The highest shoot length was noted for the *C. arvensis* seedlings for which the seeds had been treated with sand paper (Figure 2a). The treatments including control and kinetin application were the only two other treatments where seedlings had developed some shoot, and the shoot length was statistically similar for thes two treatments. No shoot was observed in the weed seeds applied with IBA, BAP or gibberellic acid hormones. Both the control and scarification with sand paper had developed the longest root and the root length for these two treatments was statistically similar (Figure 2b). Kinetin and BAP applied weeds seeds had developed very short roots (< 1 cm).

Treatments for breaking weed seed dormancy of *Convolvulus arvensis*

Fig. 2. Effect of different treatments on germination of *Convolvulus arvensis* seeds

The longest seedlings were found for the *C. arvensis* seeds that were treated with sand paper followed by the control and kinetin (Figure 3a). The highest seedling fresh weight was recorded for the treatment where *C. arvensis* seeds for treated with sand paper followed by the seedling fresh weight with the kinetin treatment (Figure 3b).

Treatments for breaking weed seed dormancy of *Convolvulus arvensis*

Fig. 3. Effect of different treatments on germination of *Convolvulus arvensis* seeds

Discussion

In this study, scarification with sand paper was the most effective treatment in breaking the dormancy in *C. arvensis* while the different hormones proved to be ineffective. The most important reason for this may be the presence of hard seed coat in *C. arvensis* seed (Sosnoskie et al. 2020). The mechanical treatment with sand paper was able to damage the hard seed coat of the weed that ultimately lead imbibition of water and ease in the excahange of gases by the weed seeds (Rocha et al. 2022). As the imbibition of water is the first step in germination of viable plant seeds, damage to hard coat by sand paper helped water movement into the seed (Orozco-Segovia et al. 2007). Similarly, the damage to the seed coat is also expected to facilitate the exchange of gases. The effectivenss of the sand paper also imply that the type of dormancy in *C. arvensis* was primary and physical dormancy.

The hormonal treatments were ineffective in removing the dormancy from *C. arvensis* seeds that implies that the dormancy in these weed seeds was not because of hormonal imbalance (Shu et al. 2006) while the mechanical damage to the seed coat of *C. arvensis* can help in removal of dormancy in this weed. These results have implications for practical weed control under field conditions. This means that the *C. arvensis* seeds present in a field may be exposed natural or artificial factors so that their seed coat is damage. The damaged and weakened seed coat will lead to germination of the weed and the weed seeds will not become a part of soil weed seedbank.

AI and IoT-Based Smart Irrigation: A Review of Challenges and Future Trends

Yusuff Lawal[1], Oluwadare Adebisi[2]

[1]Mechanical and Mechatronics Engineering, Faculty of Engineering and Technology, Abiola Ajimobi Technical University, Ibadan, Nigeria. Email: yusuff.lawal@tech-u.edu.ng
[2]Electrical and Electronics Engineering, Faculty of Engineering and Technology, Bowen University, Osun State, Nigeria.

Abstract

Artificial Intelligence (AI) and Internet of Things (IoT) integration has established a new generation of intelligent irrigation systems that deliver sustainable water management solutions to address world water scarcity problems and agricultural requirements. This literature review presents an analysis of the present situation and obstacles alongside emerging trends of AI and IoT-based smart irrigation systems supported by international examples and technological milestones. Physical water conservation through AI-driven irrigation systems combined with IoT sensor surveillance and drone monitoring results in 20-35% water savings at the same time as improved yield outcomes across Australian regions together with Indian and Spanish territories. The wide use of smart irrigation systems is limited by technical difficulties that prevent rural Africa from connecting by economic pressures on poor farmers and by ethical challenges with European data security. The deployment become challenging because of scalability issues and maintenance problems that affect different farming ecosystems. The development of emerging technologies like edge computing, blockchain, and 5G, together with solar-powered IoT systems, provides solutions alongside research efforts toward energy-efficient climate-friendly designs. A comprehensive review combines current evidence into two major parts to evaluate its impacts on farmers, policymakers, and researchers. The review also shows where scalability and accessibility remain limited. The success of AI and IoT precision farming technology relies on cooperative work between multiple fields of study together with equal policies that support their implementation. Time must be dedicated to resolving these problems because smart irrigation systems need to fulfill worldwide food security along with sustainable development targets.

Key words: AI-driven irrigation, IoT sensors, smart agriculture, precision irrigation, water management, blockchain in agriculture, edge computing, renewable energy irrigation

1.1 Introduction

Agriculture stands as the foundational element of worldwide food security, although its operation suffers from major problems because of growing populations joined with climate shifts and evaporating freshwater availability. A 40% water deficit exists in the global water supply estimation for 2050, while irrigation utilizes about 70% of worldwide freshwater withdrawals. The standard irrigation techniques present difficulties because they neither successfully optimize agricultural production nor protect the environment efficiently. The combination of Artificial Intelligence (AI) systems operating with Internet of Things (IoT) devices makes up a revolutionary irrigation solution under the name of smart irrigation. Having IoT devices monitor environmental parameters gives AI systems the ability to manage water consumption efficiently and determine irrigation requirements and guide decision-making processes. This combined technology approach will direct farming operations into a new exacting direction which brings sustainable water management practices alongside higher agricultural output.

1.2 Objectives of the Review

The review examines existing knowledge about AI and IoT-based smart irrigation systems which focuses on their applications together with their limitations as well as future potential. This paper examines three essential aspects regarding AI and IoT applications in irrigation practices: (1) describes current integration methods, (2) describes key barriers affecting adoption, and (3) investigates emerging models for future smart irrigation systems. Through this combined technical and practical approach, this study provides essential information for researchers, practitioners and officials who work in agriculture technology fields.

1.3 Scope and Methodology

This review investigates AI and IoT applications in irrigation management while not addressing broader agricultural applications except when they directly touch irrigation systems. The review examines recent research from peer-reviewed journals, conference materials, and technical reports that originate mainly from IEEE Xplore, Scopus, and Google Scholar databases during the previous ten years. The search for relevant literature relied on the selected keywords “AI in irrigation,” “IoT smart irrigation,” “precision agriculture,” and “water management technologies.” The study included research papers about AI-IoT integration challenges and innovations and future direction works that maintained a focused relevant analysis. The analysis focuses on worldwide ideas that additionally respect geographical differences between various agricultural tech acceptance and farming requirements.

2. Overview of AI and IoT in Smart Irrigation

2.1 Core Concepts

Two major functions guide smart irrigation technology through the integration of Artificial Intelligence (AI) and the Internet of Things (IoT). These functions include the acquisition of data and the implementation of intelligent decision systems. IoT consists of networked objects including sensors that monitor ground moisture and weather monitoring systems and controllers which share information through wireless communication networks (Selvam & Al-Humairi, 2023). The established monitoring infrastructure tracks vital measurements including soil water levels together with environmental humidity and prediction of rain events. AI-operated algorithms consisting of ML and DL generate insights from the processed data (Rane, *et al.,* 2024). AI analyzes weather data in combination with plant water needs to establish ideal irrigation timing which leads to better water use efficiency and reduced wastage. The combination of these technologies operates in a self-contained system which dynamically responds to environmental changes thus making smart irrigation differ from conventional approaches.

2.2 Evolution of Smart Irrigation Systems

The techniques of irrigation have experienced drastic changes as human-operated flood irrigation systems evolved to technology-powered automated irrigation systems. The early development of irrigation technology integrated timer-based sprinklers and drip irrigation yet did not offer adjustable controls (Tripathi, 2022). The early development of IoT in the 2000s enabled farmers to use mobile device connectivity for monitoring sensors which helped them modify irrigation routines. Prediction technology and automation have brought AI systems into the current irrigation development. AI-IoT combines to minimize water consumption by 30% better than traditional techniques yet produces equal or better production results (Senoo *et al.,* 2024). Precision agriculture represents the dominant movement in which resource management becomes the most critical aspect.

2.3 Key Components

The functionality of AI and IoT-based smart irrigation systems depends on various hardware and software collaborative elements. Low-power IoT devices like capacitive soil moisture sensors and weather stations together with solenoid valves constitute hardware components (Shamsudeen, 2021). These devices operate on solar-powered batteries to maintain sustainability for distant locations. Cloud platforms collect IoT network data through software components where AI algorithms execute data analysis to create irrigation strategies beginning with basic regression models and ending with neural networks (Preite & Vignali, 2024). The components of an irrigation system use ZigBee and LoRaWAN and Wi-Fi communication protocols to transfer data effectively (Dhatterwal, *et al.,* 2024). The system's scalable design operates well due to reliable connections between its parts while ensuring software interoperability.

3. Current State of Research

3.1 Applications of AI and IoT in Irrigation

AI and IoT applications for smart irrigation systems are widely adopted by international agricultural sectors to suit various needs within different climate zones and economic ranges. The precision irrigation system serves as a primary use case that uses IoT devices with Artificial Intelligence algorithms for delivering precise water dispensations to targeted plant areas at correct times. This prevents irrigation water from going to waste. The adoption of these systems within Middle Eastern arid regions enables optimal date palm management through decreased water requirements by 25% according to (Alnaim *et al.,* 2022). The combination of IoT data from meteorological measurements with AI forecasting models enables water scheduling through weather-based methods which yields good results in Asian regions dependent on monsoons (Indira *et al.,* 2023). Soil and crop monitoring uses IoT multispectral sensors to collect data which machine learning processes for agricultural evaluation in both large-scale North American maize fields and Southeast Asian rice paddies (Solano Correa, 2025). The range of agricultural settings which proves the flexibility of AI-IoT solutions includes high-tech European commercial operations in addition to Sub-Saharan African areas with limited resources.

3.2 Notable Case Studies

Zone irrigation and collective irrigation programs benefit from real-world practices of AI and IoT technologies in irrigation management. The Murray-Darling Basin conducted an IoT and AI decision support system pilot project that cut water usage by 35% without affecting cotton production rates (Parr *et al.,* 2022). The Tamil Nadu Agricultural University in India built a low-cost IoT-AI system for drip irrigation and this technology enhanced rice production by 20% while attracting use from small farmer community (Ahmad & Nabi, 2021). AI enabled Spanish vineyards to increase their water efficiency rate by 30% through European Union backing for IoT data analysis (Linaza, et al., 2021). A Kenyan research study demonstrated limited water savings of 15% because of connectivity issues despite conducting the study in the region (Karuku, 2018). This showed discrepancies in local infrastructure development. The implementation examples demonstrate the capacity for and inconsistent advancement rates of smart irrigation systems worldwide.

3.3 Technological Advancements

AI together with IoT functionalities have received major enhancements in recent times. The development of sensor technology now includes affordable yet precise devices such as capacitive soil moisture sensors made by China

which are currently deployed across Asia and Africa (Aarif KO *et al.,* 2024)]. Deep learning models enable artificial intelligence to predict irrigation requirements precisely which is apparent through studies that used neural networks in Brazilian soybean fields (Baio *et al.,* 202)]. Large-scale monitoring became possible through the data fusion of IoT information and satellite images and drones particularly in Canada's prairie farming region (Sishodia *et al.,* 2020). Cloud-based platforms operating in Japan and Germany use mobile apps to allow real-time processing and connect farmers to database resources (Zhang, 2024). Smart irrigation technologies continue to advance worldwide due to local research communities who work across multiple continents.

4. Challenges in AI and IoT-Based Smart Irrigation

4.1 Technical Challenges

The implementation of AI and IoT technologies for smart irrigation systems encounters substantial technological challenges in different areas and infrastructure networks. Sensor-driven data accuracy represents a crucial problem because environmental elements including dust in North African deserts and tropical Southeast Asian moisture can compromise sensor performance (Gualtieri, *et al.,* 2024). The connectivity issue is a major problem in regions with limited internet access like Sub-Saharan Africa since the area suffers from poor cellular network coverage that disrupts IoT data transmission (Onsomu, *et al.,* 2024). The high demands for data processing capacity from AI models create operational problems for developing countries because they do not have strong computing infrastructure or cloud access (Rehan, 2024). Research conducted in India showed real-time processing delays decreased irrigation efficiency by 15% in regions restricted by limited resources according to available findings (Nsoh, *et al.,* 2024). The technical obstacles serve as evidence that flexible systems that work well for different worldwide environments need to be developed.

4.2 Economic and Adoption Barriers

The integration of AI-IoT irrigation systems faces scalability limitations because of economic obstacles and challenges with adoption mainly affecting low-income agricultural economic settings. Poorest communities especially struggle to afford investment costs in IoT hardware coupled with AI software that can reach thousands of dollars per unit of cultivated land (Hambye & Desmet, 2021). Government aid programs in Latin American regions struggle to promote AI-IoT irrigation systems adoption because both maintenance costs and technical illiteracy prevent rural area adoption (McCarthy, *et al.,* 2024). The survey conducted in Eastern Europe revealed that 60% of farmers showed ignorance regarding smart irrigation advantages as they maintained a preference for traditional irrigation practices (Ricart & Rico-Amorós, 2021). Wealthier regions with technical proficiency such as North America as well as Western Europe receive the majority of digital technology uptake because of economic and social factors that create a divide between communities.

4.3 Environmental and Ethical Concerns

AI and IoT irrigation systems produce environmental as well as ethical concerns in addition to technical and economic challenges. The energy usage of IoT devices and AI computing requires significant power consumption that leads to carbon emission problems identified as main sustainability concerns in Scandinavia (Ruilova Alfaro, 2024). Data privacy poses an ethical problem for EU farmers since they are worried IoT devices transmit their information to external organizations under GDPR (Ryan *et al.,* 2024). The implementation of technology has encroached upon traditional farming wisdom in indigenous areas across Australia and South America, causing concern about cultural heritage maintenance (Bellwood, 2022). A fair balance needs to be established that connects smart irrigation systems to worldwide sustainability and fairness goals.

4.4 Scalability and System Maintenance Challenges

The deployment of AI and IoT irrigation systems on a large scale after successful tests faces logistical obstacles that become more difficult due to required maintenance work. Scalability is restricted because agricultural systems with different landscape variations prevent systems from successfully being implemented across multiple agricultural areas (Salpina, 2020). The Chinese national smart irrigation program encountered interoperability problems between different provinces because its IoT protocols remained unstandardized (Zeng *et al.,* 2025). Adoption becomes more difficult because remote areas like rural Mongolia and the Andean highlands lack technical support, while sensors and devices need regular maintenance procedures (Orlove *et al.,* 2024). A South African examination uncovered that 40% of IoT irrigation systems stopped functioning after two years because of poor maintenance practices, which underlines the requirement for such systems to have durable life cycles and low-maintenance provisions (Alharbi *et al.,* 2024). Smart irrigation faces sustainability threats throughout its extended application because of various obstacles that specifically affect resource-constrained and diverse agricultural regions.

5. Future Trends and Innovations

5.1 Emerging Technologies and Innovations

Smart irrigation with AI and IoT deployed by the following technological advancements will increase the efficiency and global adaptation of this system. Implementing AI predictive models equipped with deep learning and machine learning functions enables precise water need forecasting to control irrigation timings. Brazilian

soybean automation through neural networks cut water consumption by 20% in a solution suitable for Southern African rural areas (Silva *et al.,* 2024). The use of UAVs (drones) in crop monitoring leads to better real-time detection, which helped Canadian prairie farmers increase their wheat production by 15% (Al-Mallahi, 2024) and Kenyan small-scale farmers map maize fields at a reasonable cost (Wanyama *et al.,* 2021). The Dutch track water use by blockchain technology, while edge computing reduces response time at remote agricultural locations in Central Asia. Technology developments in South Korea advance 5G for quick irrigation control (Watts *et al.,* 2019). The Netherlands, along with the U.S., participates in blockchain and edge computing for data processing efficiency and security (Ahmed *et al.,* 2024). Smart irrigation technology is moving toward worldwide adoption due to recent innovative developments.

5.2 Research Directions

Scientists will tackle existing issues in research by building upon these emerging trends. The implementation of solar-powered IoT systems with renewable energy systems stands as a primary research priority because they helped Spanish olive farms conserve 40 percent of their energy costs and Ethiopian smallholder farmers received an additional 50 percent irrigation capacity (Mérida García, 2020; Tesfaye *et al.,* 2021). Solar IoT implementations in Sub-Saharan Africa help to decrease the carbon emissions of these systems (Mukisa *et al.,* 2022). Research teams in Bangladesh are developing affordable AI-Internet of Things kits that aim to give small farmers the power they need (Satapathy *et al.,* 2022), and AI software from Brazil predicts drought timing patterns compatible with Southern Africa (Chivangulula *et al.,* 2024). Through collaboration between agronomists and data scientists in Japan and Canada, researchers have found comprehensive answers (Suresh *et al.,* 2024). The established directions work to establish both sustainability and access to smart irrigation throughout agricultural locations with varied environments.

5.3 Policy and Industry Implications

The complete implementation of these innovations depends on strong support from both government policies and industrial organizations. Governments should provide financial support for solar-IoT systems. The German public-private partnerships build farmer-friendly platforms that serve as a model for European territories (Sjaf *et al.,* 2022). The adoption rate of drones and blockchain in industries continues to grow because Mexico established farmer training programs for UAV operation and IEEE developed universal IoT standards for Southeast Asia (Tiwari *et al.,* 2021; Wangere, 2024). International joint investments in AI and renewable energy research development are speeding up deployment worldwide through Chinese edge-blockchain pilot programs (Yang *et al.,* 2025). These initiatives guarantee that technology breakthroughs become practical benefits that reach all farmers justly across the board.

6. Discussion

6.1 Synthesis of Findings

Smart irrigation has experienced a revolutionary change because of AI and IoT implementation that has been proven through multiple case studies and research developments. Through the combination of IoT sensors with AI analytics systems and precision irrigation methods, water savings reached between 20-35% in Australian, Indian, and Spanish locations (Wei *et al.,* 2024) while drone-based farming and predictive analysis techniques improved agricultural productivity in North American and African territories (Guebsi & El Wai 2025). Several roadblocks, mainly stemming from technical difficulties regarding rural African internet connectivity combined with economic factors influencing Asian smallholders and European privacy rights, are preventing the widespread adoption of the proposals. The integration of solar-powered systems in Ethiopia, combined with blockchain solutions in the Netherlands, provides a solution for existing barriers, but China faces difficulties in achieving standardization following their deployment (Abiri *et al.,* 2023; Polymeni *et al.,* 2024). This work highlights two conflicting trends that show major potential restricted by continuing obstacles that affect different regions and resource amounts.

6.2 Implications for Stakeholders

The results deliver significant ramifications that affect stakeholders all over the world. The implementation of AI-IoT technology provides efficiency improvements to farmers yet necessitates affordable user-friendly solutions, which are vital for South Asian and Latin American small-scale farmers (Muhammed *et al.,* 2024). Water-scarce nations such as Morocco need policymakers to establish both training programs and financial aid schemes, which have proven successful in Israel (Tinazzi, 2024). The refinement of scalable and energy-efficient technologies requires research collaboration across different fields of study similar to Canadian research institutions (Neethirajan, 2024). The adoption of new agricultural technologies, such as edge computing in remote Central Asian regions, can be achieved through industry collaborations led by drone manufacturers and IoT developers, much like in Germany and by extending to Central Asian farms. The stakeholders must work together toward producing effective transformational outcomes from research through efforts that suit different agricultural settings.

6.3 Limitations of the Review

The review aims to be comprehensive; however, some restrictions need to be acknowledged. The majority of studies in English-language publications bias researchers against evaluating important research conducted in

Spanish or Chinese, which could hide valuable innovations from Latin America and East Asia. The examination of recent research during the last decade fails to include fundamental studies that established the framework for smart irrigation development. Successful case studies dominate the research due to published limitations since resource-limited areas, particularly Sub-Saharan Africa, often fail to report their unsuccessful implementations (Higginbottom et al., 2021). Further research should expand linguistic and geographical bounds in reviews to achieve full global representation of research.

Conclusion

Artificial Intelligence (AI) integration with the Internet of Things (IoT) brings substantial opportunities for global water shortage management and increased agricultural crop outputs. Predictive AI models and IoT monitoring, along with drone application, blockchain technology, and solar-powered systems, prove effective in water utilization optimization and increased yield production throughout Australia to Ethiopia. The extensive implementation faces multiple obstacles that include technical obstacles as well as financial hurdles and scalability problems and ethical issues which predominantly impact regions such as Sub-Saharan Africa and South Asia which have limited resources. The implementation of edge computing with 5G technology and renewable energy integration requires major combined work to achieve their future applications.

Technology in precision agriculture earns its value because it generates sustainable farming systems through precise management capabilities. Implementing these methodologies demands the elimination of the digital gap through affordable technology systems that support robust policies across the board. The authors propose that researchers should conduct more studies about energy-efficient, affordable agricultural system designs while improving collaborative work between agronomists and engineers along with policymakers. People across the world in agricultural roles alongside governmental organizations, scientific researchers, and industrial experts should join forces to lead this technology adoption. AI and IoT-based smart irrigation represent a vital opportunity in the present climate to protect both our food supply and environmental systems because water availability continues to decrease.

Acknowledgements

The authors express gratitude towards academic advisors and colleagues for contributing their knowledge to the development of this literature review. I express my gratitude to the research community, which gave us access to important studies and IoT and AI data regarding smart irrigation systems. The authors achieved their goal to submit this conference paper because of assistance and facility access from Abiola Ajimobi Technical University, Ibadan Oyo State, Nigeria. The authors accept responsibility for all potential mistakes or oversights within the document.

Mapping the Genetic Structure in Chicken Genomes Using SNP Chips: Perspectives on Conservation and Breeding

Gülsüm MANAV , Kemal ESKİOĞLU , Demir ÖZDEMİR

Department of Agricultural Biotechnology, Faculty of Agriculture, Akdeniz University, Antalya, Turkiye

Abstract

Rapidly increasing global human population has significantly raised the demand for high-quality and sustainable protein sources. In this context, chicken meat has a strategic importance in human nutrition due to its economic production efficiency, high nutritional value, and low environmental footprint. It is anticipated that meeting future protein requirements will largely depend on enhancing productivity and adopting sustainable poultry production systems. Therefore, accurately revealing the genetic potential of local chicken breeds is crucial, not only for increasing productivity but also for maintaining biological diversity. Understanding genetic structure and diversity among chicken breeds is essential for sustainable animal breeding programs and the conservation of local genetic resources. Recently, high-density Single Nucleotide Polymorphism (SNP) chip technologies have emerged as powerful tools for investigating genetic characteristics in chickens. This technology enables simultaneous analysis of thousands of SNPs, facilitating accurate and precise assessments of population structure, inbreeding levels, heterozygosity rates, and genetic differentiation indices (FST). Different SNP chip densities (e.g., 5K, 10K, 50K, and 100K SNP) are available, and their selection depends primarily on research objectives, genetic composition of populations, and budget considerations. These SNP chips offer a broad spectrum of applications, ranging from basic genetic diversity analyses to genome-wide association studies (GWAS). This review focuses on genetic analyses conducted in chickens using SNP chip technology and comprehensively evaluates current literature on comparative genomic profiling of local and commercial breeds. Additionally, it addresses methodological approaches, advantages, and limitations associated with widely-used commercial SNP chips, such as those provided by Illumina and Affymetrix. The strategic role of SNP data in identifying selection signatures, mapping homozygous a critical component not only at the molecular level but also in applied animal breeding policies.

Key Words: *SNP chip, Chicken genomics, Genetic diversity, Phylogenetics, Conservation of genetic resources*

Tavuk Genomiğinde SNP Chip Kullanımı ile Genetik Yapının Haritalanması: Koruma ve Islah Perspektifi

Özet

Küresel ölçekte insan nüfusunun hızla artması, kaliteli ve sürdürülebilir protein kaynaklarına olan talebin giderek yükselmesine neden olmaktadır. Bu bağlamda tavuk eti, ekonomik üretim avantajları, yüksek besin değeri ve düşük çevresel ayak izi ile insan beslenmesinde stratejik bir konuma sahiptir. Gelecekte beklenen protein ihtiyacının karşılanması ise tavuk üretiminde verimliliğin artırılması ve sürdürülebilir üretim modellerinin benimsenmesi ile mümkün olması düşünülmektedir. Bu nedenle, yerli tavuk ırklarının genetik potansiyelinin etkin bir biçimde ortaya çıkarılması, hem verimlilik artışı sağlanması hem de biyolojik çeşitliliğin korunması açısından büyük önem taşımaktadır. Tavuk ırklarının genetik yapılarını ve çeşitliliklerini anlamak, sürdürülebilir hayvan ıslahı programları ve yerel genetik kaynakların korunması için elzemdir. Son yıllarda, tavuklarda genetik yapının ortaya çıkarılmasında yüksek yoğunluklu tek nükleotid polimorfizm (SNP) chip teknolojileri güçlü bir araç olarak öne çıkmaktadır. Bu teknoloji, binlerce SNP eş zamanlı olarak analiz ederek, populasyon yapısı, inbreeding düzeyleri, heterozigotluk oranları ve genetik farklılaşma indeksi (FST) gibi parametrelerin güvenilir ve hassas biçimde belirlenmesini mümkün kılmaktadır. SNP chip teknolojisinde farklı yoğunluklardaki SNP chip (5K-10K-50K-100K) kullanılmakta olup, chip yoğunluklarının seçiminde çalışma amaçları, popülasyonların genetik yapısı ve araştırmanın bütçesi gibi kriterler belirleyici olmaktadır. Farklı yoğunluktaki SNP chip, temel genetik çeşitlilik analizlerinden genom çapında ilişkilendirme (GWAS) çalışmalarına kadar geniş bir uygulama alanı sunmaktadır. Bu derleme çalışması, tavuklarda SNP chip teknolojisiyle gerçekleştirilen genetik analizlere odaklanarak, yerli ve ticari ırkların genomik yapılarını karşılaştırmalı olarak değerlendiren güncel literatürü incelemektedir. Ayrıca Illumina ve Affymetrix gibi yaygın kullanılan ticari SNP chip avantajları, sınırlılıkları ve veri analizinde kullanılan metodolojik yaklaşımlar kapsamlı şekilde ele alınmaktadır. Seleksiyon kriterlerinin belirlenmesi, homozigot bölgelerin haritalanması ve koruma genetiği uygulamalarında SNP verilerinin stratejik rolüne dikkat çekilmekte, SNP chip teknolojisinin moleküler düzeyin yanı sıra uygulamalı hayvancılık politikaları açısından da kritik bir bileşen olduğu vurgulanmaktadır.

