, Nigeria located in latitude 60^0 - 80^0 N and Longitude 6^0 - 10^0 E. Makurdi has an annual precipitation ranging between 508 mm to 1016 mm, for a six to eight-month period, minimum temperature of 22.80 ^oC and maximum temperature of 40.03 ^oC and, relative humidity between 37.3% and 59.2% (Audu et al., 2022).

Fresh sweet orange peels (SOP) were collected from orange fruit retailers on the Campus and Wadata, in Makurdi metropolis and treated with rumen filtrate (RF). Fresh rumen content together with liquor was collected in covered plastics buckets from four randomly selected slaughtered cattle in a Government abattoir within the metropolis. The RF was analysed for its microbial content (Cheesbrough, 2005) in the University's Veterinary Microbiology Laboratory. Water was added to rumen content and liquor in the ratio of 1 L : 1 kg of rumen content, thoroughly stirred and squeezed manually to extract the rumen filtrate. The RF was then added to and mixed with SOP in the ratio of 1 L : 5 kg, 2 L : 5 kg, 3 L : 5 kg, 4 L : 5 kg and 5 L : 5 kg, to obtain biodegraded SOP 1,, SOP 2, SOP 3, SOP 4 and SOP 5,, respectively. Each mixture was poured in a feed sack, kept in a shade and allowed to ferment for 24 hours. Thereafter, biodegraded SOPs were spread thinly on a concrete floor and sundried until about 10% moisture content was attained within 24 – 48 hours. Samples of SOP 1,, SOP 2, SOP 3, SOP 4 and SOP 5 were milled and analysed for its proximate constituents (A.O.A.C., 2015) at the University's Animal Nutrition Laboratory and the metabolisable energy calculated (Pauzenga, 1985) as shown in Table 1.
Six experimental diets were formulated, using sweet orange peel (SOP) biodegraded with rumen filtrate (RF) in ratios 1 litre RF : 5 kg SOP (SOP 1), 2 litre RF : 5 kg SOP (SOP 2), 3 litre RF : 5 kg SOP (SOP 3), 4 litre RF : 5 kg SOP (SOP 4), and 5 litre RF : 5 kg SOP (SOP 5), as replacement for 50% maize in the control diet (T1), to obtain diets T2, T3, T4, T5 and T6, respectively (Table 2). The experimental animals were four to six-week old 30 mixed breed exotic rabbits of both sexes, housed in separate cages, and randomly assigned to the six diets at the rate of five rabbit per diet group. Each rabbit in a diet group served as a replicate, all rabbits were fed *ad-libitum* and drinking water supplied without restriction. The feeding trial lasted for 77 days. The experiment was a completely block randomized design. Medications given were antibiotics (Tridox) intramuscularly, coccidiostat (Amprolium) and Zantriviral were given orally using water as the administration route. Vitalyte was given as antistress.

Table 1: Proximate constituents of Biodegraded sweet orange peel (%DM)

Nutrients	SOP1	SOP2	SOP3	S0P4	SOP5
Dry matter	89.40	88.86	87.78	88.73	85.48
Crude protein (CP)	5.87	6.40	6.98	7.39	9.73
Crude fibre	9.97	10.03	10.48	11.75	12.20
Ether extract (EE)	1.84	2.23	2.10	2.30	2.11
Ash	9.32	10.38	10.21	10.10	10.40
Nitrogen free extract	73.00	70.42	70.23	68.45	65.56
ME[1] (kcal/kg)	2958.01	2917.56	2921.74	2890.29	2858.51

[1]ME = Metabolisable energy, SOP = sweet orange peel.

Table 2: Gross composition of experimental diets

Ingredients (%)	T1	T2	T3	T4	T5	T6
Maize	41.44	20.72	20.72	20.72	20.72	20.72
Sweet orange peel	0	20.72	20.72	20.72	20.72	20.72
Fixed ingredients[1]	58.56	58.56	58.56	58.56	58.56	58.56
Total	100	100	100	100	100	100

[1]Fixed ingredients (%); soybean 5.00, blood meal 0.50, rice bran 27.30, brewers dried grain 22.45, bone ash 2.81, vitamin/mineral premix 0.25, table salt 0.25.

The performance data collected were;

i. Initial body weight (IBW)
ii. Final body weight (FBW)
iii. Body weight gain (BWG) = $FBW - IBW \ / \ 96 \ days$
iv. Daily feed intake (DFI) = $\frac{Feed\ supplied - Unconsumed\ feed}{96\ days}$
v. Feed conversion ratio (FCR) = $\frac{DFI}{BWG}$
vi. Protein intake (PI) = DFI x % crude protein in feed
vii. Protein efficiency ratio (PER) = BWG / PI

At the end of the eleventh week of the feeding trial, three rabbits were selected per treatment having an average weight similar to treatments average weight, and used for nutrient digestibility evaluation. Experimental diets were withdrawn 18 hours prior to commencement of digestibility trial to allow for the elimination of the residual feed in the gut. Thereafter, 75% of their daily feed intake was supplied to each rabbit for four days and the corresponding faecal droppings collected and used to determine coefficient of digestibility of nutrients. Wet faecal collection was done daily using mosquito net tied under respective cages, weighed, oven dried at 105 ^{o}C for 24 hrs and weighed. The faecal droppings for each replicate was bulked and subjected to proximate analysis at the Nutrition Laboratory of the Department of Animal Nutrition in the Federal University of Agriculture Makurdi. Nutrient digestibility was computed as;
Nutrient digestibility = Nutrient consumed – Nutrient in faeces / Nutrient consumed x 100.

Data generated were subjected to the analysis of variance (ANOVA) using SPSS (2012), and the means of significantly ($P<0.05$) different indices separated with the least significant difference (LSD).

Results And Discussion

The microbial analysis of the rumen content showed that its homogenous mixture contained bacteria *E.coli* and *Klebseilla* spp. in the range of 2.4 x 10^6 – 2.8 x 10^6 cfu/g and *Aspergillus* spp. *a* fungal spp. in the range of 0.5 x 10^6 – 0.6 x 10^6 cfu/g. The ruminal ecosystem has a large diversity of microorganisms; bacteria, fungi and protozoa (Castillo-Gonzalez, 2014), working synergistically for the nutritional transformation of forage, the main feed of ruminant animals to produce metabolic energy for various physiological activities. The presence of these bacterial and fungal isolates in rumen filtrate shows that there are some ruminal microbes which can survive outside the ruminal ecosystem and can be useful to stimulate biodegradation process *in vitro* to improve the feed value of some crop residues and agricultural wastes such as sweet orange peels. The crude protein content of biodegraded sweet orange peel increased as the quantity of RF added to SOP increased from 1:5 to 5:5. The microbial load in the rumen filtrate was expected to increase the higher the quantity of rumen filtrate added to SOP. This can cause higher cell multiplication and more microbial cell mass thereby causing the increase in the crude protein content of SOP. The crude fibre level of the biodegraded SOP increased while, the nitrogen free extracts decreased as the ratio of the mixture of RF to SOP increased from 1:5 to 5:5, implying that crude fibre in the biodegraded SOP may contain higher indigestible fractions. The microbial isolates in the rumen filtrate *Klebseilla* spp., *E.coli* and *Aspergillus* spp. appeared unable to alter the structure of SOP by reducing its crude fibre content. Ash content increased as the RF : SOP ratio increased from 1:5 to 5:5, possibly because of the mineral content in the rumen mass due to mostly forage basal diet consumed by the cattle. The higher ether extract in the rumen filtrate treated SOP might be the consequence of the lipolytic activity of *E.coli*, one of the microbial isolates (Henne et al., 2020). There was a slight decrease in the metabolisable energy content of biodegraded sweet orange peel as the rumen filtrate added increased from 1:5 to 5:5. This may have been due to increased fibre and ash, and reduced digestible carbohydrate in the form of nitrogen free extract as the volume of rumen filtrate added to the sweet orange peel for biodegradation increased.

The experimental diets had no significant ($P>0.05$) effect on the FBW, daily BWG, DFI, FCR and daily PI, except PER which significantly ($P<0.05$) increased with higher amount of the rumen filtrate added to the sweet orange peel as shown on Table 3. Rabbits in diet T5, which contained 50% maize replacement with SOP treated with rumen filtrate in ratio 4:5 had a significantly ($P<0.05$) higher PER of 2.10. This result showed that as the quantity of rumen filtrate added to SOP for its biodegradation increased, PER of growing rabbits tended to increase significantly ($P<0.05$). This, most likely stimulated the relatively higher mean final body weight of 1461.40 g of the rabbits in T5 compared to the other dietary treatments.

Table 3: Effect of experimental diets on the performance of grower rabbits

Performance Indices	T1	T2	T3	T4	T5	T6	SEM
IBW (g)	418.33	425.83	425.83	425.83	425.83	376.66	14.78

Table 4: Nutrients Digestibility of grower Rabbits fed diets containing sweet orange (*Citrus sinensis*) peel treated with bovine rumen filtrate

	Experimental Diets						
Parameters	T1	T2	T3	T4	T5	T6	SEM
Dry matter	79.83[a]	60.41[bc]	55.97[c]	72.77[ab]	71.78[abc]	65.97[abc]	4.92
Crude protein	79.12[a]	75.73[ab]	64.92[b]	81.29[a]	81.26[a]	74.41[ab]	3.97
Crude fibre	37.26 [a]	54.97 [a]	44.18 [a]	55.24 [a]	63.37 [a]	53.65 [a]	8.53
Ether extract	88.22[ab]	86.76[bc]	81.49[c]	93.69[a]	91.19[ab]	87.24[b]	1.76
Nitrogen free extract	79.48[a]	67.29[bc]	65.96[c]	76.87[abc]	78.75[ab]	68.48[abc]	3.58

[abc]Means within rows with different superscripts are significantly different (P<0.05), SEM- Standard error mean,
T1= Control Diet (Maize based)
T2= Diets containing 50% biodegraded sweet orange peel as a replacement for maize.
T3= Diets containing 50% biodegraded sweet orange peel as a replacement for maize.
T4= Diets containing 50% biodegraded sweet orange peel as a replacement for maize.
T5= Diets containing 50% biodegraded sweet orange peel as a replacement for maize.
T6= Diets containing 50% biodegraded sweet orange peel as a replacement for maize.

The non-significant (P>0.05) variation of the FBW, BWG, DFI. FCR and daily PI of rabbits irrespective of the dietary treatments, is an evidence of the nutritional potential of biodegraded SOP to serve as a replacement feed resource for maize which is an energy feed ingredient in growing rabbit nutrition. Biodegradation of SOP using bovine rumen filtrate enhanced the nutritive value of SOP for growing rabbit feeding. Thus biodegraded SOP obtained when bovine rumen filtrate is added to SOP in ratio of 1:4 to 5:5 can be used to replace 50% of maize in the diet of growing rabbits. This observation has elicited increased level of utilization of SOP as a replacement for dietary maize at 50% level in the diet of rabbit as against the 30% maize replacement value earlier reported (Oluremi et al., 2018).

The result of the coefficients of digestibility of nutrients by grower rabbits is presented in Table 4. Diets containing biodegraded sweet orange peel had significant (P<0.05) effect on dry matter, crude protein, ether extract, and nitrogen free extract while, the crude fibre did not vary significantly (P>0.05) across the treatment groups. Whereas, the values obtained varied from 55.97% to 79.83% dry matter, 64.92% to 81.29% crude protein, 37.26% to 63.37% crude fibre, 81.49% to 93.69% ether extract, 65.96% to 79.48% nitrogen free extract, none had a particular sequence of variation except crude protein digestibility. Crude protein digestibility range was lower than 78.63% to 84.64% reported by Oluremi et al. (2018) when grower rabbits were fed biodegraded sweet orange peel-based diets. The crude protein digestibility of 81.29% and 81.26% in T4 and T5, respectively were higher than 79.12% in T1 (control dietary group). This suggests a high efficiency in crude protein utilization by rabbits in dietary groups T4 and T5. The crude fibre, dry matter and ether extract values range of 37.26% to 63.37%, 55.97% to 79.83% and 81.49% to 93.69% were lower than 60.48% to 74.72%, 69.49% to 75.41% and 91.93% to 94.79%, respectively reported for grower rabbits fed biodegraded sweet orange peel-based diets (Oluremi et al., 2018). However, nitrogen free extract digestibility coefficient range of 65.96% to 79.48% obtained in this study was similar to digestibility values of 67.48% to 75.54% reported by these authors for growing rabbits fed biodegraded sweet orange peel-based diets. The significant effect (P<0.05) of the experimental diets on the digestibility of dry matter, ether extract and nitrogen free extract showed that the replacement of dietary maize with biodegraded sweet orange peel affected the nutrient quality of diets. While, dietary crude fibre is important for gut motility, digestibility of crude fibre is important in the overall nutrient utilization in rabbit because of the depressive effect it has on the utilization of other nutrients needed for growth and development. The result obtained in the present study did not show that dietary crude fibre caused any adverse effect on rabbit because the live weight of rabbits in T2, T3, T4, T5 and T6 were higher than the live weight of rabbits in T1 (control group).

The bovine rumen filtrate used contained three microbial isolates *Klebseilla* spp., *Escherchia Coli* and *Aspergillus* spp. which possibly improved the feed value of raw SOP treated in ratio of 1 litre RF : 5 kg SOP to 5 litre RF : 5 kg SOP during biodegradation. The FBW, BWG, FI, FCR and PI were similar irrespective of the experimental groups, except PER which increased significantly up to 2.10 when the volume of rumen filtrate added to the sweet orange peel for biodegradation was 4 litre RF : 5 kg SOP (T5). The growth response of rabbits fed biodegraded SOP based diet in ratio 4:5 at 50% maize replacement thus have a comparative advantage over the other treatments and can be used to replace 50% of maize in the diet of growing rabbits.

Abstract

Aim: This study aims to optimize ultrasonication time, ethanol concentration, and solid-to-solvent ratio for the optimization of the ultrasonic extraction of bioactive compounds from Rumex acetosella. Method: A second-order model for the response variables was developed to obtain quadratic equations. Total phenolic content (TPC) was measured by spectrophotometric absorbance analysis, and the total phenolic compound concentration was calculated as gallic acid equivalent (GAE). Absorbance values were recorded, and calibration curves were generated for analysis. Antioxidant activity (AOA) was evaluated using the DPPH method. The percentage of DPPH radical neutralization was calculated using control and sample absorbance values Results: The quadratic models were significant ($p < 0.05$) with insignificant lack of fit, demonstrating a good fit, and the coefficient of determination values for TPC and AOA were 98.52 and 97.43, respectively. Under optimum process variables of 10 min., 90% ethanol concentration and 0.36 solid-to-solvent ratio, TPC was 692.92 ± 15.38 mg GAE/g, and AOA was 68.50 ± 12.74%. Conclusion: Findings indicate that ultrasound-assisted extraction is an effective method for optimizing the extraction of bioactive compounds from Rumex acetosella, a high total phenolic content (TPC) and antioxidant activity (AOA) under carefully controlled processing conditions. The optimized parameters demonstrated the potential of this technique to maximize the recovery of phenolic compounds and antioxidant properties, making it a promising approach for the extraction of bioactive compounds in food applications.

Key Words: *Ultrasonic Assisted Extraction, Rumex acetosella, Total Phenolic Content, Antioxidant activity, DPPH*

Introduction

Rumex acetosella, commonly known as red sorrel, is a wild plant species that contains important biomolecules and has been traditionally used for various purposes. As time goes by, people are becoming more aware of healthy nutrition, and this complex relationship directs individuals toward foods that contain specific biomolecules for certain metabolic activities (Wen et al., 2018). The components found in R. acetosella are believed to contribute to these characteristics. Its dried upper parts contain rutin, flavone glycosides, hyperin, vitamin C, vitamin A, B complex, carotenoids, chlorophyll, organic acids like oxalic and malic acids, along with various trace elements such as calcium, iron, magnesium, copper, and zinc (Tamayo et al., 2000).

Red sorrel might have different phytonutrient profiles and flavors depending on cultivated area. Some studies suggest that red sorrel species tend to maintain higher antioxidant capacity, richer flavors, and more appealing colors, fragrances, and aromatic compounds (Isbilir & Sagiroglu, 2013). As a result, this study aimed to assess the total phenolic content and antioxidant activity of ethanolic extracts from red sorrels.

The extraction processes of bioactive compounds are of great importance in terms of their utilization. One of the key points to consider in this study is the extraction method. Traditional methods include boiling extraction, Soxhlet extraction, high hydrostatic pressure extraction, and other high-pressure processes. However, these methods have disadvantages in terms of cost, environmental pollution, low efficiency, and time consumption.
In this study, the ultrasonic extraction method was utilized to achieve the most efficient extraction of bioactive compounds from Rumex acetosella. The ultrasonic extraction method we preferred facilitates the breakdown of cell walls and enhances mass transfer by generating cavitation bubbles under pressure. As a result, intracellular components are extracted more efficiently. Moreover, it is referred to as a "green extraction method". Green extraction methods are characterized by low cost, high efficiency, and minimal environmental pollution (Wen et al., 2018).

According to the literature, the optimization of ultrasonic extraction of bioactives from Rumex acetosella hasn't been researched and a comprehensive approach to maximizing the total phenolic content and antioxidant activity has not been explored yet. Therefore, this study aims to optimize ultrasonication time, ethanol concentration and

solid-to-solvent ratio across a wide range of processing conditions to maximize the total phenolic content (TPC) and antioxidant activity (AOA) in Rumex acetosella.

Materials and Methods

Materials

Rumex acetosella was obtained from www.sebzemeyvedunyasi.com. Sodium carbonate, Folin-Ciocalteau (FC) reagent, and 2,2-Diphenyl-1-picrylhydrazyl (DPPH) were purchased from Sigma-Aldrich Chemie Gmbh (Darmstadt, Germany).

Methods

The leaves of Rumex acetosella were washed and left to dry for 7 days. The leaves of Rumex acetosella were separated from the stems. The leaves of Rumex acetosella were powdered with a spice grinder.

Phenolic content extraction from Rumex acetosella powder was carried out using a 600 W ultrasonic homogenizer (JY92-IIN; Ningbo Scientz Biotech Co Ltd., China).Bioactive compounds were extracted from Rumex acetosella using three different levels of solid-to-solvent ratios (X1), three different levels of ethanol concentrations (X2) and

three different levels of ultrasonication times (X3). A total of 30 ml of solution in a 50 ml beaker was ultrasonicated under each condition. The ultrasound probe was immersed in the solvent up to the safety limit, and a temperature probe was used to maintain the temperature. The ultrasound power was set to 50%, corresponding to 300 W, with a cycle of 2 minutes on and 2 minutes off. After the extraction, the solution was centrifuged at 2000 rpm for 10 minutes.

Total phenolic content (Y1) and antioxidant activity (Y2) were the response variables in this study. A Box Behnken Design was employed due to its suitability for experiments involving three factors, each with three levels. Table 1 presents the actual values of the independent variables across a broad range of operational conditions. Using Box Behnken Design, a second-order model for the response variables was developed to obtain quadratic equations. A total of 30 experimental runs with various combinations were conducted using MINITAB 17.1 (Minitab Inc., State College, PA, USA) to investigate the main and interaction effects (Table 1). Second-order regression equations with coefficients were determined using MINITAB. MINITAB's optimization tool was utilized to determine the optimum conditions for maximizing TPC and AOA.

TPC of Rumex acetosella powder was measured in terms of gallic acid equivalents (GAE mg/g) (Waterhouse, 2002). The supernatant from the extract solution (20 µL) was mixed with 1.58 mL of distilled water and 0.1 mL of Folin-Ciocalteu reagent (0.2 N). After a 3-minute incubation period, 0.3 mL of a 7.5% Na2CO3 stock solution was added. The mixture was then allowed to stand in the dark at room temperature for 1 hours. Absorbance was measured at 765 nm using a spectrophotometer (T80+, UV/Vis spectrometer, PG Instrument Ltd.) in triplicate.
The AOA of ultrasonic-assisted extracts of Rumex acetosella powder was evaluated using the percent DPPH radical inhibition method (González-Aguilar et al., 2007), with slight modifications. The extract (0.1 mL) was mixed with 3.9 mL of a DPPH solution (0.6 mM in 80% ethanol). The mixture was kept in the dark for 60 minutes. Absorbance was then measured at 517 nm using a spectrophotometer. The antioxidant activity percentage (AOA%) was calculated using the following equation.

$$\text{AOA}\ (\%) = \frac{A_{DPPH} - A_{Sample}}{A_{DPPH}} * 100$$

Results and Discussion

Effects of different Parameters on TPC

Table 2. Effects of Sorrel (*Rumex acetosella* L.) Extraction Parameters on TPC

Parameter	TPC Coefficient	TPC P values	AOA Coefficient	AOA P values
Intercept	585.9	<0.001	43.09	<0.001
Solid-Liquid Ratio(X_1)	145.3	<0.001	-16.65	<0.001

Table 3. Optimum Conditions and TPC Values

Parameter	Optimum Value
Ethanol Concentration	90%
Solid to Liquid Ratio	0.36 mg/20 mL
Ultrasonication time	10 min.
TPC(mg GAE/g)	692.92 ± 15.38
AOA(%)	68.50 ± 12.74%

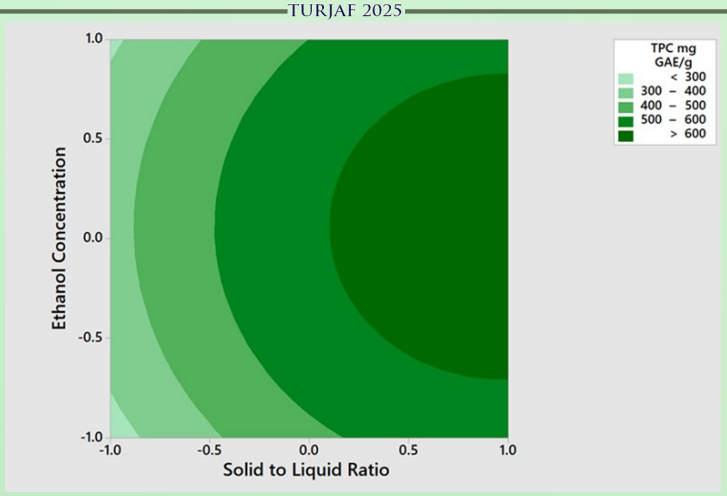

Figure 1. Contour Plot of TPC (mg GAE/g) as a Function of Ethanol Concentration and Solid-to-Liquid Ratio in Rumex acetocella L. Extract

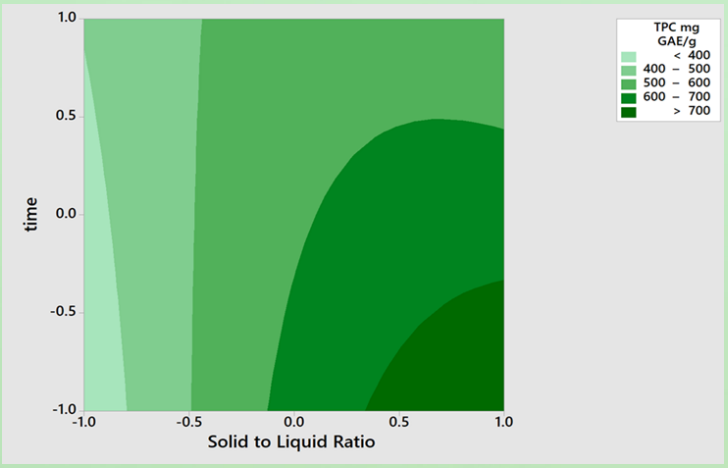

Figure 2. Contour Plot Analysis of Total Phenolic Content (TPC) Expressed as mg GAE/g: The Influence of Time and Solid-to-Liquid Ratio

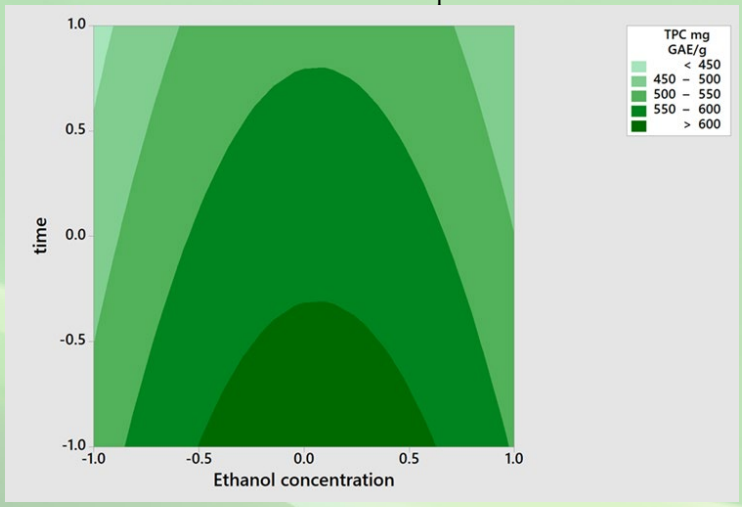

Figure 3. Contour Plot of Total Phenolic Content (TPC) in mg GAE/g: Effects of Time and Ethanol Concentration

Effect of ethanol concentration on TPC

The contour plots (Figures 1 and 3) clearly demonstrate the relationship between ethanol concentration and TPC. The graphs show that TPC values varied between 450-600 mg GAE/g corresponding to coded ethanol concentration levels ranging from -1.0 to +1.0 (equivalent to 10-90% actual concentration). The optimum TPC values (>600 mg GAE/g) were obtained at high ethanol concentrations.

The data in Table 2 show that the linear term of ethanol concentration (X_2) was statistically insignificant (p=0.509). This finding is consistent with the observation in the contour plots that variations along the ethanol axis did not

produce a linear effect on TPC. Similarly, Bouafia et al. (2021) reported that wide ethanol concentration ranges may not be suitable for optimization.

In contrast, the quadratic term (X_2^2) in Table 2 showed a highly significant effect (p=0.001), indicating that ethanol concentration has a non-linear (quadratic) influence. This result is supported by the parabolic trends observed in the contour plots, demonstrating that ethanol reduces extraction efficiency beyond a certain optimal concentration range (80-90%). Similar non-linear relationships have been reported in studies on Tartary buckwheat hull extraction by Dzah et al. (2020).

Under the optimal conditions presented in Table 3, the ethanol concentration was determined to be 90%. This value corresponds to the moderate-performance region in the contour plots and is consistent with the 80-90% ethanol concentration range recommended for phenolic compound extraction from grape seeds by Ghafoor et al. (2009).

Effect of solid-liquid ratio on TPC

This study determined that the solid-to-liquid ratio (X_1) exhibited a highly significant effect on TPC ($p < 0.001$). The positive regression coefficient (145.3) demonstrated a linear enhancement of TPC with increasing solid-to-liquid ratio.

Contour plot analyses (Figure 2) revealed that maximum TPC values (>600 mg GAE/g) were achieved at high solid-to-liquid ratios (0.36 mg/20 mL) combined with moderate ultrasonication durations (~23 min). These results align with findings by Ghafoor et al. (2009) for grape (*Vitis vinifera*) seed extraction. However, the significant negative quadratic term (X_1^2: -74.2, $p = 0.010$) suggested reduced extraction efficiency at excessively high ratios (>5 mg/10 mL), indicating an optimal range for solid loading.

A significant negative interaction between solid-to-liquid ratio and time (X_1X_3, $p = 0.004$) was observed. This suggests that prolonged extraction at high solid loading may promote release of undesirable compounds, potentially due to cell wall degradation. Similar findings were reported by Bouafia et al. (2021) for *Centaurea* sp. phenolic extraction.

Under optimized conditions (solid-to-liquid ratio: 0.36 mg/20 mL), the predicted maximum TPC reached 692.92 ± 15.38 mg GAE/g. This value substantially exceeds the 592 mg GAE/g reported by Dzah et al. (2020) for Tartary buckwheat (*Fagopyrum tataricum*) hull extracts, likely due to fundamental differences in the cell wall matrix and phenolic composition of *Rumex acetosa*. Moreover, the total phenolic content of wild and cultivated sheep sorrel was measured at 69.21 ± 8.5 (İsbilir and Sağıroğlu, 2013), which is lower than our findings, indicating that ultrasonic extraction yields more phenolic content than room temperature extraction.

Effect of time on TPC Levels

Statistical analysis revealed that ultrasonication time (X_3) significantly affected total phenolic content (TPC) (p=0.018). The regression analysis demonstrated a negative correlation between ultrasonication duration and TPC levels ($\beta = -45.1$), indicating that prolonged ultrasonication leads to degradation of phenolic compounds.

As evident from Figure 3, maximum TPC values (>550 mg GAE/g) were obtained at extraction durations of 15-20 minutes. During the initial 0-15 minute period, TPC levels increased substantially due to cavitation-induced cell wall disruption and subsequent rapid diffusion of phenolic compounds. However, with increasing extraction time and concomitant temperature elevation, thermal degradation and oxidative reactions of phenolic compounds resulted in a plateau phase (15-25 minutes) followed by a marked decline in TPC levels beyond 25 minutes, attributable to dynamic equilibrium between extraction and degradation processes. This trend was consistent with observations reported by Alonso-Riaño et al. (2020) in their study on brewer's spent grain extracts.

Effects of different Parameters on AOA

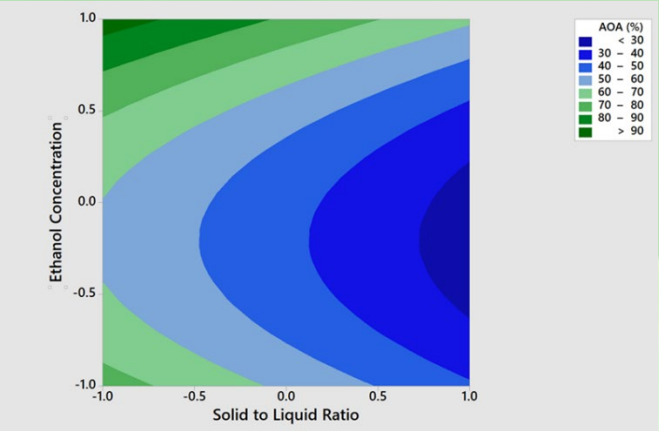

Figure 4. Contour Plot of Antioxidant Activity (AOA) in %: Effects of Ethanol Concentration and Solid-to-Liquid Ratio

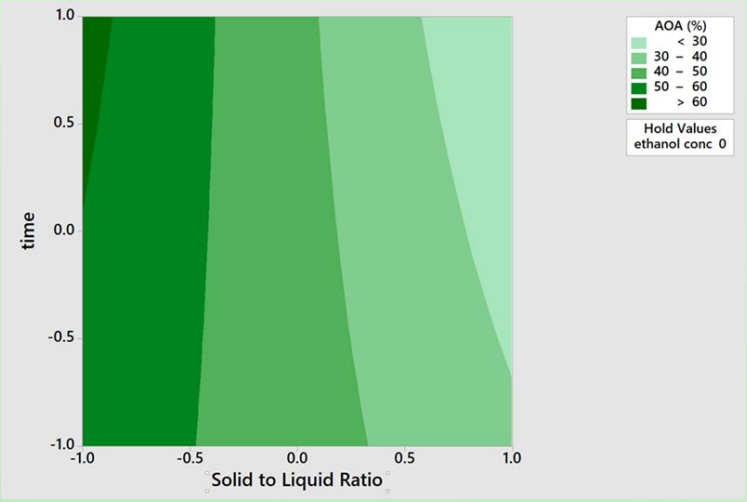

Figure 5. Contour Plot of Antioxidant Activity (AOA) in %: Effects of Extraction Time and Solid-to-Liquid Ratio

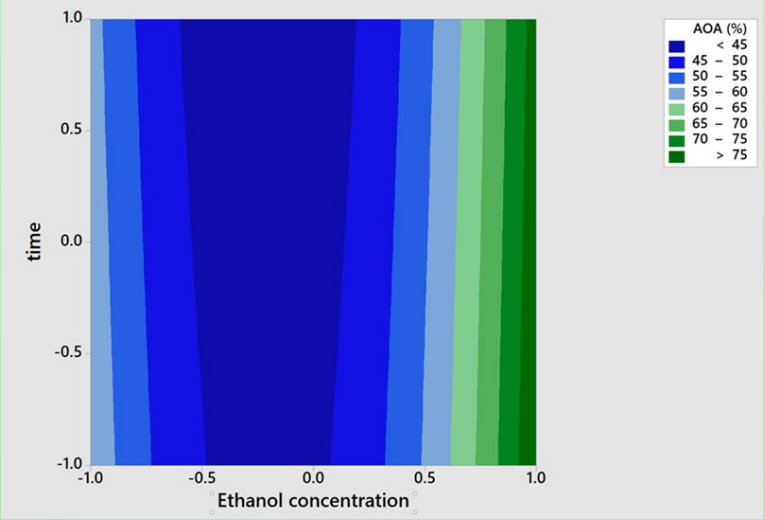

Figure 6. Contour Plot of Antioxidant Activity (AOA, %): Interaction Effects of Extraction Time and Ethanol Concentration

Effect of time and ethanol concentration on antioxidant activity

The current research investigated the sensitivity of *Rumex acetosella* antioxidant activity (AOA) levels to ethanol concentration and extraction times. The influence of ethanol concentration on antioxidant activity was not linear. Notably, the maximum AOA values recorded (68.49%) were at an ethanol concentration of 90%, as indicated in Figures 4 and 6. The reason being that elevated levels of ethanol enhance solubility, and thereby the efficiency of lipophilic phenolic compounds' extraction (Irfan et al., 2022). Yet, further increase in ethanol concentration beyond a certain level can make antioxidant compounds less stable, thereby lowering their antioxidant activity.

In terms of extraction time, it was observed that greater activity values were obtained in a shorter duration of 10 minutes than in longer durations of 30 minutes. This observation highlights the capacity of ultrasonication to break down cell structures quickly, thereby facilitating efficient extraction of antioxidant compounds (Muñiz-Márquez et al., 2013). The reduction of antioxidant activity in longer extraction is attributed to thermal degradation and oxidative degradation processes.

The highest AOA values were achieved in experiments conducted in optimal conditions with the 10-minute extraction time and 90% ethanol concentration. These results demonstrate the complex interaction of plant material's chemical composition and ultrasonic extraction parameters. The pattern of nonlinear behavior is thought to be a result of antioxidants' varying polarities and the varying effect of this polarity difference on extraction efficiency.

Effect of time and solid-liquid ratio on antioxidant activity

Influence of time and solid-to-liquid ratio on antioxidant activity. This research examined the influence of extraction time and solid-to-liquid ratio on the antioxidant activity (AOA) of *Rumex acetosella* extracts. From the contour plot analysis, it was noted that high antioxidant activity values of 65% to 70% can be attained at short extraction times of just 10 minutes. This can be explained by the fact that ultrasonication has a cavitation effect that quickly ruptures cell walls, thereby facilitating the extraction of antioxidant compounds effectively (Alara et

al., 2021). However, when the extraction time was increased to 30 minutes, there was a 10–15% decrease in AOA, suggesting that prolonged ultrasonication may demolish thermolabile antioxidant compounds (Zhou et al., 2022). Under the evaluation of the solid-liquid ratio's effect on AOA, the highest values of activity were registered at a high solid-liquid ratio of 0.36g/20mL. The findings show that a suitable solid-liquid ratio greatly improves the efficiency of extraction (Wang et al., 2023). Conversely, a low ratio of 0.36 g/20 mL (1:55.50) caused a precipitous drop in AOA due to the dilution effect of antioxidant compounds by an excess of solvent. The analysis of parameter interactions showed that the best AOA values were obtained through the combination of a 10-minute extraction time and 0.36g/20mL solid-liquid ratio. The optimal conditions described above utilize the benefits of ultrasonic extraction to achieve maximum time and solvent efficiency (Alara et al., 2021). The results emphasize the importance of optimizing time and solid-liquid ratio in the extraction process of antioxidant compounds from *Rumex acetosella*. The optimal conditions developed are of great importance as reference standards for application at the industrial level.

Effect of ethanol concentration and solid-liquid ratio on antioxidant activity

In the present research, it was investigated how changing the relationship between extraction parameters, ethanol concentration and solid-liquid ratio on the antioxidant activity of *Rumex acetosella* extracts. Figure 4 demonstrates a 1:15 ratio. These findings can be explained by the solubility of lipophilic phenolics at higher ethanol concentrations and the maximum extraction efficiency obtained with the optimum solid-liquid ratio (Ziani et al., 2023).Notably, ethanol concentration exceeded 90% AOA decreased by 12-15% which may be explained by ethanol-induced denaturation of cellular structures and subsequent breakdown of heat-sensitive bioactive components (Rajha et al., 2014).

The results showed that the highest antioxidant activity was obtained using a 1:55.5 extraction ratio (0.36g/20mL).This suggests that an adequate solvent volume ensures complete extraction of bioactive compounds while preventing excessive dilution (Rajha et al., 2014) Conversely, the 1:50 ratio (0.2 g/20 mL) yielded only 45.3% AOA attributable to the dilution effect caused by disproportionate solvent volume on antioxidant compounds.

Maximum AOA was observed 10 min extraction time with 90% ethanol at a 1:55.5 solid-liquid ratio. These conditions maximized ultrasonic cavitation, which efficiently fractured cell membranes and released antioxidant components at higher yields (Ziani et al., 2023).

However, extending the extraction time to 30 min resulted in an 18% decrease in AOA, suggesting that prolonged ultrasonication may destabilize antioxidant compounds.

This study systematically optimized three critical extraction parameters ethanol concentration, solid-liquid ratio, to maximize total phenolic content and antioxidant activity in *Rumex acetosella*. Optimal extraction conditions (90% ethanol, 1:55.5 ratio, 10 min) TPC values were measured as 692.92 ± 5.34 mg GAE/g. This observation is consistent with the findings of Irfan et al. (2022) that ethanol concentrations exceeding 90% cause degradation of heat-labile phenolics through denaturation of plant cell matrices. For AOA, maximum activity (68.49%) was obtained with short ultrasonication time (10 minutes) and a high solid-liquid ratio (0.36g/20ml). Ultrasonic waves produce microbubbles that mechanically disrupt cellular structure senabling efficient extraction of intact lipophilic antioxidants (Ziani et al., 2023). The composite desirability value (D=0.7445) indicated a balanced optimization of both TPC and AOA. However, the wide range of prediction for TPC (529.1–856.8 mg GAE/g) indicates the critical necessity for stringent control over process parameters. As it stands, therefore, the optimized condition (90% ethanol, 1:55.5 ratio, 10 min) offers a promising platform for extraction at the industrial level, with a green production strategy by reduced solvent usage (40% less than conventional) and shorter processing time (50% less).

Conclusion

This study explored the optimization of ultrasound-assisted extraction for enhancing the total phenolic content (TPC) and antioxidant activity (AOA) of Rumex acetosella (Sorrel). The results revealed significant relationships between extraction parameters, including ethanol concentration, solid-liquid ratio, and extraction time, on both TPC and AOA. Notably, ethanol concentration had a non-linear effect on TPC, with the highest phenolic content achieved at 90% ethanol. The solid-to-liquid ratio demonstrated a significant linear effect, where higher ratios (0.36 g/20 mL) led to enhanced extraction efficiency. Ultrasonication time was found to significantly influence TPC levels, with a peak at 10-20 minutes, after which degradation occurred. The optimized extraction conditions—90% ethanol, 1:55.5 solid-liquid ratio, and 10 minutes ultrasonication—produced TPC values of 692.92 ± 15.38 mg GAE/g and an AOA of 68.50%, presenting significant improvements over traditional methods. The findings underscore the potential for scaling this optimized process in industrial applications, contributing to a greener, more efficient extraction strategy by reducing solvent usage and extraction time. Future research should focus on further validating these optimized conditions in large-scale industrial applications, particularly for the extraction of bioactive compounds from other plant materials. Additionally, studies could explore the stability and bioavailability of the encapsulated phenolic compounds in food or pharmaceutical products. Investigating the impact of other extraction methods, such as supercritical fluid extraction, on the yield and quality of phenolic compounds, could offer a comparative perspective. Finally, the development of more sustainable and cost-effective extraction techniques should be prioritized, including the use of green solvents or waste-reducing technologies.

Evaluation of Individual Groundwater (GW) Irrigation in the Konya Closed Basin in Terms of Energy Consumption and Greenhouse Gas Emissions

Mehmet Akif KALENDER[1], Ramazan TOPAK[1]

[1]Department of Agricultural Structures and Irrigation, Faculty of Agriculture, Selçuk University, Konya, Turkey

Abstract

Konya Closed Basin is one of the 25 hydrological basins in Turkey. Individual groundwater irrigations in the basin have the highest ratio compared to other groundwater and surface water irrigations in terms of both irrigation area and agricultural water use. The number of individual irrigation wells in the basin is 74,621, with a total irrigation area of 414,209 hectares. In this study, individual groundwater irrigations in the Konya Closed Basin were evaluated in terms of energy consumption and greenhouse gas emissions for the years 2010, 2015 and 2020. Total energy consumption in individual groundwater irrigations was calculated as 12.875.442.516,8 MJ/year in 2010, 16.005.581.706,3 MJ/year in 2015 and 25.424.556.672,6 MJ/year in 2020. The amount of energy per unit area (E_A) was calculated as 31.084,4 MJ/ha, 38.641,3 MJ/ha and 61.381,0 MJ/ha in total for the years 2010, 2015 and 2020, respectively. The amount of energy per unit irrigation water (E_S) was 6,146 MJ/m^3 in 2010, 7,497 MJ/m^3 in 2015 and 11,691 MJ/m^3 in 2020. Total emissions from irrigation were calculated as 695.123.598,9 kgCO_2eq/year in 2010, 864.114.576,6 kgCO_2eq/year in 2015 and 1.372.629.275,6 kgCO_2eq/year in 2020. The emission amount per unit area (SG_A) was determined as 1.678,2 kgCO_2eq/ha, 2.086,2 kgCO_2eq/ha and 3.313,9 kgCO_2eq/ha for 2010, 2015 and 2020, respectively, while the emission amounts per unit irrigation water (SG_S) were determined as 0,332 kgCO_2eq/m^3, 0,405 kgCO_2eq/m^3 and 0,631 kgCO_2eq/m^3 for the same years, respectively. As a result of the evaluation, it is seen that energy consumption and greenhouse gas emissions in individual groundwater irrigation have increased over the years, with an approximately two-fold increase in 2020 compared to 2010.

Key Words: *Energy consumption, Konya Closed Basin, Greenhouse gas emission, Groundwater (GW) Irrigation*

Konya Kapalı Havzası Bireysel Yer altı (YAS) Sulamalarının Enerji Tüketimi ve Sera Gazı Emisyonu Yönünden Değerlendirilmesi

Özet

Konya Kapalı Havzası, Türkiye'deki 25 hidrolojik havzadan bir tanesidir. Havzada yer alan bireysel YAS sulamaları hem sulama alanı, hem de tarımsal su kullanımı açısından, diğer yer altı ve yer üstü sulamalarına oranla en yüksek orana sahiptir. Toplam 414.209 ha'lık sulama alanı ile birlikte, havzadaki şahıs kuyularının sayısı 74.621'dir. Bu çalışmada, Konya Kapalı Havzasında yer alan bireysel YAS sulamaları 2010, 2015 ve 2020 yılları için, enerji ve sera gazı emisyonu bakımından değerlendirilmiştir. Bireysel YAS sulamasında toplam enerji tüketimleri, 2010 yılında 12.875.442.516,8 MJ/yıl, 2015 yılında 16.005.581.706,3 MJ/yıl ve 2020 yılında 25.424.556.672,6 MJ/yıl olarak hesaplanmıştır. Birim alana karşılık enerji miktarı (E_A), 2010, 2015 ve 2020 yılları için sırasıyla toplam, 31.084,4 MJ/ha, 38.641,3 MJ/ha ve 61.381,0 MJ/ha olarak hesaplanmıştır. Birim sulama suyuna karşılık enerji miktarı ise (E_S), 2010 yılında 6,146 MJ/m^3, 2015 yılında 7,497 MJ/m^3 ve 2020 yılında 11,691 MJ/m^3 olmuştur. Sulamadan kaynaklanan toplam emisyon miktarları ise, 2010 yılında 695.123.598,9 kgCO_2eşd/yıl, 2015 yılında 864.114.576,6 kgCO_2eşd/yıl ve 2020 yılında 1.372.629.275,6 kgCO_2eşd/yıl olarak hesaplanmıştır. Birim alana karşılık emisyon miktarı (SG_A), 2010, 2015 ve 2020 yılları için sırasıyla, 1.678,2 kgCO_2eşd/ha, 2.086,2 kgCO_2eşd/ha ve 3.313,9 kgCO_2eşd/ha, birim sulama suyuna karşılık emisyon miktarları ise (SG_S), aynı yıllar için sırasıyla 0,332 kgCO_2eşd/m^3, 0,405 kgCO_2eşd/m^3 ve 0,631 kgCO_2eşd/m^3 olarak belirlenmiştir. Değerlendirme sonucunda, bireysel YAS sulamalarında enerji tüketimi ve sera gazı emisyonlarının yıllara bağlı olarak arttığı, 2020 yılında 2010 yılına kıyasla yaklaşık iki kat artışın olduğu görülmektedir.