Anahtar Kelimeler: *SNP chip, Tavuk genomiği, genetik çeşitlilik, filogenetik, Genetik kaynakların korunması*

Adoption of Good Agricultural Practices (GAP) by Vegetable Farmers for Safe Food: An Empirical Study on Dinajpur District

Rubayet Noman[1], Shahana Yeasmin[2]
[1]Department of Agricultural Extension, Faculty of Agriculture, Hajee Mohammad Danesh Science and Technology University, Dinajpur, Bangladesh
[2]Cotton Development Board, Ministry of Agriculture, Govt. of the People's Republic of Bangladesh

Abstract
In order to produce safe and healthy food and agricultural products, Good Agricultural Practices (GAPs) are a set of guidelines that should be followed during the production process on farms as well as during post-production, all the while considering the sustainability of the economy, society, and environment. Therefore, the research focus was to determine the extent of awareness and adoption of Good Agricultural Practices (GAPs). A mixed method was followed during conducting the study. A sample of 120 vegetable farmers were selected by following simple random sampling technique and by following proper sampling formula. Data were collected by a pre-tested interview schedule during 01 January to 31 May 2024 by face-to-face interview method. Descriptive statistics as well as inferential statistics like Pearson Product Moment Correlation Coefficient analysis were followed. Findings reveals that more than half of the respondents (56.7%) had medium awareness level on GAP while majority (65.0%) of the vegetable farmers had low level of adoption of Good Agricultural Practices in vegetable cultivation. Factors such as area under cultivation, experience, training received, market perception, environmental orientation, and extension contact demonstrated a positive and significant relationship, underscoring the importance of these elements in enhancing GAP adoption among farmers. The most important constraint is increased difficulty in management of pest and disease incidence having mean score of 2.7.

Key Words: GAP, Adoption, Vegetable farmer and Safe food

Introduction

In Bangladesh, agricultural sector is gradually changing from subsistence agriculture to commercial agriculture. In view of producing more food as well as increasing crops production for growing population, high yielding and hybrid varieties of crops are being used with excessive chemical fertilizers and pesticides. Sometimes organic fertilizer that contained heavy metals or chemicals harmful to human health are also used. Good Agricultural Practices (GAPs) addresses the environmental, economic and social sustainability issues for safe and quality food and non-food agricultural products like vegetables.

The demand for quality and safety in vegetables has led to the development and promotion of common principle and standards for cultivation, often referred to as Good Agricultural Practices (GAP) (Guddanti, 2015). Considering the availability of safe food, it is very important to follow Good Agricultural Practices (GAP) from the beginning of production, harvest and post-harvest processing, such as collection from field, packaging, transportation etc. to ensure safe food. The GAP is a set of principles that apply to the farm production and post-production processes to produce safe and healthy food and non-food agriculture products, considering economic, social, and environmental sustainability (Hobbs, 2003). Adoption of GAP could increase farm income by 6.2% and decrease the use of synthetic fertilizers by 31% for rice, lentil, tomato, and ginger in Nepal (Bairagi et al., 2019). Many developed countries, such as Denmark, Australia, and the United States have adopted the GAP package for integrated pest and nutrient management for decades (Waage ,1998; Zalucki et al., 2009; Remac, 2018). In Turkey, GAP has been implemented as an alternative to organic farming (Akkaya et al., 2005). Also in several Asian countries such as Nepal, India, Indonesia, Malaysia, Philippines, and Thailand, the GAP system has been implemented particularly in vegetable farming, focusing more on integrated pest and soil fertility management. GAP use is practical in wide categories of farming system of different scales through improved sustainability by integrated pest, weed and disease management, soil and water conservation, and fertilizer management (Ntshangase et al., 2018). Good Agricultural Practices are desirable increased productivity and improved quality (Dudeja and Singh, 2018).

Safe food is becoming increasingly important in terms of human health and economic aspects. Safe food production is urgent because of the competition in the global export market, as well as protecting people from food bound illness. Indiscriminate use of pesticides and chemical, presence of heavy metals, infection s of microorganism etc. from the early stages of production to various stages of food chain made food unsafe. That is why, considering the availability of safe food, it is very important to adopt Good Agricultural Practices (GAPs) from the beginning of production, harvest, and post-harvest processing such as collection from field, packaging,

transportation etc. to ensure safe food. In Bangladesh especially in the proposed study areas if the adoption of GAPs is ensured, then the vegetable produce will be safe, improved and of good quality, sustainable environment and social acceptance will be increased with income growth and economic momentum, and food and nutrition security will be ensured.

Therefore, it is really very necessary to adopt GAP for the production of vegetable for ensuring the quality of vegetable to export. Good Agricultural Practices (GAP) minimize food safety risk. However, its poor implementation along the vegetable production chain is a challenge. GAP, if carefully implemented ensures that farmers can obtain highly nutritional, good quality vegetables with higher market access. Well-managed GAPs have proven to be effective in the reduction of risks of vegetable contamination in agricultural production.

Therefore, it is necessary to have a clear understanding of the present status of the adoption of Good Agricultural Practices. The main purpose of the study is to have an understanding of the adoption of Good Agricultural Practices by the vegetable farmers in vegetable cultivation.

The proposed research study is designed by considering the following framed out specific objectives:

i) To determine the extent of awareness on Good Agricultural Practices (GAPs) in vegetable cultivation among the farmers.

ii) To assess the extent of adoption of Good Agricultural Practices (GAPs) by the vegetable farmers.

iii) To explore the relationship of the selected characteristics of the vegetable farmers on the adoption of Good Agricultural Practices (GAPs).

iv) To identify the confronted constraints of the vegetable farmers while implementing the Good Agricultural Practices (GAPs) in their field.

Review of Literature

Kharel et al. (2023) revealed that farmers were adopting different GAP, such as cropping practices, livestock integration, soil fertility management practices, and integrated pest management practices. Upon adopting these practices, farmers reduced agrochemicals' use by more than 40%. The critical incentives for surveyed farmers to adopt GAP were soil health improvement, farmers' safety, and reduction in the use of agrochemicals while improving the farm's image. Sunny et al. (2022) revealed that farmers' age, land typology, soil water retention, knowledge, and availability of cow dung significantly influenced Boro rice farmers' adoption decisions of recommended fertilizer doses. Chaudhary (2022) revealed that more than one half (57.50%) of the farmers were having medium adoption of good agricultural practices. Cherotich (2021) reported that a majority of the vegetable growers were unaware of GAP standards for vegetable production, with many deviating from the expected standards in their vegetable production activities. Most of the vegetable growers identified production costs, market exclusivity, training, government support, and access to labor as the key determinants to the use of GAP in their activities. It is also revealed that behavioural intention to adopt GAP by vegetable growers is predicted by attitude, subjective norms, and perceived behavioural control. Nagadevi (2021) explored that overall adoption index of GAP in vegetable cultivation was found to be medium (73.21). The adoption score on components of GAP viz. land preparation and soil management (79.56) and harvesting and post-harvest handling (81.05) was high, while that on seed quality parameters, sowing and intercultural operations, nutrient management and plant protection measures were medium. The component that had lowest level of adoption score was irrigation management and drainage (54.04). Thenuwara and Malknthi (2020) explored that most vegetable farmers in the Galle district have a general level of awareness on GAP and a positive attitude towards the GAP programme. However, most farmers do not adopt the GAP, and some farmers lack the required amount of information, technical know-how, inputs, capital, labour and require field conditions to practice GAP, even though thy wish to practice it. According to the results, awareness of GAP, GAP certification, and the awareness of the importance and benefits of GAP were the significant factors affecting the adoption of GAP by vegetable farmers. Joshi et al. (2020) revealed that GAP related to soil management and fertilization (87.4%) and harvesting and on-farm processing (94.2%) is adopted at a low level. Laosutsan et al. (2019) identified and investigated the factors influencing the adoption of good agricultural practices (GAP) and revealed that the income variable is the most influential factor in the GAP adoption by participating vegetable farmers. They also found that effectively increase the GAP adoption rate among the Thai vegetable growers, the exporters and relevant government agencies could make GAP certification compulsory. Pandit et al. (2017) revealed that awareness and the adoption of the critical GAPs in basmati production system was at lowest ebb, whereas the benefits of adoption were well understood by the farmers. Awareness level of farmers about Good Agricultural Practices in basmati rice was found to be 58.33%, whereas adoption was only 27.41% which is even less than half of awareness level. Srisopaporn et al. (2015) revealed that adoption and dis-adoption are highly related to household labour constraints, land ownership, and initial high expectations regarding the market opportunities of the GAP produced rice. They found several encouraging differences between non-adopters and first-time adopters, indicating better pest and nutrient management. Although they observed an important rate of dis-adoption, they also determined that farmers are maintaining those better practices even after abandoning the program. Banzon et al. (2013) revealed that a high level of GAP adoption in the Davao banana industry primarily because of the predominance of corporate farms in

the area that cater to the export markets. Athipanyakul and Pak-Uthai (2012) revealed that significant effect on program participation and farmer's knowledge that was the precursor of adoption. Farmers' experience in chili production significantly affected adoption. Age was a negative determinant of adoption. Adoption of knowledge-intensive technologies such as GAP needs an effective approach such as the participatory research program, which can improve farmers' knowledge and encourage them to adopt innovative technologies

Methodology

A mixed-method approach, combining quantitative and qualitative methods was adopted for the study, which includes farmers' surveys, key informant interviews, and in-depth interviews (Kharel et al., 2023).

Locale of the study

The proposed research study was conducted at the two upazilas namely Birol and Birganj under Dinajpur district as in these areas a plenty of vegetables are cultivated which is not only fulfil the local market demand but also export in the abroad. The proposed study areas are given in the Figure 1.

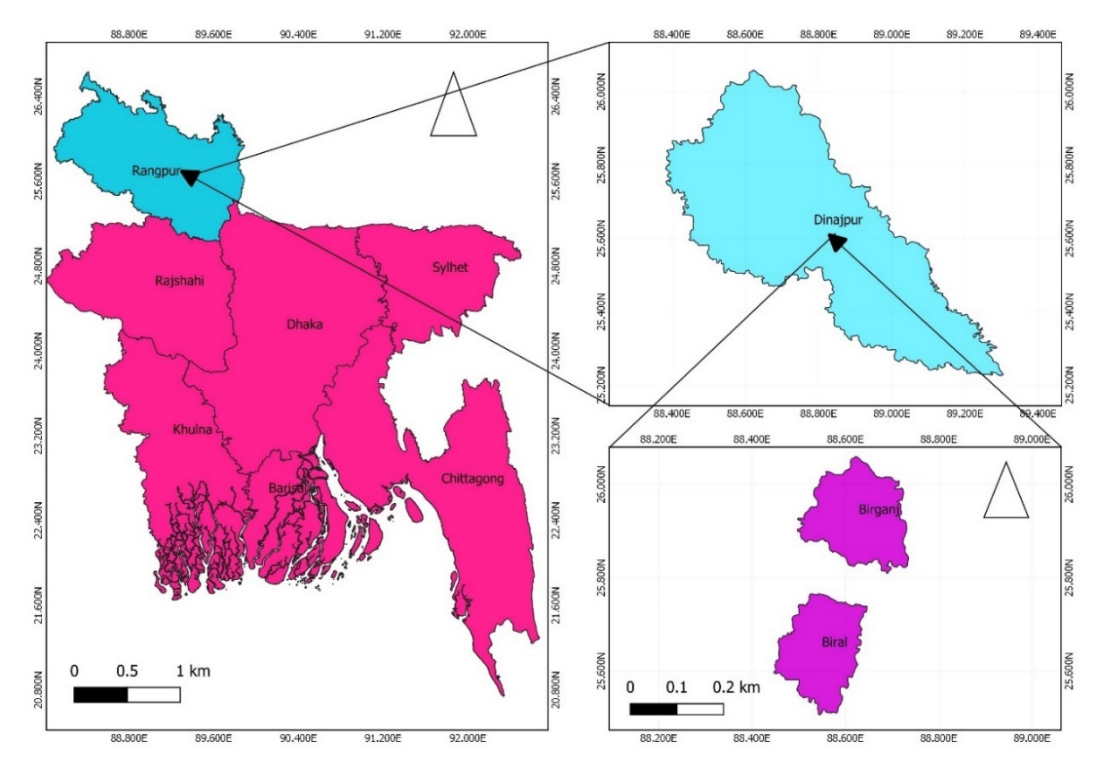

Figure 1. Map of the proposed study areas (prepared by using QGIS software)

Description of the study areas

Dinajpur is a district in the Rangpur Division of northern Bangladesh. It is the largest district among all sixteen northern districts of Bangladesh. Total area 3437.98 km^2, located in between 25°10' and 26°04' north latitudes and in between 88°23' and 89°18' east longitudes. Dinajpur experiences a hot, wet and humid tropical climate. Under the Koppen climate classification, Dinajpur has a tropical wet and dry climate. The district has a distinct monsoonal season, with an annual average temperature of 25 °C (77 °F) and monthly means varying between 18 °C (64 °F) in January and 29 °C (84 °F) in August. The economy of Dinajpur mainly depends upon agriculture-based production. There is a well-known proverb about Dinajpur – 'paddy piled up high, sheds full of cows, ponds brimming with fish' [*gola bhora dhan, goyal bhora goru, pukur bhora mach*]. People in this district are much happier than those in other districts, everything grows easily, it's a peaceful place. It grows a plenty of vegetables and seasonal fruits. Crops and grown in the district include rice, wheat, maize, potato, brinjal, and tomato.

Population and sampling

Vegetable farmers of the proposed study areas was the population of the study. An appropriate sample and reserve list was determined to avoid the uncertainty related with the availability of samples during data collection. Considering the study is intending to have statistically significant and comparable set of results for the study areas, sample size for the research was calculated using the following formula (Kothari, 2004):

$$n = \frac{Z2PQN}{(n-1)e2 + z2pq}$$

Where,
n= Sample size
Z= 1 the value of the standard normal variable at the chosen (95 percent) confidence level (1.96)
P= Probability (assume 0.5)
Q = Remaining from probability (1-P)
N = Total population
e = the level of precision (5 percent)

By using the above formula, the sample size of 120 vegetable farmers was found from a population list of 175, 60 from each selected upazila Birol and Birganj was selected by following simple random sampling techniques, respectively. Beside this, a reserved list of 12 farmers was prepared who were supposed to be interviewed only when a respondent in the original sample list was unavailable during data collection.

Measurement technique of the variables

The personal and socio-economic characteristics was selected by reviewing the relevant documents related to the present study and proper statistical techniques was followed to measure them.

Adoption of improved vegetable cultivation practices by the vegetable farmers was the focus issue of this research study. It was measured by using five-point rating scale. The respondents was requested to make response on their adoption of GAP related to vegetable cultivation. The score of the five-point rating scale against each of the GAP was given as follows:

Extent of adoption	Score assigned
Regularly (≥ 4 times in last 4 years)	4
Frequently (3 times in last 4 years)	3
Occasionally (2 times in last 4 years)	2
Rarely (1 times in last 4 years)	1
Not at all (0 times in last 4 years)	0

Based on the possible score range the respondents of the study was categorized as 'Low adoption', 'Medium adoption' and 'High adoption'. Similar measurement technique was followed by (Mou, 2015).

Adoption score= Score obtained by the vegetable farmers/Maximum possible score× 100

Awareness of GAP in vegetable cultivation will be operationalized as the information available to the vegetable growers about GAP in vegetable cultivation. To determine awareness, an audit checklist will be developed with reference to FAO, bgGAP recommendations, which captured farmers' awareness and compliance to GAP standards.

Awareness was measured through rating on a 3- point rating scale ranging from 2 for 'fully aware', 1 for 'partially aware', and 0 for 'not aware' developed by (Cherotich and Kaur, 2021). The respondents was categorized into the following three categories as none, partial, and full based on their observed score. Awareness score was calculated by using the following formula:

Awareness score= Score obtained by the farmers/Maximum possible score× 100

Confronted constraints of the vegetable farmers while implementing the GAP in their field level was measured by asking the question to the sampled farmer. In this regard, farmers were asked to assess how difficult it was for them to adopt good agricultural practices on a three-point scale of most serious, serious and least serious, with weights 3, 2 and 1 was assigned to each response.

Data collection techniques

Both quantitative and qualitative techniques was used for this research study. The flow chart of the data collection technique was followed as given below:

Preparation and administration of data collection tools

Data collection tool is a device which is used to collect the data. The interview schedule and checklist was developed on various aspects of the objectives considered in the present study. An interview schedule was prepared to collect quantitative data, while a checklist was prepared used in eliciting qualitative data through Focus Group Discussions (FGDs). Experts was employed to improve the content validity of the interview schedule and checklists for qualitative data collection. Reliability of the tools was also tested by Cronbach's alpha. Prior to the actual conduct of research, both the interview schedule and the checklist was pre-tested in similar socio-economic condition.

Statistical method employed for data analysis

Statistical analysis of quantitative data is an important aspect of research work, as it facilitates the condensation and interpretation of collected data in simple form helps in predicting future trends, helps in establishing relationship between different variables and provides sound base of policy formulation. After data collection, the data was input concerned SPSS 25.0 version data analyzing software. Then the normality of the data was tested and if any outlier present was removed. Data was analyzed in the light of the objectives set forth for the proposed study. Different types of statistical techniques like frequency, percentage, mean, standard deviation, ranking,

coefficient of correlation, was used for data analysis. The qualitative information and quantitative data analysis was performed separately, and their findings was synthesized for triangulation.

Data analysis plan

The collected data was analyzed using computer software like SPSS 25.0 version. The primary unit of analysis of the study was individuals, with results summarized for the study areas.

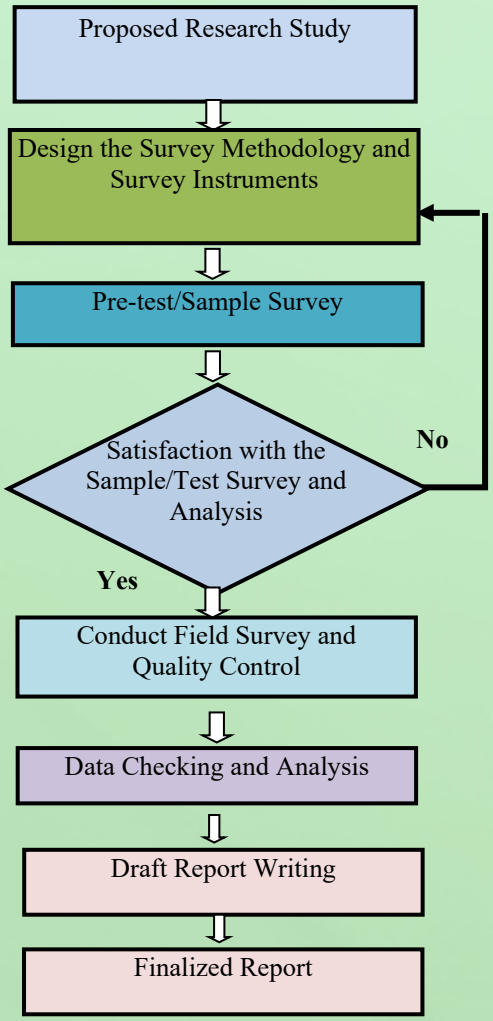

Figure 2. Flow chart for data collection

Results and Discussion

Selected characteristics of the respondents

Age

The age group of the vegetable farmers of the study areas included in the present study is given in Figure 3. It could be observed that more than half (58.3%) of the farmers fall under middle aged group of 36 to 50 years followed by exactly one-fourths of the respondents (25.0%) belonging to young aged category and only 16.7% of the vegetable farmers belong to the old aged category of above 50 years.

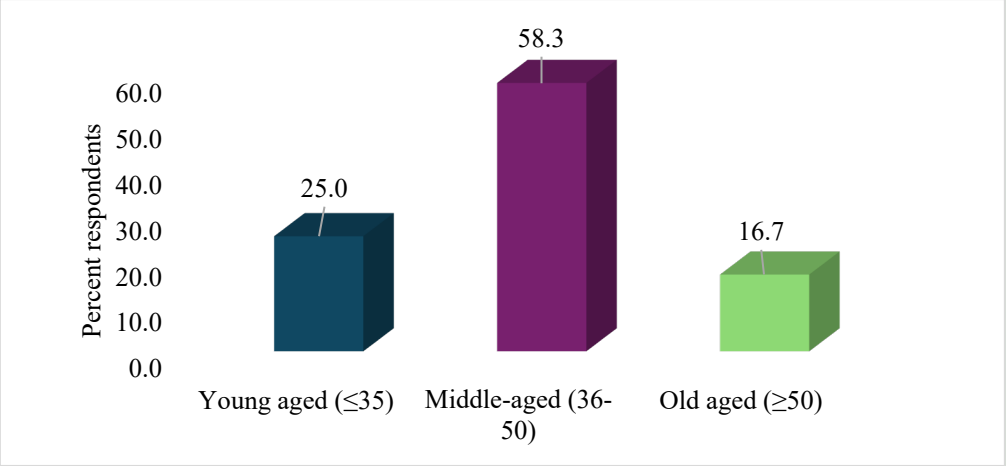

Figure 3. Distribution of the respondents according to their age

This indicates that all the age groups of the farmers were engaged in vegetable cultivation in the study areas. The results are found to be in tune with the natural trend of majority of the farmers under young to middle aged category as young are getting engaged in agricultural entrepreneurships.

Education

Educational qualification is regarded as an instrument of change and transformation of society. Education can be seen in the emancipation of women from the patriarchal society.

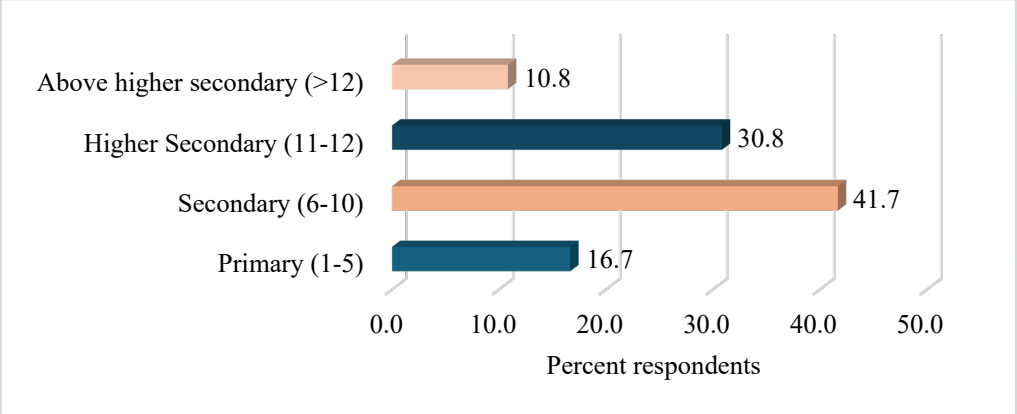

Figure 4. Distribution of the respondents according to their education

Findings presented in the Figure 4 show that majority (41.7%) of the farmers fall under secondary education category followed by one-third of the respondents (30.8%) belonging to higher secondary category, 16.7% of the vegetable farmers belong to the primary education category and only 10.8% are educated above higher secondary.

4.1.3 Area under vegetable cultivation

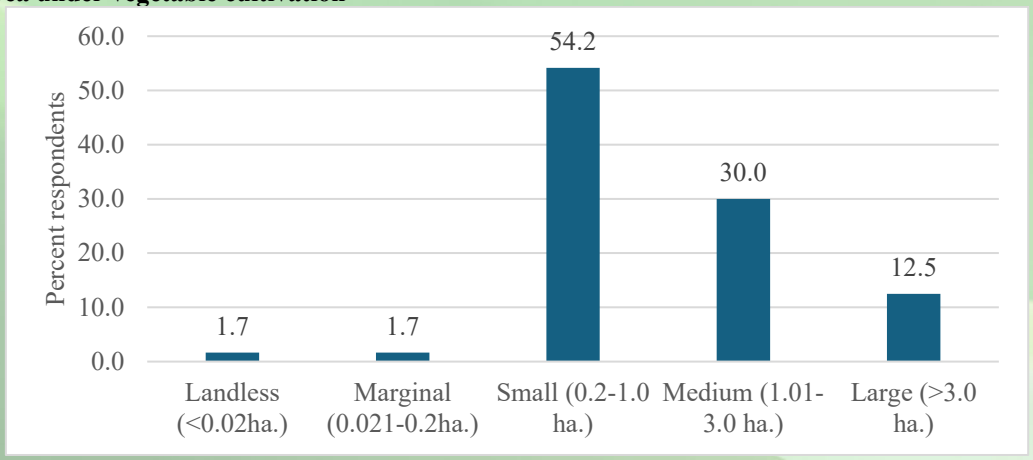

Figure 5. Distribution of the respondents according to their area under vegetable cultivation

The analyzed data in Figure 5 shows the distribution of vegetable farmers based on the area under vegetable cultivation. The categorization as made with five categories of landholding size (hectare) under vegetable cultivation. It is evident from Figure 5 that just more than half (54.2%) of the vegetable farmers fell under the group of land holdings 0.2 to 1.0 ha. whereas 30% of the farmers fell under the group of landholdings 1.01 to 3.0 ha, 12.5% fell under large land holding while only a negligible portion of the farmers i.e. 1.7% equally fell under landless and marginal landholding categories respectively.

4.1.4 Experience in vegetable cultivation

The vegetable farmers were grouped into three categories based on their experience in vegetable cultivation as given in Figure 6. The majority of the farmers (54%) had more than six years of experience in vegetable cultivation. Exactly one-fourths (25%) of the respondents had experience of 5-6 years while only 21% had experience of up to 4 years. The probable reason of the findings might be that the major crops cultivated in the study areas are vegetable.