Anahtar Kelimeler: *Enerji tüketimi, Konya Kapalı Havzası, Sera Gazı Emisyonu, Yer altı (YAS) Sulaması*

The Effect of Solid-State Fermentation using *Aspergillus niger* on the Nutritional Composition of Grape Seed, Cherry Kernel, and Maize Seed Mixture

Emrah Güngör

Department of Animal Science, Faculty of Agriculture, Ondokuz Mayis University, Samsun, Turkey

Abstract

The effect of solid-state fermentation using *Aspergillus niger* strains on the nutritional composition of the mixture of grape seed, cherry kernel, and maize seed was investigated in this study. Fermentation substrate consisting of 40 g of grape seeds, 40 g of cherry kernel, and 20 g of maize was fermented by *A. niger* strains (ATCC 200344, 200345, 201572, 52172). The substrate was enriched with a nutrient medium and sterilized with an autoclave. Each strain of *Aspergillus niger* was inoculated with 10^6 spores into the substrate. Incubation was carried out for seven days at 30 °C. Crude protein, ether extract, ash, nitrogen-free extract, and crude fiber contents of substrate were determined before and after fermentation. Solid-state fermentation using *A. niger* increased ($P<0.001$) crude protein content of the substrate. In addition, the ether extract content of the substrate was increased ($P<0.001$) by *A. niger*. Similarly, *A. niger* increased ($P=0.001$) the ash content of the grape seed, cherry kernel, and maize mixture. However, crude fiber was declined ($P<0.001$) by fermentation using *A. niger*. Similarly, solid-state fermentation decreased the nitrogen-free extract of the substrate. The obtained results showed that solid-state fermentation using *A. niger* can improve the nutritional composition of the mixture of grape seed, cherry kernel, and maize seed.

Key Words: *Solid-state fermentation, Aspergillus niger, Grape seed, Cherry kernel, Corn seed*

İklim ve Arazi Örtüsü Değişikliği Bağlamında Havza Ölçeğinde Gelecekteki Toprak Erozyonun Tahmini

Oğuz Ateş[1], Engin Kabataş[2], Fürüzan Çelik[3]

[1,2,3]Department of Landscape Architecture, Faculty of Architecture, Kırklareli University, Kırklareli, Türkiye

Özet

Yaşam sürdüğümüz çevrede var olan antropojenik faaliyetler doğanın kendi içerisindeki işleyişi etkilemektedir. Bu etkiler doğal süreçlerin olması gerekenden daha hızlı veya daha yavaş olmasına yol açarak çeşitli olumsuzluklar yaratmaktadır. Özellikle artan nüfus ve kentleşmeye bağlı arazi kullanım arazi örtüsünde meydana gelen değişimlerin yanında küresel bir sorun olan iklim değişikliği gibi faktörler doğal sistemlerde dönüşü olmayan olumsuzluklar ve kayıplar oluşturmaktadır. Bu olumsuzluklar yer yüzünde yaşam sağlayan canlıların besin kaynağını oluşturan alanları da doğrudan ya da dolaylı olarak etkilemektedir. Bu bağlamda yer yüzünde var olan doğal kaynakların korunması, gelecek yıllardaki olası durumlarının araştırılması önem arz etmektedir. Bu nedenle canlıların besin kaynaklarının temelini oluşturan verimli toprakların erozyona bağlı olarak gelecekte nasıl etkileneceğinin araştırılması çalışmanın amacını oluşturmaktadır. Bu amaç doğrultusunda dünyada ve ülkemizde oldukça fazla kullanılan RUSLE modeli aracılığıyla Meriç-Ergene Havzasında meydana gelebilecek potansiyel erozyon durumları CBS ortamında analiz edilmesi ve haritalandırılması hedeflenmiştir. Bu amaç ve hedef doğrultusunda çalışma 3 aşamalı bir yöntem dahilinde yürütülmüştür. Birinci aşamada; CMIP6 iklim modellerinden alınan SSP 2-4.5 (Orta) senaryo verileri aracılığıyla gelecekte meydana gelecek yıllık ortalama yağış miktarı haritalası 2050 yılı için coğrafi bilgi sistemleri aracılığıyla haritalandırılmıştır. İkinci aşamada; ESRİ tarafından sağlanan küresel AKAÖ verileri kullanılarak (2017-2023) 2050 yılında meydana gelebilecek AKAÖ haritası Gelecekteki Arazi Kullanımı Simülasyonu (FLUS) modeli aracılığıyla üretilmiştir. Üçüncü aşamada ise; . Uzaktan Algılama (UA) ve Coğrafi Bilgi Sistemleri (CBS) teknolojileri ile desteklenen ve alt faktörün (R, K, L, S, C ve P faktörleri) bileşiminden oluşan Revize Edilmiş Evrensel Toprak Kayıp Denklemi (RUSLE) kullanılarak Günümüz ve 2050 yılında meydana gelebilecek potansiyel erozyon miktarı analiz edilmiş ve haritalandırılmıştır. Yapılan analiz sonucunda iklim değişikliği ve AKAÖ değişimlerinin potansiyel erozyon miktarını ve şiddetini etkilediği tespit edilmiş olup, buna yönelik öneriler ortaya konulmuştur. Bu çalışmanın çıktıları özellikle iklim değişikliği ve AKAÖ değişikliğine bağlı olarak gelecekte meydana gelecek potansiyel kayıpların önceden tespit edilmesi, alternatif önleme çözümlerinin geliştirilmesi ve sürdürülebilir arazi yönetimi konularına önemli katkılar sağlayacaktır.

Abstract

Beekeeping is a labor-intensive profession that necessitates constant exposure to outdoor environmental conditions. As a result, beekeepers are frequently subjected to various physical and chemical agents, which can lead to dermatological conditions such as eczema. Eczema is a chronic inflammatory skin disorder characterized by redness, itching, dryness, and blister formation. One of the primary occupational risk factors for eczema in beekeepers is prolonged contact with bee products—including honey, propolis, and beeswax—which can trigger allergic reactions. Despite its potent antibacterial properties, propolis is a well-known contact allergen that may cause allergic contact dermatitis in sensitized individuals. Working conditions also significantly contribute to eczema development. Beekeepers often wear boots, gloves, and protective suits for extended periods, leading to sweating and sustained skin moisture, which can aggravate irritation and inflammation. Prolonged exposure to heat and sunlight may further weaken the skin barrier and increase sensitivity. Additionally, inadequate hygiene or improper sanitation practices, along with frequent use of chemical repellents and disinfectants to prevent bee stings, may exacerbate skin damage. Excessive use of soaps and detergents can deplete the skin's natural oils, increasing dryness and susceptibility to eczema. This paper discusses the etiology, risk factors, clinical symptoms, and diagnostic approaches for occupational eczema among beekeepers. Furthermore, it outlines preventive strategies such as proper use of personal protective equipment, skin care routines, and treatment options. Recommendations for minimizing occupational skin diseases in the beekeeping sector are also provided.

Keywords: *Beekeeping, propolis, allergic contact dermatitis, occupational health, eczema*

Introduction

Due to its ecological diversity and socio-economic structure, beekeeping is practiced in almost every region of Turkey. Although approximately 75% of the world's nectariferous plants grow in Turkey, only about 10% of this potential is currently utilized (Doğanay, 2007). Turkey ranks second globally in honey production with about 7% of the total share and third in terms of colony numbers (Güneşdoğdu & Akyol, 2019). The country's favorable climate and rich natural flora offer a suitable environment for beekeeping (Güneşdoğdu & Şekeroğlu, 2020).
However, beekeeping involves significant occupational hazards due to both physical and chemical exposure. Beekeepers are at higher risk of developing dermatological diseases, particularly eczema and contact dermatitis, due to frequent contact with bee products and the chemicals used in pest management.

Dermatological Risk Factors in Beekeeping

Propolis, a natural compound collected by bees from various plants, is a common allergen that may cause contact sensitivity (Bunney, 1986). The reported prevalence of allergic reactions to propolis ranges from 1.2% to 6.6% (Münstedt & Kalder, 2009). Geographic variation in its chemical composition complicates the evaluation of contact allergies (Nyman et al., 2020). Beekeepers also use acaricides containing formic acid, oxalic acid, and essential oils such as thyme, lavender, and bay leaf to control parasitic mites. These substances are known to be irritant and allergenic (Qayoom et al., 2024).
Dermatitis is a common inflammatory skin disorder caused by disruption of the skin barrier due to chemical or physical agents (Uter et al., 1998). Pathophysiologically, it is classified into irritant contact dermatitis (ICD) and allergic contact dermatitis (ACD). ACD arises from an acquired immune response to specific antigens, while ICD results from activation of the innate immune system by irritant substances (Krasteva et al., 1999a).
Frequent use of soap and disinfectants weakens the skin barrier, potentially leading to hand eczema. Symptoms include itching, dryness, fissures, and bleeding (Singh et al., 2020). If left untreated, eczema may worsen over time and negatively affect the patient's quality of life (Agner et al., 2008; Techasatian et al., 2021).

Prevalence and Prevention of Eczema in Beekeepers

Due to regular exposure to substances like propolis, beeswax, bee venom, and acaricides, beekeepers often develop compromised skin barriers. While protective equipment such as gloves and masks can reduce contact with irritants, prolonged use may cause sweating and further irritation.

Figure 1. ChatGPT-Assisted Scientific Illustration: Pathogenesis of Occupational Eczema and Associated Skin Lesions in Beekeepers.

Living conditions also influence eczema risk. Beekeepers in rural areas may face limited access to hygiene facilities, which hinders proper skin care. Inadequate laundering of clothing may contribute to bacterial or fungal infections, worsening eczema.

Heat and perspiration are additional risk factors. Sweat disrupts the skin barrier, promoting irritation and microbial growth. Therefore, it is recommended that beekeepers wear breathable cotton clothing, cleanse their skin after sweating, and wash garments regularly. A visual representation of eczema lesions and etiological factors generated by an AI tool (ChatGPT) is provided in Figure 1.

Oosterhaven et al. (2019) reported a one-year prevalence of dermatitis among Dutch beekeepers at 13.2%, with a lifetime prevalence of 20.5%. The development of allergic sensitivity to propolis typically requires about 9.5 years of occupational exposure (Münstedt & Kalder, 2009). Illg and Sanokowska (1976) documented a 4.04% prevalence of propolis-induced allergy in Polish beekeepers. Among the 26 allergens identified in propolis, the most significant is LB-1, which contains three pentenyl caffeate esters derived from poplar buds. These include 3-methyl-2-butenyl caffeate (54.2%), 3-methyl-3-butenyl caffeate (28.3%), and 2-methyl-2-butenyl caffeate (4.3%), as well as phenethyl caffeate (7.9%), caffeic acid (1.3%), and benzyl caffeate (1.0%). Other compounds such as caffeic acid phenethyl ester (CAPE), benzyl salicylate, and benzyl cinnamate also contribute to contact dermatitis (Basista-Sołtys, 2013).

To mitigate the risk of eczema and related skin conditions, beekeepers should wear appropriate protective clothing, adhere to hygiene practices, and minimize contact with irritant substances. Regular skin care and medical checkups are also advised. Figure 2 illustrates eczema-related lesions on the hands, feet, knees, and scalp of beekeepers.

Conclusion and Recommendations

Etiological factors of eczema:

1. Genetic predisposition, immune responses, and environmental conditions.
2. Continuous exposure to bee products and external elements places beekeepers in a high-risk category.

Preventive measures:

1. Use protective gloves and suitable clothing.
2. Maintain regular skin care using non-irritating moisturizers.
3. Avoid contact with harsh chemicals and detergents.
4. Prefer dermatologically appropriate products over regular soaps.

Figure 2. Clinical Manifestations of Occupational Eczema in Beekeepers Across Different Body Regions

Recommendations for beekeepers:

1. Implement measures to reduce allergen exposure in the workplace.
2. Choose latex-free, breathable gloves.
3. Keep headgear and underarm areas clean, as they accumulate sweat.
4. If boots are worn for foot protection, they should be cleaned regularly.
5. Choose apiary locations near water sources and launder clothing frequently.
6. Prioritize personal hygiene.
7. Seek dermatological care at the early signs of eczema.
8. Suggestions for future research:
9. Conduct large-scale epidemiological studies on the prevalence of eczema in beekeepers.
10. Examine the dermatological effects of bee products in detail.
11. Develop effective and natural preventive solutions for eczema.

[2]Urban and Regional Planning Department, Faculty of Architecture, Nigde Omer Halisdemir University, Nigde, Turkiye

Abstract

Agricultural activities play a crucial role in food production; however, excessive use of synthetic fertilizers has raised serious concerns regarding soil, water, and environmental pollution. Nutrient deficiency, how well crops use available nutrients and how effectively agricultural inputs (synthetic fertilizers, manure applied to soils, nitrogen deposition, biological fixation and seed) are applied have gained importance. Therefore, the study analyzes cropland nutrient balance, nutrient use efficiency and greenhouse gas emissions from synthetic fertilizers and crops in Turkiye. Data is retrieved from FAOSTAT (Food and Agricultural Organization of the United Nations) for the 1961-2022 period. This article also proposes sustainable alternatives to mitigate adverse effects, emphasizing the need for balanced agricultural practices to ensure agricultural and environmental sustainability. An increasing N surplus and increasing K deficit was found, which can be explained by higher increase in crop removal than mineral fertilizers. Nitrogen use signaled for possible deficiency due to efficiency falling below the treshold. Quantity of cereal production explained 93% of the variability in total N2O GHG emissions. N2O emissions from cereals were not significantly different from CH4 emissions from rice cultivation in 2022. Although nutrious dioxide emission intensity had a logaritmic trajectory, variations were high in the last decade. Overall, greenhouse gas emissions from fertilizers and cereals are in desired levels despite some risks for nitrogen and potassium deficiencies. N interventions and altering composions of fertilizers should be promoted to balance crop removal and mineral fertilizers. Future studies should consider greenhouse gas emmisions from pesticide use in relation to environmental effects. Farmers in Türkiye should adopt sustainable agricultural practices such as use of organic fertilizers; precision agriculture techniques to optimize fertilizer application; and crop rotation and cover crops to maintain soil health and prevent nutrient depletion. Policymakers and farmers must collaborate to promote these practices through education, incentives, and regulatory frameworks.

Antifungal Activity of Methanol Extracts Obtained from *Verbascum* L. (Mullein) Species Collected from Different Regions Against *Rhizoctonia solani*

Bahadır Şin[1], Raziye Koçak[2], Özden Salman[3]

[1]Department of Plant Protection, Faculty of Agriculture, Sakarya Universty of Aplied Science, Sakarya, Türkiye
[2]Animal and Plant Production Department, Çumra Vocational School, Selçuk University, Konya, Türkiye
[3]Department of Plant Protection, Faculty of Agriculture, Selçuk University, Konya, Türkiye

Abstract

Plants are among the important natural resources preferred in combating plant pathogens due to their secondary metabolites. In this study, the antifungal effects of methanol extracts obtained from regional *Verbascum* (Mullein) species collected from ecologically different locations (Karasu, Konya, Bolu, Arifiye, and Manisa) were investigated under *in vitro* conditions against *Rhizoctonia solani* (J.G. Kühn), a soil-borne phytopathogenic fungus with a wide host range. For this purpose, methanol extracts were obtained from the flower and leaf parts of *Verbascum* species, and the potential of these extracts at different concentrations (0.5%, 1%, 2%, and 4%) to inhibit mycelial growth in the culture medium was evaluated. All tested extracts exhibited antifungal activity at varying levels. The extract prepared from samples collected in Konya showed the highest inhibition of mycelial growth, suppressing it by 55%. This was followed by the extract from Karasu with an inhibition rate of 45%. Extracts obtained from other locations exhibited antifungal activity at varying degrees, inhibiting mycelial growth between 7.5% and 36.25%. The findings indicate that methanol extracts obtained from *Verbascum* species exhibit antifungal activity against *Rhizoctonia solani* and that this effect increases with the applied dose. These results suggest that the active compounds present in *Verbascum* species should be identified and that their potential as alternative natural fungicides in biological control should be further supported by advanced research.

Key Words: *Antifungal activity, Rhizoctonia solani, Verbascum spp., Methanol extract, Natural fungicide.*

Farklı Bölgelerden Toplanan *Verbascum* L. (Sığırkuyruğu) Türlerinden Elde Edilen Metanol Ekstraktlarının *Rhizoctonia solani*'ye Karşı Antifungal Aktivitesi

Özet

Bitkiler, bitki patojenleriyle mücadelede sekonder bileşikler içermeleri nedeniyle tercih edilen önemli doğal kaynaklar arasında yer almaktadır. Bu çalışmada, ekolojik olarak farklı lokasyonlardan (Karasu, Konya, Bolu, Arifiye ve Manisa) toplanan bölgesel *Verbascum* (Sığırkuyruğu) türlerine ait metanol ekstraktlarının, toprak kökenli, geniş konukçu aralığına sahip fitopatojen bir fungus olan *Rhizoctonia solani* (J.G. Kühn) üzerindeki antifungal etkileri *in vitro* koşullarda araştırılmıştır. Bunun için *Verbascum* türlerinin çiçek ve yaprak kısımlarından metanol ekstraktları elde edilmiş ve bu ekstraktların farklı konsantrasyonlarının (%0,5, %1, %2 ve %4) besi ortamında miselyal gelişimi inhibe etme potansiyeli değerlendirilmiştir. Test edilen tüm ekstraktlar belirli düzeylerde antifungal aktivite göstermiştir. Miselyal gelişimi en fazla baskılayan ekstrakt, Konya'dan toplanan örneklerden hazırlanmış olup, bu ekstrakt miselyal gelişimi %55 oranında engellenmiştir. Bunu %45 inhibisyon oranı ile Karasu ekstraktı takip etmiştir. Diğer lokasyonlardan elde edilen ekstraktlar ise değişen oranlarda antifungal aktivite sergilemiş ve miselyal gelişimi %7,5 ile %36,25 arasında inhibe etmiştir. Elde edilen bulgular, *Verbascum* türlerinden elde edilen metanol ekstraktlarının *Rhizoctonia solani*'ye karşı antifungal aktivite gösterdiğini ve bu etkinin uygulanan doz miktarına bağlı olarak arttığını ortaya koymaktadır. Bu sonuçlar, *Verbascum* türlerinin içerdiği aktif bileşiklerin belirlenmesi ve biyolojik mücadelede alternatif doğal fungisitler olarak kullanım potansiyellerinin ileri araştırmalarla desteklenmesi gerektiğini göstermektedir.

Anahtar Kelimeler: *Antifungal aktivite, Rhizoctonia solani, Verbascum spp., Metanol ekstraktı, Doğal fungisit.*

Abstract

Biopesticides are compounds derived from natural sources such as plants, bacteria, and minerals, serving as environmentally friendly alternatives to synthetic pesticides. They are generally preferred due to their lower toxicity and specificity towards target organisms. However, their impact on non-target species, particularly bees, which play a crucial role in ecosystem sustainability and agricultural production, must be carefully evaluated. Bees contribute significantly to biodiversity conservation and agricultural productivity through pollination. This study examines the potential risks and benefits of biopesticides on bee populations. Research indicates that although biopesticides tend to be less toxic than synthetic pesticides, their effects on bees vary depending on the active ingredient, formulation, and level of exposure. For instance, microbial biopesticides such as Bacillus thuringiensis (Bt) are considered to pose minimal risk to bees. In contrast, plant-based compounds such as neem oil and pyrethrins have been observed to negatively affect bee foraging behavior and reproduction. Additionally, interactions between biopesticides and other environmental stressors, such as pathogens and nutritional deficiencies, may exacerbate their adverse effects on bee health. Despite these concerns, biopesticides offer advantages, including biodegradability and lower environmental persistence, reducing unintended impacts on beneficial insects. When integrated pest management (IPM) strategies are applied effectively, the risks to pollinators can be minimized while maintaining agricultural productivity. Therefore, further research is needed to understand the long-term effects of biopesticides on bee populations and to develop safe application guidelines. A balanced approach is essential to ensure both agricultural productivity and pollinator conservation, supporting ecological and agricultural sustainability.

Key Words: *Bee health, Biopesticide, Ecological balance, Integrated pest management (IPM), Agricultural sustainability*

1. Introduction

Pollinators, particularly honeybees (*Apis mellifera*), play a vital role in maintaining biodiversity and ensuring food security through the pollination of agricultural crops and wild plants (Khalifa et al., 2021; Requier et al., 2023). However, in recent decades, significant declines in bee populations have raised global concern, prompting extensive research into the multifactorial causes of these losses (Lima et al., 2022). Among the various anthropogenic stressors, the use of pesticides in modern agriculture has been widely implicated in the deterioration of bee health (Zhao et al., 2022) . While conventional synthetic pesticides are known for their acute and chronic toxicity to pollinators, biopesticides—marketed as safer, eco-friendly alternatives—have increasingly gained attention as part of integrated pest management (IPM) strategies (Cappa et al., 2022; Demirözer et al., 2022) .

Biopesticides, which are derived from natural organisms such as bacteria, fungi, viruses, or plant extracts, are generally assumed to be less harmful to non-target organisms, including pollinators (Cappa et al., 2022; Guedes et al., 2024). This perception has led to their widespread acceptance and use without sufficient evaluation of their sublethal or chronic impacts on beneficial insects. Recent studies, however, have begun to challenge this assumption, highlighting that certain biopesticides may impair critical physiological and behavioral functions in bees, such as foraging efficiency, learning and memory, immune response, and colony development (Carlesso et al., 2020; Almeida et al., 2022). Moreover, the synergistic effects of biopesticides when combined with other environmental stressors, such as nutritional deficiencies, pathogens, or climate change, remain poorly understood. Given the essential ecological role of bees and the growing reliance on biopesticides in sustainable agriculture, it is crucial to reassess the environmental safety profiles of these products. This study aims to investigate the potential adverse effects of commonly used biopesticides on honeybee health, with a particular focus on sublethal behavioral and physiological impacts. By doing so, it seeks to contribute to a more nuanced understanding of how "green" plant protection strategies may still pose risks to vital pollinator species.

2. Biopesticides Effects on Bee

Biopesticides are derived from natural organisms such as bacteria, fungi, viruses, or plant extracts.