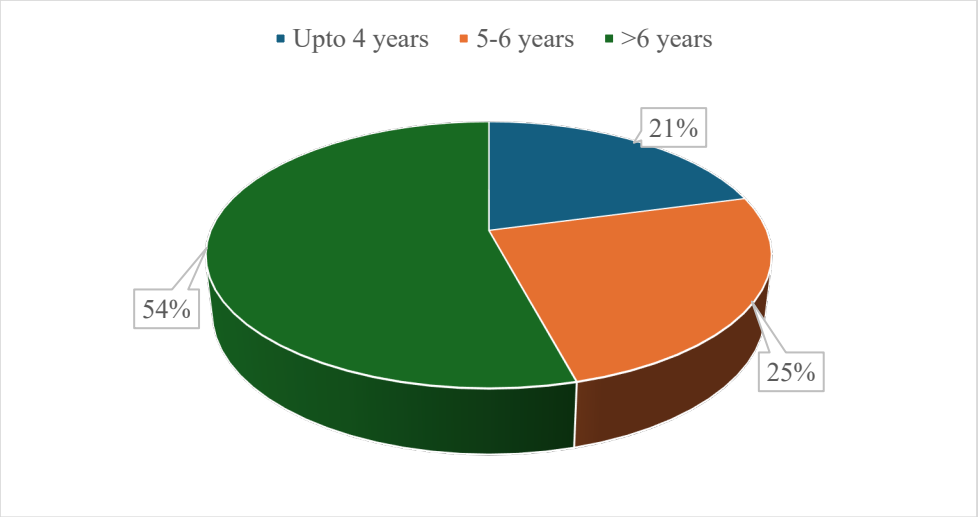

Figure 6. Distribution of the respondents according to their experience in vegetable cultivation

Training received

The expertise of an individual is enhanced by training and improves their skills, knowledge, and even attitude. Based on training received on, the vegetable farmers have been categorized as shown in Table 1.

Table 1. Distribution of the respondents according to their training received

Categories (Days)	Percent respondents
Low (1-2 days)	79.2
Medium (3-4 days)	12.5
High (>4 days)	8.3
Total=	100.0

More than three-fourths (79.2%) of the vegetable farmers were fell under low training received category followed by only 12.5 percent fell under the training received category of 3 to 4 days while only a vey negligible portion of the farmers i.e. 8.3% fell under high training received category i.e. more than four days.

Annual income

In a society individual levels of status determine by different factors, among them money is the most powerful, influential, and potential component. It is well known that the higher is the income of a family, the greater control over the society by the family. Family annual income is an important variable for explaining the economic characteristics of vegetable farmers.

Findings presented in the Figure 7 shows that more than half (58.3%) of the vegetable farmers fall under medium income category followed by exactly one-fourths of the respondents (25.0%) belonging to low-income category, 16.7% of the vegetable farmers belong to the high-income category.

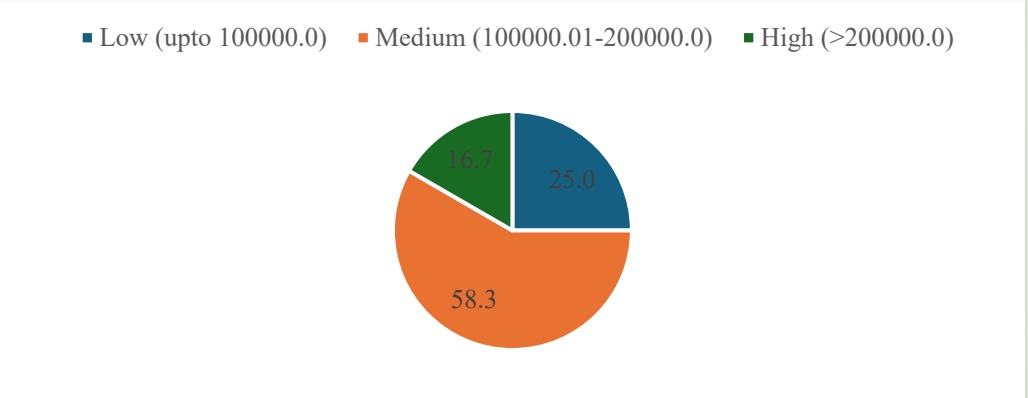

Figure 7. Distribution of the respondents according to their annual income

Market perception

The result in Figure 8 showed that the distribution of the vegetable farmers based on their market perception. It could be observed that about half (49.2%) of the farmers had medium level of market perception followed by just more than one-third (34.1%) of the respondent had low market perception and only 16.7 percent of the vegetable farmers had high level of market perception.

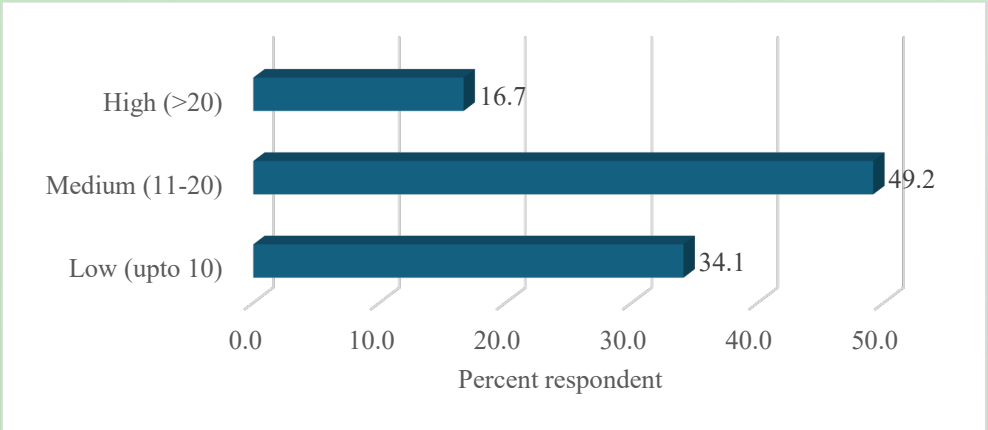

Figure 8. Distribution of the respondents according to their market perception

The possible reason for this finding might be that the vegetable farmers are more concerned about the market opportunities available for vegetables and the possibility to get remunerative price for GAP vegetables.

Environmental orientation

It could be inferred from the result in Figure 9 that exactly half (50.0%) of the respondents had low level of environmental orientation followed by 32.5% of them had medium and only 17.5 percent of the respondent had a low level of environmental orientation.

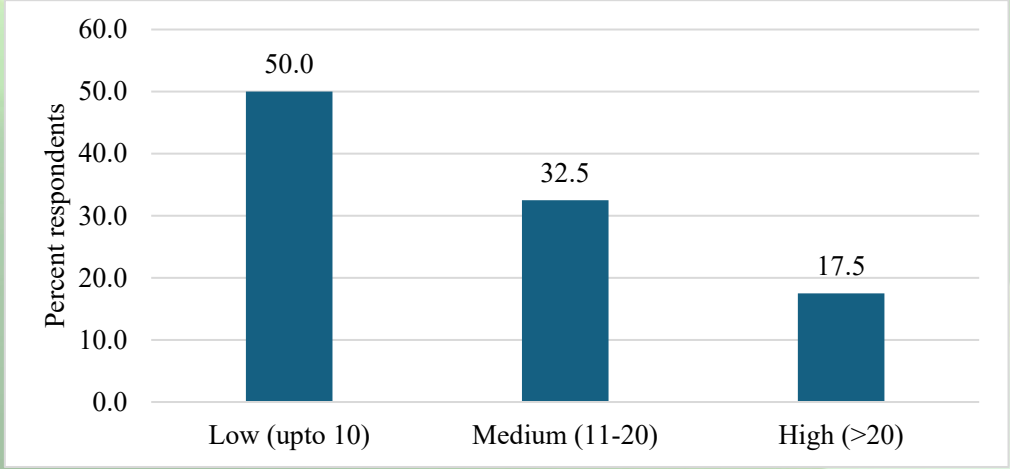

Figure 9. Distribution of the respondents according to their market perception

The probable reason for such finding might be that the higher educational level of the farmers which contributed towards achieving high environmental orientation among vegetable farmer.

Extension contact

The findings in Figure 10 showed that just about half (49.2%) of the vegetable farmers had medium extension contact followed by exactly one-third (33.3%) had low level and only 17.5% had high level of extension contact.

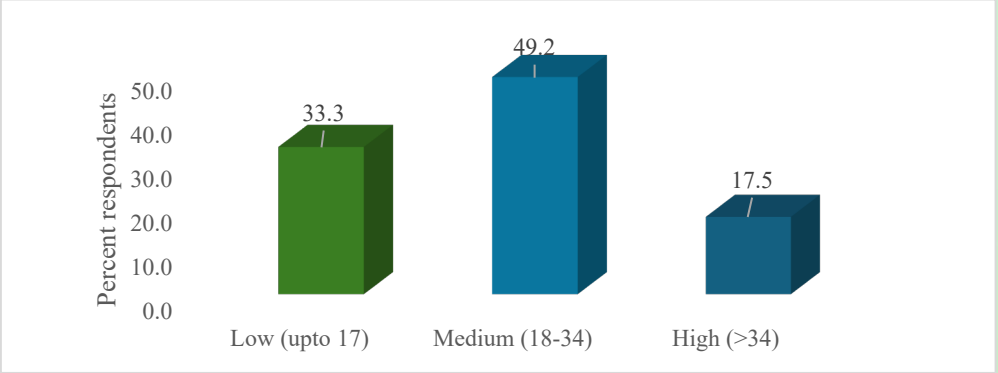

Figure 10. Distribution of the respondents according to their extension contact

The possible reason behind this finding might be that selected respondents from the study areas are the beneficiaries of CIG group members of DAE and majority of the farmers had frequent contact and interaction with the officials of different public and private level extension organizations like DAE, Ministry of Agriculture, Bangladesh.

Awareness on Good Agricultural Practices (GAP) on vegetable cultivation

The extent of awareness of vegetable farmers on various Good Agricultural Practices in vegetable cultivation is discussed below. Table 2 reveals that the distribution of the vegetable farmers based on their awareness level on GAP.

Table 2. Distribution of the respondents according to their awareness score

Awareness categories (Score)	Number	Percent	Mean	SD
Low (up to 51.0)	32	26.7	61.28	10.22
Medium (52-71.0)	68	56.7		
High (>71.0)	20	16.6		
Total=	120	100.0		

It could be inferred that more than half of the respondents (56.7%) had medium awareness level on GAP, 26.7% had low level of awareness and only 16.6% of them had high level of awareness on Good Agricultural Practices (GAP).

Component wise awareness level on GAP among vegetable farmers

The findings of Table 3 shows component-wise awareness level on GAP among vegetable farmers. It could be observed that GAP components like pest and disease management gained high range of awareness score. Awareness score of GAP component land and soil preparation (55.2), nutrient management (52.3), harvesting and post-harvest handling (60.1) were found to be medium level.

Table 3. Component wise awareness level on GAP among vegetable farmers

Sl. #	Component wise awareness score	Awareness score
1.	Land and soil preparation	55.2 (Medium)
2.	Seed / seedling quality parameters	48.8 (Low)
3.	Sowing/transplanting parameters	49.1 (Low)
4.	Nutrient management	52.3 (Medium)
5.	Irrigation management	40.5 (Low)
6.	Pest and disease management	71.5 (High)
7.	Harvesting and post-harvest handling	60.1 (Medium)

Good agricultural practices awareness score on the practices like seed/seedling quality parameters (48.8), sowing/transplanting parameters (49.1) and irrigation management (40.5) were found to be low.

The findings means that the vegetable farmers of the study areas had not a fairly well awareness about Good Agricultural Practices, therefore, it could be inferred that they are not fully aware about all the aspects of GAP.

Adoption level of Good Agricultural Practices (GAP)

The findings revealed in Figure 11 indicated that majority (65.0%) of the vegetable farmers had low level of adoption of Good Agricultural Practices in vegetable cultivation while 26.7% of the study respondent had medium and only a negligible portion of the respondents had low level of adoption.

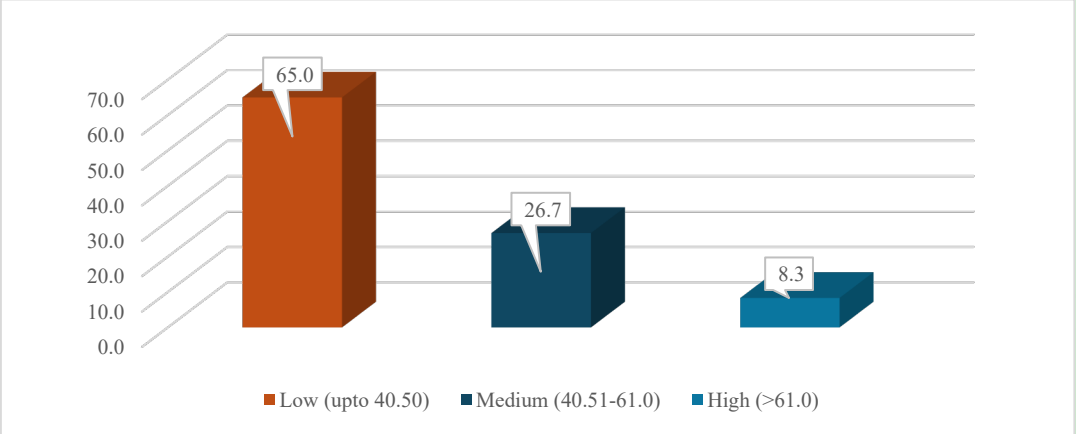

Figure 11. Distribution of the respondents according to their extension contact

The possible reason for such types of findings might be that in the study area, the Good Agricultural Practices are very new idea among the farmer's level. DAE, under the Ministry of Agriculture just started different awareness creation as well as GAP dissemination activities among the farmers. Farmers are gradually getting aware along with adopting different GAP components for cultivation of vegetables by considering environmental as well as in broad context sustainability issue of production of vegetables.

Component wise adoption level of GAP among vegetable farmers

The extent of adoption of Good Agricultural Practices among vegetable farmers was measured with adoption score values. Among the listed seven components of GAP, pest and disease management (61.5) gained highest range of adoption score. The probable reason might be that farmers were benefitted form the adoption of Good Agricultural Practices related to pest and disease management.

Table 4. Component wise adoption level of GAP among vegetable farmers

Sl. #	Component wise adoption score	Adoption score
1.	Land and soil preparation	50.1 (Medium)
2.	Seed / seedling quality parameters	39.5 (Low)
3.	Sowing/transplanting parameters	38.1 (Low)
4.	Nutrient management	45.3 (Medium)
5.	Irrigation management	36.5 (Low)
6.	Pest and disease management	61.5 (High)
7.	Harvesting and post-harvest handling	59.1 (Medium)

It was also found that adoption score for remaining practices viz. land and soil preparation (50.1), nutrient management (45.3) and harvesting and post-harvest handling (59.1) had gained medium level of adoption score. Whereas seed / seedling quality parameters (39.5), sowing/transplanting parameters (38.1) and irrigation management (36.5) gained low level of adoption among the vegetable farmers in the study areas.

Association between extent of awareness and extent of adoption of Good Agricultural Practices by vegetables farmers

For more clarity about the extent of awareness and extent of adoption of GAP, an association between extent of awareness and extent of adoption of GAP situation of the vegetable farmers is presented in Table 5.

Table 5. Awareness and adoption of Good Agricultural Practices by the vegetable farmers

Extent of awareness	Extent of adoption			Adoption Indices	χ2-value
	Low (up to 40.50)	Medium (40.51-61.0)	High (>61.0)		
Low (up to 51.0)	75.8	21.2	3.0	127.3	82.54**
Medium (52-71.0)	78.4	9.8	11.8	133.3	
High (>71.0)	36.1	41.7	22.2	186.1	

** Significant at the 0.01 level of probability, df=4

Analysis of data contained in Table 5 indicates that there were appreciable variations in the level of adoption of GAP by vegetable farmers according to the variations in their extent of awareness. Percentage of farmers with low adoption of GAP was the highest (75.8%) in the low awareness category compared to 78.4% in the medium category and 36.1 percent in the high adoption category. Proportion of the farmers with high adoption was highest (22.2%) in the high awareness category, compared to 11.8% in the medium awareness category and only 3.0% in the low awareness category. These variations were statistically significant at 0.01 level of probability as indicated by the chi-square value of 82.54.

In view of the above findings the null hypothesis was rejected and it was concluded that there is a relationship between the awareness among the farmers and level of adoption of GAP. The adoption indices indicate that the adoption consistently increased from the low awareness category to the high awareness category. Hence, the relationship was positive. The finding indicates that awareness about GAP among the farmers helps to improve their adoption of different components of GAPs.

Relationship between selected characteristics of the respondents and adoption of GAP

This section deals with the relationship between the nine selected characteristics of the respondents and adoption level of GAP by vegetable farmers. The relationships were computed by using the Pearson's product moment correlation co-efficient. The co-efficient of correlation (5% level) was used to test the null hypothesis and analysis is presented in Table 6 as follows.

Table 6. Relationship between selected characteristics of the respondents and adoption of GAP

Focus Issue	Selected Characteristics	Pearson's Product Moment Correlation Coefficient (r) at 118 df
Adoption of GAP by the vegetable farmers	Age	0.086ns
	Education	0.038ns
	Area under vegetable cultivation	0.275**
	Experience in vegetable cultivation	0.474**
	Training received	0.290**
	Annual income	0.040ns
	Market perception	0.365**
	Environmental orientation	0.294**
	Extension contact	0.374**

According to the computed correlation coefficients among the nine selected characteristics of the farmer's age, education, and annual income had no significant relationship with the adoption of GAP by the vegetable farmers. On the other hand, area under vegetable cultivation, experience in vegetable cultivation, training received, market perception and Environmental orientation and extension contact had positive significant relationship with adoption of GAP by the vegetable farmers.

Constraints faced by the farmers in adoption of Good Agricultural Practices (GAPs) in vegetablecultivation

It is evident from the Table 7 that the most important constraint is increased difficulty in management of pest and disease incidence having mean score of 2.7.

Table 7. Item wise constraints faced by the farmers in adoption of Good Agricultural Practices (GAPs) in vegetable cultivation

Constraints	Mean score	RO
Lack of awareness of good agricultural practices	2.5	4th
Lack of knowledge in use of good agricultural practices	2.6	2.5nd
Lack of technical guidance	2.3	6th
Lack of market knowledge	2.4	5th
Lack of local market demand	2.2	7th
Lack of better pricing for GAP	2.6	2.5nd
Increase in cost of production of Good Agricultural Practices	2.0	9th
Decline in income during conversion of conventional farming to good agricultural practices	1.9	10th
Inadequate loan/credit facility	1.7	12th
Unavailability of bio inputs like fertilizers, plant protection chemicals, herbicides etc.	2.1	8th
Increased labour and land management requirements	1.8	11th
Increased difficulty in management of pest and disease incidence	2.7	1st

To counter this constraint promoting group action by the farmers is one of the ways. Various biological methods of control by the farmers as a group would enable them to eradicate the pests and diseases problem as a whole in the study areas. Farmers also have to follow stringent measures under GAP to control pests and diseases. The logistic support of an extension system and government policy for group action would be necessary for managing this constraint.

Lack of knowledge in use of good agricultural practices and Lack of better pricing for GAP having mean score of 2.6, respectively gained the second position in the constraint table and jointly ranked. The reason for this finding might be due to those farmers of the study area as just getting training on GAP for awareness creation on this issue as well as for adoption. Therefore, the knowledge level of the farmers in the study areas still have less awareness as well knowledge regarding GAP. While some of the progressive farmers started to adopt different components of GAP but still their product in the market are not treated especially therefore, they are not getting price fairly.

The last ranked constraint is inadequate loan/credit facility having mean value of 1.7. This finding could be due to that now various farmers are getting credit from different micro-credit organization as well as bank on agricultural practices. Therefore, farmers are not faced high extent of constraint in this regard.

Conclusions and Recommendation

In conclusion, the findings reveal that a majority of vegetable farmers operate small landholdings and possess substantial experience in cultivation, yet face challenges with low training received, market perception, and environmental orientation, underscoring the need for enhanced support and education to improve their overall agricultural effectiveness. While the majority of respondents exhibit a medium level of awareness regarding Good Agricultural Practices (GAP), the varying awareness scores across specific components indicate opportunities for targeted educational initiatives to further enhance farmers' understanding and implementation of these practices.

A significant majority of vegetable farmers have a low level of adoption of Good Agricultural Practices, with pest and disease management emerging as the most adopted component, highlighting the need for strategies to improve overall adoption across all GAP areas. The study highlights that a significant constraint for vegetable farmers lies in the lack of knowledge and better pricing for Good Agricultural Practices (GAP), so there is still a considerable gap in awareness, understanding and adoption of GAP. Factors such as area under cultivation, experience, training received, market perception, environmental orientation, and extension contact demonstrated a positive and significant relationship, underscoring the importance of these elements in enhancing GAP adoption among farmers.

Creating more awareness regarding GAP components among the farmers as well as ultimate consumers would be required which increase the demand for GAP products and thereby contribute to higher income to the farmers. More intensive training, motivational activities and capacity building programs are required for the farmers to enhancing awareness, skill on GAP ultimately increase the adoption. Similar research studies could be conducted in the other vegetable growing areas of the country for making the findings generalize as the current study was limited to only one district.

[4]Department of Agriculture, School of Agriculture and Industrial Technology, Babcock University, Ilishan-Remo, Ogun State, Nigeria

Abstract

Global warming poses a significant threat to poultry production, inducing heat stress that reduces feed intake, egg production, and reproductive capacity, while increasing mortality rates. However, limited research exists on poultry farmers' awareness, knowledge, and perceptions of climate change, which are essential for developing effective adaptation strategies. This study examines poultry farmers' perceptions of climate change in Ogun State, Nigeria. Primary data were collected from 154 registered members of the Poultry Association of Nigeria, Ogun State Chapter (PANOG) using a multistage sampling technique. Data analysis involved the use of descriptive and inferential statistics, including frequency, percentages, and chi-square tests. Results show that 64.5% of poultry farmers were male, 78.3% had tertiary education, and 93.4% were aware of climate change. Over 80% associated climate change with rising environmental temperatures, while more than 70% linked it to increased water intake in poultry birds. Additionally, 75% of respondents identified well-ventilated housing as a mitigation strategy. However, fewer than 50% strongly agreed on the effectiveness of improving feed quality, veterinary services, reducing stocking density, or integrating other livestock. Statistical analysis revealed significant ($P<0.05$) relationships between awareness and factors such as age, education level, experience, and access to information. Furthermore, awareness levels significantly ($P<0.05$) influenced the adoption of mitigation strategies. The study highlights the need for targeted education on climate change impacts and adaptive measures, particularly through feed management, to enhance poultry farmers' resilience and productivity in Ogun State.

Key Words: *Awareness, Perception, Climate change, Mitigation strategies,Poultry farmers, Nigeria.*

Introduction

Climate change has emerged as one of the most pressing global challenges, affecting various sectors, including agriculture. It is primarily caused by the accumulation of greenhouse gases in the atmosphere, leading to rising environmental temperatures, commonly referred to as global warming. This phenomenon has significant implications for food production systems worldwide, particularly in regions highly dependent on agriculture for economic sustenance. Among the most vulnerable agricultural sectors is poultry farming, which is crucial for food security, employment, and economic development in many countries, including Nigeria.

Poultry farming is a major component of the livestock industry and plays a pivotal role in meeting the protein requirements of growing populations. Poultry consists of birds which are of economic value to humans as the primary supplier of meat, egg, and raw materials to industries (feathers, waste products), they are also a source of income to man (Akanwa & Joe-Ikechebelu, 2019). The poultry industry in Nigeria is one of the most well-organized and most commercialized agricultural sub-sectors, contributing significantly to the nation's Gross Domestic Product (GDP). It is estimated to account for 25% of the agricultural GDP and provides a livelihood for millions of people across rural and urban areas (Mackenzie et al., 2020).

According to the Central Bank of Nigeria (CBN, 2019), the poultry industry has an estimated market value of ₦1.6 trillion. The demand for poultry products continues to rise, with an estimated annual production of 180 million birds, 3.8 million of eggs, and over a billion tonnes of poultry meat. However, despite the industry's potential, local production has struggled to meet this growing demand, leading to the smuggling of poultry products into the country (Oloso, 2020). This challenge is compounded by climate change, which negatively impacts poultry production and reduces its productivity (Liverpool-Tasie et al., 2019).

Poultry birds are homeothermic animals, meaning they thrive within specific temperature ranges known as the Thermo-Neutral Zone (TNZ). The TNZ ensures optimal feed conversion, growth, development, and productivity (Aroyehun, 2023). When temperatures exceed or fall below this range, poultry birds experience physiological stress, affecting their performance. In particular, high temperatures lead to heat stress, which reduces feed intake,

lowers egg production, increases mortality rates, and negatively affects reproduction. These adverse effects of climate change on poultry farming necessitate urgent interventions to mitigate its impact and ensure the sustainability of poultry production.

While climate change has been widely recognized as a significant threat to agriculture, there remains a gap in understanding its specific impact on poultry productivity. Several studies (Chah, 2013; Adebisi, 2017; Aroyehun, 2022) have documented the detrimental effects of climate change on livestock, including reduced fertility, poor egg quality, increased disease susceptibility, and higher production costs. However, there is limited information on poultry farmers' awareness, perceptions, and adaptive strategies regarding climate change. Many farmers may be aware of climate change but lack the knowledge and resources to implement effective mitigation measures. As a result, they continue to experience losses due to heat stress, feed inefficiencies, and disease outbreaks.

Research has shown that farmers' socio-economic characteristics, such as age, gender, education level, and access to information sources, play crucial roles in farmers' perception and adaptation strategies (Sesay & Kallon, 2022; Adepoju & Osunbor, 2018). Farmers with higher education levels and access to extension services are more likely to be aware of climate change impacts and adopt appropriate adaptation measures to counteract climate-induced challenges (Adepoju & Osunbor, 2018; Aroyehun, 2022). Those with limited knowledge may struggle to implement appropriate interventions. Additionally, training programs and climate-related information play a critical role in shaping farmers' perceptions and responses. Without adequate knowledge, poultry farmers may fail to adopt adaptive measures such as improving housing conditions, optimizing feeding practices, enhancing veterinary care, and reducing stocking densities to mitigate climate change effects.
Despite government efforts to boost local poultry production, policy frameworks have not fully considered the implications of climate change. In 2015, the Nigerian government implemented measures to promote local production by restricting the importation of poultry products and cracking down on smuggling activities (Amata, 2022). While these policies aimed to enhance domestic poultry farming, they did not address the environmental challenges that threaten the sector's growth. Consequently, many poultry farmers continue to face climate-related obstacles without adequate support or guidance.