2.1. Entomopathogenic bacteria

The most studied entomopathogenic bacteria include species from the genera Bacillus, Beauveria, and Metarhizium. Among these, *Bacillus thuringiensis* (Bt) is perhaps the most widely recognized for its use in pest control. These bacteria produce toxins that can damage the insect's gut, leading to death. While these bacteria are often lethal to pests, their effects on non-target organisms like bees are not always well understood (Rousset and Gallet, 2025). Entomopathogenic bacteria, particularly strains of *B. thuringiensis*, have been shown to be toxic to bees under certain conditions. While bees are not the intended targets of these bacteria, they may encounter them when foraging on contaminated plants or surfaces. Bees can ingest or come into contact with bacterial spores or toxins, which can potentially disrupt their digestive systems, impair their health, or even result in death. However, some strains of Bacillus may have minimal or no direct lethal effects on bees, depending on the concentration and strain involved (Mommaaerts et al., 2010; Alkassab et al., 2022). Exposure to entomopathogenic bacteria could also suppress the bee's immune system (Steinigeweg et al., 2021). Bees rely heavily on their immune response to fend off pathogens, parasites, and other environmental stressors. If bees are infected by harmful bacteria, their immune system might be compromised, leaving them more susceptible to other diseases or pathogens, such as Nosema or the varroa mite (Alquisira-Ramírez et al., 2017). A weakened immune system can lead to colony collapse, affecting not only individual bees but also the entire hive. Sublethal exposure to entomopathogenic bacteria might not kill bees immediately but can cause behavioral changes. Affected bees may become less efficient in foraging, decrease in grooming or nursing activities, or exhibit altered communication such as waggle dancing (Malone et al., 2001; Mommaerts et al., 2010). These behavioral shifts could affect the overall productivity of the colony, impairing pollination efforts and leading to decreased honey production. The widespread use of entomopathogenic bacteria in agriculture or horticulture may pose a risk to bees if these bacteria are applied to crops that bees frequent. Pesticide treatments containing entomopathogenic bacteria could persist in the environment, and bees could be exposed to these pathogens during their foraging activities. The long-term ecological impact of such exposure is not fully understood but could have cumulative effects on bee populations over time. While there are concerns about the harmful effects, some studies suggest that entomopathogenic bacteria may have potential benefits for bee health under certain conditions. For example, Bacillus species have been found to outcompete or inhibit the growth of harmful pathogens that affect bees, like *Nosema apis* (a protozoan that causes Nosema disease). In this sense, entomopathogenic bacteria could serve as a form of natural biological control to support colony health, though careful management would be necessary to avoid inadvertent harm.

2.2. Entomopathogenic Fungi

Entomopathogenic fungi, such as Beauveria bassiana and Metarhizium anisopliae, are increasingly utilized in integrated pest management due to their specificity and environmental safety; however, their non-target effects on pollinators warrant careful evaluation. Although adult bees generally exhibit low susceptibility to infection under field-relevant concentrations, sublethal impacts—including behavioral alterations, reduced foraging efficiency, and impaired learning—have been documented following exposure to certain fungal strains (Almeida et al., 2022; Leite et al., 2022; Bava et al., 2022). Moreover, the larval stages may be more vulnerable, especially when spores are introduced into the hive environment (Omuse et al., 2022). These effects, while often subtle at the individual level, could potentially accumulate to impair colony-level function, particularly when compounded by additional stressors such as pesticide exposure or nutritional deficiencies. Therefore, risk assessments of entomopathogenic fungi should consider strain-specific virulence, exposure routes, and the health status of bee populations to ensure pollinator safety in biological control programs.

2.3. Entomopathogenic Nematodes

Entomopathogenic nematodes (EPNs), primarily from the genera Steinernema and Heterorhabditis, are widely used as biological control agents due to their ability to parasitize and kill a broad range of insect pests. These nematodes harbor symbiotic bacteria (e.g., *Xenorhabdus spp*. and *Photorhabdus spp*.) that contribute to the host's death by releasing toxins. Although EPNs are generally considered safe for non-target organisms, including pollinators, the potential effects on bees have become an emerging area of concern (Erler et al., 2022). Bees, particularly *Apis mellifera* and other eusocial species, are not typical hosts for EPNs due to their mobility, grooming behavior, and relatively dry external cuticle, which collectively reduce the likelihood of successful infection. However, under laboratory conditions or when EPNs are applied in high concentrations and in moist environments—such as hive interiors or floral resources—there is evidence of possible adverse interactions. Some studies have shown that EPNs can cause high mortality (Dutka et al., 2015). Despite these risks, most field applications of EPNs appear to pose minimal direct threat to bee populations. Their survival and infectivity are limited on dry surfaces like flowers, and they are not typically attracted to or capable of breaching the protective defenses of adult bees. Nevertheless, comprehensive risk assessments are essential, particularly for stingless bees or solitary bee species that nest in soil or decaying wood, where EPNs are more likely to persist and interact with developing brood.

2.4. Viruses

Honey bees are known to host more than 20 distinct viruses, which typically remain latent and asymptomatic unless activated by external stressors (McMenamin and Genersch, 2015). When such stressors compromise the bees' immune function, viral replication can increase, and elevated viral loads have been associated with colony collapse (McMenamin and Genersch, 2015). Although RNA viruses from the families Dicistroviridae and Iridoviridae are frequently detected in collapsing colonies and have been proposed as potential biopesticides (Bromenshenk et al., 2010; McMenamin and Genersch, 2015), there remains a significant paucity of targeted studies investigating their direct effects on honey bees. In contrast, studies examining the impacts of nuclear polyhedrosis viruses (NPVs), granulosis viruses, and entomopoxviruses—originally isolated from other insect species—have reported no adverse effects on honey bees, thereby suggesting host specificity and indicating their relative safety in microbial pest management programs (Alves et al., 1996). With respect to the potential impacts of viral biocontrol agents on bumble bees, the body of research remains limited. Nevertheless, existing studies suggest that granuloviruses isolated from *Cydia pomonella* do not negatively affect *Bombus terrestris* worker survival, foraging behavior, or overall colony fitness (Mommaerts et al., 2009).

2.5. Plant Extracts

The use of plant-based biopesticides has emerged as a sustainable alternative to synthetic chemical pesticides, offering potential advantages such as biodegradability, target specificity, and lower toxicity to non-target organisms (Haritha et al., 2021). However, growing evidence indicates that certain plant extracts employed as biopesticides may pose unforeseen risks to pollinators, particularly bees, which are essential for ecosystem functioning and agricultural productivity. Despite being considered environmentally friendly, the phytochemical constituents in some biopesticides can exert sublethal or even lethal effects on various species of bees, including honeybees (*Apis mellifera*), bumblebees (*Bombus spp*.), and solitary bees (Morandin et al., 2015; Tome et al., 2015).

Plant-derived compounds such as essential oils, alkaloids, saponins, and phenolics are designed to deter or kill insect pests, but these bioactive substances can also affect the physiology and behavior of bees (Demirözer et al., 2022). For example, neem-based biopesticides containing azadirachtin have demonstrated antifeedant and growth-regulating effects in target pests, yet studies have shown that exposure to sublethal doses can impair bee foraging efficiency, navigation, and learning capacity (Bernardes et al., 2017; Barbosa et al., 2015; Gomes et al., 2020). Similarly, essential oils such as thymol and eugenol may disrupt neural signaling pathways in bees, potentially altering their olfactory perception and communication.

Sublethal exposure to these compounds may also compromise bees' immune responses, making them more susceptible to pathogens such as *Nosema spp*. and viruses (Chaimanee et al., 2021). Additionally, repeated exposure to plant biopesticides through contaminated nectar, pollen, or water sources can result in cumulative toxicity, especially during peak foraging seasons. Larval development may also be disrupted when brood food is contaminated, affecting colony health and productivity over the long term.

3. Conclusion

The reviewed literature underscores the complexity of biopesticide interactions with honeybee health, challenging the common assumption that these products are inherently safe for pollinators. While biopesticides—including entomopathogenic bacteria, fungi, nematodes, viruses, and plant extracts—are widely promoted as eco-friendly alternatives to synthetic pesticides, mounting evidence reveals that some of these agents can have unintended sublethal or chronic effects on bees. These effects range from impaired foraging behavior, learning deficits, and immune suppression to increased vulnerability to pathogens and potential colony-level impacts. Such outcomes are particularly concerning given the central role of honeybees in pollination services and ecosystem stability.

Among the biopesticide groups, Bacillus thuringiensis and other entomopathogenic bacteria can interfere with bee gut health and immunity; certain fungal strains, though generally low in direct virulence, may subtly impair behavior and larval development; entomopathogenic nematodes, while less likely to infect bees directly, pose possible risks under moist conditions or in species nesting in exposed habitats; and plant-based biopesticides, despite their natural origin, can contain bioactive compounds that disrupt key physiological and neurological functions in bees. Viral agents, although largely species-specific, remain under-studied in terms of their long-term ecological impacts, particularly in diverse bee communities.

4. Future Directions

Comprehensive Risk Assessments: Future studies must include standardized, long-term risk assessments of biopesticides under realistic field conditions. These assessments should consider species-specific sensitivities, life stages (e.g., larvae vs. adults), and exposure routes (e.g., contaminated pollen, nectar, or water).

Sublethal and Synergistic Effects: Greater emphasis should be placed on investigating sublethal effects and the potential for synergistic interactions between biopesticides and other stressors, such as poor nutrition, climate change, or existing pathogen loads.

Diversity of Bee Species: Most current research focuses on *Apis mellifera*; however, *non-Apis* pollinators such as bumblebees and solitary bees may exhibit different susceptibilities. Expanding studies to include a broader range of species is critical for biodiversity conservation.

Biopesticide Formulation Improvements: There is a need for the development of safer biopesticide formulations that minimize non-target effects on bees, including innovations in application timing, dosage, and delivery methods that reduce pollinator exposure.

Policy and Regulatory Updates: Regulatory frameworks should be updated to reflect new scientific insights into biopesticide toxicity. This includes integrating pollinator health benchmarks into the approval process for biopesticide products.

Integrated Pest and Pollinator Management (IPPM): Holistic strategies that align pest control goals with pollinator protection—such as using ecological intensification, crop diversification, and habitat conservation—should be promoted.

By pursuing these directions, researchers, regulators, and agricultural stakeholders can more effectively balance pest control needs with the imperative to protect pollinators, thereby advancing sustainable and resilient agroecosystems.

Immobilizing Pb in soil polluted with Pb batteries effluents: Confirmation at biological and chemical scales

Muhammad Iqbal[1]

[1]Department of Environmental Sciences, Government College University, Faisalabad, Pakistan,

Abstract

Untreated effluents from Pb battery repair workshops pollute the soil when released. Resultantly, higher concentrations of Pb in the surrounding soils are observed in several areas of Punjab, Pakistan. Fortunately, cement containing phosphate (PC) can efficiently immobilize Pb in soil and reduce ecological and human health issues linked with Pb. In this experiment, we collected Pb battery polluted soil having Pb concentrations of 711 mg kg^{-1} and amended with six doses of PC, i.e. 0, 0.5, 1, 1.5, 2, and 2.5% of soil. The soil was initially incubated for 50 days and later used for plant experiment, earthworm incubation, and chemical scales for a further 50 days. Pb fixation in soil was measured by different scales, i.e., chemical scales [$Ca(NO_3)_2$ and diffusive gradient in thin films (DGT)] and biological scales (lettuce plants and earthworms). After the experiment, concentrations of Pb in lettuce roots and shoots and earthworms decreased with increasing PC dose to 2%, while no significant changes were observed for 2 and 2.5% doses. Biomass of both biological entities also followed identical patterns. Moreover, bioavailable Pb in the soil after the experiment, as assessed by $Ca(NO_3)_2$ and DGT, significantly decreased by raising the PC dose to 2%, and there was no change thereafter. Correlations between Pb concentrations in biological entities and chemical scales were > 0.96, depicting the efficacy of PC for remediating Pb-polluted soils. Phosphate in PC reacted with Pb to form a stable Pb-phosphate compound, leading to Pb fixation in soil. A 2% PC dose was more efficient and economical than 2.5% for ecological restoration.

[2]Ankara University, Animal Science, Ankara, Türkiye

Abstract

This study was carried out to determine the effect of sex and genotype on slaughter and carcass characteristics of 4 different quail genotypes (Cyprus black, Texas white, Italian yellow, Pharaoh (wild type)). The animal material of the study consisted of a total of 40 quails, 5 females and 5 males from 4 genotypes at the age of 5 months. Quails were randomly selected from an actively mating and laying flock. Slaughtering was done individually and carcass weight, edible viscera weights and intestine lengths were measured in all quails. Testicular weight was measured in male quails and oviduct length was measured in females. After slaughter, the hot carcass was cooled for 12 hours and cold carcass weight and cold carcass ratio were calculated. In the study, live weight of female and male sex groups were 295.71 and 244.72 g, respectively ($p<0.001$). When genotypes were evaluated in terms of live weight, Pharaoh, Italian yellow, Cyprus black and Texas white genotypes were determined as 278.88, 249.51, 239.21 and 313.25, respectively ($p<0.001$). In terms of hot carcass, the yields of genotypes were 164.76, 167.41, 158.65 and 215.48, respectively ($p<0.001$). Carcass yield, which is an important yield characteristic, was calculated as 60.17, 67.34, 66.53 and 69.17% in the same order for genotype groups ($p<0.001$). When evaluated in terms of sex groups, it was calculated as 60.82% and 70.79% in female and male sex groups ($p<0.001$). When the groups were evaluated in terms of cold carcass ratio, 62.73% and 73.68% were determined as 62.92%, 69.38%, 69.03% and 71.48% in gender groups, respectively ($p<0.001$). In the study, part weights were also calculated and the yields of the genotype groups in terms of thighs were 39.59, 39.06, 37.90 and 53.07 g, respectively ($p<0.001$). In terms of whole wing weight, the yields of genotype groups were 12.52, 12.80, 12.73 and 16.47 g, respectively ($p<0.001$). When we evaluated the sex and genotype groups in terms of thigh carcass ratio and wing carcass ratio, no difference was found ($p>0.05$). Breast weights of genotypes were 64.40, 69.93, 64.70 and 90.14 g and boneless breast weights were 51.94, 56.31, 52.74 and 73.40, respectively ($p<0.001$).When we looked at the breast carcass ratios of genotypes, the averages were 37.48, 40.33, 39.31 and 40.44%, respectively ($p<0.001$). When we looked at the breast carcass ratios of the sex groups, it was determined as 40.63% and 38.15%, respectively ($p<0.05$). According to gender groups, liver weights were 8.48 and 4.44, respectively ($p<0.001$). The liver carcass ratios of the genotypes were 1.19%, 1.30, 1.18 and 1.00, respectively ($p<0.05$). When an evaluation was made in terms of gizzard weight, the genotype yields were 4.67, 4.00, 3.67 and 5.06, respectively ($p<0.001$). There was no difference between the sex groups in terms of heart weight, while heart carcass ratios were 1.24% and 1.10%, respectively. When evaluated in terms of gut length trait, genotype yields were 79.45, 82.40, 76.30 and 95.75 and sex groups were 91.88 and 75.08 cm, respectively ($p<0.001$). When the genotype groups were evaluated in terms of testis carcass ratio, it was determined as 3.57, 3.67, 3.71 and 3.72% ($p<0.001$).When the results of the research are considered, if a breeding for meat production is to be done, it is more appropriate to use the males of the Texas white genotype due to its advantage in both live weight, carcass yield and piece and edible internal organ weights. When we look at the characteristics of the carcass, it was seen that the breast constituted a large part of the carcass and this ratio was the lowest in the pharaoh quails.

Bıldırcınlarda Genotipin ve Cinsiyetin Kesim ve Karkas Özelliklerine Etkisi

Özet

Bu çalışma 4 farklı bıldırcın genotipinde (Kıbrıs karası, Teksas beyazı, İtalyan sarısı, Firavun(yabani tip)) kesim ve karkas özelliklerine cinsiyet ve genotipin etkisini belirlemek amacıyla yürütülmüştür. Çalışmanın hayvan materyalini 5 aylık yaştaki 4 genotipten 5 dişi 5 erkek olmak üzere toplamda 40 adet bıldırcın oluşturmuştur. Bıldırcınlar aktif olarak çiftleşen ve yumurtlayan bir sürüden rastgele seçilmiştir. Kesimler bireysel olarak yapılmış olup bütün bıldırcınlarda karkas ağırlığı, yenilebilir iç organ ağırlıkları, bağırsak uzunlukarı ölçülmüştür. Erkek bıldırcınlarda testis ağırlığı, dişilerde ise yumurta kanalı uzunluğu ölçümleri yapılmıştır. Kesimin ardından sıcak karkas 12 saat dinlendirilerek soğutulmuş ve soğuk karkas ağırlığı ve soğuk karkas oranı hesaplanmıştır. Çalışmada dişi ve erkek cinsiyet gruplarında canlı ağırlık sırasıyla 295.71 ve 244.72 g olarak belirlenmiştir ($p<0.001$). Canlı ağırlık bakımından genotipler değerlendirildiğinde Firavun, İtalyan Sarısı, Kıbrıs karası ve Teksas beyazı genotipleri sırasıyla 278.88, 249.51, 239.21 ve 313.25 olarak belirlenmiştir ($p<0.001$). Sıcak karkas bakımından genotiplerin verimlerine bakıldığında aynı sırayla 164.76, 167.41, 158.65 ve 215.48 olarak bulunmuştur ($p<0.001$). Önemli bir verim özelliği olan karkas randımanı genotip grupları bakımından aynı sırayla %60.17, 67.34, 66.53 ve 69.17 olarak hesaplanmıştır ($p<0.001$). Cinsiyet grupları bakımından değerlendirildiğinde ise dişi ve erkek cinsiyet gruplarında %60.82 ve 70.79 olarak hesaplanmıştır ($p<0.001$). Gruplar soğuk karkas oranı bakımından değerlendirildiğinde cinsiyet gruplarında sırayla %62.73 ve 73.68 genotip grupları bakımından değerlendirildiğinde ise aynı sırayla %62.92, 69.38, 69.03 ve 71.48 olarak tespit edilmiştir ($p<0.001$). Çalışmada parça ağırlıklarıda hesaplanmış olup kalçalı but bakımından genotip gruplarının verimleri sırayla 39.59, 39.06, 37.90 ve 53.07 g olarak tespit edilmiştir ($p<0.001$). Bütün kanat ağırlığına baktığımızda genotip gruplarının verimleri sırayla 12.52, 12.80, 12.73 ve 16.47 g olarak tespit edilmiştir ($p<0.001$). Cinsiyet ve genotip gruplarını but karkas oranı ve kanat karkas oranı bakımından değerlendirdiğimizde herhangi bir farklılık tespit edilmemiştir ($p>0.05$). Genotiplerin göğüs ağırlıkları 64.40, 69.93, 64.70 ve 90.14 g kemiksiz göğüs ağırlıkları ise sırasıyla 51.94, 56.31, 52.74 ve 73.40 olarak ölçülmüştür ($p<0.001$).Genotiplerin göğüs karkas oranlarına baktığımızda ortalamalar aynı sırayla %37.48, 40.33, 39.31 ve 40.44 olarak tespit edilmiştir ($p<0.001$). Cinsiyet gruplarının göğüs oranlarına baktığımızda sırayla % 40.63 ve 38.15 olarak tespit edilmiştir ($p<0.05$). Cinsiyet gruplarına göre ciğer ağırlıkları sırayla 8.48 ve 4.44' dür ($p<0.001$). Genotiplerin ciğer karkas oranlarına baktığımızda sırayla %1.19, 1.30, 1.18 ve 1.00 olarak tespit edilmiştir ($p<0.05$).Taşlık ağırlığı bakımından bir değerlendirme yapıldığında genotip verimleri sırasıyla 4.67, 4.00, 3.67 ve 5.06' dır ($p<0.001$). Cinsiyet gruplarında kalp ağırlığı bakımından herhangi bir farklılık tespit edilemezken kalp karkas oranları sırasıyla %1.24 ve 1.10 olarak tespit edilmiştir. Bağırsak uzunluğu özelliği bakımından değerlendirildiğinde genotip verimleri sırasıyla 79.45, 82.40, 76.30 ve 95.75 cinsiyet grupları ise 91.88 ve 75.08 cm olarak tespit edilmiştir($p<0.001$). Genotip grupları testis karkas oarnı bakımından değerlendirilmesinde ise %3.57, 3.67, 3.71 ve 3.72 olarak tespit eilmiştir ($p<0.001$).Araştırma sonuçlarına bakıldığında et üretim amaçlı bir yetiştiricilik yapılacaksa hem canlı ağırlık hem karkas randımanı hemde parça ve yenilebilir iç organ ağırlıklarındaki avantajı dolayısıyla teksas beyazı genotipinin erkeklerinin kullanılması daha uygundur. Karka özelliklerine baktığımızda karkasın büyük bir kısmını göğüsün oluşturduğunu, bu oranında en düşük firavun bıldırcınlarında olduğu görülmüştür.

Abstract
Rice (*Oryza sativa* L.) is the staple food of Bangladesh, with its production tripling since independence. However, declining cultivable land and climate change, particularly erratic rainfall, have led to prolonged water scarcity during the Boro season. To ensure future rice security, genetic improvements for short-duration, high-yielding varieties are essential. In response, the Bangladesh Rice Research Institute (BRRI) developed genotypes with a life cycle of ≤145 days, requiring less water while maintaining productivity. This study evaluated four advanced fixed lines (V1 = BR11318-5R-63, V2 = BR11337-5R-72, V3 = SVIN109, V4 = IR17A1723) alongside two reference varieties (V5 = BRRI dhan81, V6 = BRRI dhan96) across 11 locations in Bangladesh during the 2022–23 Boro season. Combined ANOVA revealed significant genotype, environment, and genotype-environment interaction (GEI) effects ($p \leq 0.001$) on yield and related traits. Broad-sense heritability (h^2b) ranged from 0.05 to 0.50, with most traits showing high selection accuracy (>0.80). Stability analysis using weighted average of absolute scores biplots (WAASB) identified V1 and V3 as the most stable, while GGE biplots highlighted V2's superior grain yield (GY) in multiple locations. Multi-trait stability index (MTSI) ranked V2 as the most stable based on GY and seven yield-contributing traits. Factor analysis further confirmed its agronomic superiority, with GD and TGW showing the highest broad-sense heritability (0.92), followed by PHT (0.885) and GY (0.833), with selection gains ranging from 1.48% to 9.54%. Overall, BR11337-5R-72 (V2) emerged as the most promising short-duration, high-yielding, and stable genotype for Boro rice cultivation, requiring further evaluation and promotion for large-scale adoption.
Key words: *BRRI; Rice; Yield; stability; GEI.*

1. Introduction

Rice (*Oryza sativa* L.) holds a predominant position as the primary grain crop in Bangladesh's agricultural sector. Given the dietary patterns, ensuring "rice security" plays a pivotal role in achieving food security, a situation mirrored in numerous other nations (Brolley, 2015). Rice production has increased by three times since the liberation of Bangladesh and reaching about 39.1 MT in 2023 (Kabir et al., 2020) and hold third-largest producer of rice globally (Sun et al., 2023). However, future projections indicate a rising demand for rice due to population growth. (Kabir et al., 2015) estimated that approximately 44.6 million metric tons of rice will be needed by 2050. On the other hand, the cultivable land area will be 11.07 M ha in 2050 compared to 12.10 M ha in 2020 (Kabir et al., 2020). Additionally, the country is grappling with the impacts of climate change, including erratic rainfall

patterns and prolonged droughts. Therefore, enhancing the genetic potential of rice crops to increase yield remains crucial for meeting the future rice demand in Bangladesh.