Furthermore, Nigeria is expected to be a key driver of global meat consumption in the coming decades (The Economist, 2019). This projection underscores the importance of developing climate-resilient poultry farming systems to meet future food demands. As climate change intensifies, it is imperative to equip poultry farmers with the necessary knowledge and resources to adapt and build resilience against environmental stressors. Sustainable practices, such as climate-smart housing, strategic feeding, genetic selection for heat-resistant breeds, and efficient waste management, must be prioritized to safeguard the industry's future.

Given the critical role of poultry farming in Nigeria's economy and food security, it is essential to assess poultry farmers' awareness, knowledge, and adaptive capacity concerning climate change. Understanding their perceptions and identifying the challenges they face will provide valuable insights into effective mitigation strategies. This study aims to fill the existing knowledge gap by assessing farmers' level of awareness, perceived effects, and mitigation strategies that could reduce the effects of climate change on poultry production.

Hypothesis
Ho_1: No significant relationship between selected socio-economic characteristics of poultry farmers and their awareness of climate change.
Ho_2: No significant relationship was found between their level of awareness and adoption of practices for mitigating the effects of climate change.

Materials and Methods

This study employed a cross-sectional survey design to gather data from members of the Poultry Association of Nigeria, Ogun State Chapter (PANOG). PANOG is divided into six zones, namely, Ijebu, Remo, Egba, Ota, Yewa, and Mowe. A total of 154 poultry farmers were selected using a multi-stage random sampling technique.
In the first stage, purposive sampling was used to select three zones—Ijebu, Remo, and Egba—due to their proximity. The second stage involved proportional random sampling to determine the number of farmers from each selected zone. In the final stage, convenience sampling was employed during monthly meetings, with the assistance of the PAN Ogun State secretary, to recruit farmers who were available and willing to participate.
Data were collected on farmers' socioeconomic characteristics, awareness, perceived effects, and mitigation strategies related to climate change. Descriptive statistics, including frequency and percentages, were used to analyze socioeconomic characteristics and awareness levels. Inferential analysis using chi-square was conducted to test the study's hypotheses and draw relevant conclusions.

Results and Discussion

The socioeconomic characteristics of the poultry farmers were analysed using descriptive statistics. These include gender, age, level of education, farming experience, types of birds raised, number of birds in stock, management system, awareness of climate change and source of awareness.
The results indicate that 64.5% of the respondents were male, with a significant proportion falling within the age groups of 45-54 years (26.3%) and 55-65 years (23.7%). The majority (78.3%) of poultry farmers had tertiary education.
Regarding experience, 38.2% of farmers had 6-10 years of experience, while 25.7% had 11-16 years, suggesting that most respondents were experienced poultry farmers. Half (50.0%) of the farmers raised layer breeds, while only 33.6% reared broilers.

Table 1.0 Socio-Economic Characteristics of Poultry Farmers in the Study Area

Characteristics	Frequency	Percentage
Gender		
Male	95	64.5
Female	54	35.5
Age		
25-34	38	25.0
35-44	31	20.4
45-54	40	26.3
55-65	36	23.7

Source: Field Survey, 2024

More than half (52.0%) of the respondents practiced the battery cage system of poultry production, likely due to the high proportion of layer farmers, as battery cages facilitate egg collection.
The majority (93.4%) of respondents reported being aware of climate change, which may be attributed to the high level of education among poultry farmers in the study area. Television and radio were identified as the primary sources of climate change information for these farmers.

Awareness of Climate Change by Poultry Farmers

Table 2.0 indicates a relatively high level of awareness of climate change among poultry farmers in Ogun State. The majority of the farmers were very moderately aware of what climate entails. A significant 79.9% of respondents acknowledged their awareness that climate change involves an increase in environmental temperature (global warming). This is consistent with the findings of Ezihe et al. (2020), who reported that 90.9% of poultry farmers agreed that they are aware of climate change**.** 54.6% are aware that climatic changes can lead to unfamiliar disease symptoms in birds. This awareness highlights the interconnectedness of climate change, environmental factors, and livestock health, which has been documented in previous studies (Thornton et al., 2022).
The majority (75.7%) of the poultry farmers agreed that there have been changes in rainfall patterns in recent years. This result supports the findings of Aroyehun (2022), who reported that 86.7% of the poultry farmers agreed that climate change increases in rainfall.

Table 2.0 Awareness of climate change by Poultry Farmers

Awareness	**Very Aware (VA)** Frq (%)	**Moderately Aware (MA)** Frq (%)	**Somehow Aware (SA)** Frq (%)	**Not Aware (ND)** Frq (%)
Climate change involves increase in environmental temperature (global warming)	120 (79.9%)	19 (12.5%)	6 (3.9%)	4 (2.6%)
Climate change is a global issue	117 (77.0%)	19 (12.5%)	9 (5.9%)	6 (3.9%)
There have been changes in rainfall pattern in recent years	115 (75.7%)	118 (11.8%)	10 (6.6%)	5 (3.3%)
Human activities are responsible for climate change	96 (63.2%)	32 (21.1%)	12 (7.9%)	8 (5.3%)
Weather has become unpredictable	113 (74.3%)	19 (12.5%)	13 (8.6%)	6 (3.9%)
Climatic changes increases unfamiliar diseases symptoms in birds	83 (54.6%)	44 (28.9%)	12 (7.9%)	7 (4.6%)
Flooding is a result of climate change	84 (55.3%)	32 (21.1%)	17 (11.2%)	17 (11.2%)
Poultry contributes to green house gas emission	67 (44.1%)	44 (28.9%)	19 (12.5%)	19 (12.5%)
Dry season is now more prolonged than before.	84 (55.3%)	35 (23.0%)	23 (15.1%)	7 (4.6%)

Source: Field Survey, 2024

Perceived Effects of Climate Change on Poultry Production

Table 3.0, shows perceived effects of climate change on poultry production by the farmers. Over 50% strongly agreed that climate change increases the water intake of poultry birds and increases maintenance costs. However, less that 50% strongly agreed on other listed perceived effects with the least percentage (30.9%) strongly agreeing to climate change effect on quality of feed ingredient. Other listed percieved effect of climate change include rate of feed intake,egg and meat production, growth rate, availability and cost of feed, maintanance cost, diseases susceptibility,mortality rate and income.
About 47.4% of the poultry farmers strongly agree that climatic change reduces the rate of feed intake of birds. Result agrees with Olorede (2021) findings that climate change increases feed intake in birds.While 32.9% of the poultry farmers strongly agree that climate change reduces the availability of feed, 22.4% are neutral. Effect of feed grain availability may be due to hash climatic conditions resulting in low harvest and hence scarcity of feed grain. Poultry farmers who are neutral on climate change effect are between 11.2% and 22.4%. This implies that they are not knowledgeable on climate change effect. Results indicate the need to educate the poultry farmers on the effect of climate change on poultry production.

Table 3.0. Distribution of Respondents on Perceived Effects of Climate Change on Poultry Production

Perceived effects of climate change on poultry production	Strongly Agree (SA) Frq (%)	Agree (A) Frq (%)	Neutral (N) Frq (%)	Strongly Disagree (SD) Frq (%)	Disagree (D) Frq (%)
Climatic changes increase water in take of poultry birds	97 (59.9%)	37 (24.3%)	17 (11.2%)	4 (2.6%)	2 (1.3%)
Climatic changes reduces the rate of feed intake of birds	72 (47.4%)	46 (30.3%)	23 (15.1%)	5 (3.3%)	4 (2.6%)
Climate change limit egg and meat production	72 (47.4%)	48 (31.6%)	22 (14.5%)	3 (2.0%)	5 (3.3%)
Climatic changes slow down the growth of the poultry birds	62 (40.8%)	50 (32.9%)	26 (17.1%)	8 (5.3%)	3 (2.0%)
Climatic changes increases disease susceptibility	52 (34.2%)	41.4 (27.2%)	17.1 (11.3%)	2.0 (3%)	2.0 (3%)
Climate change increase maintenance cost	85 (55.9%)	36 (22.7%)	18 (11.8%)	5 (3.3%)	3.0 (2%)
Climate change increases the cost of feed	62 (40.8%)	42 (27.6%)	30 (19.7%)	5 (3.3%)	6 (3.9%)
Climate change reduces the availability of feed	50 (32.9%)	50 (32.9%)	34 (22.4%)	9 (5.9%)	8 (5.3%)
Climate change reduces the quality of feed ingredient	47 (30.9%)	51 (33.6%)	29 (19.1%)	11 (7.2%)	8 (5.3%)
Climate change increased mortality of birds.	65 (42.8%)	48 (31.6%)	24 (15.8%)	5 (3.3%)	7 (4.6%)
Reduces farmers income	62 (40.8%)	50 (32.9%)	23 (15.1%)	6 (3.9%)	5 (3.3%)

Strategies to Mitigate Climate Change in Poultry Production

Table 4.0 shows the mitigation strategies proposed by poultry farmers to counteract the negative effects of climate change on poultry production. 75.0%, 66%, and 63% of the poultry farmers strongly agree that construction of buildings with a good ventilation system, planting to provide shade, and using an efficient cooling system could mitigate the effect of climate change on poultry production, respectively. This result is in agreement with Liverpool-Tasie et al. (2019), who reported that air ventilation and cooling systems are adaptation strategies recommended to be used in response to heat stress. 69% and 73% strongly agreed to maintaining good hygiene and supplying adequate water respectively. While 27% strongly agreed to increased use of veterinary services and use of herbs and spices, 19% strongly agreed to keeping other livestock, and 37.5% were neutral. 12.5% and 13.8% strongly disagree with the use of herbs and spices and keeping other livestock, respectively. This indicates the need for further enlightenment on strategies for building the resilience of poultry against climate change for improved productivity.

Relationship between Selected Socioeconomic Characteristics of Poultry Farmers and their Awareness of Climate Change

The results of the test of hypothesis (Table 5.0), show the relationship between selected socioeconomic characteristics of the poultry farmers and their awareness of climate change. Age, level of education, experience, and information were significantly ($P<0.05$) related to awareness, perception, and measures in mitigating and controlling the effects of climate change. This finding agrees with Okocha et al. (2024), who reported that education and access to information influence farmers' perceptions and adoption of mitigation strategies. The more educated, experienced, and the easier the accessibility to information, the more aware the farmer is about climate change. The result also agrees with Debela et al. (2015), who reported that personal attributes such as age, education, and access to information affect how individuals perceive climate change.

Relationship between the Level of Awareness and Practices for Mitigating the Effects of Climate Change.

Table 6.0 shows that there is a significant ($P<0.05$) relationship between the level of awareness of poultry farmers and farm practices for mitigating the effects of climate change. This shows that the more aware the farmers are about what climate change is, the more their knowledge on the mitigation practices.

Table 4.0. Strategies to Mitigate Climate Change Effect on Poultry Production

Strategies to mitigate climate change effect on poultry production	**Strongly Agree (SA)** Frq (%)	**Agree (A)** Frq (%)	**Neutral (N)** Frq (%)	**Strongly Disagree (SD)** Frq (%)	**Disagree (D)** Frq (%)
Construction of buildings with a good ventilation system	114 (75.0%)	26 (17.1%)	6 (3.9%)	1 (0.7%)	3 (0.2%)
Planting trees to provide shade for the birds	101 (66.4%)	30 (19.7%)	10 (6.6%)	4 (2.6%)	3 (2.0%)
Use of efficient cooling system like fans.	96 (63.2%)	30 (19.7%)	19 (12.5%)	3 (2.0%)	2 (1.3%)
Seeking more information on climate change.	98 (64.5%)	35 (23.0%)	13 (8.6%)	1 (0.7%)	1 (0.7%)
Improving quality of feeds	42.1 (28%)	23.7 (15.6%)	17.1 (11.3%)	9.2 (6.1%)	5.9 (4%)
Increased use of veterinary services	41.4 (27.2%)	31.6 (20.8%)	15.1 (10%)	2.6 (2%)	5.9 (4%)
Maintaining good hygiene.	105 (69.1%)	27 (17.8%)	12 (7.9%)	1 (0.7%)	2 (1.3%)
Vaccination of birds	79 (52.0%)	38 (22.4%)	24 (15.8%)	6 (3.9%)	5 (3.3%)
Supplying adequate water	112 (73.7%)	28 (18.4%)	6 (3.9%)	1 (0.7%)	2 (1.3%)
Decreasing stocking density.	65 (42.8%)	44 (28.9%)	28 (18.4%)	7 (4.6%)	2 (1.3%)
Use of herbs and spices	41 (27.0%)	39 (25.7%)	43 (28.3%)	19 (12.5%)	7 (4.6%)
Keeping other livestock	29 (19.1%)	32 (21.1%)	57 (37.5%)	21 (13.8%)	9 (5.9%)

Conclusion

The study indicates a high level of awareness among poultry farmers in Ogun State regarding the impacts of climate change on poultry production. Despite this awareness, there is a pressing need to implement effective mitigation strategies to address the adverse effects of climate change on poultry farming.

As the evidences of climate change are becoming more pronounced all over the world and in Nigeria, adopting climate-smart agricultural practices, improving infrastructure, enhancing veterinary services, good housing systems, manipulation of feed and feeding systems, supplying adequate water of good quality, ensuring adequate stocking density, and capacity building are essential steps towards building climate-resilient poultry farming systems in the area. Since the majority of poultry farmers got climate change information from radio and TV programs, enlightenment programs should be sponsored on the media (particularly radio and television) to create more awareness on mitigation and adaptive strategies that can reduce the effects of climate change on poultry production.

Aged Garlic Extract: Bioactive Components and Functional Properties

Hatice Kübra SASMAZ[1], Hasim KELEBEK*[1]

[1] *Department of Food Engineering, Faculty of Engineering, Adana Alparslan Turkes Science and Technology University, 01250 Adana/ Türkiye

Abstract

Garlic, a member of the Liliaceae family, has approximately 15 genera and more than 700 species, with Allium sativum L. being the most common. This review study evaluated the bioactive compounds and functional properties of aged garlic. Aged garlic extract is a commercial product obtained by ageing sliced fresh garlic in aqueous ethanol at room temperature for over ten months. This extract contains characteristic sulfur-containing compounds such as S-1-propenylcysteine and S-alliin, which are responsible for garlic's antioxidant, antihypertensive, and immunomodulatory effects. Previous studies have shown that aged garlic extract has high bioavailability and exhibits biological activity in both animal and human studies. Research has revealed that this extract offers pharmacological effects, such as immune-enhancing and cardiovascular protective properties. Furthermore, it has been found to have higher antioxidant effects compared to fresh garlic. The amount of S-alliin in aged garlic extract has been reported to range from 1.6 to 2.4 mg/g (dry weight). Studies show that the total flavonoid and flavonol concentrations in aged garlic extract are higher than in fresh garlic. Sensory evaluations indicate that the "sharp" odor in aged garlic extract is significantly reduced, while "spicy," "acidic," "metallic," and "caramelized" characteristics are more pronounced compared to fresh garlic. This review provides comprehensive information on the bioactive compounds of aged garlic extract and its health effects, offering valuable insights into its potential use in functional foods and pharmacology.

Key Words: *Allium sativum* L.*, Aged garlic, bioactive compounds, antioxidant capacity, pharmacological activity*

Özet

Yıllanmış Sarımsak Ekstraktı: Biyoaktif Bileşenleri ve Fonksiyonel Özellikleri

Sarımsak, Liliaceae ailesine ait olup yaklaşık 15 cins ve 700'den fazla türe sahiptir. En yaygın sarımsak türü *Allium sativum* L.'dir. Bu derleme çalışmasında, yıllanmış sarımsağın biyoaktif bileşikleri ve fonksiyonel özellikleri değerlendirilmiştir. Yıllanmış sarımsak ekstraktı, dilimlenmiş taze sarımsakların sulu etanol içinde oda sıcaklığında on aydan uzun bir süre olgunlaştırılmasıyla elde edilen ve Uzak Doğu'da sıklıkla tüketilen ticari bir üründür. Bu ekstrakt, hazırlanma sürecine bağlı olarak yüksek oranda S-1-propenilsistein ve S-allilsistein gibi kükürt içeren karakteristik bileşikler içermektedir. Söz konusu bileşikler, yıllanmış sarımsağın antioksidan, antihipertansif ve immünomodülatör etkilerinden sorumludur. Yıllanmış sarımsak ekstraktının yüksek biyoyararlanıma sahip olduğu ve hem hayvan hem de insan çalışmalarında biyolojik aktivite gösterdiği daha önceki araştırmalarda belirlenmiştir. Yapılan çalışmalar, bu ekstraktın bağışıklık sistemini güçlendirici ve kardiyovasküler koruyucu özellikler gibi çeşitli farmakolojik etkiler sunduğunu ortaya koymuştur. Ayrıca, antioksidan özellikleri açısından taze sarımsağa kıyasla daha yüksek etki gösterdiği tespit edilmiştir. Yıllanmış sarımsak ekstraktında S-allilsistein miktarının 1.6–2.4 mg/g (kuru ağırlık) aralığında olduğu bildirilmiştir. Çalışmalar, yıllanmış sarımsak ekstraktının toplam flavonoid ve flavonol konsantrasyonlarının taze sarımsağa göre daha yüksek olduğunu göstermektedir. Duyusal değerlendirmelerde ise yıllanmış sarımsak ekstraktında "keskin" koku önemli ölçüde azalırken, "baharatlı", "asitli", "metalik" ve "karamelize" özelliklerin taze sarımsağa kıyasla daha belirgin olduğu bildirilmiştir. Bu derleme çalışması, yıllanmış sarımsak ekstraktının biyoaktif bileşikleri ve sağlık üzerine etkileri hakkında kapsamlı bilgiler sunarak, fonksiyonel gıda ve farmakoloji alanlarındaki potansiyel kullanımına dair önemli veriler sağlamaktadır.

Anahtar Kelimeler: *Allium sativum* L.*, Yıllanmış sarımsak, biyoaktif bileşikler,antioksidan kapasite, farmakolojik aktivite,*

Giriş

Sarımsak, **Liliaceae** ailesine ait olup yaklaşık 15 cins ve 700'den fazla türe sahiptir. Bu türler arasında en yaygın olanı *Allium sativum* L.'dir. Sarımsak (*Allium sativum* L.), kalp hastalıkları, kanser ve enfeksiyonlar dahil olmak üzere çeşitli hastalıkların önlenmesi ve tedavisinde uzun süredir kullanılmaktadır (Hiramatsu ve ark., 2016). Aynı zamanda kanser, diyabet, enfeksiyon ve felç gibi hastalıkların gelişme riskini azaltmada sahip olduğu terapötik potansiyel sayesinde dikkat çeken önemli bir bitkisel üründür. Bu terapötik etkinlik, sarımsağın kimyasal bileşenlerinin güçlü biyolojik aktivitelerine atfedilmektedir (Cervantes ve ark., 2013). Sarımsak, çeşitli formülasyonlarda kullanılabilen değerli bir bileşen olup, bunlardan biri de yıllanmış sarımsak ekstraktıdır. Bu ekstrakt, dilimlenmiş çiğ sarımsağın oda sıcaklığında %15–20 oranında sulu etanol içinde 10 ila 20 ay boyunca bekletilmesiyle elde edilmektedir. Olgunlaştırma sürecinin ardından ekstrakt süzülür ve düşük sıcaklık ile düşük basınç altında konsantre hale getirilir. Son aşamada ise etanol çözeltisi uzaklaştırılabilir ve ürün toz formuna dönüştürülebilir (Ohkubo ve ark., 2017; Elosta ve ark., 2017). Bu olgunlaşma sürecinde, sarımsaktaki keskin kokulu ve tahriş edici bileşikler, kokusuz, daha yumuşak ve güvenli sülfürlü bileşiklere dönüşmektedir (Elosta ve ark., 2017). Bu işlem sırasında allisin miktarında azalma olurken; S-alil sistein (SAC, 1.6–2.4 mg/g kuru madde), S-alil merkaptosistein (SAMC), suda çözünür allisin türevleri ve selenyum gibi organosülfür bileşiklerinin düzeylerinde artış gözlemlenmektedir. Bu bileşiklerin tümü güçlü antioksidan özellikler göstermekte olup, yıllanmış sarımsak ekstraktının sağlık açısından önemli faydalar sunmasına katkı sağlamaktadır (Elosta ve ark., 2017).

Yıllanmış sarımsak ekstraktı, taze sarımsağın oda sıcaklığında uzun süreli ekstraksiyonuyla elde edilen kokusuz bir ürün olup, yüksek biyoyararlanıma sahiptir. Hem hayvan hem de insan çalışmalarında in vitro olarak biyolojik aktivite göstermiştir. Bu ekstrakt, özellikle yaşlanma süreci sırasında oluşan SAC ve SAMC açısından zengindir. Bu durum, yıllanmış sarımsak ekstraktına taze sarımsak ve diğer ticari sarımsak takviyelerine kıyasla daha yüksek antioksidan aktivite kazandırmaktadır (Borek, 2001). Yıllanmış sarımsak ekstraktı 50 yılı aşkın süredir üretilmesine rağmen, aroma profiline ilişkin çalışmalar oldukça sınırlıdır. Üretim süreci boyunca aroma bileşiminde değişiklikler meydana gelmekte; sarımsağa özgü keskin koku büyük ölçüde ortadan kalkmaktadır. Keskin kokudan sorumlu tiyosülfinat ve sülfit bileşiklerinin parçalanarak veya başka bileşiklere dönüşerek kaybolduğu, buna karşılık kükürt içermeyen aroma aktif bileşiklerin olgunlaşma sürecinde çeşitli kimyasal reaksiyonlarla ortaya çıktığı düşünülmektedir (Abe ve ark., 2020).

Bu derleme çalışması, yıllanmış sarımsak ekstraktının aroma bileşenleri ve sağlık üzerindeki olumlu etkilerini ayrıntılı biçimde ele alarak, bu doğal ürünün fonksiyonel gıda ve farmakolojik preparat olarak potansiyel kullanım alanlarına ışık tutmayı amaçlamaktadır.

Sağlık üzerine faydaları

Kardiyovasküler hastalıklar, her yıl yaklaşık 17,9 milyon kişinin ölümüne neden olmakta ve tüm küresel ölümlerin %31'ini oluşturarak dünya genelinde başlıca ölüm nedeni olarak kabul edilmektedir. Hipertansiyon ve hiperlipidemi, kardiyovasküler hastalıkların en önemli iki risk faktörü arasında yer almaktadır. Hipertansiyon, dünya genelinde 1 milyardan fazla yetişkini (yaklaşık her dört kişiden birini) etkilemekte ve 70 yaş altı erken ölümlerin yaklaşık %40'ından sorumlu tutulmaktadır (Wlosinska ve ark., 2020). Avrupa'da, kardiyovasküler olay riski taşıyan bireylerle gerçekleştirilen randomize, çift kör, plasebo kontrollü bir çalışmada; bir yıl boyunca günlük 2400 mg yıllanmış sarımsak ekstraktı tüketiminin, koroner arter kalsifikasyonunun ilerlemesini anlamlı düzeyde yavaşlattığı, kan glikoz seviyelerini düşürdüğü ve sistolik kan basıncını azalttığı tespit edilmiştir (Wlosinska ve ark., 2020).

Son yıllarda yapılan klinik çalışmalar, tedavi altındaki ancak kan basıncı yeterince kontrol altına alınamayan hipertansiyon hastalarında sarımsak preparatlarının olumlu etkilerine dair umut verici sonuçlar ortaya koymuştur (Mahdavi-Roshan ve ark., 2016; Sobenin ve ark., 2009). Elosta ve ark. (2017) tarafından gerçekleştirilen bir çalışmada, sarımsak ve yıllanmış sarımsak ekstraktlarının antioksidan aktiviteleri ABTS [2,2'-azino-bis(3-etilbenzotiyazolin-6-sülfonik asit)] radikal süpürme analizi ile değerlendirilmiştir. Elde edilen sonuçlar, her iki ekstraktın da $ABTS^{+}$ radikallerini temizleme kapasitesi sayesinde anlamlı düzeyde antioksidan özellik gösterdiğini ortaya koymuştur. Özellikle, yıllanmış sarımsak ekstraktının taze sarımsak özütüne kıyasla daha yüksek bir Trolox Eşdeğer Antioksidan Kapasitesi'ne (TEAC) sahip olduğu belirlenmiştir. Bu bulgu, yıllanmış sarımsak ekstraktında bulunan stabil organosülfür bileşiklerinin (örneğin SAC ve SAMC) artmış biyoyararlanımı ve antioksidan potansiyeli ile ilişkilendirilmektedir.

Yıllanmış sarımsak ekstraktının antioksidan özellikleri, artan metabolizma hızı veya kronik inflamasyon sonucunda oluşan reaktif oksijen türlerini (ROS) azaltarak, aterosklerozun erken bir göstergesi olan endotel disfonksiyonunu önlemeye yardımcı olur (Tsuneyoshi, 2020). Rastgele, çift kör, plasebo kontrollü bir beslenme müdahalesinde, üç ay boyunca günde 400 mg sarımsak ekstraktı alımının antioksidan durumu artırdığı ve bunun sonucunda obez bireylerde C-reaktif protein (CRP), düşük yoğunluklu lipoprotein kolesterol (LDL), yüksek yoğunluklu lipoprotein kolesterol (HDL), trigliseritler ve plazminojen aktivatör inhibitörü-1 (PAI-1) gibi endotel biyobelirteçlerinin düzenlenerek kardiyovasküler riskin azaldığı rapor edilmiştir. Ayrıca, randomize, çift kör,

plasebo kontrollü bir klinik çalışmada, yıllanmış sarımsak ekstraktında bulunan organosülfür bileşiklerinin obezite kaynaklı inflamasyon üzerindeki etkileri değerlendirilmiştir. Bu çalışmada, yıllanmış sarımsak ekstraktının içerdiği S-alil sistein (SAC) gibi bileşiklerle sistemik inflamasyon arasında anlamlı düzeyde negatif bir korelasyon saptanmıştır. Katılımcılar, altı hafta boyunca günde 3,6 gram yıllanmış sarımsak ekstraktı takviyesi almış ve bu sürenin sonunda SAC'nin hidrojen sülfür (H_2S) üretimini artırarak obeziteye bağlı inflamasyonu azalttığı belirlenmiştir. H_2S, vücutta doğal olarak bulunan; antiinflamatuar, vazodilatör ve antioksidan etkilere sahip önemli bir sinyal molekülü olarak bilinmektedir (Xu ve ark., 2018).

Metabolik sendrom, abdominal obezite, hipertansiyon, aterojenik dislipidemi, protrombotik ve proinflamatuar durumları içeren bir dizi metabolik bozukluktan oluşan bir rahatsızlıktır. Bu sendrom, etkilenen bireylerde tip 2 diyabet gelişme riskini yaklaşık beş kat, kardiyovasküler hastalık riskini ise iki kat artırmaktadır (Samson & Garber, 2014). Son yıllarda yapılan klinik araştırmalar, yıllanmış sarımsak ekstraktının bu metabolik bozuklukların yönetiminde umut verici sonuçlar ortaya koyduğunu göstermektedir. Örneğin, 24 hafta boyunca günde 1.2 gram yıllanmış sarımsak takviyesi uygulanan bireylerde plazma adiponektin seviyelerinde anlamlı artış gözlenmiş ve buna paralel olarak metabolik sendrom risk faktörlerinde belirgin iyileşmeler rapor edilmiştir (Gómez-Arbeláez ve ark., 2013).

Klinik öncesi çalışmalarda, yıllanmış sarımsak ekstraktının altı günlük uygulama sonrası doza bağlı olarak yara iyileştirme potansiyeli gösterdiği bildirilmiştir (Ejaz ve ark., 2009). Başka bir çalışmada, yıllanmış sarımsak ekstraktı ile beslenen farelerde nöronal nitrik oksit sentaz (nNOS) aracılığıyla kolon düz kas gevşemesinde artış gözlenmiş, enterik sinir sistemi (ENS) hücrelerinde proliferasyonun teşvik edildiği ve ekstraktın belirgin nöroprotektif etkiler gösterdiği saptanmıştır. Bu bulgular, yaşlanmaya bağlı kolorektal dismotilite belirtilerinin azaltılmasında yıllanmış sarımsak ekstraktının potansiyel faydalarını ortaya koymaktadır. Çalışma aynı zamanda, yaşlı farelerde gastrointestinal (GI) motilite özelliklerinin detaylı karakterizasyonunu sunarak, yıllanmış sarımsak ekstraktının GI motilite bozuklukları ve ENS hücre işlevleri üzerindeki olası terapötik etkilerine dikkat çekmektedir (Ohishi ve ark., 2025). Elde edilen sonuçlar, bu doğal ürünün yaşa bağlı sindirim sistemi disfonksiyonlarının yönetiminde umut vadeden bir yaklaşım olabileceğini göstermektedir.

Bitkilerden elde edilen doğal ajanlar, takviyeler, antibiyotikler ve kanser önleyici ilaçların geliştirilmesinde yoğun şekilde araştırılmaktadır. Bu kapsamda sarımsak, hem bir gıda maddesi olarak hem de geleneksel tıpta yaygın biçimde kullanılmaktadır. Yapılan bilimsel çalışmalar, sarımsak ve özellikle yıllanmış sarımsak ekstraktının çeşitli kanser türlerinin önlenmesi ve tedavisinde önemli bir potansiyele sahip olduğunu ortaya koymuştur (Tanaka ve ark., 2006; Jikihara ve ark., 2015; Ohkubo ve ark., 2018; Ishikawa ve ark., 2006; Li ve ark., 2019).

Ayrıca, yıllanmış sarımsak ekstraktının anlamlı antiinflamatuvar özellikler sergilediği ve özellikle oral bakteriyel enfeksiyonların tetiklediği yaygın bir kronik inflamatuvar hastalık olan periodontitis üzerinde olumlu etkiler sağladığı gösterilmiştir. İlgili çalışmalar, yıllanmış sarımsak ekstraktı uygulamasının inflamatuvar semptomları belirgin şekilde azalttığını bildirmiştir (Ohtani ve ark., 2020; Nango ve ark., 2023).

Aroma bileşikleri

Yapılan bir çalışmada, allisin ve S-metilmetantiosülfinat gibi sülfür içeren aroma maddelerinin, taze sarımsağın baskın aroma bileşenleri olduğu, ancak bu bileşiklerin yıllanmış sarımsak ekstraktında bulunmadığı bildirilmiştir. Yaşlanma süreci sırasında, tiyosülfinatlardaki azalmanın, yıllanmış sarımsak ekstraktının keskin kokusunun kaybolmasına yol açtığı saptanmıştur (Abe ve ark., 2020). Aynı çalışmada, aroma-aktif bileşiklerin seyreltme faktörleri (FD), gaz kromatografisi-olfaktometri (GC-O) tabanlı aroma ekstrakt seyreltme analizi (AEDA) yöntemi kullanılarak belirlenmiştir. Elde edilen verilere göre, yıllanmış sarımsak ekstraktında $FD \geq 1$ değerine sahip toplam 39 farklı bileşik tanımlanmış ve bu bileşiklerin, meyveli, fenolik, fındıksı ve sülfürlü aromalar gibi çeşitli aroma karakterlerini sergilediği gözlemlenmiştir. Çalışma, yıllanmış sarımsak ekstraktının kompleks bir aroma yapısına sahip olduğunu ve aroma profilinde esterler, aldehitler, fenoller, pirazinler ve laktonlar gibi bileşiklerin yanı sıra sülfür içeren bileşiklerin de önemli bir rol oynadığını bildirmiştir (Abe ve ark., 2020). Abe ve ark. (2020) tarafından yapılan bir diğer çalışmada, taze dilimlenmiş sarımsak ile yıllanmış sarımsak ekstraktı duyusal analiz yöntemiyle kıyaslamıştır. Araştırma bulguları, taze sarımsakta "keskin" kokunun öne çıkan baskın özellik olduğunu, ancak diğer aroma bileşenlerinin daha düşük yoğunluklarda tespit edildiğini göstermektedir. Bununla birlikte, yaşlandırma işleminin sarımsağın aroma profilini önemli ölçüde değiştirdiği gözlemlenmiştir. Yıllanmış sarımsak örneklerinde, "keskin" notanın anlamlı derecede azaldığı, buna karşın "baharatlı", "asidik", "metalik" ve "karamel" notalarının belirgin şekilde ön plana çıktığı tespit edilmiştir. Bu sonuçlar, yıllanmış sarımsak ekstraktının, taze sarımsağa kıyasla daha az keskin fakat daha kompleks ve zengin bir aroma profiline sahip olduğunu ortaya koymaktadır.

Tartışma

Derlenen çalışmalar, yıllanmış sarımsak ekstraktının sağlık üzerinde olumlu etkiler gösterdiğini ortaya koymaktadır. Yıllanmış sarımsak ekstraktının antioksidan ve anti-inflamatuvar özellikleri, hipertansiyon, hiperlipidemi, tip 2 diyabet ve obezite gibi metabolik hastalıklar üzerinde olumlu etkiler sunmaktadır. Klinik veriler, yıllanmış sarımsak ekstraktının reaktif oksijen türlerini azaltarak endotel fonksiyonlarını iyileştirdiğini ve ateroskleroz sürecini yavaşlattığını göstermektedir. Ayrıca, antioksidan özellikleri açısından taze sarımsağa kıyasla daha yüksek bir etkiye sahip olduğu tespit edilmiştir. Çalışmalar, yıllanmış sarımsak ekstraktının toplam flavonoid ve flavonol konsantrasyonlarının taze sarımsaktan daha yüksek olduğunu göstermektedir. Duyusal değerlendirmelerde, yıllanmış sarımsak ekstraktında "keskin" koku önemli ölçüde azalırken, "baharatlı", "asidik", "metalik" ve "karamelize" özelliklerin taze sarımsağa kıyasla daha belirgin olduğu bildirilmiştir. Mevcut literatür verileri, yıllanmış sarımsak ekstraktının fonksiyonel bir gıda bileşeni olarak kullanım potansiyelini güçlendirmektedir. Bu alandaki çalışmaların daha da detaylandırılması, bu doğal bileşiğin daha geniş bir kitleye fayda sağlayacak şekilde kullanılması için önemli fırsatlar yaratacaktır.

Abstract

Three cases of oviductal impaction in budgerigars (*Melopsittacus undulatus*) caused by torsion and egg binding in the oviduct are described in this study. In two birds, egg bound diagnosis could be made by radiography, and manual transcloacal removal was performed under general anesthesia. Exploratory coeliotomy was performed in one bird with salpingitis and torsion. Clinical findings, diagnostic method, treatment, and results of three cases are presented. Reproductive tract diseases are common in avian practice, especially among female birds. We conducted a systematic review of the case report and case series on oviductal impaction in birds In three major databases, relevant articles published in 1980–2024 were identified. Most information on studies was recorded in India. Data from 27 patients presented as cases in 21 different studies were evaluated. This study performs a systematic review of the species of birds, methods, treatments, and prognoses described in the literature about oviductal impaction in birds and is intended to be reference material for students, researchers, and clinicians.

Keywords: *Dystocia, Birds, Oviduct impaction, Egg bound, Salphingohysterectomy*

Introduction

Egg binding and dystocia are the most common emergencies in many species of adult female birds in captivity. (Harcourt- Brown, 1996; Crosta et al., 2003) It refers to delayed ovulation due to mechanical obstruction or suppression as a result of cloacal dysfunction. (Vavlas et al. 2025) Dystocia is more complicated than just egg entrapment. There are many underlying causes, including functional (malformed eggs, cloacal masses, oviductal pathologies, obesity), metabolic (vitamin E, selenium deficiency, calcium imbalance and nutritional deficiency), environmental (temperature changes, lack of exercise and stressors) and hereditary diseases (Echols and Speer, 2022; Vavlas et al., 2025). Small birds such as canaries, nightingales and parakeets are much more affected by the disease (Lorenzo et al., 2003; Harcourt-Bown, 1996).
Clinical symptoms include dyspnea, unilateral or bilateral paresis of the legs, depression, and lethargy (Vavlas et al., 2025). Diagnosis is based on clinical signs, palpation and imaging techniques such as radiography, fluoroscopy, CT and US. (Vavlas et al., 2025; Crosta et al., 2003; Harcourt- Brown, 1996)
Treatment options can be categorized as follows: medical treatment; ovocentesis; mechanical support; surgical treatment. Sometimes, in cases diagnosed early, fluid replacement, calcium supplementation, and analgesia can successfully stabilize the patient. (Vavlas et al., 2025) Salpingohysterotomy and salpingohysterectomy are indicated in cases of postovulatory stasis or dystocia where medical treatment fails. (Gorham et al., 1992; Mehler and Bennett, 2022)
This study describes a case report of three budgerigars suffering from oviduct impaction. We then present a systematic review of the literature on oviductal impaction in birds, including diagnostic methods, treatments, and prognosis.

Case Reports

Case 1

A 3-year-old female budgerigar (*Melopsittacus undulatus*) was evaluated because of labored breathing and tail wagging. Befor presented the bird increased territorial behavior of approximately one weeks duration and laid four eggs in cage (Figure 1). The bird's diet consisted of commercial budgerigar food and table food. On initial evaluation, the bird was lethargic and depressed. The physical examination revealed a swelling in the abdomen, and the egg could be palpated within it. To facilitate a complete physical examination, whole-body radiography was performed. Latero lateral whole-body radiography revealed a smooth, mineralized egg of normal shape, localized to the caudal coelomic cavity (Figure 2). Based on the history, clinical signs, and findings from the physical examination, the case was diagnosed as an egg-bound condition. The bird was placed in an oxygen chamber with Ventolin for 15 minutes. Prior to induction of anesthesia with isoflurane via a mask, the animal was

premedicated with intramuscular butorphanol, 2 mg/kg (Butomidor©; Richter Pharma, Wels, Austria). The patient was placed in dorsal recumbency and the vent region was cleaned with the isotonic and lubricated with 7.5% Povidone iodine. The retained egg was gently manipulated with a hand and the egg was removed carefully through the cloacal opening without breaking (Figure 3). The patient was treated with enrofloxacin (25 mg/kg PO q24h for 10 days; compounded suspension), meloxicam 0.5 mg/kg PO q12h (Metacam©; Boehringer Ingelheim, Ingelheim am Rhein, Germany), and calcium multivitamin supplement. The bird recovered uneventfully in 2 weeks, and there was no further follow-up from the owner.

Figure 1. Increased nesting behavior and four eggs laid.

Figure 2. Lateral radiographic view of a budgerigar (*Melopsittacus undulatus*) with an mineralized egg.

Figure 3. Egg that removed by manual trans cloacal removing technique in case 1.

Case 2

A 2-year-old female budgerigar (*Melopsittacus undulatus*) was presented to Istanbul University Cerrahpasa Faculty of Veterinary Science Hospital, Emergency Clinics with a primary complaint of straining, loss of appetite and tail wagging. The bird had no previous egg-laying history, and no clear diagnosis could be made on clinical examination and palpation. To facilitate diagnosis, whole-body radiography was performed. Ventral whole-body radiography revealed an incompletely formed or broken egg localized to the caudal coelomic cavity (Figure 4). The bird was then anesthetized with the same technique as case 1, for examination of the cloacal opening of the oviduct. The patient was placed in dorsal recumbency and the vent region was cleaned with isotonic and lubricated with 7.5% Povidon iyodinThe egg pieces were not visible in the terminal oviduct; however, the eggshell was removed using forceps. The removed shell pieces were non-mineralized and soft. The bird recovered from the

anesthesia after the lavage and aspiration of the cloacal opening. No bleeding or prolapse complications were observed after the intervention. The bird was treated with the same medical protocol in case 1. no egg-like residues were found in the control x-ray. The patient was followed up for 2 weeks, and no complications were reported.

Figure 4. Radiography shows that a broken egg localized to the caudal coelomic cavity.

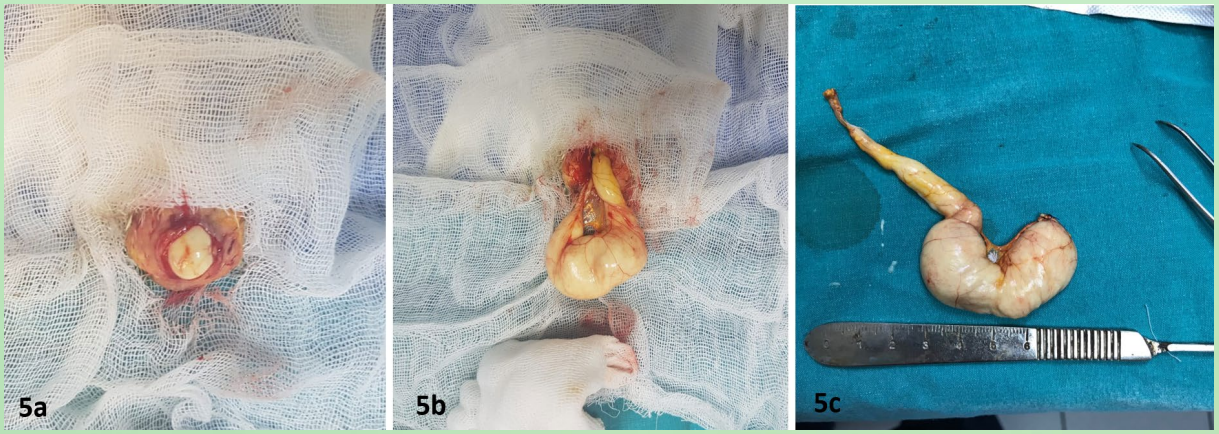

Figure 5. Salphyngohiysterectomy operation descreibed in case 3.

Case 3

A two-year-old female budgerigar (*Melopsittacus undulatus*) presented to our clinics with symptoms including weakness, reduced activity, swelling in the abdomen and inappetence. The bird had been treated with antibiotics and vitamins by the referring veterinary clinic for 5 days, but had failed to respond to treatment. Given the physical findings and history, an ultrasound examination was performed. The ultrasound examination of the coelomic cavity revealed a sac containing hypoechoic contents. There was no definitive diagnosis, but an experimental laparotomy was recommended.

The bird was then anesthetized with the same technique as cases 1 and 2. The bird was placed in dorsal recumbency. Feathers were plucked from the surgical site, which was prepared aseptically using chlorhexidine scrub and sterile saline. A sterile gauze drape was placed over the bird. A standard ventral midline approach to the coelomic cavity was performed. Skin and abdominal muscle were incised and a distended oviduct was easily seen (Figure 5a). The oviduct appeared torsioned (Figure 5b). All ligations were made manually, with 4/0 monofilament absorbable suture (Maxon, Covidien, Minneapolis, MN, USA), and the oviduct was removed. The oviduct was removed as far proximally as possible (Figure 5c). Closure of the abdominal cavity was performed in two layers in a simple interrupted pattern. The bird died in the anesthetic recovery period.

Materials and Methods

Search Methods and Inclusion Criteria

A systematic review of the case reports and case series was conducted searching PubMed, EBSCOhost, and Google Scholar databases using the keywords dystocia, egg binding, oviduct impaction, prolapse, salphingitis, etc., for articles published up to January 2025. To identify different articles in the databases and search engines, keywords were combined using the Boolean operators “AND” and “OR”. The documents were screened for the presence of the keywords in the title and abstract. This systematic review followed the PRISMA (Preferred Reported Items for Systematic Review and Meta-Analyses) guidelines as shown in Figure 6. (Page et al., 2021).

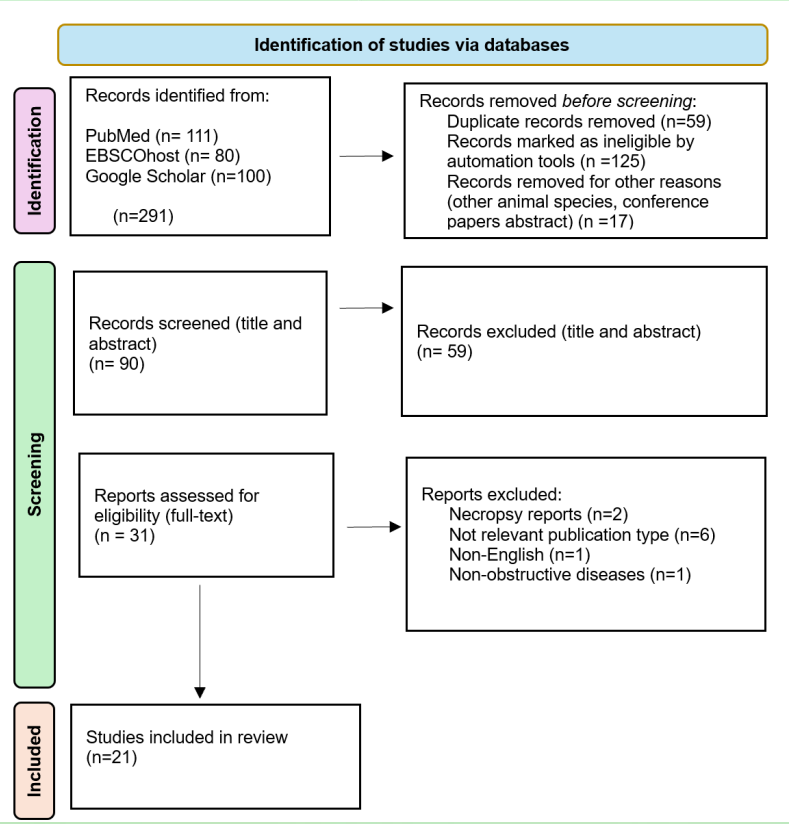

Figure 6. PRISMA flow diagram to select the included studies

The inclusion criteria of the primary studies were based on PICOS (Population, Intervention, Comparison, Outcomes, Study design). Scientific articles with the following designs were included: clinical case reports and case series. The studies included in this review were required to report data on clinical signs, treatments, and prognosis that had been used and/or observed in birds. Aviary birds, poultry, and wild birds were included in the study.

Selection of Studies and Data Collection

Two independent reviewers assessed the primary studies after excluding the duplicates identified from three search databases. Studies were screened based on a two-step assessment. The first step was the assessment of both titles and abstracts of the studies. The unsuitable studies were excluded, and the assessment continued to the second step, which involved a full-text screening. The appropriate studies were then classified as suitable for the systematic review and presented in Table 1, where they are organized based on the alphabetical order of the first author's surname. The following data were extracted from each of the selected studies.

1) Study characteristics (author's name, year of publication, journal, country, database)
2) Patient characteristics (bird's scientific names, age, number of patient in a study)
3) Oviductal impaction conditions characteristics (clinical signs, diagnostic methods, cause of impaction)
4) Intervention characteristics (surgical versus nonsurgical treatment options, complications, prognose)
5) Main results of the included studies.

Results

The studies were conducted between 1993 and 2024. Most of the studies were recorded in India, with 12 out of 21 studies conducted there. Data from 27 patients presented as cases in 21 different studies were evaluated. The species distribution was as follows: *Melopsittacus undulatus, Aratinga nenday, Eclectus roratus, Psittacula eupatria, Columba livia, Gallus gallus domesticus, Nymphicus hollandicus, Spheniscus demersus, Columba livia domesticus, Agapornis, Dromaius novaehollandiae, Anas platyrhynchos domesticus*. The distribution of the bird species and numbers that presented oviduct impaction in the analyzed literature is presented in Table 2.
The most frequent clinical signs were abdominal distension and swelling, and anorexia. Palpation and radiography have been documented as a strategy for diagnosing mineralized egg binding in birds. Additionally, in cases of oviductal impaction with hernia, torsion, or non-mineralized eggs, ultrasound, tomography, cytology, and hematology are recognized as diagnostic methods (Table 3).

*After reoperation 5 months later bird was clinically normal.

Egg binding was the cause most frequently diagnosed through radiographic analysis and exploratory surgery in birds suffering from oviduct impaction. Hernia and torsion of oviduct was reported in three cases. In the analyzed articles, the range of ages was from one to 18 years. Four cases documented individuals younger than one year.

Results showed that surgical treatment (n=16/27) was mainly used for oviduct impaction, followed by manual transcloacal removal (n=11/27), and medical treatment (n=1/27). In one case, two eggs were present, and more than one method was presented because one of the eggs was removed manually, and the other was removed surgically. The analyzed study documented that prolapsus occurred following manual removal of the egg in three cases. In the manual transcloacal removal technique, two cases were reported to have used general anesthesia (Table 4). Nine authors in the reviewed studies did not provide information on post-intervention prescription. Other authors generally focused on antibiotics, calcium, and analgesics. Two authors also emphasized the importance of suppressing the ovarian activity with leuprolide acetate treatment. All the authors highlighted that lubricant or anesthetic jelly drugs help to remove the egg (Table 5).

According to the ten authors who followed the patients, no complications were observed during the follow-up period. In a study conducted by Honnas et al. (1993), two cases of complications arose following egg removal. The prognosis of patients described in Table 6 is discussed in detail.

Discussion

The unique anatomy and physiology of the avian reproductive tract result in a highly productive yet poorly accessible organ system. Affected birds are commonly presented with nonspecific lethargy, anorexia, coelomic swelling, and sometimes lay abnormal eggs (Echols and Speer, 2022; Vavlas et al., 2024).

The oviduct can be divided into five portions: infundibulum, magnum, isthmus, uterus, and vagina. An impaction may occur in one or all portions. The diagnosis of egg binding should be based on clinical signs, physical examination, and radiography. Suspicion should arise if the clinician is presented with a female bird with distended coelom and tenesmus (Harcourt-Brown, 1996; Orosz et al., 1997). Other signs might include abdominal swelling, tail wagging, or respiratory difficulty. We believe that pododermatitis, noted in a single case reported by Anderson et al. (2018), was related to the conditions of care. In cases where the eggshell is formed, palpation is sufficient for diagnosis. When diagnosis is not possible, the authors recommend using ultrasound, radiography, or tomography. Although blood tests were utilized in four cases, we believe they serve as an auxiliary diagnostic method for oviduct impaction. It is important to note that blood tests are particularly valuable for diagnosing dystocia caused by hypocalcemia or for obtaining information about the patient's condition.

A treatment protocol for oviduct impaction must be designed for clinical signs, patient condition, and etiology (Harcourt-Brown, 1996). This study proposes protocol focused on supplemental treatment, analgesia , and minimizing complications through antibiotics after egg removal or salpingohysterectomy. The study reported that no infection-related complications were observed in the follow-up of 7 cases who were prescribed antibiotics after the intervention. We recommend that patients be followed up annually to gather more accurate data.
The analyzed studies showed that surgical treatment (n=16/27) was mainly used for oviduct impaction. For surgical treatment, a common approach is a ventral midline approach (Vavlas et al., 2024).
There is little information on oviductal impaction and management of egg binding in wild birds. In the study, we analyzed cases where no reports were found in wild birds. Further studies are needed to classify the different presentations of reproductive diseases in female birds. Prospective studies with frequent and defined follow-up are required to assess therapeutic options and prognosis for birds with oviductal disease.

Acknowledgements

We would like to thank Assoc. Prof. Lora Koenhemsi from the Istanbul University Cerrahpaşa, Faculty of Veterinary Medicine for performing the ultrasonographic examination of the patient.

Conflict of Interest

The authors declared that there is no conflict of interest.

Phytochemical and Antioxidative Properties of *Kaempferia* Species Found in Bangladesh

Merin Monira Khanam, Karmokar Arup, Hossain AKM Zakir, Ashrafuzzaman* Md

Bangladesh Agricultural University, Bangladesh

Abstract

The genus *Kaempferia* (Zingiberaceae) comprises medicinally significant species widely utilized in traditional medicine for their diverse bioactive compounds and therapeutic potential. This study systematically investigates the phytochemical composition, antioxidant capacity, and pigment profile of the rhizomes of five *Kaempferia* species indigenous to Bangladesh. The total phenolic content (TPC) and total flavonoid content (TFC) were quantified, while antioxidant activity was assessed using DPPH and FRAP assays from the methanolic extract of rhizome. Additionally, major pigments, including chlorophyll a, chlorophyll b, total chlorophyll (a+b), and total carotenoids, were analyzed from the leaf extract. Among the studied species, *K. pulchra* exhibited the highest TPC (14.45 mg GAE/g) and TFC (31.31 mg QE/g), whereas *K. angustifolia* demonstrated the strongest DPPH radical scavenging activity (153.1 mg/mL) and the highest FRAP value (910.01 µM Fe^{2+}/L), indicating superior antioxidative potential. Conversely, *K. galanga* exhibited the lowest antioxidant activity (186.5 mg/mL DPPH and 50.23 µM Fe^{2+}/L FRAP). Pigment analysis revealed that *K. rotunda* contained the highest concentrations of chlorophyll a (0.60 mg/g FW), chlorophyll b (0.70 mg/g FW), and total chlorophyll (1.30 mg/g FW), while *K. parviflora* exhibited the highest total carotenoid content (0.15 mg/g FW). These findings underscore the considerable antioxidative and pharmacological potential of *K. pulchra* and *K. angustifolia*, highlighting their suitability for applications in herbal medicine and pharmaceutical formulations. Further investigations into their bioactive compounds and mechanistic pathways could facilitate their integration into evidence-based therapeutics.