Bangladesh experiences distinct wet and dry seasons, with the dry season, known as the boro season, posing a challenge for rice cultivation due to water scarcity. Therefore, the resilience of short-duration boro rice (BR-SD) varieties becomes particularly valuable. According to research by Rabbi et al. (Rabbi et al., 2020), rice varieties in Bangladesh are classified based on their ecological adaptation and product requirements to better understand the changing potential yield over time. Favorable boro rice (FBR) varieties are categorized as short duration (SD), cultivated during the boro season in favorable environments with minimal abiotic stresses apart from natural disasters. The SD varieties typically have a lifespan of up to 145 days. Conversely, long-duration boro rice types include cultivars grown in similarly favorable environments but with a lifespan exceeding 145 days. FBR-SD varieties have proven to be well-suited for the conditions, requiring less water and completing their life cycle within the limited duration of the dry season. It's important to note that the Bangladesh Rice Research Institute (BRRI) is the leading institution for rice research in the country, having released 108 inbred and 08 hybrid rice varieties. Additionally, the Adaptive Research Division (ARD) of BRRI is tasked with conducting validation and adaptation trials across various agro-ecological zones (AEZs) to identify stable cultivars for release in Bangladesh. While scientists are actively working on genetically enhancing crops by selectively incorporating elite alleles and traits into desired genetic backgrounds, conducting multi-environment trials (METs) is a crucial step in breeding programs before releasing varieties to farmers. Selecting superior genotypes based on yield across diverse AEZs can be highly effective, given that yield is a complex quantitative trait heavily influenced by environmental variations. However, choosing the best genotype from a genetic pool based on their observable traits presents a significant challenge (Alam, 2019; Alam, Akter, Khan, Alam, et al., 2023; Alam, Akter, Khan, Amin, et al., 2024). In the pursuit of stable genotypes, the additive main effects and multiplicative interaction (AMMI) model plays a pivotal role. Moreover, a novel index called weighted average absolute scores (WAAS), derived from the AMMI model, is integrated into METs analysis indices (Alam, Akter, Khan, Alam, et al., 2024). Alongside AMMI, the genotype-genotype environment (GGE) biplot graphical model is commonly utilized to identify environments and winning genotypes within those environments (Akter et al., 2015). The GGE biplot method is also employed to pinpoint stable genotypes and evaluate their interaction with yield and environments. On the flip side, linear mixed models (LMMs) are commonly utilized to improve selection efficiency in various studies (Ahsan et al., 2024; Alam, Akter, Khan, Alam, et al., 2024; Alam, Akter, Khan, Amin, et al., 2024; Alam, Akter, Khan, Rashid, et al., 2023; Khan et al., 2024; Olivoto & Nardino, 2021; Pimentel et al., 2014; Schmidt et al., 2019). Yet, comprehending the genetic mechanisms dictating trait inheritance and the impact of genetic elements on their manifestation is crucial for the triumph of a breeding program (Fotirić-Akšić et al., 2011). An efficient method for analyzing and estimating genetic parameters using agronomic traits is through the restricted maximum likelihood (REML) model (Marchi et al., 2019). This method has been employed across diverse crop breeding endeavors, such as sweet potato (Alam, Akter, Khan, Alam, et al., 2024), white Guinea yam (Norman et al., 2022), soybean (Follmann et al., 2019), and others. An exposition by Olivoto et al. (Olivoto et al., 2019) delves into the theoretical foundations of the Multi-Trait Stability Index (MTSI), facilitating the selection of superior genotypes in METs based on high yield and stability, while considering multiple traits.

Introducing advanced breeding methods and employing METs in conjunction with modern stability analysis models like AMMI, GGE biplot, and MTSI in Bangladesh's rice farming can facilitate the discovery and choice of resilient genotypes with strong yield capabilities. This approach will aid in addressing the growing need for rice production amid environmental constraints and shrinking arable land. The present study was undertaken to examine the four advanced lines with two released varieties from BRRI at diverse environment to check the stability and yield advantages of advanced lines compared to released varieties.

2. Materials and methods

2.1. Description of the study area

The study was conducted over the 2022-23 growing season across 11 districts in Bangladesh: Rangpur, Gopalganj, Faridpur, Barishal, Natore, Sirajganj, Feni, Kushtia, Habiganj, Manikganj, and Gazipur, as illustrated in Figure 1. The experimental fields were chosen in collaboration with the Department of Agriculture Extension (DAE), taking into account variations in soil texture (BRRI, 2024) and elevation, which are detailed in Table 1. Additionally, monthly data on maximum and minimum temperatures, and relative humidity were collected from November to May 2022-23 at the research sites, covering the Boro growing season (BMD, 2023) (Figure 2).

2.2 Plant materials

This research included four advanced lines of FBR-SD: BR11318-5R-63, BR11337-5R-72, SVIN109, and IR17A1723. Two varieties released by BRRI were also included as checks to compare their yield and related characteristics. One check was BRRI dhan81, with the pedigree BR7358-5-3-2-1-HR2. The other check, BRRI dhan96, has the pedigree BR(Bio) 9787-BC2-63-2-2. All six genotypes exhibited uniform flowering, grain maturity, and good wrapping quality with culms. The flag leaves of the studied rice genotypes were erect. Detailed information about these six rice genotypes is presented in Table 2, while a visual representation of the raw rice grain is depicted in Figure 3.

Table 1. Description of the eleven selected locations during the Boro 2022-23 season

Location	Agro-ecological representation	Latitude	Longitude	Elevation	Soil texture
Rangpur	AEZ3	25°44'17"N	89°17'01"E	34	Loam- clay loam
Gopalganj	AEZ14	23°01'78"N	89°81'05"E	3.1	Clay loam-sandy loam
Faridpur	AEZ12	23°25'10"N	89°53'56"E	11	Clay loam-sandy loam
Barishal	AEZ13	22°42'35"N	90°20'00"E	2	Silty clay- clay
Natore	AEZ11	22°36'22"N	89°22'19"E	17	Clay loam
Sirajganj	AEZ4	24°39'34"N	89°65'72"E	13	Clay to loamy
Sonagazi	AEZ23	22°81'28"N	91°38'89"E	5	Clay
Kushtia	AEZ10	23°88'36"N	89°13'28"E	27	Clay-loam
Habiganj	AEZ19	24°31'05"N	91°21'46"E	6	Clay to loamy
Manikganj	AEZ8	23°86'56"N	90°00'98"E	15.92	Loamy/Clay
Gazipur	AEZ28	23°59'26"N	90°24'09"E	34	Silty clay loam

Table 2. The detailed information of FBR-SD genotypes

Genotype code	Genotypes	Year of release	Grain type
V1	BR11318-5R-63	NR	Medium slender
V2	BR11337-5R-72	NR	Medium slender
V3	SVIN109	NR	Medium slender

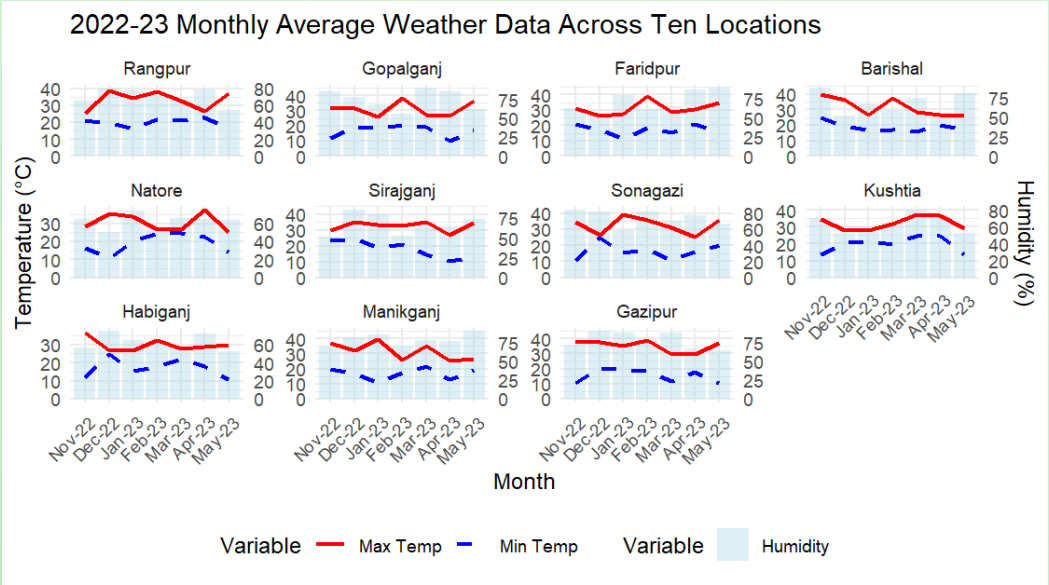

Figure 2. Monthly mean Maximum Temperature (°C), Minimum Temperature (°C) & Relative Humidity (%) of selected eleven (11) experiment locations in Bangladesh during 2022-23 Boro season.

Figure 3. A pictorial view of raw grain for the six FBR-SD genotypes. [CK] check

2.3 Experimental design

In every location, the entire experimental field was partitioned into three blocks, each comprising six plots, making a total of eighteen plots. These trials were replicated three times in each location, adhering to a randomized complete block design (RCBD). Each plot had a size of 20 m^2 (measuring 4.0 m by 5.0 m). Seedlings aged between 35 to 40 days were transplanted with a spacing of 20 cm by 20 cm.

2.4 Crop husbandry

The research site was plowed until achieving a finely textured seedbed for seedbed preparation. Seeding occurred between the last week of November and the last week of December 2022 across eleven locations. Fertilizers were applied at a ratio of 260:100:120:110:10 kg/ha of Urea:DAP:MoP:Gypsum:ZnSO4, respectively (Ahmmed et al., 2018). All fertilizers except urea were applied as basal, while urea was split into three equal portions applied at 10 days, 30 days after transplanting, and 5 days before the panicle initiation stage. Weeding and irrigation followed BRRI's recommended management practices as needed, and appropriate measures were implemented for pest control (BRRI, 2022).

2.5 Data collection

Data was be recorded of grain yield (GY) (t/ha), growth duration (GD), plant height (PHT) (cm), thousand grain weight (TGW) (g), panicle per m^2 (PPM), filled grains per panicle (GPP), unfilled grains per panicle (UFG), and sterility percentage (STR%). Harvesting commenced when 80% of the grains were fully ripened of panicle. A designated area of 3 m by 3 m, totaling 9 m^2, was demarcated excluding the border lines of the experimental plot. Any missing hills within the sample area were carefully counted, and an equivalent number of hills from other areas outside the plot's border lines were added to the harvested sample hills to ensure accurate yield estimation for the 9 m^2 area. Subsequently, the GY was converted into t/ha. Threshing was carried out using either a pedal thresher or manually by removing leaves, straws, and other debris from the grains. The weight was accurately recorded while simultaneously measuring the moisture content of the grains, adjusting the grain yield to 14% moisture content. To determine PHT, data were collected from ten plants in each plot, measuring from the soil level to the tip of the panicle in centimeters, and then averaged. For measuring TGW, 1000 grains were manually counted from the harvested site of the experimental plot and weighed using a scale of grams. For PPM estimation, a 1 m by 1 m area was marked, and the number of panicles within the marking was counted. Ten panicles were randomly selected outside the marking for both GY and PPM, and the total number of filled grains and unfilled grains was counted. Subsequently, the total number of filled and unfilled grains was averaged to calculate the GPP and UFG. STR% was calculate by following formula,

STR% = Total unfilled grain/ (Total filled grain+ Total unfilled grain) ×100

2.6 Statistical analysis

The study employed a combined two-way analysis of variance (ANNOVA) and mean separation for genotypes, environments, and GEI using Statistics 10. The least significant difference (LSD) test was utilized to distinguish mean values at a significance level of $p < 0.05$. The genetic parameters of studied traits were analyzed using "metan" package of R software. The coefficient of correlation (Pearson's Correlation) of studied traits of rice genotypes was performed using 'metan' package of R statistical software. A heatmap for genotypes and studied traits was prepared by using "pheatmap" package of R. The AMMI analysis of variance, WAAS biplot and GGE biplot were analyzed using 'metan' package of R. The MTSI analysis was performed utilizing the "metan" package within the R statistical software environment (R studio, 2020), employing a positive selection criterion for all traits with a selection pressure set at 15%.

3. Results

3.1 Analysis of variance

Table 3 displays the combined analysis of variance (ANOVA) outcomes for eight yield and yield-related traits in six FBR-SD genotypes across eleven locations of Bangladesh during the 2022-23 boro growing season. The results indicated that all sources of variation, including replication (R), genotypes (G), locations/ environments (E), and genotype-environment interactions (GEI), had a significant impact on the traits studied ($p \leq 0.001$).

3.2 Genetic parameters of studied traits

The effect of G, E and GEI on the studied traits was found significant at $p<0.05$ based on the likelihood ratio test (LRT) of restricted maximum likelihood (REML) model (Table 4). In the linear mixed model (LMM), Table 4 presents the genetic parameters of various traits in six FBR-SD rice genotypes. The genetic variance (σ^2_g) percentages were highest for GD (50.24%) and TGW (44.27%), while environmental variance (σ^2_e) percentages were highest for GY (39.80%) and GPP (59.60%). PHT, PPM, UFG, and STR% showed the highest variance percentages for genotype-environment interaction (σ^2_{GEI}) at 53.06%, 51.37%, 49.46%, and 65.82%, respectively. The broad-sense heritability (h^2_b) ranged from 0.05 to 0.50 across the studied genotypes for the eight traits. The genetic advance in a percent of mean (GAPM) ranged from 0.47 to 0.92. Selection accuracy (SA) was high (>0.80) for all traits except UFG (0.68). The ratio of genotypic (CV_g) to residual coefficient of variation (CVr) ranged from 0.34 to 4.13.

3.3 Mean performance of FBR-SD genotypes

Table 5 presents the mean values of eight yield and yield-contributing traits for six rice genotypes. The GY was recorded for V1 at 7.29 t/ha, followed by V2 at 7.20 t/ha and V3 at 7.25 t/ha. Regarding other yield-contributing traits, V2 exhibited significantly higher values for PPM (303.73) and GPP (144.76) compared to the other genotypes, while TGW was highest in V3 (23.48 g). V4 had the shortest mean GD (138.50 days), followed by V1 (139.88 days). Additionally, V1 displayed the tallest PHT (109.81 cm), while V2 had the lowest PHT (93.33 cm). V5 exhibited the highest STR% (23.17%), while the lowest was in V6 (15.47%). The UFG was found highest in V5 at 34.74 and the lowest was in V6 (24.48).

Table 6 depicts the GEI effects on GY. Variability in GY is evident across E and G, with significant differences observed in mean yield values. The highest GY was recorded in the Natore region for the V2 genotype, reaching 9.48 t/ha, followed by V1 at 9.31 t/ha and V3 at 8.64 t/ha. Conversely, the lowest yield was observed in V5, measuring 3.77 t/ha in the Sonagazi region. The highest GY was recorded in Natore at 8.29 t/ha, followed by Sirajganj at 8.21 t/ha and Faridpur at 7.89 t/ha.

3.4 Correlation analysis of among traits

Figure 4 presents the Pearson's correlation coefficients between the studied traits of rice genotypes. The traits STR and UFG exhibited a significant positive correlation (r=0.95 at p<0.001). GY showed a significant positive correlation with growth duration (GD) (r=0.89 at p<0.05). Additionally, GY and GPP were significantly positively correlated (r=0.84 at p<0.05). There was no significant negative correlation was found between studied traits.

3.5 Heatmap of genotypes' contribution to the studied traits

Figure 5 illustrates the trait contributions of different rice genotypes using a heatmap. Genotypes V1, V2, V3, and V6 positively contribute to GY. Among them, genotype V2 stands out as the highest contributor to PPM, GPP, and GD, while negatively affecting TGW. Genotypes V5 and V4 are the primary contributors to UFG and STR. Genotype V1 has the highest contribution to PHT and GY, while V3 contributes significantly to TGW. Although genotypes V4, V5, and V6 negatively influence GD, genotype V6 still positively contributes to GY.

3.6 AMMI analysis of variance

Table 7 presents the AMMI ANOVA, highlighting the contributions of different sources of variation to the total sum of squares (TSS) observed in the dataset for GY. The analysis of variance revealed that GY was significantly affected by E, G and GEI, with a p-value less than 0.001. The majority of the total sum of squares (TSS) in the model was attributed to E (174.576), followed by GEI (61.708) and G (36.903). The interaction of the first two principal components (PCs) accounted for approximately 77.5% of the variance. Among the PCs of the AMMI ANOVA, the first three PCs were significant at ≤0.01 probability, contributing to a total of 90.7% of the variance.

3.7 Stability analysis through WAAS biplot

Figure 6 presents a WAAS biplot showing the performance of six rice genotypes across eleven locations. The vertical axis represents the average GY across all environments, with genotypes to the right indicating higher GY and those to the left indicating lower GY. The horizontal axis represents the mean WAAS, dividing the biplot into four quadrants. Genotypes in different quadrants are classified based on their stability and yield performance. Quadrant I typically contain genotypes with low stability and yield, including V6, V8, and V5. Genotype V2 in quadrant II shows high WAAS values, indicating high GEI influence and high yield. Quadrants III and IV have low WAAS values, indicating high stability. Genotypes V1 and V3 in quadrant IV exhibit high GY and stability across environments. There were no genotypes fall into the quadrant III.

3.8 GGE polygonal biplot analysis for MET

Within the GGE biplot, a polygon is formed by connecting the vertex genotypes (V1, V2, V6, V4, and V5) (Figure 7). This polygon is then divided into five distinct sectors by rays (dotted lines) originating from the plot's origin and extending perpendicular to the polygon's sides. In regions where environments are located and genotypes are positioned above them, it indicates that these specific genotypes perform optimally in those particular environments.

Figure 6. WAAS biplot of AMMI stability model with stability and mean performance of grain yield (GY) (t/ha).

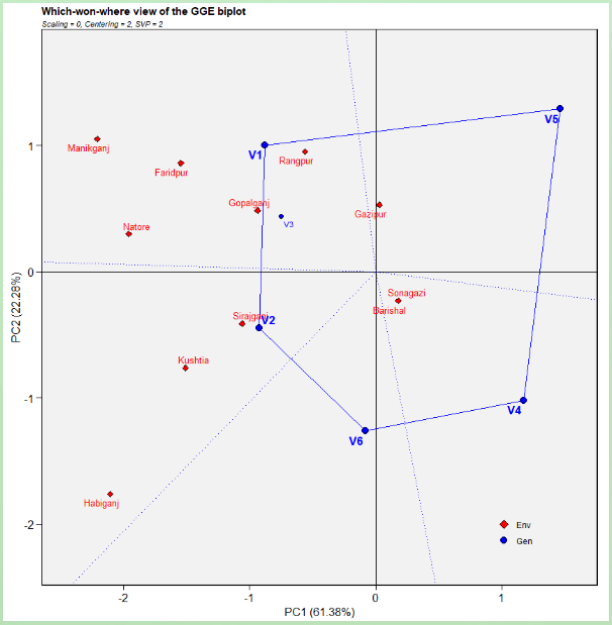

Figure 7. Polygonal view of GGE biplot for winner genotype in respective environment/ location for grain yield (GY) (t/ha).

Genotypes located in areas without any environments are considered unsuitable for cultivation in the examined environments and are classified as weak genotypes in most environments. Genotype V2 demonstrated superior GY performance in Sirajganj, Kushtia, and Habiganj, while Genotypes V1 and V3 showed desirable GY in Manikganj, Faridpur, Natore, Gopalganj, and Rangpur. Additionally, V4 performed well in the Sonagazi and Barishal environments, while V5 excelled in the Gazipur region. However, Genotype V6 was positioned without any associated environment.

3.9 Multitrait stability index (MTSI)

Table 8 displays the results of the factor analysis, which reveal the broad sense heritability (h^2), selection gain percentage (SG) (%), desired selection sense, and the achievement status of the goal based on factor analysis of selected rice genotypes using eight traits. The factor analysis revealed that contributing factors formed into three distinct groups consisting of eight traits under study. The desired selection sense was to increase for all traits. The goal was successfully achieved for all traits, with the exception of TGW. Among the studied traits, the h^2 was highest for GD and TGW (0.92), followed by PHT (0.885) and GY (0.833). Furthermore, the SG (%) for studied traits was ranged from 1.48 to 9.54 %. The selected genotype, however, possesses a negative SG (%) in TGW (-3.04%).

Figure 8 presents the representation of the order of the most stable genotype determined by the multi-trait stability indexing (MTSI). Within this context, the red circle symbolizes the threshold for selecting the stable genotype. The rice genotype named V2 stands out as the most stable compared to other genotypes.