Native Chicken of the Black Sea Region: Trabzon Gugullisi

Gülsüm MANAV [1], Demir ÖZDEMİR[2]

[1]Department of Agricultural Biotechnology, Faculty of Agriculture, Akdeniz University, Antalya, Turkiye
[2]Department of Agricultural Biotechnology, Faculty of Agriculture, Akdeniz University, Antalya, Turkiye

Abstract

Chicken breeds account for 63% of all bird species worldwide, representing a significant proportion. The global chicken population is approximately 2.5 times larger than the human population, with the majority of chickens concentrated in Asia, Latin America, and the Caribbean. Europe and the Caucasus account for 13% of the world's chicken population, while Africa follows with 7%. Local breeds represent a significant portion of global poultry genetic diversity. Domestic chicken breeds have developed traits such as broad ecological adaptation, disease resistance, and economic efficiency during evolutionary processes and expansion. However, the widespread use of commercial chicken breeds has caused a substantial reduction in local poultry genetic resources, threatening the genetic diversity of local breeds. In this context, the most effective way to preserve biodiversity is by conserving native chicken breeds. In Turkiye, although only two native chicken breeds Denizli and Gerze are officially recognized, there are many locally adapted chicken breeds, like the Trabzon Gugullisi, which have developed over many years in our region. The Trabzon Gugullisi is known for its high egg production and meat yield, while also being considered a decorative breed due to its visual appeal. Characteristically, it has a bony protrusion on its head, a trait that is also observed in its chicks. Additionally, it is notable for its upright and majestic walk. The aim of this study is to describe the Trabzon Gugullisi chickens and to provide a scientific basis for conservation and breeding efforts of this native breed.

Key Words: *Trabzon Gugullisi, Native chicken breeds, Biological conservation, Biodiversity, Chicken genetics*

Karadeniz Bölgesinin Yerel Tavuğu: Trabzon Gugullisi

Özet

Tavuk ırkları, dünyadaki tüm kuş türlerinin %63'ünü oluşturarak büyük bir orana sahiptir. Dünya genelindeki tavuk sayısı, insan nüfusunun yaklaşık 2,5 katıdır ve bu tavukların büyük bir kısmı Asya, Latin Amerika ve Karayipler'de yoğunlaşmıştır. Avrupa ve Kafkaslar ise dünya tavuk nüfusunun %13'ünü oluştururken, Afrika bu oranı %7 ile takip etmektedir. Yerli ırklar, dünya çapındaki kanatlı genetik çeşitliliğinin önemli bir kısmını temsil etmektedir. Evcil tavuk ırkları, evrimsel süreçler ve genişleme sırasında geniş ekolojik adaptasyon, hastalık direnci ve ekonomik verimlilik gibi özellikler geliştirmiştir. Ancak, ticari tavuk ırklarının yaygınlaşması, yerel tavuk genetik kaynaklarında büyük azalmalar yaratmış ve bu durum, yerel ırkların genetik çeşitliliğinin tehdit altına girmesine yol açmıştır. Bu bağlamda, biyolojik çeşitliliğin korunmasının en etkili yolu, yerel tavuk ırklarının korunmasıdır. Ülkemizde Denizli ve Gerze olmak üzere yalnızca 2 yerli tavuk ırkı tescillenmiş olmasına rağmen, Trabzon Gugullisi gibi coğrafyamıza özgü ve uzun yıllar adaptasyon geliştirmiş pek çok yerel tavuk ırkı mevcuttur. Trabzon Gugullisi, yüksek yumurta verimi ve karkas et oranıyla dikkat çekerken, aynı zamanda görsel olarak süs tavuğu kategorisinde değerlendirilebilecek güzellikte bir ırktır. Karakteristik olarak kafasında bir kemik çıkıntısına sahiptir ve bu özellik civcivlerinde de gözlemlenmektedir. Ayrıca, dik ve heybetli yürüyüşleri ile dikkat çekmektedir. Bu bildirinin amacı, Trabzon Gugullisi tavuklarını tanıtmak ve bu yerli ırkın korunması ile ıslahına yönelik çalışmalara bilimsel bir temel oluşturmaktır.

Anahtar Kelimeler: *Trabzon gugullisi, yerli tavuk ırkları, biyolojik koruma, biyoçeşitlilik, tavuk genetiği*

Bioactivities of *Thymbra spicata*: Exploring its Cytotoxic, Antibacterial and Antiviral Activities

Furkan Ozan Çöven[1], Tülay Öncü-Öner[1*]

[1]Department of Bioengineering, Faculty of Engineering and Natural Sciences, Manisa Celal Bayar University, Manisa, Türkiye

Abstract

Thymbra spicata, locally known as zahter, is a medicinal plant-rich in bioactive compounds, including phenolic compounds, flavonoids, and essential oils. *T. spicata* is used to regulate blood sugar levels and digestive system, strengthen immunity, improve memory, be calm, and care for the skin. It is known to have remarkable antibacterial, antifungal, antioxidant, and insecticidal activities. The aim of this study was to investigate the cytotoxic, antibacterial, and antiviral activities of *T. spicata* ethanol extract. Firstly, ultrasound-assisted extraction was performed using 70% ethanol. Then, total phenolic and total flavonoid contents were determined. The cytotoxic activity was assessed against lung adenocarcinoma (A-549), breast adenocarcinoma (MDA-MB-231), breast adenocarcinoma (MCF-7), prostate cancer (PC-3), and neuroblastoma (SH-SY5Y) cell lines using the MTT assay to determine cell viability and IC_{50} values. Antibacterial activity was tested against *Escherichia coli* and *Staphylococcus aureus* using the disk diffusion and minimum inhibitory concentration methods. The antiviral potential was evaluated *in ovo* against infectious bronchitis virus. Herein, total phenolic content was measured as 31.84±0.09 mg GAE/g, total flavonoid content as 5.42±0.13 mg CE/g. MTT assay revealed dose-dependent cytotoxicity to all cell lines. IC_{50} values were found as 335.78±39.10 µg/ml for A549, 592.18±20.83 µg/ml for MDA-MB-231, 473.00±27.52 µg/ml for MCF-7, 308.99±31.51 µg/ml for PC-3, and 370.668±11.85 µg/ml for SH-SY5Y cell lines. The zone diameter was measured as 8.19 mm for *S. aureus*, and 7.12 mm for *E. coli*, demonstrating antibacterial potential of *T. spicata*. In addition, MIC values were 6.25 mg/ml and 12.5 mg/ml for *S. aureus* and *E. coli*, respectively. The antiviral activity of the extract was determined between 125-500 µg/ml concentrations, indicating promising inhibitory effects. These findings highlight the potential of *T. spicata* as a natural source of bioactive compounds for biomedical and pharmaceutical applications. Further studies are needed to identify its active components and elucidate its mechanism of action.

Key Words: *Thymbra spicata, zahter, cytotoxic, antibacterial, antiviral*

Patates Mini Yumru Üretiminde Akan Su Kültürü, Aeroponik ve Topraklı Ortam Yöntemlerinin Verim ve Verim Unsurları Yönleriyle Karşılaştırılması

A. Çağlı, U. Pırlak, T. Özkan, Dr. N. O. Demir, G. Kaçar Avcı, E. İnan, M. Uzlaşır

Patates Araştırma Enstitüsü Müdürlüğü, Niğde, Türkiye
Sorumlu Yazar: abdurrahman.cagli@tarimorman.gov.tr

Özet

Patateste meristem kültüründen elde edilen fidelerden süper elit kademede mini yumru üretiminde geleneksel topraklı yetiştiriciliğin yanı sıra sağladığı avantajlar nedeniyle son yıllarda aeroponik yöntemlerde kullanılmaya başlanmıştır. Ülkemizde sertifikalı tohumluk üretimi ise ithalat yoluyla başta Hollanda ve Almanya'dan getirilen çoğunlukla orijinal kademedeki tohumluklarla yapılmaktadır. Son yıllarda yapılan çeşit geliştirme çalışmaları neticesinde 2025 yılı itibari ile tescil edilen çeşit sayısı 47 olmuştur (TTSM 2025). Patates tohumluğunda dışa bağımlılığı azaltmak için özellikle yerli çeşitlerimize ait tohumluk üretimimizi arttırmamız gerekmektedir. Patates mini yumru üretiminde topraklı yetiştiriciliğin dışında daha avantajlı olan hidroponik sistemlerle daha fazla üretim yapılabilir.

Araştırmada elde edilen verilerin istatistiki analizleri sonucunda geleneksel topraklı üretime göre hidroponik üretim sistemlerinden akan su kültürü ve aeroponik sistemle mini yumru üretiminin daha avantajlı olduğu tespit edilmiştir. 2021 ve 2022 yılları ortalamasında Nigşah, Leventbey ve Onaran 2015 çeşitlerinden aeroponik sistemde 32 adet, akan su kültürü sisteminde 29,3 adet ve topraklı yetiştiricilikte ise bitki başına ortalama 5,3 adet mini yumru elde edilmiştir. Bitki başına ortalama mini yumru sayısı açısından topraklı yetiştiricilik, aeroponik sistem ve akan su kültürü sistemi ile yetiştiriciliğin çok gerisinde kalmıştır.

***Anahtar Sözcükler**:* Patates, Mini Yumru, Akan su kültürü, Aeroponik, Topraklı Ortam, Doku Kültürü

Comparison of Flowing Water Culture, Aeroponic and Soil Media Methods in terms of Yield and Yield Elements in Potato Mini Tuber Production

Abstract

In potato, in the production of mini tubers in the super elite stage from seedlings obtained from meristem culture, in addition to traditional soil cultivation, aeroponics methods have started to be used in recent years due to the advantages they provide. In our country, certified seed production is carried out with mostly original stage seeds brought from the Netherlands and Germany through import. In order to reduce external dependency in potato seeds, we need to increase our seed production, especially of our local varieties. In potato mini tuber production, more production can be made with hydroponic systems, which are more advantageous than traditional soil cultivation. For this reason, studies are needed to increase the production of mini tubes in the super elite stage, which constitutes the beginning of seed production in potatoes.

In this study, the yield and yield elements of super elite stage mini tuber production, which is the first stage of potato seed production in flowing water culture, aeroponics and soil cultivation, were examined and which method was more advantageous was determined.

***Keywords**:* Potato, mini tuber. flowing water culture, aeroponik, grounded environment, tissue culture

1. Giriş

Patateste meristem kültüründen elde edilen bitkilerle süper elit kadem mini yumru üretimi, topraklı yetiştiriciliğin yanı sıra son yıllarda avantajları nedeniyle aeroponik yöntemlerle de yetiştiricilik yapılmaktadır. Ülkemizde ise sertifikalı tohumluk üretimi,Avrupa ülkelerinden genellikle orijinal kademedeki tohumlukların ithalatı yoluyla gerçekleştirilmektedir. Son yıllarda yapılan çeşit geliştirme çalışmaları neticesinde 2025 yılı itibari ile tescil edilen çeşit sayısı 47 olmuştur (TTSM 2025). Patates tohumluğu üretiminde dışa bağımlılığı azaltmak amacıyla son yıllarda ülkemizde geliştirilen çeşitlerimizin tohumluk üretiminin artırılması büyük önem taşımaktadır. Mini yumru üretiminde topraklı yetiştiriciliğin dışında, hidroponik sistemler gibi daha verimli yöntemlerle üretim artırılabilir. Bu nedenle, patates tohumluğu üretiminin temelini oluşturan süper elit kademedeki mini yumru üretiminin arttırılması konusunda daha fazla araştırma ve çalışma yapılması gerekmektedir.

2. Materyal ve Metot

2.1 Materyal

Araştırmalar 2020-2023 yılları arasında Patates Araştırma Enstitüsü Müdürlüğü doku kültürü laboratuvarında ve tam kontrollü serasında yürütülmüştür.

Araştırmada Onaran 2015, Leventbey, Nigşah çeşitleri kullanıldı. Aşağıdaki çizelgede çeşitlerin genel özellikleri verilmiştir.

Çizelge 1. Denemede kullanılan çeşitlerin özellikleri

Çeşit	Özellik	Olgunluk	Verim Ortalaması kg/da	Kuru madde içeriği (%)	Nişasta içeriği (%)
ONARAN 2015	Yemeklik	Geççi	5.487	18,8-20,1	12,7-13,9
NİĞŞAH	Yemeklik	Orta Erkenci	4.900	19,0-21,0	13,0-15,0
LEVENBEY	Yemeklik	Orta Erkenci	5.523	19,2-19,8	13,1-13,6

2.2 Metot

Çalışmada 2 farklı deneme yürütüldü.

2.2.1. Akan Su Kültürü, Aeroponik ve Topraklı Ortam Karşılaştırma Denemeleri; 2021-2022 yıllarında, Su Kültürü, Aeroponik ve Topraklı Ortam yöntemleri üzerine yapılan denemeler, tesadüfi parsellerin kullanıldığı bir deneme desenine göre gerçekleştirilmiştir. Denemeler, iki yıl boyunca her biri 4 tekerrürlü olarak kurulmuştur. Ana parsellerde uygulamalar, alt parsellerde ise farklı çeşitler üzerinde çalışılmıştır. Sıra arası mesafe 10 cm, sıra üzeri mesafe ise 20 cm olacak şekilde, her metrekareye 50 bitki dikilmiştir.

2.2.2. Akan Su Kültürü, Aeroponik ve Topraklı Ortam Denemelerinden Elde Edilen Farklı Boyuttaki Yumruların Verim ve Verim Unsurları Yönünden Karşılaştırılması Denemeleri;

2022 ve 2023 yıllarında, 10-30 mm ve 30 mm'den büyük boyutlardaki mini yumrular kullanılarak, tül seralarda çift sıralı bir tarla denemesi kurulmuştur. Denemede, sıra arası 70 cm, sıra üzeri ise 20 cm olarak belirlenmiş ve her sırada 25 yumru olacak şekilde bir düzenleme yapılmıştır. Çalışmalar, her iki yıl için tesadüf blokları deneme desenine uygun olarak faktöriyel deneme düzeniyle, 4 tekerrürle gerçekleştirilmiştir.

Akan Su Kültürü:

Akan su kültürü sistem, her bir kanal 300 cm uzunluğunda, 5 cm yüksekliğinde, 10 cm genişliğinde kanallardan oluşturuldu. m^2' ye 50 bitki yerleştirildi. Besin solüsyonu, bir 3000-L tanktan 2.5 L / dk'lık bir hızda bir dalgıç pompa kullanılarak kanalın girişine pompalandı, daha sonra besin solüsyonu kanalın giriş ucundan 2 cm daha düşük olan kanalın karşı ucuna doğru besin tankına geri çekildi. Bitkicikler, bitki örtüsünü desteklemek için hidroponik sisteme köpüklerle monte edildi. Aynı kanalda yetiştirilen bitkiler aynı muameleye tabi tutuldu ve besin çözeltisinin konsantrasyonu tam olarak sağlandı. Makro besinler için; kalsiyum süper fosfat, potasyum nitrat, amonyum nitrat. Mikro besinler için; bakır sülfat, çinko sülfat, amonyum molibdat, borik asit, mangan sülfat, magnezyum sülfat, demir-EDTA besinleri kullanıldı (Farran ve ark. 2006). Vejetasyon süresi boyunca bitkinin gelişimine göre besin çözeltisi tankındaki çözelti yenilendi.

Aeroponik Sistem: 8 m boyunda 1 m eninde 1 m yüksekliğindeki tezgahlar metal profil iskelet üzerine straforla kaplandı. Tezgahların üstüne konulacak siyaha boyanmış polikarbonlara 10*20 cm dikim sıklığında m^2' ye 50 bitki yerleştirildi. Her bir masaya besleme borusu boyuna 2' şer adet 8 m uzunluğunda borular ve her bir tezgaha ana besleme borusuna 360° dereceli 1 m aralıklarla aeroponik püskürteçler ile sisleme yapıldı. Sistemde besin tankı ve drenaj sistemi kullanıldı. Bitkilerin gelişim durumlarına göre besin çözeltisi tankındaki çözelti yenilendi.

Topraklı Ortam: Topraklı yetiştiricilikte in vitro koşullarda yetiştirilen bitkiler saksılara aktarıldı. Yetiştirme ortamı olarak steril torf kullanıldı. Bitki çeşitleri bir sıraya 30 bitki gelecek şekilde her bir saksıya 20 cm aralıklı olacak şekilde 2 bitki yerleştirildi.

Akan su kültürü, aeroponik ve topraklı yetiştiricilikte bitkilerin hasadı farklı zamanlarda yapıldı. Akan su kültürü ve aeroponik yöntemde sıralı hasat yapılırken, topraklı yetiştiricilikte ise hasat olgunluğuna gelen bitkiler tek seferde hasat edildi. Hasat edilen mini yumrular tül seralarda dikim tarihine kadar iklimlendirme dolabında +4 °C 'de muhafaza edildi.

3. Bulgular

3.1. Bitki Başına Mini Yumru Sayısı(adet/bitki):

2021 yılında denemeye alınan patates çeşitlerinin bitki başına yumru sayısına çeşit, metot ana etkisi ile çeşitxmetot interaksiyonu ortalama değerler bakımından istatistiki olarak önemli bulunmuştur (Çizelge 2). Çizelge 2' de görüldüğü gibi denemede kullanılan çeşitlerin m^2 deki mini yumru sayıları akan su kültürü sistemindeki Leventbey çeşidi bitki başına 42,9 adet ile a grubunda ilk sırada, aeroponik sistemde Niğşah çeşidi 38,1 adet ile b grubunda ikinci sırada, yine aeroponik sistemde 30,5 adet ile Onaran 2015 çeşidi c grubunda üçüncü sırada yer almışlardır. Topraklı yetiştirme ortamında Niğşah çeşidi ise 3,9 adet ile h grubunda son sırada yer almıştır. Bitki başına ortalama mini yumru sayıları açısından topraklı ortamda yetiştiricilik, aeroponik sistem ve akan su kültürü sistemi ile yetiştiriciliğin çok gerisinde kalmıştır.

2022 yılında denemeye alınan patates çeşitlerinin bitki başına yumru sayısına çeşit, metot ana etkisi ile çeşitxmetot interaksiyonu ortalama değerler bakımından istatistiki olarak önemli bulunmuştur (Çizelge 2). Çizelge 2' de görüldüğü gibi denemede kullanılan çeşitlerin bitki başına mini yumru sayılarında akan su kültürü sistemindeki Leventbey çeşidi bitki başına 40,7 adet ile a grubunda ilk sırada, aeroponik sistemde Niğşah çeşidi 36,4 adet ile b grubunda ikinci sırada, yine aeroponik sistemde 34,4 adet ile Leventbey çeşidi b grubunda üçüncü sırada yer almışlardır. Topraklı yetiştirme ortamında Niğşah çeşidi ise 4,2 adet ile f grubunda son sırada yer almışlardır. Bitki başına ortalama mini yumru sayıları açısından topraklı ortamda yetiştiricilik, aeroponik sistem ve akan su kültürü sistemi ile yetiştiriciliğin çok gerisinde kalmıştır.

Çizelge 2. Denemeye alınan çeşitlerin bitki başına mini yumru sayısı(adet/bitki)

Akan Su Kültürü, Aeroponik ve Topraklı Ortam Denemelerinden Elde Edilen 10-30 mm Boyutundaki Yumruların Verim ve Verim Unsurları Yönünden Karşılaştırılması Denemeleri; 2021 yılında elde edilen 10-30 mm boyutlarındaki mini yumrularla, 25 Mayıs 2022 tarihinde tül seralarda çift sıralı bir tarla denemesi kurulmuştur. Bu denemede, sıra arası 70 cm, sıra üzeri 20 cm ve her sırada 25 yumru olacak şekilde deneme kurulmuştur. Elit yumrular 6 Ekim 2022'de hasat edilmiştir.

2022 yılında üretilen 10-30 mm boyutlarındaki mini yumrularla ise, 27 Mayıs 2023 tarihinde benzer şekilde tül seralarda çift sıralı tarla denemesi kurulmuştur. Elit yumrular 14 Ekim 2023'te hasat edilmiştir.

3.2. Tek Bitki Verimi (adet/bitki):

2022 yılında denemeye alınan patates çeşitlerinin tek bitki verimine etkilerinin çeşit ana etkisinin ortalama değerler bakımından istatistiki olarak önemli olduğu, çeşitxmetot interaksiyononun ise istatistiki olarak önemsiz olduğu belirlenmiştir (Çizelge 3). Duncan Çoklu Karşılaştırma Testinde %5 önem seviyesine göre oluşan gruplar da Çizelge 3' te verilmiştir. Topraklı ortamdan elde edilmiş mini yumru dikiminden Leventbey çeşidi bitki başına 7,3 adet elit yumru ile ilk sırada, akan su kültürü sisteminden elde edilmiş mini yumru dikiminde Nığşah çeşidi bitki başına 5,6 adet ile son sırada yer almıştır. Topraklı ortamda elde edilmiş mini yumrular daha iri sürgünler oluşturduğundan bu yumruların dikiminden daha fazla sayıda ön elit kademe yumru elde edilmiştir.

2023 yılında denemeye alınan patates çeşitlerinin tek bitki verimine etkilerinin çeşit ve metot ana etkisinin ortalama değerler bakımından istatistiki olarak önemli olduğu, çeşitxmetot interaksiyononun ise istatistiki olarak önemsiz olduğu belirlenmiştir (Çizelge 3). Duncan Çoklu Karşılaştırma Testinde %5 önem seviyesine göre oluşan gruplar da Çizelge 3' te verilmiştir. Çizelge 3' te görüldüğü gibi topraklı ortamdan elde edilmiş mini yumruların dikiminden daha fazla sayıda elit yumru elde edilmiştir.

Denemeye alınan patates çeşitlerinin iki yıl ortalamasında tek bitki verimine etkilerinin çeşit ve metod ana etkisinin ortalama değerler bakımından istatistiki olarak önemli olduğu, çeşitxmetot interaksiyononun ise istatistiki olarak önemsiz olduğu belirlenmiştir (Çizelge 3). Topraklı yetiştiricilikten elde edilmiş mini yumru dikiminden Leventbey çeşidi bitki başına 7,0 adet elit yumru ile a grubunda ilk sırada, akan su kültürü sisteminden elde edilmiş mini yumru dikiminde Nığşah çeşidi bitki başına 5,3 adet ile d grubunda son sırada yer almıştır.

4. Tartişma Ve Sonuç

Geleneksel topraklı yetiştiriciliğin yanında aeroponik ve akan su kültürü gibi modern sistemlerle de patateste mini yumru üretimi yapılmıştır. Aeroponik ve akan su kültürü yetiştiricilikte sistem kurulumunun maliyeti ve profesyonel eleman gerekliliği topraklı ortama göre dezavantaj oluşturmaktadır. Mini yumru üretiminde bitki başına yumru sayısı önemli olduğundan Topraklı Ortamla yetiştiriciliğe göre 5-6 kat daha fazla sayıda yumru elde edilen aeroponik ve akan su kültürü sistemi daha avantajlı bulunmuştur. Čížek vd. (2022) çalışmalarında buldukları bitki başına ortalama mini yumru sayısı 24 ve 41 adet, Rykaczewska (2016) 32,5 ve 36 adet, Bag vd. (2015) 38 ve 42 adet ile deneme sonuçları uyumlu bulunmuştur. Aeroponik sistemde bitki kökleri havada asılı durduğundan daha iyi havalanmakta, bu nedenle kökleri akan su kültürü sistemine göre daha sağlıklı gelişmektedir. Akan su kültürü sisteminde bitkinin yeşil aksamı diğer iki sisteme göre daha iyi gelişmiştir. Aynı çeşitlerde akan su kültürü sisteminde aeroponik sisteme göre bir hafta kadar daha geç yumru oluşturmuştur. Aeroponik ve akan su kültürü sisteminde bitkilerin vejetasyon süresi (6-7 ay) topraklı yetiştiriciliğe göre daha uzun sürmekte bu nedenle daha fazla sayıda hasada imkan sağladığından bitki başına yumru sayısı artmıştır. Akan su kültürü sisteminde su içerisinde bulunan yumruların hasadı geciktirildiğinde yumruların bir kısmında çürümeler olmuştur. Aeroponik ve akan su kültürü yöntemi ile elde edilen mini yumruların depoya alınmadan önce oda sıcaklığında kontrollü şartlarda bir hafta kadar tutulmaları depo kayıplarını azaltmıştır. Her üç sistemden elde edilen yumrular +4 ºC' de muhafaza edildiklerinde topraklı yetiştirme ortamından elde edilen mini yumruların daha erken sürgün oluşturdukları tespit edilmiştir. Aeroponik ve akan su kültürü sistemlerinden elde edilen mini yumruların 6-8 ºC' de dikime kadar muhafaza edilmeleri daha uygun olacağı tespit edilmiştir. Leventbey çeşidinin akan su kültürü sistemine daha uyumlu olduğu tespit edilmiştir. Her üç yöntemden elde edilen mini yumruların araziye dikimlerinde bitki çıkışlarında bir problem tespit edilmemiştir. Yumruların araziye dikimlerinde bitkilerin çıkış sürelerinde ve bitki başına elit yumru sayısında mini yumru yetiştiricilik metodunun %5 önem seviyesinde etkisinin olduğu tespit edilmiştir. Patateste mini yumru yetiştirme metotlarından akan su kültürü ve aeroponik sistemleri kendi aralarında kıyasladığımızda bitki başına verimlerinin yanında özellikle depo kayıplarının daha az olmasından dolayı aeroponik sistem daha avantajlı bulunmuştur.