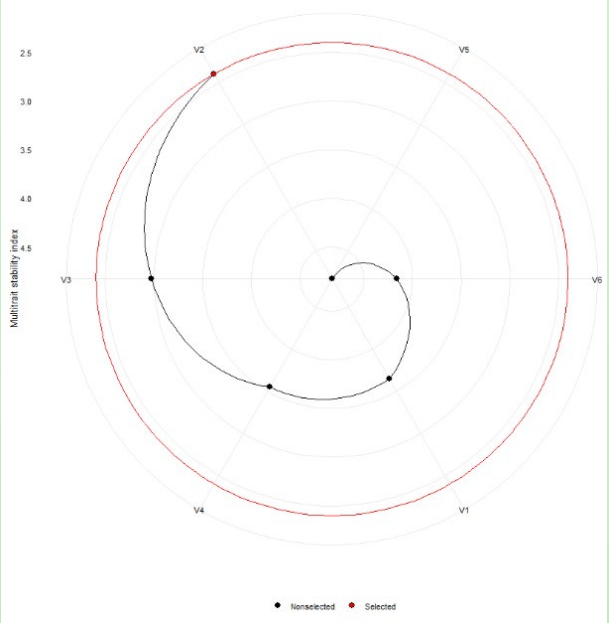

Figure 8. Ranking of genotype stability based on MTSI index

4. Discussion

The study observed significant variations in yield and its attributing traits among different genotypes (G), environmental/locational conditions (E), and genotype-environment interactions (GEI) (Table 3). The percentages of genotypic (σ2g), environmental (σ2e), and GEI variance (σ2GEI) in Table 4 confirm the differences observed in the studied traits. The success of crop breeding programs largely depends on genetic diversity and the transmission of desirable characteristics. Analyzing the genetic diversity of a species with the involvement of plant breeders can lead to the enhancement of commercially desirable traits (Sarker, 2020). To assess genetic diversity, researchers often utilize σ2g, σ2e, and σ2GEI, as well as coefficients of variation (CV) (Baraki et al., 2020; Khan et al., 2024). A CV ratio of genotypic CV (CV g) and residual CV (CV $_r$) higher than 1 indicates high genetic diversity, while a lower ratio suggests low genetic diversity (Sharma et al., 2021). In this study, the CV ratios for growth duration (GD), plant height (PHT), and thousand grain weight (TGW) were all above 1, indicating high genetic diversity. Moreover, these traits exhibited high broad-sense heritability (h^2_b) and selection accuracy (SA) (Table 4). Traits with high genetic diversity, h^2_b, and SA suggest potential for improvement through trait-based selection (Alam, Akter, Khan, Alam, et al., 2024; Alam, Akter, Khan, Amin, et al., 2024; Alam, Akter, Khan, Rashid, et al., 2023; Hasan et al., 2020). High h^2_b combined with a high percentage of genetic advance relative to the mean (GAPM) is important for trait selection in breeding programs. In this study, GD, PHT, and TGW showed both high h^2_b and high GAPM, indicating additive gene action, thus making them suitable targets for rice improvement. Previous studies have also reported similar findings regarding high h^2_b and GAPM for various yield-related traits (Sarker, 2020). Except for grain yield (GY), the traits showed high GAPM, suggesting the influence of both additive and non-additive gene actions in trait expression. This aligns with findings from other research on rice (Faysal et al., 2022).

Yield and its contributing traits of rice are influenced by various factors (Kiniry et al., 2001; Kumar et al., 2017). According to Sarker et al. (Sarker, 2020), genotype plays a significant role in determining rice yield and its contributing characteristics, although numerous factors such as meteorological conditions, soil texture, nutrient composition, and genetic traits also influence these traits (Dou et al., 2016; Xuan et al., 2019). Boro rice cultivation, typically practiced in irrigated ecosystems due to low rainfall during the boro growing season (Mainuddin et al., 2021), tends to perform better in coarse-textured soils compared to fine-textured soils, despite careful farmer management practices (Bhuyan et al., 2023; Frimpong et al., 2023). In our study, locations like Natore, Sirajganj, and Faridpur exhibited the highest average grain yield for FBR-SD rice genotypes, indicating the presence of favorable environmental conditions in those areas. Rice varieties exhibit substantial variation in the duration from sowing to harvest (Vergara et al., 1966). In our study, the average GD significantly differed among rice genotypes, with the V4 genotype displaying the shortest GD. Opting for a short-duration crop offers numerous advantages over a long-duration one, even if their total grain yields are equivalent. A shorter-duration crop requires less water per cycle, faces reduced exposure to risks such as pests, diseases, droughts, and storms, and extends the window

for subsequent plantings of rice or other crops (Vergara et al., 1966). PHT also varied among rice genotypes, consistent with findings by Zhang et al. (Zhang et al., 2017), who highlighted the role of the OsMPH1 gene in regulating plant height. They observed that high OsMPH1 expression in rice nodes and pulvini, and its nuclear localization, led to increased plant height through cell elongation in internodes. TGW exhibited significant variability across rice genotypes, as reported by Zuo et al. (Zuo et al., 2022), who identified OsMADS56 as the gene responsible for a QTL affecting grain weight and size. Wang et al. (Wang et al., 2024) proposed increasing panicle numbers as a viable strategy to enhance rice yield potential, noting that the Lemont genotype showed a substantial increase in panicle count, albeit with a decrease in grain numbers. Discrepancies in filled grain per panicle (GPP) and panicles per m^2 (PPM) underscore the genetic basis of these traits, aligning with our study's findings. Unfilled grain (UFG) and grain sterility (STR%) varied significantly with genotype and environmental conditions. Elevated temperature coupled with high humidity at heading induces nearly complete grain sterility in rice, with a 30% reduction in relative humidity at high temperatures resulting in decreased grain sterility (De Abeysiriwardena et al., 2002; Osada et al., 1973). Puteh et al. (Puteh et al., 2014) observed significant genotype-dependent variation in UFG and STR%.

The correlation among traits facilitates the identification of specific traits that, through indirect selection, can enhance overall yield performance. Heatmap analysis provides a practical evaluation of the direct and indirect influences of each trait associated with the genotypes. The primary economic trait, GY, demonstrated a significant positive correlation with GPP in our study, consistent with previous findings (Kayastha et al., 2022; Wang et al., 2024). In the present study, there was no significant correlation between GPP and Additionally, GD showed a significant positive correlation with GY. Genotypes V1, V2, V3, and V6 were identified as the top contributors to GY (Figure 5), suggesting that enhancing GPP in these genotypes may lead to improved GY performance. According to Huang et al. (Huang et al., 2018), rice yield tends to increase with prolonged GD, although some rice cultivars with shorter GD also exhibit high GY (Chen et al., 2019), indicating the potential for high GY in short-duration cultivars as well. In our study, V6 negatively contributed to GD but positively contributed to GY. Okamura et al. (Okamura et al., 2018) found a positive and significant correlation between STR% and UFG, consistent with our study findings.

AMMI analysis revealed that the error mean sum of squares for GY was lower compared to G, E, and GEI, indicating the model's accuracy. Studies by Abdelrahman et al. (Abdelrahman et al., 2022) and Sharifi et al. (Sharifi et al., 2017) supported this observation. Additionally, Fathi Sadabadi et al. (Sadabadi et al., 2018) and Hassani et al. (Hassani et al., 2023) found that the first and second principal components (PCs) of GEI collectively explained 71.60% of the variability, aligning closely with our study's findings (77.5%). Understanding GEI assists in decision-making regarding adaptation to different environmental conditions, as noted by Ghazy et al. (Ghazy et al., 2024) and Lee et al. (Lee et al., 2023). The WAAS biplot differs from the AMMI model in that it incorporates all scores of the PCs rather than focusing solely on the first two. Genotypes with low WAAS values falling into quadrant IV in the biplot are identified as high yielding and stable, according to Ghazy et al. (Ghazy et al., 2024). In our WAAS biplot analysis, considering both GY and WAAS values, genotypes V1 and V3 emerge as superior performers with stable performance. In a similar rice genotype study, Ghazy et al. (Ghazy et al., 2024) categorized the WAAS biplot into four categories: high-yielding stable, high-yielding not stable, low-yielding stable, and low-yielding unstable genotypes. This classification aids rice breeders in predicting the genotypic performance of each genotype under study before integrating them into different programs, which aligns with our study findings.

Utilizing a GGE polygonal biplot, as recommended by Gauch and Zobel (Gauch & Zobel, 1997), assists in suggesting suitable genotypes for specific environments. In our study, the biplot identified five mega-environments among 11 tested locations for GY. Among these, five locations (Manikganj, Natore, Faridpur, Gopalganj, and Rangpur) were deemed favored environments for genotype V1, characterized by conducive environmental conditions and soil properties for optimal rice growth. Akter et al. (Akter et al., 2015) also observed similar outcomes and identified appropriate genotypes for specific environments using GGE biplot analysis. Moreover, among the 11 environments assessed, genotype V2 exhibited superior performance in three environments (Sirajganj, Kushtia, and Habiganj), while V5 showed favorable performance only at Gazipur, and V4 displayed good performance in Sonagazi and Barishal. These results underscore the significant influence of GEI on the performance of tested genotypes. GEI negatively impacted the performance of evaluated genotypes by compromising their yield under unfavorable conditions. This observation is corroborated by the findings of other studies, such as those by Liang et al. (Liang et al., 2015) and Singh et al. (Singh et al., 2023). Conversely, V6 demonstrated poor performance in all tested environments, indicating its unsuitability across the eleven locations studied. This finding aligns with the conclusions drawn by Ghazy et al. (Ghazy et al., 2024).

The selection process considers variations among characteristics in relation to their level of hereditary influence. The relationship between broad sense heritability (h^2) and genetic gain (SG) is a crucial factor in breeding programs, as there is a direct association between the h^2 of traits and the increase in SG (Alam, Akter, Khan, Amin, et al., 2024). Chattopadhyay et al. (Chattopadhyay et al., 2011) indicated that traits with h^2 exceeding 60% are considered highly heritable, those with 30 to 60% are moderately heritable, and those with 0 to 30% are lowly heritable. Our findings reflect this pattern, with h^2 demonstrating high values for all traits except UFG.

Additionally, the SG for the studied traits was also notably high. This suggests that direct selection of genotype V2 could effectively enhance the studied traits in rice cultivation. However, for TGW, although the aim of selection was positive, the selection goal was not met, resulting in a negative SG, which is considered desirable for rice varietal selection in the context of Bangladesh (Choudhury, 1979; Mottaleb & Mishra, 2016). The slender grain type exhibits low TGW due to the reduced individual weight of rice grains. The MTSI index was computed based on eight attributes related to yield and its contributing characteristics to rank stable genotypes with higher mean trait values. Several researchers have employed the MTSI index for selecting stable genotypes of rice and other crops (Alam, Akter, Khan, Rashid, et al., 2023; Lee et al., 2023; Olivoto et al., 2019; Sharifi et al., 2017). These findings align with the results obtained from our investigation, where genotype V2 emerged as the top-ranked stable genotype.

5. Conclusions

The extensive evaluation of advanced rice lines and reference varieties across various locations during the 2022-23 boro season unveiled significant impacts of genotype, environment, and their interactions on yield and associated traits. V1 exhibited the highest grain yield, closely trailed by V2 and V3, with V3 showing remarkable performance. Natore stood out as the location with the highest yield, and grain yield showed a positive correlation with growth duration and filled grain per panicle. Heatmap analysis revealed favorable contributions to yield from V1, V2, V3, and V6. The WAAS and GGE biplot emphasized the stability and adaptability of different genotypes across locations, with V2 emerging as the top stable genotype using MTSI. Factor analysis showcased promising results for most traits, with significant broad-sense heritability observed for growth duration, plant height, and grain yield. Overall, this study offers valuable insights into genotype performance and stability across diverse environments, aiding in the selection and breeding of high-yielding boro rice varieties. It's important to acknowledge the study's limitation of being conducted for a single growing season, potentially overlooking annual variability in environmental conditions such as climate, soil, and pest pressures. Hence, a comprehensive, multi-seasonal investigation incorporating identified genotypes is recommended to enhance the reliability and precision of results. Considering the alignment of traits with stability analysis, ARD, BRRI proposes advancing the V2 genotype for proposed variety trials with MEs before finalizing its release.

Declarations

Ethical Approval Certificate

The experimental procedures of this study were approved by the authority of Bangladesh Rice Research Institute, 1701, Gazipur, Bangladesh.

Evaluation of the Relationship Between Condensed Tannin Content and Rumen Protein Degradability in Sainfoin (*Onobrychis viciifolia*)

Hülya Hanoğlu Oral[1]
[1] Department of Animal Sciences and Technologies, Faculty of Applied Sciences, Muş Alparslan University, Muş, Türkiye

Abstract

Condensed tannins, naturally occurring polyphenolic compounds present in certain legumes such as sainfoin (*Onobrychis viciifolia*), can bind dietary proteins at ruminal pH levels. These tannin-protein complexes resist microbial degradation in the rumen but dissociate in the acidic environment of the abomasum, thereby enhancing amino acid absorption in the small intestine. This study aimed to evaluate the relationship between condensed tannin content and ruminal protein degradability in sainfoin, with a focus on the potential role of condensed tannins in protecting dietary proteins from microbial breakdown. Twenty-five sainfoin samples, harvested as green forage from various regions of Türkiye at 50–100% flowering stage, were used in this study. Crude protein content was determined according to the AOAC (2003) method 954.01, while condensed tannin content was measured using the hydrochloric acid (HCl)-butanol assay. Effective protein degradability of the samples was assessed using the *in situ* nylon bag technique, following the method of Ørskov and McDonald (1979). The effective protein degradability values, calculated at a ruminal outflow rate of k = 0.06 h^{-1}, ranged from 53.7% to 62.5%, indicating variability in protein degradation characteristics among the samples. Correspondingly, condensed tannin content ranged from 34.2 to 50.9 g kg^{-1} dry matter. Regression analysis revealed a strong negative linear relationship between condensed tannin concentration and effective protein degradability, with a coefficient of determination (R^2) of 0.80. These findings suggest that condensed tannins play a significant role in reducing ruminal protein degradation by forming stable tannin-protein complexes, thereby enhancing the potential for feed proteins to bypass the rumen and be absorbed in the small intestine as undegraded protein.

Key Words: *Sainfoin, Condensed tannins, Protein, Rumen degradability*

Introduction

Tannins are phenolic compounds known for their strong ability to bind proteins and other macromolecules, forming stable complexes (Mangan, 1988). By protecting dietary proteins from microbial breakdown, these complexes reduce both the rate and extent of protein degradation in the rumen (McSweeney et al., 1988; Min et al., 2001). Tannins bind forage proteins at the neutral pH of the rumen, forming complexes that resist microbial enzymatic activity. These complexes then dissociate in the acidic environment of the abomasum, releasing proteins for digestion and thus enhancing nitrogen utilization efficiency (Jones & Mangan, 1977; Waghorn & Shelton, 1995; Hudson, 2001).

Tannins are typically classified into two main groups: hydrolysable tannins (HT) and condensed tannins (CT). Condensed tannins, also known as proanthocyanidins, are polymers of flavan-3-ols that yield colored anthocyanidins when treated with acidified alcohol (Mueller-Harvey & McAllen, 1992). While HT can be toxic to ruminants, CT are generally considered non-toxic or less harmful due to their poor absorption in the gastrointestinal tract.

Forage legumes containing CT have been shown to stabilize dietary proteins in the rumen by reducing proteolysis, thereby allowing more intact protein to bypass the rumen and reach the abomasum (Kingston-Smith et al., 2004). This bypass protein, also known as rumen undegraded protein (RUP), is then digested and absorbed in the small intestine. Differences in protein degradation rates among legume species have been used to assess the impact of tannins on ruminal proteolysis (Broderick & Albrecht 1994). In CT-containing forage plants, protein–tannin complexes are formed during mastication, limiting microbial access to plant proteins. These complexes resist microbial degradation in the rumen and pass intact to the abomasum, where they dissociate at low pH, making the proteins available for digestion and absorption in the small intestine (Woodward, 2000).

Sainfoin (*Onobrychis viciifolia*) is among the most prominent CT-rich forage legumes. Due to its CT content, sainfoin typically shows lower ruminal protein degradability than other forages, such as alfalfa (Van Soest, 1994). In sainfoin, CT are distributed across most plant tissues except for the cotyledons and roots, with the highest concentrations found in the leaves (Less et al., 1993; 1995). Concentrations of CT ranging from 5% to 8% of dry matter have been reported to reduce protein solubility and limit degradation in the rumen (Waghorn et al., 1998).

Tannin-rich legumes reduce ruminal protein degradation and improve nitrogen utilization efficiency (Reid et al., 1974; Egan & Ulyatt, 1980). For example, CT in sainfoin and birdsfoot trefoil have been associated with improved protein metabolism and digestibility in ruminants (Reed, 1995). Thomson et al. (1971) reported greater protein utilization from dried sainfoin compared to alfalfa, attributing this to its tannin content. As such, sainfoin is

recognized as a valuable source of bypass protein. Its low ruminal protein degradability enables more protein to reach the small intestine intact for digestion and absorption (Wilkins & Jones, 2000).

Multiple studies have demonstrated that CT in sainfoin reduce ruminal protein breakdown, lower ammonia concentrations, and increase the flow of bypass protein and amino acids to the duodenum (Hart & Sahlu, 1993; Broderick & Albrecht, 1997; McMahon et al., 2000; Broderick, 2001; Wang et al., 2003). The inhibitory effect of CT on ruminal protein degradation increases proportionally with tannin concentration (Broderick & Albrecht, 1997), and has been associated with residual dry matter (DM) and crude protein (CP) after incubation (Julier et al., 2003). Protein degradability in buffer and *in vitro* systems has shown a strong negative correlation with tannin levels (Hedqvist, 2004). In sainfoin silage, higher CT levels have significantly reduced total tract nitrogen digestibility and *in situ* nitrogen degradability in sheep, especially in early-flowering silages (Theodoridou et al., 2012). A significant negative relationship between CT content and effective protein degradability (DE) has also been reported (Azuhnwi et al., 2012), with CT concentrations being negatively correlated with rapidly degradable fraction (a) and degradation rate of the slowly degradable fraction (c) (Aufrère et al., 2014). Similarly, increased CT levels in early-stage sainfoin were found to reduce ruminal CP degradability and nitrogen digestibility (Özbilgin, 2019).

Accordingly, the aim of this study was to evaluate the relationship between CT content and DE in sainfoin samples collected from different regions of Türkiye during the same vegetative stage. In this context, the hypothesis of the study was that naturally varying levels of CT in sainfoin samples grown in different regions would have a significant effect on ruminal protein degradability, and that increasing tannin content would lead to decreased protein degradability.

Materials and Methods

Experimental forages and chemical analyses

In the present study, twenty-five samples sainfoin (*Onobrychis viciifolia*) were harvested as green forage from various regions of Türkiye, were used. The samples were harvested at 50-100% flowering period. Forage samples collected were dried in an air-forced oven at 60°C for at least 72 hours until a constant weight was achieved, then ground to pass through a 1-mm screen using a Retsch mill (Retsch GmbH, Haan, Germany) and analyzed for DM (930.15), and CP (954.01) according to AOAC (2003) methods. The CT content was determined by the hydrochloric acid (HCl)-butanol assay (Reed, 1986).

In situ disappearance in the rumen

The ruminal degradation of CP was evaluated using the nylon bag technique. Dacron bags (Ankom Co., Macedon, NY, USA), with a pore size of 53 ± 15 µm and an internal surface area of 5 × 11 cm, were heat-sealed after being filled with approximately 4 g of air-dried sainfoin samples (1 mm mesh) collected at the 50–100% flowering stage. These bags were incubated in the rumen of three cows maintained on a diet consisting of 70% hay and 30% concentrate (DM basis). *In situ* degradation was measured at incubation times of 4, 8, 16, 24, 48, 72, and 96 h. Dehydrated lucerne samples, used as a standard, were incubated in duplicate in the rumen of each cow to monitor potential changes in ruminal degradation activity throughout the experiment. After removal from the rumen, the bags were thoroughly rinsed and stored at −20°C until further analysis. Prior to analysis, they were thawed and washed in a household washing machine with cold water (three cycles of 10 minutes each) until the rinse water became clear. Finally, the bags were dried at 60°C for a duration of 72 hours.

In situ CP rumen disappearance curves of samples were fitted to the model of Ørskov & McDonald (1979) using a non-linear regression procedure (SAS, 2000):

$$P = a + b\,(1 - e^{-ct})$$

where P is the potential degradable, a is the rapidly degradable fraction, b is the slowly degradable fraction, e is the base of the natural logarithm, c is the degradation rate of the slowly degradable fraction, and t is the incubation time. The residual fraction was calculated as $(100 - a - b)$.

The effective protein degradability (DE) was estimated using the following equation:

$$DE = a + bc / (c + kp)$$

where kp, the fractional passage rate, was assumed to be 0.06/h.

Statistical analysis

A simple linear regression analysis was conducted using SAS Version 8.0 Statistical Package (SAS Institute Inc., Cary, NC, USA) to determine the relationship between content of CT and DE.

Results and Discussion

The distribution of DE values of sainfoin samples is presented in Figure 1. The effective protein degradability values of samples, calculated at a ruminal outflow rate of k = 0.06 h^{-1}, ranged from 53.7% to 62.5%, with a mean of 58.1%. The majority of the values were clustered within the 56% to 60% range, indicating that the DE of sainfoin was minimally affected by environmental factors.

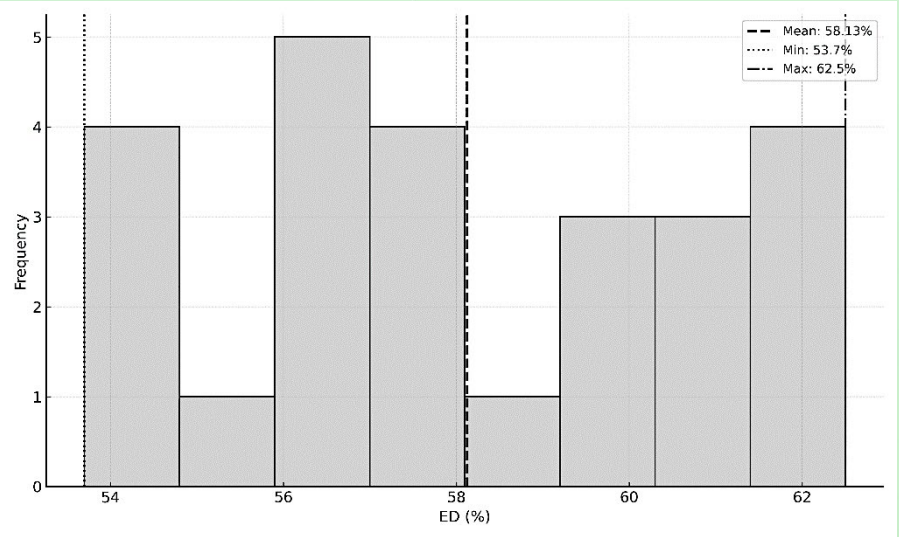

Figure 1. Distribution of effective protein degradability values of sainfoin

These results indicated that sainfoin generally exhibited a moderate level of ruminal protein degradability. In various studies, the DE of sainfoin has typically been reported within the range of 53% to 61%, which is lower than that of more commonly used forage legumes such as alfalfa (Ocak, 1997; Sarıçiçek & Kılıç, 2002; Hanoglu, 2004, Azuhnwi et al., 2012; Aufrère et al., 2014). This difference is primarily attributed to the presence of CT in sainfoin, which are known to form stable complexes with proteins. These complexes limit microbial proteolysis in the rumen and promote the transfer of undegraded protein to the abomasum and small intestine, thereby enhancing bypass protein availability (Jones & Mangan, 1977; Waghorn et al., 1987; McSweeney et al., 1988). Aufrère et al. (2014) reported that tannin-rich forages such as sainfoin exhibit significantly lower DE values compared to tannin-free species, a difference attributed to the interaction between CT and the molecular structure of plant proteins.