Effect of synthetic insecticides and botanical extract against whitefly, *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) in different okra varieties

Muhammad Salim[1], Shahid Sattar[1]

[1]Department of Plant Protection, Faculty of Crop Protection Sciences, The University of Agriculture, Peshawar, Pakistan.

Abstract

The whitefly, *Bemisia tabaci*, is a major pest of okra (*Abelmoschus esculentus*), causing significant yield losses. Therefore this study was designed to evaluate the population dynamics of *B. tabaci* and the efficacy of synthetic insecticides and neem seed extract in different okra varieties during 2024. In the first experiment, the population trend of *B. tabaci* was monitored in five okra varieties: Marvi, Viraj, Sabz Pari, Green Finger, and Advanta. In this experiment, the infestation started in late May, peaked in late July (6.21 whiteflies per leaf), and declined by early September. Green Finger exhibited the lowest infestation (2.08 whiteflies per leaf), while Viraj had the highest (4.05 whiteflies per leaf). Green Finger also recorded the highest yield (6064.4 kg/ha), whereas Viraj had the lowest (1834.8 kg/ha). In the second experiment, synthetic insecticides (Cypermethrin and Acetamiprid) and neem seed extract were evaluated. Acetamiprid was the most effective, reducing *B. tabaci* populations to 1.58 and 1.56 whiteflies per leaf after the first and second sprays, respectively. Neem seed extract also suppressed whitefly populations (4.79 and 4.84 whiteflies per leaf). Acetamiprid resulted in the highest yield (2984 kg/ha) and cost-benefit ratio (26.52), followed by Cypermethrin (22.26) and neem seed extract (19.69). Green Finger showed higher resistance to *B. tabaci*, while Acetamiprid and neem seed extract effectively reduced infestation. The study concluded that these treatments should be integrated into pest management strategies to improve okra productivity.

Lethal and sublethal effects of neem leaves extract (*Azadirachta indica)* against pink hibiscus mealy bug (*Maconellicoccus hirsutus*) (Hemiptera: Psudococcidae)

Muhammad Salim

[1]Department of Plant Protection, Faculty of Crop Protection Sciences, The University of Agriculture, Peshawar, Pakistan.

Abstract

Maconellicoccus hirsutus, commonly known as the pink hibiscus mealybug, is a polyphagous insect pest with a global presence, posing significant economic and ecological threats to a wide range of host plants. This study evaluated the lethal and sub lethal effects of neem (*Azadirachta indica*) leaves extract against *Maconellicoccus hirsutus* under laboratory conditions. Adult female's *M. hirsutus* were treated with dilutions of neem leaves and the greatest mortality (54%) was observed at 5% neem leaves extract after 72 hours, while no mortality was recorded in the control after 72 hours. The LC_{50} value of 4.85 ppm of the neem leaves extract was calculated for female adult of *M. hirsutus* after 72 hours of exposer and was further tested on the fresh eggs and nymphs of *M. hirsutus*. Contact exposing of the eggs and nymphs to neem leaves extract significantly reduced the % hatch rate of *M. hirsutus* eggs (45.23%) and caused significantly high mortality of the nymph (62.22%) after 72 hours as compared with the control. The sub-lethal effect of the neem leaves extracts on the female adult of *M. hirsutus* showed that the insects treated with 5% neem leaves extract concentration had significantly lower values of finite rate of increase *(λ)* (1.09±0.004 day^{-1}), intrinsic rate of increase (*r)* (0.08±0.004 day^{-1}) and net reproductive rate (R_o) (32.56±4.75 eggs/female) as compared with the population treated with lower neem leaves concentrations. Similarly, the age-stage specific life expectancy (e_{xj}) and age specific reproductive value (v_{xj}) of *M. hirsutus* were recorded lower when treated with 5% neem leaves extract as compared to other treatments. This study revealed that neem leaves extracts are highly effective in reducing *M. hirsutus* infestation and can be used in mealybug IPM programs.

Effects of milking methods on test-day milk yield and milk quality traits in early lactating multiparous buffalo cows and the relationships among these parameters

İbrahim Cihangir Okuyucu[1]

[1]Department of Animal Science, Faculty of Agriculture, Ondokuz Mayis University, 55139 Samsun, Türkiye

Abstract

Buffaloes are not fully adapted to machine milking because they are generally milked manually. Therefore, a comprehensive examination of the relationships between milking practices and productivity is critical to obtain high quality milk products. The aims of the present study were i) to investigate the effects of different milking methods on test-day milk yield (TDMY) and milk quality traits [dry matter (DM), fat, solids-not-fat (SNF), protein, fat-to-protein ratio (FPR), lactose, density, freezing point (FP), somatic cell count (SCC), pH and electrical conductivity (EC) in multiparous Anatolian buffalo cows and ii) to investigate the relationships among these milk quality traits. The study material consisted of 120 milk samples collected from 60 buffalo cows machine and hand milked in five barns at the same location on a family farm. The collected milk samples were analysed for their milk components (DM, fat, SNF, protein lactose, density and FP), SCC, pH value, and EC value using the following devices: i) a milk analyser, ii) a portable somatic cell counter, iii) a pH meter, and iv) an EC-meter equipped with a conductometric sensor. The statistical analyses were conducted using *t-test* and Pearson Correlation procedures. The quantitative (DM, fat, protein, density, SCC, EC, and pH)-qualitative (TDMY) milk parameters of hand-milked cows was found to be higher than that of machine-milked cows. Furthermore, a positive correlation was found between SCC and pH and EC values. It was determined that milk DM, SNF and lactose percentages decreased as TDMY value increased. The SCC and EC displayed a negative correlation with the milk fat percentages, and a positive correlation with milk mineral percentages. Although manual milking improves quantitative-qualitative milk parameters in buffalo cows, it may pose more risks to their udder health and milk hygiene. Therefore, the advantages and disadvantages of current milking practices should be carefully considered.

Key Words: *Buffalo cows, hand milking, machine milking, quantitative-qualitative milk parameters*

Introduction

It is evident that buffalo milk, which has high nutritional content, has recently attracted the consumers' interest because it can be transformed into high value-added products (Akdağ et al., 2024). Therefore, it is important to improve the quality and quantity traits of milk produced from buffalo cows (*Bubalus bubalis)*. The quantitative-qualitative milk parameters of buffalo cows (Okuyucu et al., 2024; Akdağ et al.,2024) can be influenced by i) resource-based factors (e.g. space allocation, barn facilities, soil and climatic factors), ii) management-based factors (e.g. handling strategies, breeding strategies, milking practices and health plan) and iii) animal-based factors (e.g. body condition, udder hygiene, lameness and milking temperament). Particularly, milking practices are important for buffalo cows because buffaloes are sensitive to non-routine practices and environmental stimuli (Napolitano et al., 2013). This process can cause considerable stress to buffalo cows (Erdem et al., 2022). As buffalo farming is predominantly extensive worldwide (Erdem et al., 2022), manual milking is a common practice. However, with increasing intensification, the use of mechanical milking on dairy farms has also increased. Therefore, the advantages and disadvantages of milking methods applied to buffalo cows should be carefully considered. Since manual milking is one of the most labour- and time-consuming practices, manual milkers may encounter health problems such as stiff shoulders, pain and weakness in the knee joints and spine (Khatri et al., 2021). In addition, contamination of the cow's teat in manual milking can result in an increase in microorganisms in milk. Although machine milking, which is another milking method, is beneficial in terms of milk hygiene and reducing labour use, the responsiveness of buffalo cows to machine milking may quantitative [dry matter (DM), fat, solids-not-fat (SNF), protein, fat-to-protein ratio (FPR), lactose, density, freezing point (FP), somatic cell count (SCC), pH and electrical conductivity (EC)]-qualitative [test-day milk yield (TDMY)] milk parameters (Erdem et al., 2022; Okuyucu et al., 2024; Akdağ et al.,2024). Therefore, milking cows under hygienic conditions with milking methods that provide optimum welfare conditions is the most critical management practice for quality milk production.

A large body of authors has reported that effective milk extraction plays an important role in milking techniques and procedures and can influence milk yield and its components (Argov-Argaman, 2019; Couvreur and Hurtaud, 2017; Palii et al.,2020). However, the literature on the effects of different milking methods on TDMY and milk components of buffalo cows is limited. The aims of this study were i) to investigate the effects of different milking methods on quantitative (DM, fat, SNF, protein, FPR, lactose, density, FP, SCC, pH and EC)-qualitative (TDMY) milk parameters and ii) to investigate the relationships among milk parameters.

Materials and Methods

This study was conducted in five barns at the same location on a family farm in Samsun, located in the Black Sea Region of Türkiye. The study material consisted of 120 milk samples collected from 60 multiparous buffalo cows machine and hand milked in barns (closed-tied-stall barns). The cows included in the study were cows of parity 2 (n= 10), 3 (n=10) and 4 (n=10). The data were collected during once per week visits to the farm between January 2025 and February 2025.All cows were not grazed on pasture and were fed ad libitum with a TMR in the barn. The TMR available consisted of wheat straw, maize silage and concentrate.

Routine practices on the farm were not changed throughout the study. The farm were visited and milk was collected twice during the study. Manual and machine milking practices were as shown in Table 1.

Table 1. Manual and mechanical milking processes

Milking methods	Milking processes		
	Milking processes	Pre-milking processes	Post-milking processes
Manual	Cows milked manually by two stockperson	Calves suckled their dams for approximately two minutes. Then, the cow's udders were washed with fresh water and dried with a clean cloth.	After the milking process no iodine teat dip was applied.
Machine	Each cow was milked individually with a portable milking machine (PLS-2/1; Sezer, Bursa, Türkiye).		

At the end of milking, the milk samples were weighed on an electronic scale and the TDMY values were determined. Approximately 50 ml of milk samples were then collected in plastic milk tubes. These samples were transported to the laboratory at 4°C to evaluate the content of milk components and physical traits. All analyses were performed when the milk was at 30°C to 32°C. The milk components (milk fat, protein, lactose, and mineral percentages), and physical traits [density (mg/mL), and the FP (°C)] of the milk samples were analyzed using an milk analyzer (Lactostar, Funke-Gerber, Germany). Furthermore, FPR were calculated as fat percentage/protein percentage. The milk EC (mS/cm) and pH were measured using an EC-meter equipped with a conductometric sensor (FiveEasy Plus, Mettler Toledo, Switzerland) and pH meter (Testo 205), respectively. The SCC value of the milk was determined using a portable cell counter (DeLaval, Tumba, Sweden).

The statistical analyses were conducted using the SPSS software program (version 21.0, SPSS Inc., Chicago, IL, USA). Prior to analysis, the normality and variance homogeneity of data from test-day records of quantitative (DM, fat, SNF, protein, lactose, mineral, density, FP, SCC, EC, and pH)-qualitative (milk yield) milk parameters were screened using the Kolmogorov-Smirnov and Levene's tests, respectively. The logarithmic transformation procedure was applied to the SCC data, which is one of the available milk quality traits, because the data did not show a normal distribution.

To determine the effects of milking practices on quantitative-qualitative milk parameters, *t-test* procedure was applied. To this end, the cows were allocated to ensure that an equal number of cows were represented in each group [machine (n=30) and manual (n=30) milking]. Correlation coefficients among these traits were calculated by applying Pearson correlation procedure.

Results and Discussion

In the present study, the mean values of quantitative-qualitative milk parameters of Anatolian buffalo cows in early lactation were as shown in Table 2. In previous studies on buffaloes, the mean TDMY (5.37 kg, Tripaldi et al., 2010; 5.7 kg, Şekerden, 2011; 3.96-4.53 kg, Sarıözkan et al., 2021) value was lower than the results obtained in the current study. However, the current results were higher than those (2.95 kg) reported by Özcan and Erdem, (2022). Furthermore, the milk DM percentage was higher than the findings reported in several studies (16.207-17.230%, Sahin et al., 2014; 14.18-15.67%, Sarıözkan et al., 2021; 17.29% for Nili-Ravi, 18.23% for Murrah, Abdel-Hamid et al., 2023), but lower than in other reported studies (20.18% for Mediterranean, Abdel-Hamid et al., 2023). The findings of this study demonstrated a congruence with the outcomes documented in several preceding studies, particularly with regard to the percentage of fat in milk (Özcan and Erdem, 2022; Yuan et al., 2022). Similarly, the milk protein percentage was also consistent with those reported in previous studies (4,515-4,955% for Anatolian Buffalo, Sahin et al., 2014; 4.38 % for Nili-Ravi, Abdel-Hamid et al., 2023). The percentage of milk lactose was higher than reported reported by Tripaldi et al. (2010). However, the percentage of lactose was lower than that reported in other studies (Özcan and Erdem, 2022; Yuan et al., 2022; Abdel-Hamid et al., 2023). Also, the milk mineral percentage was not in agreement with those reported by Özcan and Erdem, (2022).

The density value, which is one of the physical traits of milk, was consistent with those reported in previous studies (Sarıözkan et al., 2021; Özcan and Erdem, 2022). However, the milk FP value was not in agreement with those reported in previous studies (Özcan and Erdem, 2022; Okuyucu et al., 2024; Akdağ et al., 2024). The SCC value was lower than those reported in previous studies (Sarıözkan et al., 2021; Viana et al., 2024) but higher than those reported in others studies (Özcan and Erdem, 2022; Yuan et al., 2022). The milk pH value was consistent with those reported in previous studies (Şekerden and Avşar, 2008; Tripaldi et al., 2010). Similarly, the milk EC values were also in accordance with those reported in previous studies on Anatolian buffaloes (Okuyucu et al., 2024; Akdağ et al., 2024).

Table 2. Means test-day milk yield and milk quality traits of Anatolian buffalo cows

Variables	Number of records	Mminumum	Maximum	Mean	SE
Milk yield trait (kg)					
TDMY	120	2.00	4.78	3.38	0.066
Milk components (%)					
DM	120	14.99	23.46	18.62	0.241
Fat	120	6.10	12.35	8.48	0.169
SNF	120	7.13	13.39	10.14	0.160
Protein	120	3.00	6.09	4.40	0.093
FPR	120	1.19	4.00	1.98	0.060
Lactose	120	3.36	6.61	4.94	0.740
Mineral	120	0.45	0.98	0.65	0.013
Milk physical traits					
Density (mg/ml)	120	1.00	1.06	1.03	0.001
FP (˚C)	120	-0.42	-0.87	-0.60	0.014
SCC (x10^3 cells/ml)	120	10	347	76.4	7.333
logSCC	120	4.00	5.54	4.78	0.042
pH	120	6.23	7.00	6.59	0.027
EC (mS/cm)	120	3.00	5.30	3.50	0.070

TDMY: Test-day milk yield; DM: Dry matter; SNF: Solids-not-fat; FPR: Fat-to-protein ratio; SCC: Somatic cell count; FP: Freezing point; EC: Electrical conductivity

The TDMY obtained from machine milked cows was lower than those milked manually (p=0.018; Table 3). Similarly, the DM (p=0.028), fat (p=0.043) and protein (p=0.047) precentages and density (p=0.029) in the milk of machine milked cows was lower than that of hand milked cows. Although the design of this study was not suitable to prove the following hypotheses, the higher TDMY value, DM, fat and protein content in hand milked cows compared to machine milked cows may be related to i) negative effects of machine milking on oxytocin release mechanism of cows, ii) high reactivity (increase in behavioural responses) to machine milking and iii) machine milking equipment not being suitable for buffalo udder physiology (Okuyucu et al., 2024; Ahmet et al., 2024). It was a remarkable finding that milk SCC (p=0.049), pH (p=0.048) and EC (p=0.038) values, which are considered important indicators of udder health and milk quality, were higher in hand milked cows compared to machine milked cows. In a previous study on dairy cows, it was reported that the number of microorganisms (microorganisms x 1000/ml) in the milk of cows milked by hand was higher than that of cows milked by machine (Filipovic and Kokaj, 2009). In the same study, it was reported that the several milk components (fat and protein percentages) and SCC values of hand-milked cows were comparatively higher than those of machine-milked cows, although this difference was not statistically significant. Simlarly, milking methods (manual and machine milking) did not statistically affect milk components and SCC values (Sarıözkan et al., 2021; Li et al., 2024). The results obtained suggest that milk yield and the content of some milk components are positively influenced, whereas udder health (high SCC, pH and EC values) and milk hygiene may be negatively influenced.

Table 3. Means test-day milk yield and milk quality characteristics of cows according to milking practices

Variables	Milking methods		SEM	p-value
	Machine	Manual		
Milk yield trait (kg)				
TDMY	3.23	3.53	0.066	0.018
Milk components (%)				
DM	18.09	19.14	0.241	0.028
Fat	8.14	8.82	0.169	0.043
SNF	9.96	10.32	0.160	0.254
Protein	4.22	4.57	0.093	0.047
FPR	2.0	1.96	0.060	0.745
Lactose	4.91	4.98	0.740	0.629
Mineral	0.64	0.66	0.013	0.718
Milk physical traits				
Density (mg/ml)	1.02	1.03	0.001	0.029
FP (˚C)	-0.60	-0.61	0.014	0.838
SCC (x10^3 cells/ml)	61.5	91.2	7.333	0.049
pH	6.53	6.64	0.027	0.048
EC (mS/cm)	3.4	3.7	0.070	0.038

TDMY: Test-day milk yield; DM: Dry matter; SNF: Solids-not-fat; FPR: Fat-to-protein ratio; SCC: Somatic cell count; FP: Freezing point; EC: Electrical conductivity

The TDMY value of buffalo cows displayed a negative correlation with the milk DM (p=0.041), SNF (p=0.008), and protein percentages (p=0.005; Table 4).

Table 4. Correlations between the qualitative milk trait (TMDY) and quantitative milk traits examined

	DM	Fat	SNF	Protein	FPR	Lactose	Mineral	Density	FP
TDMY	-0.313 (p=0.041)	-0.040 (p=0.760)	-0.339 (p=0.008)	-0.201 (p=0.123)	0.093 (p=0.481)	-0.359 (p=0.005)	0.026 (p=0.843)	0.189 (p=0.148)	-0.144 (p=0.274)

TDMY: Test-day milk yield; DM: Dry matter; SNF: Solids-not-fat; FPR: Fat-to-protein ratio; SCC: Somatic cell count; FP: Freezing point; EC: Electrical conductivity

The SCC displayed a negative correlation with the milk fat percentages (p=0.030), and a positive correlation with milk mineral percentages (p=0.041; Table 5). Similarly, the EC values correlated positively with the mineral percentages (p=0.026) and negatively with the fat percentages (p= 0.003), FPR (p=0.024), and density values (p= 0.020). However, no statistically significant relationship was found between quantitative-qualitative milk parameters and pH (Table 5). High SCC in milk causes changes in milk enzymes. This may result in the breakdown of milk fat globules. The aforementioned statements elucidate the mechanism responsible for the observed decline in milk fat percentages concomitant with elevated SCC (Aytekin and Boztekin, 2014). Also, the SCC increases due to damage in the mammary tissue, resulting in increased Na+ and Cl concentrations (Aytekin and Boztekin, 2014). Thus, a high mineral content can lead to a significant increase in the EC value of milk.

Table 5. Correlations between milk components and SCC, pH and EC parameters

	SCC	pH	EC
TDMY	-0.068 (p=0.606)	-0.116 (p=0.375)	-0.030 (p=0.818)
DM	0.159 (p=0.225)	0.148 (p=0.258)	0.210 (p=0.107)
Fat	-0.280 (p=0.030)	-0.238 (p=0.067)	-0.383 (p=0.003)
SNF	-0.057 (p=0.668)	-0.028 (p=0.831)	-0.088 (p=0.506)
Protein	0.054 (p=0.684)	0.009 (p=0.944)	-0.048 (p=0.715)
FPR	-0.127 (p=0.335)	-0.119 (p=0.363)	-0.292 (p=0.024)
Lactose	-0.046 (p=0.729)	0.023 (p=0.864)	-0.012 (p=0.927)
Mineral	0.265 p=0.041	0.177 (p=0.177)	0.287 (p=0.026)
Density	-0.206 (p=0.115)	-0.063 (p=0.634)	-0.299 (p=0.020)
FP	0.018 (p=0.892)	-0.092 (p=0.484)	0.071 (p=0.591)

TDMY: Test-day milk yield; DM: Dry matter; SNF: Solids-not-fat; FPR: Fat-to-protein ratio; SCC: Somatic cell count; FP: Freezing point; EC: Electrical conductivity

A positive correlation was found between SCC and pH values (p<0.001). Furthermore, the highest correlation coefficient was calculated between SCC and EC (r = 0.710; p<0.001; Table 6). Similarly, in a study conducted on Mediterranean buffalo cows (Tripaldi et al., 2003), it was reported that milk pH increased as SCC increased. In a another study on Murrah cross buffaloes, a positive correlation was found between SCC and EC values (Dhakal et al., 2008). The findings were consistent with those reported in previous studies (Tripaldi et al., 2003; Dhakal et al., 2008). The present results indicate that pH and EC parameters can be reliably used to indirectly assess udder health and SCC.

Table 6. Correlations between SSC, ph and EC values

	pH	EC
SCC	0.511 (p<0.001)	0.710 (p<0.001)
pH		0.382 (p=0.003)

SCC: Somatic cell count; FP:Freezing point; EC: Electrical conductivity

In the present study, hand milked buffalo cows had higher milk yield and some milk components but higher SCC, which are considered important indicators of milk hygiene and udder health, compared to machine milked buffalo cows. Although available evidence suggests that manual milking improves milk yield and milk composition, it also poses a risk to milk hygiene and udder health. Also, manual milking, a common practice on buffalo dairy farms, is one of the most labour- and time consuming practices. In this regard, manual milkers may encounter health problems such stiff shoulder, pain in knee joints and backbone and weakness (Khatri et al.,2021). Therefore, the advantages and disadvantages of differences in the milking methods of buffalo cows should be carefully examined. Furthermore, the effects of these methods on both animal welfare and the quality of the human-animal interaction should be investigated in detail.

Multivariate Analysis Of The Effect Of Different Pre-Treatment Methods Before Drying On Some Quality Properties Of Potato

Katibe Sinem Coruk[1], Betül Oskaybaş-Emlek[1] , Cansel Murat[1], Arife Nur Kanber[1], Hande Baltacıoğlu[1]

[1]Department of Food Engineering, Engineering Faculty, Niğde Ömer Halisdemir University, Niğde, Türkiye

Abstract

In this study, it was aimed to investigate the physicochemical properties of potato powder obtained from different pre-gelatinization processes applied to yellow-fleshed potato. Steam , microwave , ultrasonication, and thermosonication blanching were applied as pre-gelatination processes. A control sample dried at 55°C, without any pretreatment, was taken as a reference to compare the effect of the treatments on physicochemical properties. Total phenolic content, antioxidant activity, color, water activity, ash and moisture content were analyzed in potato powders dried at 55°C after preliminary gelatinization processes. It was observed that pre-treatments caused a decrease in bioactive substance content while improving color values. Moreover, each of the different pregelatinization treatments gave different results. Steam blanching was the closest to the control sample in terms of preservation of bioactive components and ash content. This is considered an important study in terms of adding new information to the literature with the results obtained using different pregelatinization techniques on potatoes.

Key Words: *Potato, pre-gelatinization, bioactive compound, color, drying*

Abstract

The objective of this study was to isolate and identify cellulose-degrading bacteria from the adult digestive tract of the *Leptinotarsa decemlineata* (Colorado potato beetle). Soluble carboxymethyl cellulose (CMC) degradation assays were used to identify five bacterial strains and assess their cellulolytic activity. The development of a clear zone on CMC plate media and the cellulolytic index were used to calculate cellulolytic activity. The highest cellulolytic index (2.2) was found in MOC6. This strain was identified and described using morphological, biochemical, and partial 16S rDNA sequencing. New cellulose-degrading bacteria from the *Leptinotarsa decemlineata*'s gut have been identified in this investigation. The isolate had relatively high cellulolytic activity was identified as *Bacillus pumilus* strain MOC6. The potential use of this strain in the breakdown of cellulose makes its identification significant.

Key Words: Cellulolytic bacterium, Digestive tract, *Leptinotarsa Decemlineata*

Introduction

The most diverse and prevalent group of animals on the planet are insects, whose ability to survive depends mostly on their exceptional environmental adaptations and food sources. In order to accomplish this, insects have developed highly specialized and complex digestive systems that can break down a wide range of meals, primarily lignocellulose, which is the dry substance found in plant cell walls (Dar et al., 2022). The guts of insects are home to a variety of bacteria that benefit their hosts physiologically and ecologically (Ozdal et al., 2016; Jang and Kikuchi, 2020). Insect digestive systems have been known as the smallest natural bioreactors in the world because of their exceptional lignocellulose digestion (Breznak and Brune, 1994).

Among this diverse group of insects, one species with significant agricultural importance is Leptinotarsa decemlineata (Colorado potato beetle). Belonging to the order Coleoptera and the family Chrysomelidae, this species is a pest primarily feeding on plants of the Solanaceae family, causing substantial yield losses in potato fields worldwide (Muratoğlu et al. 2011). The adult individuals measure 10–12 mm in length, with a yellow-reddish coloration and a strongly convex dorsal surface. The elytra bear a total of ten longitudinal black stripes, five on each side. The mature larvae have a hunched posture, with a dark brown head and a bright orange body (Kekillioğlu and Yılmaz, 2018). *L. decemlineata* overwinters in the soil as an adult. In the spring, it leaves its overwintering sites in search of host plants, during which process it can disperse over large areas (Muratoğlu et al., 2011).

In terms of feeding habits, *L. decemlineata* primarily consumes the leaves of the plant, and then feeds on the stems and tubers. Both larvae and adults typically feed by starting from the edges of the leaves and moving inward, or by creating holes on the leaf surface and continuing to feed (Bouchard et al., 2003). The most destructive period is the late larval stage, which accounts for approximately 90% of total leaf consumption. Furthermore, *L. decemlineata* not only causes physical damage but also serves as a vector for various pathogens, including brown rot, potato ring rot, and spindle tuber viroid**.** The feeding habits and digestive processes of *L. decemlineata* result in a significant specialization of its gut microbiota. The gut of *L. decemlineata* supports a complex microbiota capable of degrading lignocellulose and other plant-derived components (Efimenko et al., 2022).