Effective protein degradability can be influenced by various factors such as plant species (Turgut & Yanar, 2004), growth stage and harvest time (Aufrère et al., 2014), and forage structure and chemical composition (Broderick & Albrecht, 1997). However, since all sainfoin samples used in this study belonged to the same cultivar and were harvested at similar developmental stages, the DE values exhibited only limited variation.

The distribution of CT content in sainfoin is presented in Figure 2. Condensed tannin concentrations varied between 34.2 and 50.9 g·kg^{-1} DM, averaging 43.0 g·kg^{-1} DM. The data demonstrate a narrow variability, suggesting that most samples had similar CT levels within the given range. Tannin levels in plants can differ substantially not only between species but also among tissues and developmental stages within a species. Their concentrations are modulated by various environmental factors such as drought, soil nutrient status, pH, herbivore pressure, ozone exposure, and atmospheric CO_2 levels (Kraus et al., 2003). In line with this, CT levels in sainfoin have also been shown to vary depending on the plant variety, the location where it is grown, and the timing of harvest (Azuhnwi et al., 2011).

Azuhnwi et al. (2012) reported that CT contents in different sainfoin varieties ranged from 26.6 to 57.3 g·kg^{-1} DM, with this variation being largely attributed to genetic differences, while environmental influences were considered limited. Aufrère et al. (2014) reported CT contents ranging from 35.5 to 48.6 g·kg^{-1} DM across three sainfoin cultivars grown under the same conditions, suggesting that variation was primarily attributable to genetic differences rather than environmental factors. Theodoridou et al. (2012) reported CT concentrations ranging from 33.1 to 51.4 g·kg^{-1} DM in sainfoin silages, and found that both the CT content and its biological activity were affected by the phenological stage at harvest. Özbilgin (2019) reported that CT content in sainfoin increased with advancing maturity, with the highest levels observed at full flowering and the lowest at the budding stage.

The relationship between CT content and DE in sainfoin samples is presented in Figure 3. The derived linear regression equation is:

$y = -0.54x + 81.42$

where y is effective protein degradability, x is condensed tannin content.

This equation indicates that for every 1 g·kg^{-1} DM increase in CT content, the DE value decreases by approximately 0.54 percentage points. This result highlights the inhibitory effect of tannin compounds on protein degradability. The coefficient of determination was calculated as $R^2 = 0.80$, $P = 0.001$, suggesting that 80% of the variation in DE can be explained by differences in CT levels. This high R^2 value demonstrates that the regression model provides a strong fit to the data. Furthermore, the distribution of data points closely around the regression line supports the appropriateness of a linear model. These findings confirm a strong and statistically meaningful inverse relationship between CT content and DE in sainfoin.

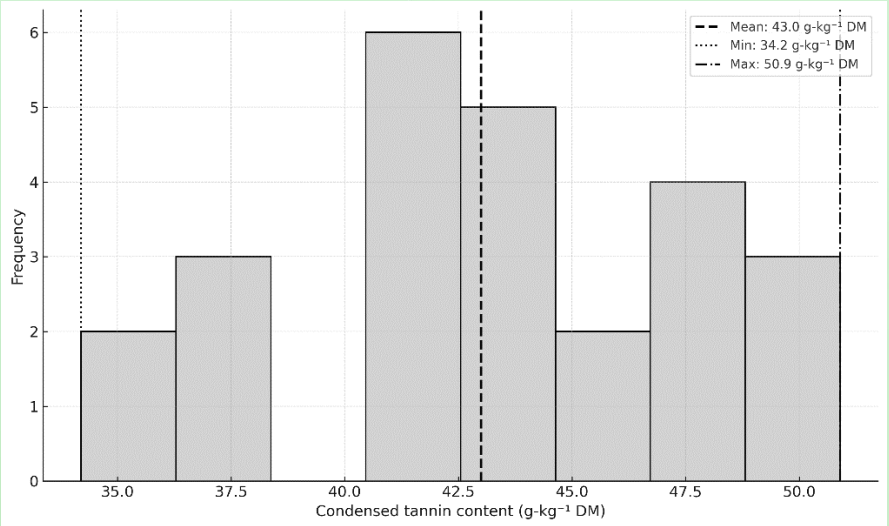

Figure 2. Distribution of condansed tannin content of sainfoin

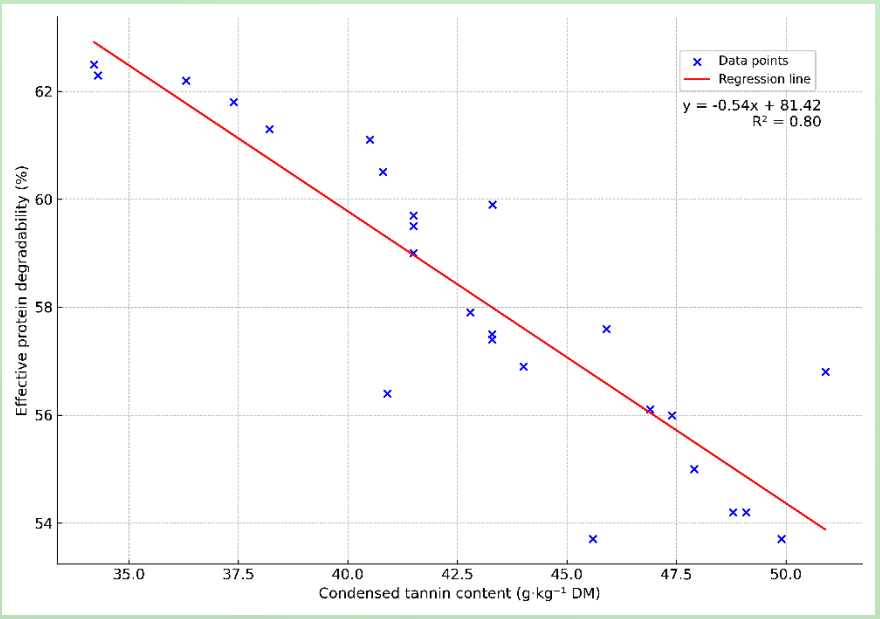

Figure 3. Relationship between condensed tannin content and effective protein degradability in sainfoin

Similarly, the literature clearly demonstrates that CT have a direct inhibitory effect on protein degradability in the rumen. Tannins form strong complexes with proteins under rumen pH, making them resistant to microbial degradation; these complexes then dissociate in the acidic environment of the abomasum, rendering the proteins digestible and thereby increasing the proportion of by-pass protein (Barry et al., 1986; Mangan, 1988; McSweeney et al., 1988; Waghorn et al., 1987, 1994; McNabb et al., 1996; Beck, 2001; Min et al., 2001, 2002).

Azuhnwi et al. (2012) reported that as the CT content increased in sainfoin, the DE significantly ($R^2 = 0.36$, $P = 0.003$) decreased. They noted that this relationship was generally linear and that the reduction in protein degradability was more pronounced in samples from the second harvest. Aufrère et al. (2014) reported a strong negative correlation ($r = -0.81$) between ruminal nitrogen degradability and CT content. Condensed tannins was shown to inhibit both the rapidly degradable nitrogen fraction (a) and the degradation rate of the slowly degradable fraction (c). These results indicate that CT can reduce the rate of protein breakdown in the rumen and potentially enhance the proportion of by-pass protein. Similar findings were reported by Theodoridou et al. (2012), clearly demonstrating that CTs in sainfoin silage have a direct inhibitory effect on protein digestibility.

Conclusion

This study revealed a statistically significant negative relationship between CT content and DE in sainfoin. The increase in CT levels was associated with reduced ruminal protein degradability, indicating that sainfoin can be considered a valuable forage source in terms of bypass protein. However, excessive levels of condensed tannins

may have adverse effects on animal performance and should be carefully evaluated. Therefore, as long as CT content remains within nutritionally appropriate limits**,** sainfoin not only enhances protein utilization efficiency in ruminant nutrition but also stands out as a promising forage crop that supports sustainable livestock production systems thanks to its drought tolerance and adaptability to environmental stress under the challenges of climate change.

Constraints in Aromatic Rice Cultivation: Insights from Smallholder Farmers of Northern Bangladesh

Rayhan Kabir[1], Saiful Huda[2], Abu Mondol[2] and Rubayet Noman[2]

[1]Soil Resources Development Institute, Ministry of Agriculture, Govt. of the People's Republic of Bangladesh
[2]Department of Agricultural Extension, Faculty of Agriculture, Hajee Mohammad Danesh Science and Technology University, Dinajpur, Bangladesh

Abstract

Though Bangladesh a south asian country takes pride in being home to exclusive fine aromatic rice, it has done precious little to retain this much-valued product. The traditional varieties with excellent aroma are almost at the verge of extinct from the fields. The purpose of this study was to determine farmers' constraints in aromatic rice production, and to explore the relationship between the selected characteristics of the farmers with their constraints in aromatic rice production. Data were collected using pre-designed and pre-tested structured interview schedule from a sample of 92 farmers out of 653 farmers selected by simple random sampling procedure. The data collection was done in Uthrail unions of sadar upazila under Dinajpur district. Besides the usual descriptive statistical parameter, Pearson's Product Moment Correlation Coefficient (r) was used for the statistical analysis. About three-fourths (67.3 percent) of the respondents had faced medium constraint while 20.7 percent had low constraints and only 12.0 percent had faced high constraints. Among the constraints, "Diseases" (CFI= 270.6) was found the first ranked constraints in aromatic rice production faced by the farmers. The lowest constraints in aromatic rice production faced by the farmers was 'Erosion' (CFI= 78.2) among the selected constraints. According to the computed value of correlation coefficients (r), among ten selected characteristics of the farmer's age, education, family size, farm size and annual income had no significant relationship with farmers' constraints in aromatic rice production. On the other hand, area under aromatic rice cultivation, agricultural knowledge, extension media contact, training received and aspiration had positive significant relationship with farmers' constraints in aromatic rice production.

Key Words: *Constraints, Aromatic rice, Farmers' and Northern Bangladesh*

Introduction

The slogan "rice is life" is most appropriate for Bangladesh as it is the most widely consumed grain and key to the food security of the nation. In Bangladesh, there are about more than 7,000 varieties of rice are grown in various parts of the country (Shamsi, *et al.*, 2010). In general, rice is classified by its length, thickness and aroma. The length of long-grain rice is four to five times that of its width. One of the more exotic varieties in the long-grain is the aromatic East Indian Basmati and Kalijira rice. It was mentioned by various historians that Bengal was famous for spices, Kalijira and Moslin fabrics. Rice is the staple food of half the world's population that contributes to 20% of the total man caloric intake (Bhattacharjee *et al.*, 2002). Nevertheless, total caloric intake for the Asian population is around 40% to 80% where 95% of world rice production comes from Asian countries such as China, India, Indonesia, Bangladesh, Vietnam and India. The biggest rice exporter is Thailand with 9.8 million tons of rice export per year (BRF, 2015). World trade figures are very different to those for production, as only about 5% to 7% of rice produced is traded internationally. Due to the small volume, the price of rice can rise sharply when something happens to the major exporter countries such as the uncertainty of the climate conditions that will affect the rice production (Ghosh, 2008; Walker, 2008) and impose restricting export. Fragrant rice (Basmati and Jasmine type) shows the highest price in the world market and accounts for about 15% to 18% of world trade. About 70 percent of the world's poor live in rural areas and mostly depend on agriculture as the main source of income and employment (World Bank, 2010). Rice alone contributes of 97% of the food grain production in Bangladesh (BBS, 2013). The quantity of rice traded is relatively small, about 4 to 5 percent of total production. Among different groups of rice, transplant aman (T. Aman) rice cover about 49.11% of total rice area and it contributes to 38.11% of the total rice production in the country (BBS, 2013). In Bangladesh, rice dominates over all other crops and covers 75% of the total cropped area (Rekabdar, 2004) of which around 27% is occupied by fine rice varieties (BBS, 2003).

Different varieties of rice have different characters. Rice grain is categorized into coarse, medium coarse and fine with different color based on physical properties. Some of them have special appeal for their aroma. There are two type of transplant aman rice viz. coarse and fine rice and some of the fine rice are aromatic. The major aromatic varieties identified are Kalijira, Chinigura, Kataribhog, BR5, Bashful, BRRI dhan 34, BRRI dhan 37, BRRI dhan 38 (Bashmotitype), Khaskani, Badshabhog, Dudshagar, Tulshimala, Khirshabhog, Horibhog, Parbatjira, Khasha, Modhumadab, Tilkapur, Chinikanai, Khirkon and Shakhorkora. Some of the features of Kataribhog rice are: this variety is fine quality rice, scented, and sweet to taste, nutritious, delicious. Aromatic rice is generally low yielding (Gangaiah and Prasad, 1999) but they are considered best in quality and also highly valued. Aromatic rice is now an important commodity in international trade having small grain with pleasant aroma. Aromatic rice of

Bangladesh on account of its high export potential and its taste as well as better eating quality like polau, khir, firny, paish, chira, khoi, biriany etc. have great demand. Milled aromatic rice is also used as popular food in ceremonies like marriage day, Eid day etc. According to Bangladesh Rice Exporters Association (BREA) statistics, Bangladesh exported 700 metric tons of aromatic rice in 2001, 780 metric tons in 2002, 1000 metric tons in 2003, and 3300 metric tons in 2004. Export value of aromatic and fine rice stood at 200,000 US dollars in 2003-2004 fiscal years. So, the production of aromatic rice in the country is economically profitable.

The above facts indicate that there is a need for an investigation aiming at an understanding on the constraints faced by the farmers in aromatic rice cultivation. However, very few systematic investigations have been done in this context. Hence, the researcher undertook a study relating to the constraints faced by the farmers in aromatic rice cultivation. The research work was conducted with the following objectives:

a) To determine and describe the selected characteristics of farmers. The characteristics were: age, education, family size, farm size, area under aromatic rice cultivation, annual income, agricultural knowledge, extension media contact, training received and aspiration.

b) To determine farmers' extent of constraints in aromatic rice production.

c) To explore the relationship between the selected characteristics of the farmers with their constraints in aromatic rice production.

d) To know the suggestions provided by the farmers to overcome the constraints.

Methodology

Study areas

The present study was conducted in 7 no Uthrail union of Sadar upazila under Dinajpur district. There are 13 upazilas in Dinajpur district. Among these, sadar upazila is one of the agriculturally important upazila where rice, wheat, maize, vegetables are intensively cultivated along with plantation. Most of the farmers of this area are directly and/or indirectly engaged in agricultural activities and few people are service holders and businessmen.

Design of the study

Designing the research for the present study was taken in a scientific manner. Firstly, different research themes are collected and analyzed followed by research problem formulation. Reviews were studied to select appropriate variables and preparation of questionnaire. Pretesting of the interview schedule was done before final data collection. Finally data were collected, analyzed and report was prepared.

Data collection tools and technique

In order to collect desired information, an interview schedule was prepared keeping the objectives of the research in mind. The schedule was prepared in Bangla for better understanding of the respondents. The questions included were simple and direct to ascertain the opinion of the farmers regarding a number of aspects. Simple random sampling procedure was followed in this study. Dinajpur district was purposively selected due to a number of reasons: Firstly, the districts have the highest percent and area under Kataribhog rice and secondly investigator's familiarity in the area, language and culture of the people. Among the 13 Upazilas, Dinajpur sadar was selected by purposive sampling procedure because aromatic is mostly cultivated in this upazila. One union of sadar upazila namely 7 no. Uthrail was selected by random sampling procedure from 10 unions. An up-to-date list of 653 aromatic rice producing farmers was prepared with the help of the Upazila Agriculture Office of the DAE. From these farmers, 92 (about 15 percent) were selected as the sample by using simple random sampling procedure. A reserve list of 10 farmers (about 10 percent) was prepared so that these farmers could be used for interview in case any farmer included in the original sample was not available in spite of utmost effort during collection of data.

Measurement of farmers' constraints in aromatic rice production

Farmers' constraints in aromatic rice production were the major focus of the study. Thus farmers' constraint in aromatic rice production was the focus issue of this research work. The respondent was asked to express their opinion on the extent of constraints in each of 15 mentioned constraints along a 4-point rating scale; 'not at all (0)', 'low (1)', 'medium (2)', and 'high (3)'. The responses of the scale was given scores as 3 for 'high', 2 for 'moderate', 1 for 'low' and 0 for 'not at all'. The summation of the scores against all the 15 mentioned constraints express the farmers' opinion towards constraints.

For comparative analysis of constraints a "Constraints Facing Index" was calculated by using the following formula:

Constraints Facing Index (CFI) = C_{hi} x 3 + C_{mo}x 2 + C_l x 1 + C_{na} x 0

Where,

C_{hi} = Percentage of farmers opined constraint as high

C_{mo} = Percentage of farmers constraint as moderate

C_l = Percentage of farmers opined constraint as low

C_{na} = Percentage of farmers opined constraint as not at all.

In respect of any perception "Constraints Facing Index" could range from 0 to 300, where 0 indicating no constraint and 300 indicating high constraint.

Statistical analysis

The analysis was performed using Statistical Package for Social Science (SPSS) computer package. Descriptive analysis such as range, number, percentage, mean, standard deviation and rank order were used whenever necessary. For clarity of understanding tables were also used for presenting the data. Pearson's Product Moment Correlation Co-efficient (r) was used to examine the relationships of independent variables of the respondents with the perception of the farmers towards constraints in aromatic rice production.

Results and Discussion

The results of the study are presented in this chapter with the help of proper statistical analysis along with their logical interpretations. This study has been conveniently presented in three sections according to the objectives. The first section deals with the selected characteristics of the farmers. The second section deals with the perception of the farmers towards constraints in aromatic rice production and the third section deals with the relationships between the selected characteristics of the farmers with the perception of the farmers towards constraints in aromatic rice production.

Characteristics of the Respondents

Many characteristics of farmers may have influence to their constraints in aromatic rice production. However, only 10 characteristics namely age, education, family size, farm size, area under aromatic rice cultivation, annual income, agricultural knowledge, extension media contact, training received and aspiration are included in this study. It was assumed that the farmers with their constraints in aromatic rice production would vary according to their various characteristics. The salient features of the different characteristics have been presented in Table 1.

Table 1. Salient features of the selected characteristics of the farmers (N=92)

Characteristics	Scoring method	Range	Categories	Respondents		Mean	SD
		Observed (Possible)		No.	Percent		
Age	No. of year	10-60 (Unknown)	Young aged (≤35)	44	47.8	38.17	12.06
			Middle aged (36-50)	33	35.9		
			Old aged (>50)	15	16.3		
Education	Year of schooling	0.0-17 (Unknown)	Illiterate (0)	32	34.8	5.63	5.13
			Can sign only (0.5)	2	2.2		
			Primary level (1-5)	10	10.9		
			Secondary level (6-10)	34	37.0		
			Above secondary level (>10)	14	15.2		
Family size	No. of members	2-9 (Unknown)	Small (≤ 3)	9	9.8	5.71	1.87
			Medium (4-6)	50	54.3		
			Large (>6)	33	35.9		
Farm size	Hectare	0.07-8 (Unknown)	Marginal (0.02-0.20)	5	5.4	1.53	1.70
			Small (0.21-1.0)	46	50.0		
			Medium (1.01-3.0)	28	30.4		
			Large (>3.0)	13	14.1		
Area under aromatic rice cultivation	Hectare	0.04-8 (Unknown)	Marginal (0.02-0.20)	24	26.1	1.30	1.29
			Small (0.21-1.0)	26	28.3		
			Medium (1.01-3.0)	36	39.1		
			Large (>3.0)	6	6.5		
Annual income	('000' Tk.)	40.2-840 (Unknown)	Low income (≤50)	22	23.9	188.17	183.84
			Medium income (51-250)	48	52.2		
			High income (>250)	22	23.9		
Agricultural knowledge	Score	8-18 (0-25)	Fair (≤8)	15	16.3	13.40	3.00
			Good (9-16)	66	71.7		
			Excellent (>16)	11	12.0		
Extension media contact	Score	2-29 (0-36)	Low (≤12)	19	20.7	14.32	7.26
			Medium (13-24)	57	62.0		
			High (>24)	16	17.4		
Training received	No. of days	0-10 (unknown)	No (0)	44	47.8	1.43	2.17
			Short (≤2)	32	34.8		
			Medium (3-7)	12	13.0		
			Long (>7)	4	4.3		
Aspiration	Score	10-29 (6-30)	Low (≤10)	15	16.3	23.35	6.36
			Medium (11-20)	67	72.8		
			High (>20)	10	10.9		

Age

The age of the respondents ranged from 10 to 60 years with a mean of 38.17 and standard deviation of 12.06. According to age the farmers were classified into three categories are 'young aged' (up to 35), 'middle aged' (36-50) and 'old aged' (>50) based on their observed score (Table 1).

Data contained in Table 1 reveals that about half (47.8 percent) of the respondents were young aged compared to 35.9 percent of the respondents belonged to the middle-aged categories and 16.3 percent were in the old aged category. These findings indicated that the majority of the farmers were young aged. The findings imply that the aromatic rice farmers were young and middle-aged groups.

Education

The educational qualification scores of the farmers ranged from 0.0 to 17, the mean being 5.63 and standard deviation 5.13. Based on educational qualification scores the respondents were classified into five categories such as 'illiterate' (0) 'can sign only' (0.5), 'primary level' (1-5), 'secondary level' (6-10) and 'above secondary level' (>10) as presented in Table 1.

Data presented in Table 1 indicate that highest proportion (37.0 percent) of the farmers had secondary education, 34.8 percent were illiterate, 2.2 percent were can sign only, 10.9 percent had primary education and 15.2 percent of the farmers had above secondary education level. The finding indicated that 65.2 percent of the respondents were educated. The average literacy rate in Bangladesh is 72.76 percent (Dhaka Tribune, 2017). So, the education rate of the study area is lower than the average literacy rate in the country.

Family size

The family size scores of the farmers ranged from 2 to 9. The average family size was 5.71 with a standard deviation of 1.87. The respondents were classified into three categories like 'small' (≤3), 'medium' (4-6) and 'large' (>6) are presented in Table 1.

The data furnished in the Table 1 revealed that more than half (54.3 percent) of the respondents had medium family size, 9.8 percent had small family size and 35.9 percent had large family. The national average family size in Bangladesh is 4.85 (BBS, 2014) which is near the mean value of the present study (5.71). It is quite logical that prevalence of joint family system in the study area might have also contributed to the large family size.

Farm size

The farm size scores of the farmers ranged from 0.07 to 8, the average being 1.53 and standard deviation 1.70. The farmers were classified into four categories as 'marginal' (0.02-0.20), 'small' (0.21-1.0), 'medium' (1.01-3.0) and 'large' (>3.0) as shown in Table 1.

Data presented in Table 1 show that exactly half (50.0 percent) of the respondents were small farm size, 5.4 percent were marginal farm size, 30.4 percent had medium farm size and 14.1 percent had large farm size. Most of the farmers had medium farm size. Moreover, it enriches their perception towards improved farming practices and enlightens power of understanding and abilities to analyze facts and situations to make appropriate decisions on farming activities.

Area under aromatic rice cultivation

The farm size under aromatic rice cultivation scores of the farmers ranged from 0.04 to 8, the average being 1.30 and standard deviation of 1.29. The farmers were classified into four categories as 'marginal' (0.02-0.20), 'small' (0.21-1.0), 'medium' (1.01-3.0) and 'large' (>3.0) as shown in Table 1.

Data presented in Table 1 show that most of the (39.1 percent) of the respondents were medium farm sized, 26.1 percent were marginal farm size, 28.3 percent had small farm size and 6.5 percent had large farm size. Most of the farmers (67.4 percent) had small to medium farm size. This means that the aromatic rice growers are the scenario on the basis of farm size.

Annual income

The family income scores of the farmers ranged from 40.2 to 840 with a mean of 188.17 and standard deviation of 183.84. Based on the annual income the farmers were classified into three categories such as 'low income' (≤50), 'medium income' (51-250), 'high income' (>250) as shown in Table 1.

Data furnished in Table 1 indicate that a little more than half (52.2 percent) of the farmers had medium income compared to 23.9 percent under low and only 23.9 percent under high income group. The overwhelming (76.1 percent) of the respondents were under low to medium income category.

Agricultural knowledge

Agricultural knowledge scores of the growers varied from 8 to 18 against a possible range of 0 to 25. The average agricultural knowledge score was found to be 13.40 and standard deviation was 3.00. Based on the observed overall knowledge scores, the respondents were classified into three categories as 'fair' (≤8), 'good' (9-16), and 'excellent' (>16) as shown in Table 1.

Data presented in Table 1 shows that about three-fourths of the (71.7 percent) of the respondents had good agricultural knowledge compared to 16.3 percent had fair knowledge and only 12.0 percent had excellent agricultural knowledge. A respondents who receives high level of education but less involvement in farming might possess lower knowledge than the growers who is actively involved in farming for a long period of time.

Extension media contact

The extension contact scores of the farmers ranged from 2 to 29, against the possible score 0 to 36. The mean and standard deviation were 14.32 and 7.26 respectively. The respondents were classified into three categories based on their extension contact as 'low' (≤12), 'medium' (13-24) and 'high' (>24) as shown in Table 1.

Data presented in Table 1 shows that majority (62.0 percent) of the farmers had medium extension media contact, 20.7 percent had low extension contact and 17.4 percent had high extension contact. The findings indicate that above three-fourths (79.4 percent) of the farmers had medium to high extension media contact. This may be due to the reason that the respondents contact highly with different extension media.

Training received

The training received scores of the respondents ranged from 0 to 10 with a mean of 1.43 and standard deviation of 2.17. According to the training received scores, respondents were classified into four categories like 'no training' (0), 'short' (≤2), 'medium' (3-7) and 'long' (>7) in Table 1.

Data presented in the Table 1 revealed that 47.8 percent of the respondents had no training followed by 34.8 percent received short training, 13.0 percent received medium training and 4.3 percent received long training. Training increases skills and knowledge which makes the respondents much more competent in performing different activities.

Aspiration

The aspiration scores of the farmers ranged from 10 to 29 against the possible range 6 to 30 with a mean and standard deviation of 23.35 and 6.36 respectively. Based on their aspiration scores, the respondents were classified as 'low' (≤10), 'medium' (11-20) and 'high' (>20) which is presented in the Table 1.

It is revealed from the Table 1 that the highest proportion (72.8 percent) of the respondents had medium aspiration, 16.3 percent of the respondents had low and only 10.9 percent of the respondents had high aspiration respectively. Findings showed that majority of the farmers possessed their aspiration and the result might be due to the effect of better educational qualification, better communication system of the respondents.

Farmers' Constraints in Aromatic Rice Production

For having the better understanding regarding farmers constraints in aromatic rice production, it was necessary to have an idea about the comparative constraints in 15 selected constraints. For this purpose, Constraint Facing Index (CFI) was computed. The computed CFI of the 15 constraints ranged from 78.2 to 270.6 against a possible range from 0 to 300 which are arranged in rank order according to their CFI as shown in Table 2.

Table 2. Distribution of farmers according to constraints of aromatic rice production

Sl. No.	Constraints	Percentage of farmers				*CFI	Rank order
		Not at all	Low	Medium	High		
A.	**Biotic constraints**						
1.	Weeds	3.3	6.5	20.6	69.6	256.5	2
2.	Rodents	4.3	8.7	35.9	51.1	233.8	4
3.	Diseases	0	1.1	27.2	71.7	270.6	1
4.	Insects	2.2	20.7	12	65.1	240	3
B.	**Abiotic constraints**						
5.	Drought	28.3	15.2	48.9	7.6	135.8	12
6.	Erosion	37	48.9	13	1.1	78.2	15
7.	Heat Stress	31.5	48.9	13	6.6	94.7	13
8.	Soil Fertility	23.9	19.6	52.2	4.3	136.9	11
C.	**Socioeconomic constraints**						
9.	Difficulties to access to credit	5.4	25	52.2	17.4	181.6	7
10.	Unavailability of labour	13	14.1	63	9.9	169.8	10
11.	High price of seed	60.9	8.7	17.4	13	82.5	14
12.	Low market price	7.6	21.7	52.2	18.5	181.6	8
13.	High transportation cost	10.9	16.3	48.9	23.9	185.8	6
D.	**Extension service related constraints**						
14.	Insufficient regular information from extension worker	8.7	20.7	35.9	34.7	196.6	5
15.	Lack of new technology in aromatic rice cultivation	5.4	18.5	66.3	9.8	180.5	9

***CFI= Constraints Facing Index**

Data in Table 2 indicate that "Diseases" (CFI= 270.6) was found the first ranked constraints faced by the farmers. All the farmers of the study are aromatic rice cultivars. They cultivate aromatic rice for high profit but high yielding varieties are not available all time. 'Weeds' was found as the second ranked (CFI= 256.5) constraints faced by the farmers. The result may be due to that weed control is the vital factor for good yield of crop. 'Insects' (CFI= 240.0) was emerged as the third most important constraints among the selected constraints. The farmers opined that insect reduce the yield of rice. The lowest constraints faced by the farmers was 'Erosion' (CFI= 78.2) among the selected constraints. The result may be due to that there have very little challenges about erosion.

Overall farmers' constraints in aromatic rice production

Overall constraint scores for 15 selected constraints in aromatic rice cultivation could theoretically range from 0 to 45, where 0 indicating no constraint and 45 indicating high constraint. However, the observed constraint scores of the respondents ranged from 18 to 34 with a mean of 26.25 and standard deviation 3.24. Based on their constraint scores, the respondents were classified into three categories viz. 'low' (up to 23), 'medium' (24-30) and 'high' (above 30) has been presented in the Table 3.

Table 3. Distribution of the farmers according to their overall constraints in aromatic rice production

Categories (score)	Respondents (N=92)		Mean	Standard Deviation
	Number	Percent		
Low (up to 20)	19	20.7	26.25	3.24
Medium (21-30)	62	67.3		
High (above 30)	11	12.0		

Data furnished in the table 3 revealed that near about three-fourths (67.3 percent) of the respondents face medium constraint while 20.7 percent had low constraint and only 12.0 percent had high constraint. The average (mean) value of the constraint indicates that the respondents in average had medium constraints faced in aromatic rice cultivation. So, from this finding, it can be said that the desired level dissemination of aromatic rice cultivation technology will not occur if the constraints of the respondents are not minimized by the concerned authority.

Relationship between the Selected Characteristics of the respondents and farmers' constraints in aromatic rice production

This section deals with the relationship between the 10 selected characteristics of the respondents and farmers' constraints in aromatic rice production. The relationships were computed by using the Pearson's product moment correlation co-efficient(r). The co-efficient of correlation (5 percent level) was used to test the null hypothesis and analysis is presented in Table 4.

Table 4. Relationship between dependent and independent variables

Dependent variable	Independent variables	Pearson Correlation (r) values with 90 df
Farmers' constraints in aromatic rice production	Age	-0.032
	Education	-0.131
	Family size	0.082
	Farm size	0.096
	Area under aromatic rice cultivation	0.227*
	Annual income	-0.047
	Agricultural knowledge	0.277**
	Extension media contact	0.264*
	Training received	0.214*
	Aspiration	0.300**

* = Correlation is significant at the 0.05 level, ** = Correlation is significant at the 0.01 level

Age and farmers' constraints in aromatic rice production

The correlation coefficient between age of the respondents and farmers' constraints in aromatic rice production was -0.032 (Table 4). Based on the computed 'r' value the relationship between age and farmers' constraints in aromatic rice production was negative. Hence, the concerned null hypothesis could not be rejected. Thus, it could be said that the age of the respondents had no significant role on farmers' constraints in aromatic rice production.

Education and farmers' constraints in aromatic rice production

The correlation coefficient between education of the respondents and farmers' constraints in aromatic rice production was -0.131 (Table 4). Based on the computed 'r' value the relationship between education and farmers' constraints in aromatic rice production was negative and not significant with 90 degrees of freedom. Hence, the

concerned null hypothesis could not be rejected. Thus it could be said that the educational qualification of the respondents had no significant relationship with the farmers' constraints in aromatic rice production.

Family size and farmers' constraints in aromatic rice production

The computed value of correlation coefficient (r) between family size of the respondents and farmers' constraints in aromatic rice production was 0.082 (Table 4). Based on the computed 'r' value the relationship between family size and farmers' constraints in aromatic rice production was positive and not significant with 90 degrees of freedom. Hence, the concerned null hypothesis could not be rejected. Thus, it could be said that the family size of the respondents had no relationship with the farmers' constraints in aromatic rice production.

Farm size and farmers' constraints in aromatic rice production

The computed value of correlation coefficient (r) between farm size of the respondents and farmers' constraints in aromatic rice production was 0.096 (Table 4). Based on the computed 'r' value the relationship between farm size and farmers' constraints in aromatic rice production was positively not significant with 90 degrees of freedom. Hence, the concerned null hypothesis could not be rejected.

Area under aromatic rice cultivation and farmers' constraints in aromatic rice production

The computed value of correlation coefficient (r) between area under aromatic rice cultivation of the respondents and farmers' constraints in aromatic rice production was 0.227 (Table 4). Based on the computed 'r' value the relationship between farm size under aromatic rice cultivation of the respondents and farmers' constraints in aromatic rice production was positive and significant with 90 degrees of freedom at 0.05 level of probability. Hence, the concerned null hypothesis could be rejected. The data revealed that the higher the farm size under aromatic rice cultivation the higher constraints of the farmers in aromatic rice production.

Annual income and farmers' constraints in aromatic rice production

The computed value of correlation coefficient (r) between annual income of the respondents and their farmers' constraints in aromatic rice production was -0.047 (Table 4). Based on the computed 'r' value the relationship between family income of the respondents and farmers' constraints in aromatic rice production was negative and not significant with 90 degrees of freedom. Hence, the concerned null hypothesis could not be rejected. Thus, it could be said that the family income of the respondents had no significant relationship with constraints in aromatic rice production.

Agricultural knowledge and farmers' constraints in aromatic rice production

The computed value of correlation coefficient (r) between agricultural knowledge of the respondents and farmers' constraints in aromatic rice production was 0.277 (Table 4). Based on the computed 'r' value the relationship between agricultural knowledge farmers' constraints in aromatic rice production was positively significant at 0.01 level of probability with 90 degrees of freedom. Hence, the concerned null hypothesis could be rejected. Thus it could be revealed that the higher agricultural knowledge the higher constraints in aromatic rice production.

Extension media contact and farmers' constraints in aromatic rice production

The correlation coefficient between extension media contact of the respondents and their farmers' constraints in aromatic rice production was 0.264 (Table 4). Based on the computed 'r' value the relationship between extension contact of the respondents and farmers' constraints in aromatic rice production was positively significant at 0.05 level of probability with 90 degrees of freedom. Hence, the concerned null hypothesis could be rejected. Thus it could be revealed that the higher extension media contact the higher constraints in aromatic rice production.

Training received and farmers' constraints in aromatic rice production

The correlation coefficient between training received among the respondents and their farmers' constraints in aromatic rice production was 0.214 (Table 4). Based on the computed 'r' value the relationship organizational participation of the respondents and constraints of aromatic rice production was positively significant at 0.05 level of probability with 90 degrees of freedom. Hence, the concerned null hypothesis could be rejected. Thus, it could be revealed that the higher training received the higher the farmers' constraints in aromatic rice production.

Aspiration and farmers' constraints in aromatic rice production

The correlation coefficient between aspiration of the respondents and their farmers' constraints in aromatic rice production was 0.300 (Table 4). Based on the computed 'r' value the relationship aspiration of the respondents and farmers' constraints in aromatic rice production was positively significant at 0.01 level of probability with 90 degrees of freedom. Hence, the concerned null hypothesis could be rejected. Thus, it could be revealed that the higher aspiration the higher the farmers constraints in aromatic rice production.

Suggestions offered by the farmers to overcome the constraints

Many suggestions were offered by the farmers to overcome the constraints in aromatic rice production. These are given in Table 5.

It is evident from the data contained in the table 5 that 'Develop high resistance varieties to pests and diseases' (70.65 percent) were found as the most important suggestions to overcome the problems in aromatic rice production. The lowest numbers of farmers opined that 'Easy access of credit facility from bank' (22.82 percent) among the mentioned suggestions.

Table 5. Rank order of suggestions offered by the farmers to overcome the constraints in aromatic rice production

Sl. No.	Suggestions	Respondents	
		Number	Percent
1.	Develop high resistance varieties to pests and diseases	65	70.65
2.	Quality seed and fertilizer should be available	57	61.95
3.	Marketing channel of aromatic rice should be developed	43	46.73
4.	Organizing more training program for the farmers	37	40.21
5.	Easy access of credit facility from bank	21	22.82

Conclusions

Based on the findings and their logical interpretations in the light of relevant facts the researcher has drawn the following conclusions:

1. "Diseases" (CFI= 270.6) was the first ranked constraints faced by the farmers whereas 'Erosion' (CFI= 78.2) was the last ranked constraints faced by the farmers. Based on this findings it may be concluded that this scenario may be due to that farmers faced disease oriented problem frequently and farmers remain concerned more on this issue but erosion is not familiar at farmers level.
2. About three-fourths (67.3 percent) of the respondents had faced medium constraints while 20.7 percent had low constraints and only 12.0 percent had high constraints in aromatic rice cultivation. From this findings it can be concluded that majority of the farmers are aware about the constraints they faced during production of aromatic rice.
3. Among the ten selected characteristics of the farmer's, area under aromatic rice cultivation, agricultural knowledge, extension media contact, training received and aspiration showed positive significant relationship with farmers constraints in aromatic rice production. So, this may be concluded that these characteristics of the farmers should be taken under consideration and played important role in case of constraints faced by the farmers.

Recommendations

The following recommendations were made on the basis of the findings, related conclusions and their logical interpretations.

1. The farmers' constraints in aromatic rice production should be overcome by taking adequate measures. Different Government and Non-Government authority should take initiatives so that the participants get the financial help and necessary agricultural inputs at very easy and short process. Necessary supports for the farmers to increase household income are essential from the authority.
2. Relatively younger farmers who are more democrats in decision making, thus relatively younger target participant could be selected for aromatic rice cultivation because they can easily take decision in any challenging situation.
3. The farmers mentioned a number of constraints in different extent which they faced during aromatic rice cultivation. The authority should consider these facts during formulation of any program.
4. Adequate training of the farmers will help to mitigate the constraints in aromatic rice production.
5. Government should take special emphasis on the necessary supportive measures for ensuring easy availability of inputs needed for aromatic rice production at reasonable prices.

Seed scarification relieves weed seed dormancy in *Convolvulus arvensis*

Khawar Jabran[1]

[1]Department of Plant Production and Technologies, Faculty of Agricultural Sciences and Technologies, Nigde Omer Halisdemir University, Nigde, Turkiye
Email: khawarjabran@gmail.com

Abstract

Field bindweed (*Convolvulus arvensis* L.) is a perennial weed, which has a creeping growth habit and deep root system. This is one among the most troublesome and aggressive weeds around the world and infest a large number of field crops and orchards. The weed has a strong dormancy character, which makes working on this weed under laboratory conditions a difficult task. This study aimed to check the dormancy breaking impact of several hormones and scarification with sand paper in the seeds of *C. arvensis*. The results showed that the most effective treatment for removing weed seed dormancy in *C. arvensis* was the mechanical method i.e., scarification with sand paper. This method resulted in a 55% germination of the weed seeds, which was the highest among all the germinated seeds. None of the hormones was effective in improving the germination of *C. arvensis*. The most efficient among the hormones was kinetin that resulted only in 5% germination of the weed seeds, which was equal to the germination percentage observed in the control treatment. It is concluded that the mechanical scarification can act as a successful method to remove dormancy in the seeds of *C. arvensis*.

Key Words: *Dormancy, Field bindweed, Weeds, Weed control, Hormones*

Introduction

The discipline of crop protection includes protecting the crops from a wide variety of pests such as viruses, disease pathogens, nematodes, rodents, weeds and insect pests. Weeds hold a significance among the different crop enemies owing to their large number, high competitive ability and resilience (Ahmad et al. 2023). High seed production and dormancy in seeds are the other characteristics of weeds that make them a tough pest (Gaba et al. 2017; Batlla et al. 2020).

Several of the weed species have been recognized as noxious or troublesome due to the great degree of damage caused by these weeds. Field bindweed (*Convolvulus arvensis* L.) is one among such weeds that infests several crops and is highly difficult to control (Davis et al. 2018). This weed belong to the Convolvulaceae family, possesses a perennial life cycle and a creeping growth habit, and propagates both vegetatively and through seeds (Sosnoskie et al. 2020). The dormancy character of the seeds of this plant make it a resilient weed (Ma et al. 2023). The dormancy in the seeds of this weed is mainly caused by its hard seed cover that does not allow the movement of moisture into the seed (Jayasuriya et al. 2008). There is a possibility to apply scarification, which is a mechanical method of removing dormancy from any plant seeds (Rocha et al. 2022). The process of seed scarification can be done either through sand paper or using some other appropriate tools. Other than this, several hormones may also play a role in germinating the dormant weed seeds. A few among such hormones are indole-3-butyric acid (IBA), 6-benzylaminopurine, benzyl adenine (BAP), gibberellic acid and kinetin (Xiong et al. 2018).

The presence of dormancy in the *C. arvensis* seeds not only provides a persistence in the nature but also creates hurdles when researchers intends to use these seeds in their laboratory or greenhouse experiments. Hence, this study was aimed to evaluate different seed dormancy breaking methods to remove dormancy from the seeds of *C. arvensis*. Determing such methods will be helpful in germinating this weed easily under laboratory conditions for the subsequent research studies.

Materials and Methods

This study was conducted at the weed science laborator of the Department of Plant Production and Technologies, Faculty of Agricultural Sciences and Technologies, Nigde Omer Halisdemir University, Nigde, Turkiye.

The seeds of the weed *C. arvensis* were collected from environments such as apple orchards, potato fields and non-cropped areas during August to October 2024. The laboratory work was conducted during the months of January to February 2025. The weed seeds were surface sterilized with a deterjan at the start of the experiment. The dormancy status of the weeds seeds was checked through a germination test. This germination test was done by putting 10 weed seeds on a filter paper in three 9-cm diametered petri dishes (i.e., replicated thrice). The seeds were watered appropriately and allowed to germinate for two weeks in an incubator at 25 °C. As the *C. arvensis* seeds were found dormant after this initial experiment, subsequently the following experiment was conducted.

Four hormones and one mechanical method were applied to check their efficacy to break dormancy in *C. arvensis*. The weed seed dormancy breaking treatments included the followings. (1) Control (no treatment) i.e., treatment

only with distilled water, (2) Scarification of the weed seeds with sand paper, i.e., application of a mechanical method for removal of the weed seed dormancy. Further, the four hormonal treatments were: (3) Treatment of the weed seeds with indole-3-butyric acid (IBA), (4) Treatments of the weed seeds with 6-benzylaminopurine, benzyl adenine (BAP), (5) Treatment of the weed with gibberellic acid (GA3), and (6) Treatment of the weed seeds with kinetin. The sand paper used for mechanical scarification of the weed seeds was obtained from a local market. The solutions of the hormones used in the study were prepared in the laboratory and stored in a 500 ml conical flask until used in the study. The salts of these chemicals (IBA, BAP, gibberellic acid, kinetin) were dissolved in distilled water to obtain solutions with a strength of IBA = 20 mg/L, BAP = 20 mg/L, gibberellic acid = 8 mg/L, and kinetin = 8 mg/L.

The experiment was conducted according to the completely randomized design with four replication. The petri dishes were fitted with a double layer of filter paper and 10 weed seeds were arranged in each petri dish. The control treatment was applied with distilled water while others were applied with the relevant hormonal solution. A five ml of a solution was applied to the relevant petri dishes, which were checked thoroughly to top-up the solution if required.

The experiment was continued for a period of 15 days and the number of germinated seeds was noted upon the termination of the experiment. Any seed producing a radicle of >2 mm was considered as germinated seed. Germination percentage was calculated based on the number of germinated seeds. Moroever, the other parameters including shoot length, root length and seedling height were measured with meter rod. The seedling fresh weight was recorded by weighing the seedlings on a sensitive balance.

The data corrected were processed through Microsoft Excel. The program was used to calculated the means and standard errors of the replicated data. The mean data was represented as bar charts, which were fitted with their relevant error bars to be used to compare the significance of difference among the treatment means.

Results

None of the seeds of *C. arvensis* were germinated in a germination test conducted to check the dormancy of the weed seeds (data not presented). As all of the weed seeds were dormant, subsequently the dormancy breaking treatments were applied on *C. arvensis* seeds. The results showed that the effect of dormancy breaking treatments was significant on the germination of *C. arvensis*, and the treatments had a variable effect on the weed germination (Figure 1). Seed scarfication with sand paper was the most effective treatment, which resulted in the highest weed seed germination (55%) while none of the hormonal treatments were effective in improving germination in *C. arvensis* seeds. Kinetin and BAP were the only two hormonal treatments that resulted in some germination but this was only 5% or less than it, and was similar with the germination achieved in the control treatment.