The aim of this study is to isolate cellulolytic microorganisms from the *L. decemlineata* gut. Numerous insect guts have been found to harbor significant populations of bacteria with cellulolytic activity. (Uddin et al., 2021; Han et al., 2024). Therefore, insects are considered attractive biological sources for discovering new cellulolytic enzymes with extraordinary catalytic potential.

Materials and Methods

Collection of *Leptinotarsa decemlineata* specimens

Leptinotarsa decemlineata collected from potato fields in Erzurum, Pasinler were used in the study. The collected adult specimens were placed in glass jars. These jars were covered with a fine-mesh cloth and transported to the laboratory environment where the experiments were carried out. The beetles were fed on potato plant leaves for a week.

Isolation of bacteria

The beetles were surface sterilized in 70% ethanol, rinsed with sterile distilled water and air dried for 5 minutes at room temperature (25ºC). The beetles were then dissected with a sterile scalpel and the entire gut was removed and suspended in 20 ml of 0.85% NaCl. 0.2 ml of the gut suspension was inoculated into Nutrient Agar (NA, Merck). After 24 hours, colonies that developed on the medium were isolated separately.

Morphological and molecular identification of the bacterial isolates

A colony of each isolate was then moved onto sterile glass slides after the isolates had been subcultured on nutrient agar plates for twenty-four hours. The KOH test (Powers, 1995) and Gram stain (Coico, 2006) were used. To find the gram response, the KOH test employs 3% potassium hydroxide. The cultural, morphological and biochemical properties of the bacterial species (Gram, cell shape, catalase, oxidase) were determined (Harley and Prescott, 2002; Ozdal et al., 2016). The 16S rDNA gene was utilized for molecular identification.

Screening for cellulose-degrading capacity

The isolated bacteria were inoculated individually onto Nutrient Agar (NA, Merck) medium containing 1% CMC. CMC degradation was tested by staining the plates with 1 g/L congo red dye (Sigma, USA) for 15 min and then washing with 1M NaCl. After staining with congo red dye, clear zones around bacterial colonies on CMC plates indicated cellulolytic activity. Cellulase activity index (CAI) was then calculated according to the following equation CAI=[(Diameter clear zone – Diameter bacterial colony)/Diameter bacterial colony] (Handique et al., 2017; Nelson et al., 2021).

Results and Discussion

A total of twenty bacterial strains were isolated from adult digestive tract of the *Leptinotarsa decemlineata*. Purified isolates were screened on CMC plates for cellulase activity. Based on the widths of the clear hydrolysis zones surrounding the colonies on CMC plates, five possible cellulotic isolates were chosen for the quantitative cellulase activity assay (Figure 1).

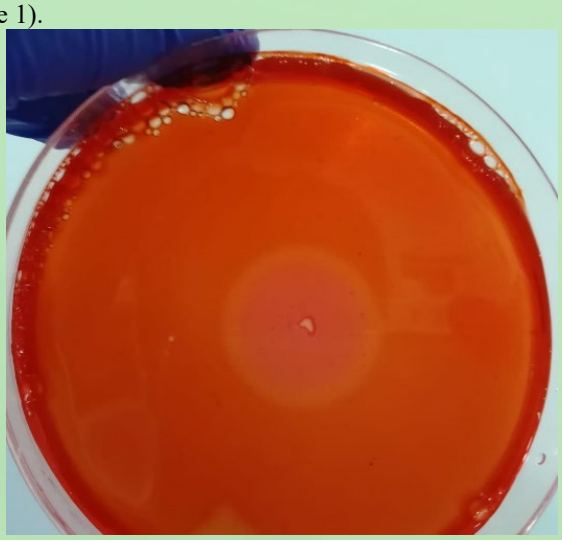

Figure 1. Cellulolytic hydrolysis zones around the streaks of isolate grown on CMC plate for 2 days at 30 °C.

In this study, three Gram-positive and two Gram-negative bacterial species that were determined to produce cellulase were isolated. Additionally, it was shown that every isolated bacterium exhibited catalase and protease activity (Table 1). A range of 0.8 to 2.2 for the cellulolytic index indicated significant cellulase production. MOC6 had the highest cellulolytic index (2.2), whereas MOC3 had the lowest (0.8) (Table 1). The sequence data based on 16 S rDNA region analysis, were compared with sequences in the NCBI database. The MOC6 isolate was identified as *Bacillus pumilus*.

Bacillus group is commonly found in many insect digestive systems due to its cellulolytic properties. The study by MsangoSoko et al. (2020) supports these results; Bacillaceae was reported as the dominant group of cellulolytic gut bacterial symbionts in Coleopteran insects. *B. licheniformis* cellulolytic bacteria have been reported isolated from the gut of white worm species (Van Dyk et al., 2009). Similar to the B. pumilus bacteria we isolated in this study, there are many studies showing that this species produces cellulase (Shankar et al., 2021; Dar et al., 2022; Yilmaz and Gurkok, 2025).

Table 1. Identification of cellulase producing isolates on the basis of morphological / biochemical tests and cellulolytic activities.

Tests	MOC3	MOC4	MOC5	MOC6	MOC7
Gram strain	+	+	-	+	-
Catalase	+	+	+	+	+
Oxidase	+	+	-	+	-
Urease	-	-	+	-	+
Protease	+	+	+	+	+
Shape	Rod	Rod	Rod	Rod	Rod
CAI	0.8	1.3	2.0	2.2	1.6

The findings of this article were that bacteria with cellulolytic activity were isolated from the digestive system of the *Leptinotarsa decemlineata* and *B. pumilus* was determined as the most effective species. In conclusion, complex cellulose-rich organic wastes may be broken down by cellulolytic bacteria that were isolated from *L. decemlineata* guts. Therefore, more research is required to assess how well these cellulolytic bacterial strains break down organic waste and agricultural byproducts. In order to prepare strong strains of bacterial consortium that degrade organic matter and use them for the generation of biofuel at the industrial level, more research is necessary to identify and characterize cellulolytic bacteria from the gut of cellulolytic-feeding *L. decemlineata*.

Abstract

Peanuts (*Arachis hypogaea* L.) belong to the legume family and originated in South America. Over time, they have spread to various parts of the world, especially China, India, the United States, and Türkiye. According to 2019 data, about 48 million tons of peanuts are produced worldwide, with Turkey producing 169 thousand tons of this amount. Anatomically, peanuts consist of three parts: the shell, membrane, and kernel. These components differ in the bioactive compounds they contain. During processing, these parts are separated at various stages in the factory. However, these by-products are often not sufficiently valorized, leading to underutilization of their potential. In recent years, waste valorization has gained significant attention in the peanut industry. Peanut shells highlight their potential as a valuable and sustainable resource. Moreover, extracting bioactive compounds from these by-products using innovative methods has become a key focus of recent research. The aim of this study was to recover the bioactive potential of peanut shell waste using a cloud point extraction technique, employing lecithin as a surfactant. Different parameters were tested through single-factor analysis, one at a time. An increase in the bioactive potential of peanut shells was recorded when the surfactant concentration was 10% w/v, the phase separation temperature was 90 °C for 40 minutes, the salt concentration was 10% w/v, and the pH was 2. The cloud point extraction method is regarded as an advantageous technique for recovering the total phenolic content potential of peanut shell waste.

Keywords: *Peanut shell, bioactive compounds, cloud point extraction*

Yer Fıstığı Kabuklarından Bulutlanma Noktası Ekstraksiyon ile Biyoaktif Bileşiklerin Geri Kazanımı

Özet

Yer fıstığı (*Arachis hypogaea* L.) baklagiller familyasına aittir ve Güney Amerika kökenlidir. Zamanla dünyanın farklı bölgelerine yayılarak, özellikle Çin, Hindistan, Amerika Birleşik Devletleri ve Türkiye gibi birçok ülkede yetiştirilmiştir. 2019 yılı verilerine göre dünyada yaklaşık 48 milyon ton yer fıstığı üretilirken, Türkiye'de bu miktar 169 bin ton olarak kaydedilmiştir. Yer fıstığı anatomik olarak üç bölümden oluşur: kabuk, zar ve tohum. Bu kısımlar, içerdiği biyoaktif bileşenler açısından farklılık göstermekle birlikte yer fıstığı işlenirken, fabrikada çeşitli aşamalarda ayrılmaktadırlar. Ancak, bu yan ürünler genellikle yeterince değerlendirilmemekte ve potansiyelleri yeterince bilinmemektedir. Son yıllarda, atık değerlendirme yer fıstığı endüstrisinde de önemli derecede dikkat çekmiştir. Yer fıstığı kabuklarının, değerli ve sürdürülebilir bir kaynak olarak potansiyeli vurgulanmaktadır. Ayrıca, bu yan ürünlerden yenilikçi yöntemler kullanarak biyoaktif bileşenlerin çıkarılması son araştırmalarda önemli bir odak haline gelmiştir. Bu çalışmanın amacı, yerfıstığı kabuğu atığının biyoaktif potansiyelini bulutlanma noktası ekstraksiyon tekniği ile geri kazanmaktır. Bu süreçte, lesitin yüzey aktif madde olarak kullanılmıştır. Farklı parametreler için, tek faktörlü analiz yöntemi kullanılarak denemeler gerçekleştirilmiştir. Yer fıstığı kabuklarının biyoaktivite potansiyelindeki artış, yüzey aktif madde konsantrasyonunun %10 w/v, faz ayrışma sıcaklığının 90 °C'de 40 dakika, tuz konsantrasyonunun %10 w/v ve pH'ın 2 olduğu durumlarda kaydedilmiştir. Bulutlanma noktası ekstraksiyon yönteminin, yer fıstığı kabuğu atıklarının toplam fenolik ve flavonoid potansiyelinin geri kazanımı için son derece avantajlı bir yöntem olduğu düşünülmektedir.

Anahtar Kelimeler: *Yer fıstığı kabuğu, biyoaktif bileşikler, bulutlanma noktası ekstraksiyonu*

Giriş

Yer fıstığı (*Arachis hypogaea* L.), dünya genelinde esas olarak tohumu ve yağı için yetiştirilen, protein açısından zengin bir baklagil bitkisidir (Bertioli ve vd., 2011). Yer fıstığı, çok yönlü kullanım alanları nedeniyle küresel ölçekte önemli bir endüstriyel üründür (Sorita vd., 2020). Besin açısından zengin içeriği, sağlığa faydalı özellikleri ve kendine özgü aroması sayesinde dünya genelinde yaygın olarak tüketilmektedir.

2019 yılında dünya genelinde 30 milyon hektar alanda 49 milyon ton kabuklu yer fıstığı üretilmiş, üretimin büyük kısmı Çin, Hindistan ve Nijerya'dan sağlanmıştır. Son 60 yılda dünyada ve Türkiye'de yer fıstığı ekim alanları artarken, tarım teknolojilerindeki ilerlemelerle birim alandaki verimlilik de yükselmiştir. Türkiye'de 2020 yılında 215 bin hektar alanda 55 bin ton yer fıstığı üretilmiş olup, üretimin büyük bölümü Çukurova bölgesinde, özellikle Adana ve Osmaniye illerinde gerçekleşmektedir. Türkiye, yer fıstığı üretiminde genellikle kendi ihtiyacını karşılamakta olup, zaman zaman küçük oranlarda ithalat gerçekleştirmektedir (FAOSTAT, 2020).
Türkiye'de Virginia tipi yer fıstıkları, nispeten düşük yağ içeriği ve iri taneli yapıları nedeniyle üretim ve ithalatta tercih edilmekte; genellikle atıştırmalık gıda olarak tüketilmektedir.(Şahin, 2014). Osmaniye'de yetiştirilen yer fıstığı, 2002 yılında Türk Patent ve Marka Kurumu'ndan 54 numaralı tescil belgesi ile coğrafi işaret almıştır. Türkiye'deki yer fıstığı verimi dünya ortalamasının iki katından fazladır (Çiftçi, 2022).
Yer fıstığı kabuk, zar ve tohum (tane) olmak üzere üç ana bölümden oluşmaktadır (Win vd., 2011). Biyoaktif bileşenlerin bileşimi ve miktarı yer fıstığının farklı kısımlarında değişiklik göstermektedir (Zhao vd., 2012). Örneğin çiğ yer fıstığı tanesi; *p*- hidroksibenzoik asit, klorojenik asit, *p*-kumarik asit, kuersetin ve kaempferol polifenolleri içermektedir. Yer fıstığında fenolik bileşikler açısından en zengin bölüm zardır; bu kısım özellikle epikateşin ve kateşin gibi bileşenleri içermektedir. Luteolin ise yer fıstığı kabuğunda en fazla bulunan bileşik olarak rapor edilmiştir (Win vd., 2011, Liu vd., 2022).
Biyoaktif bileşiklerin ekstraksiyonu için yeni teknolojilerin kullanılması ile ekstraksiyon veriminin ve elde edilen bileşiklerin fonksiyonel ve besinsel özelliklerinin iyileştirilebileceği bilinmektedir (Imran vd., 2022). Yer fıstığı kabuğundan fenoliklerinin ekstraksiyonunda çoğunlukla Sokshalet, katı-sıvı ekstraksiyonu veya sıvı-sıvı ekstraksiyonu gibi geleneksel yöntemler çözücü olarak ise metanol, etanol, aseton, dietil eter ve etil asetat kullanılmıştır. Bu yöntemler yüksek verimli ve biyoaktif özellikleri korunmuş ekstraktlar elde edilmesine imkan sağlasa da uzun ekstraksiyon süreleri, fazla çözücü kullanılması ve çoğu toksik olan çözücülerin ekstraktta kalıntı bırakması gibi nedenlerle yerini son yıllarda yenilikçi ekstraksiyon tekniklerine bırakmaktadır. Bulutlanma noktası ekstraksiyon (BNE), biyoaktif bileşiklerin karmaşık matrikslerden etkili bir şekilde ayrıştırılması ve konsantre edilmesine olanak tanıyan yenilikçi bir ekstraksiyon tekniğidir. Ayrıca, geleneksel çözücü bazlı yöntemlere kıyasla daha çevre dostu ve sürdürülebilir bir süreç sunmasıyla öne çıkmaktadır.(Motikar vd., 2021). Bu yöntem, hedef moleküllerin yüzey aktif maddeler aracılığıyla karmaşık materyallerden seçici olarak ayrılması ve izole edilmesine dayanmaktadır (More vd., 2022). BNE işleminde, hedef molekül ve yüzey aktif madde içeren sulu çözelti, bulutlanma noktası sıcaklığının üzerine ısıtıldığında, yüzey aktif madde hedef molekülleri kapsülleyerek misel yapıları oluşturur. Bunun sonucunda, yoğunluk farkları nedeniyle sulu faz ve miseller iki farklı faza ayrılmaktadır (More vd., 2019). BNE, düşük çözücü tüketimi, ekonomik oluşu, çevre dostu yapısı ve enstrümantasyon açısından sağladığı kolaylıklar gibi çeşitli avantajlara sahip bir ayırma yöntemidir (Katsoyannos vd., 2006). Bu yöntemin etkinliği; kullanılan yüzey aktif maddenin türü ve miktarı, inkübasyon sıcaklığı (Melnyk vd., 2015), ortamın pH değeri (Sun vd., 2006), inkübasyon süresi (Gökkaya, 2014) ile tuz konsantrasyonu (Ulusoy vd., 2013) gibi çeşitli faktörlerden etkilenmektedir.
Son yıllarda, tarımsal atıklardan biyoaktif bileşenlerin yenilikçi ekstraksiyon teknikleriyle geri kazanılması, bilimsel çalışmaların odak noktalarından biri hâline gelmiştir. Bu bağlamda, bu çalışmanın amacı; yer fıstığı kabuğu atığındaki biyoaktif potansiyelin, çevre dostu ve seçici bir yöntem olan BNE kullanılarak geri kazanılmasını sağlamaktır.

Materyal ve Yöntem

Bu çalışmada kullanılan yer fıstığı kabukları (Virginia market tipi), Osmaniye'de faaliyet gösteren ve bölgedeki önemli yer fıstığı işleme tesislerinden 2024 yılında temin edilmiştir. Kabuğun elde edildiği işlem aşaması, ticari üretim sürecinde uygulanan ıslak kırım yöntemidir. Bu yöntemde, yer fıstıkları mekanik kırma işleminden önce su ile nemlendirilerek kabukların yumuşaması sağlanmakta ve böylece çekirdeğin kabuktan daha kolay ayrılması hedeflenmektedir. Çalışmada kullanılan yer fıstığı kabukları, ıslak kırım sonrası elde edilen kabuk atığıdır. Atık, fabrikada üretim hattından çıktıktan hemen sonra toplanmış ve olası mikrobiyal bozulmaların önlenmesi amacıyla açık havada 2 gün boyunca kurutularak stabilize edilmiş ve ondan sonra laboratuvara getirilmiştir. Fıstık kabukları 500'er gramlık porsiyonlar halinde vakumlanarak oda sıcaklığında depolanmıştır. Bu depolama yöntemi, numunelerin tazeliğini ve özelliklerini korumak amacıyla uygulanmıştır.

Bulutlanma Noktası Ekstraksiyon Yöntemi

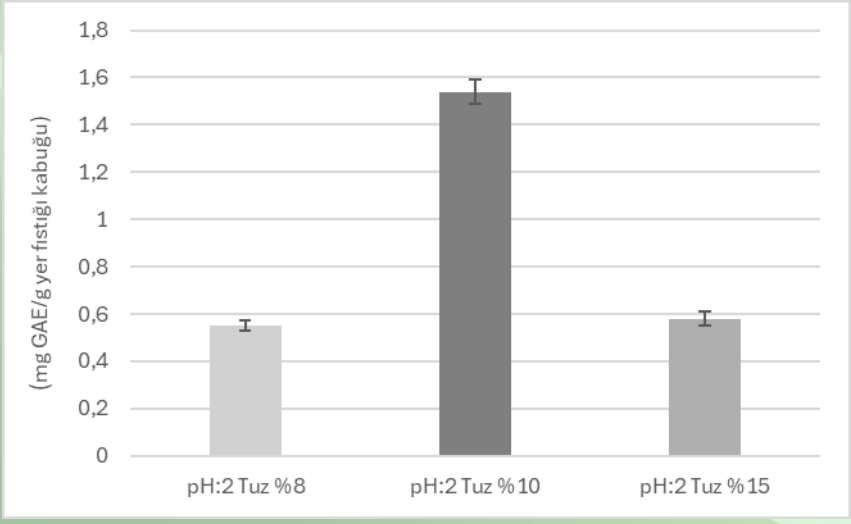
Ekstraksiyon için (0.05, 0,1 ve 0,15 gram) öğütülmüş yer fıstığı kabuğu 50 mL distile su içeren bir Falcon tüpüne alınarak süspanse edilmiştir. Karışım, oda sıcaklığında ve karanlık ortamda 1 saat bekletilmiştir. Ardından katı-sıvı ayrımı için süspansiyon, 10000 rpm'de 10 dakika boyunca oda sıcaklığında santrifüj edilmiştir. Elde edilen süpernatant, kaba partiküllerin uzaklaştırılması amacıyla Büchner hunisi ve kaba gözenekli filtre kağıdı kullanılarak süzülmüştür. Berraklaştırılan sıvı faza, belirlenen konsantrasyonda yüzey aktif madde (%10) eklenmiş ve vorteks karıştırıcı ile homojen karışım elde edilmiştir. Çözeltinin pH değeri (2-4-6), pH metre ile ayarlanmıştır. Ardından belirli miktarda sodyum klorür (NaCl) (%8, %10, %15) eklenmiş ve tamamen çözünmesi sağlanmıştır. Karışım, (70-80-90°C) belirli bir sıcaklık değerlerine ayarlanan su banyosuna bırakılmıştır. Faz ayrımını

netleştirmek amacıyla karışım, 7500 rpm'de 10 dakika süreyle tekrar santrifüjlenmiştir. Santrifüjleme işlemi sonucunda, biri yüzey aktif maddece zengin, jelatinöz yapıda ve fenolik ile flavonoid bileşikler içerdiği düşünülen; diğeri ise sulu faz olmak üzere iki ayrı faz elde edilmiştir.

Toplam Fenolik Madde Analizi

Ekstraktların toplam fenolik bileşik miktarı Shahidi ve Ambigaipalan, (2015)'e göre yapılmıştır. Bir deney tüpü içerisine uygun oranda seyreltilen örneklerden 0.2 mL ve 1.5 mL 10 kat seyreltilmiş 2 N Folin-Ciocalteu reaktifi eklenmiştir. Tüp vortekste iyice karıştırılıp beş dakika bekledikten sonra üzerine 1.5 mL sodyum karbonat (%6, ağırlık/hacim (a/h)) eklenmiş ve tüpler yeniden vortekslenmiştir. Kör çözelti ise ekstrak yerine tüpe aynı miktarda saf su ilave edilerek, diğer işlemler aynı olacak şekilde hazırlanmıştır. 1,5 saat oda koşullarında ve karanlık bir ortamda bekletilen örnekler 765 nm'de spektrofotometrede köre karşı okunmuştur. Sonuçlar ise oluşturulan standart eğri kullanılarak gallik asit cinsinden ifade edilmiştir.

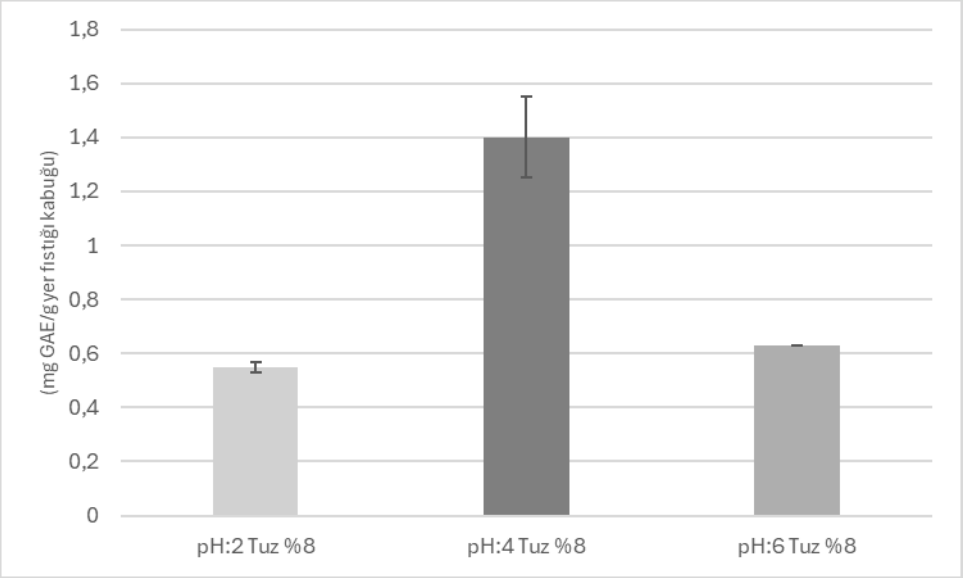
Toplam Flavonoid Madde Analizi



Ekstraktların toplam flavonoid bileşik miktarı Zhishen vd., (1999)'e göre yapılmıştır. Bir deney tüpü içerisine uygun oranda seyreltilen örneklerden 2 mL ve 150 µL sodyum nitrit (%5 a/v) eklenip, tüp vortekste iyice karıştırılıp beş dakika bekledikten sonra üzerine 150 µL alüminyum klorür (%6, a/v) eklenerek tüpler yeniden vortekslenmiştir. Üzerine 1 mL sodyum hidroksit eklenip vortekslendikten sonra 1,2 mL saf su eklenerek hazırlanmıştır. Kör çözelti ise ekstrakt yerine tüpe aynı miktarda saf su ilave edilerek, diğer işlemler aynı olacak şekilde hazırlanmıştır. 10 dakika oda koşullarında ve karanlık bir ortamda bekletilen örnekler, 510 nm'de spektrofotometrede köre karşı okunmuştur. Sonuçlar, oluşturulan standart eğri kullanılarak luteolin cinsinden ifade edilmiştir.

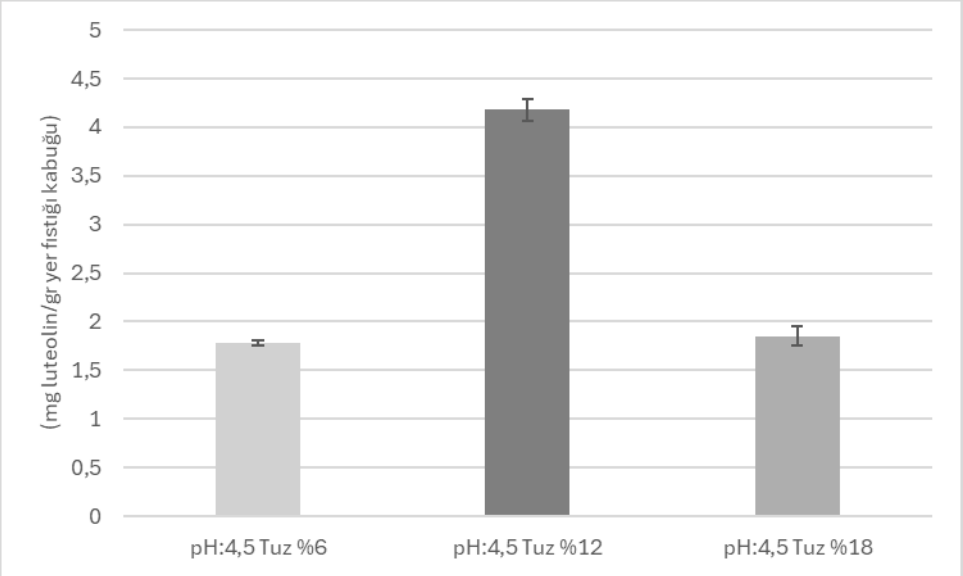
Bulgular ve Tartışma

Bulutlanma noktası ekstraksiyonu üzerine pH, tuz konsantrasyonu, sıcaklık ve örnek madde miktarının etkileri incelenmiş olup bu parametrelerin, biyoaktif bileşiklerin geri kazanım verimi üzerindeki etkilerini değerlendirmek amacıyla deneyler gerçekleştirilmiştir. Bu kapsamda, en yüksek verimle biyoaktif bileşiklerin elde edilmesini sağlayan koşullar belirlenmeye çalışılmıştır.



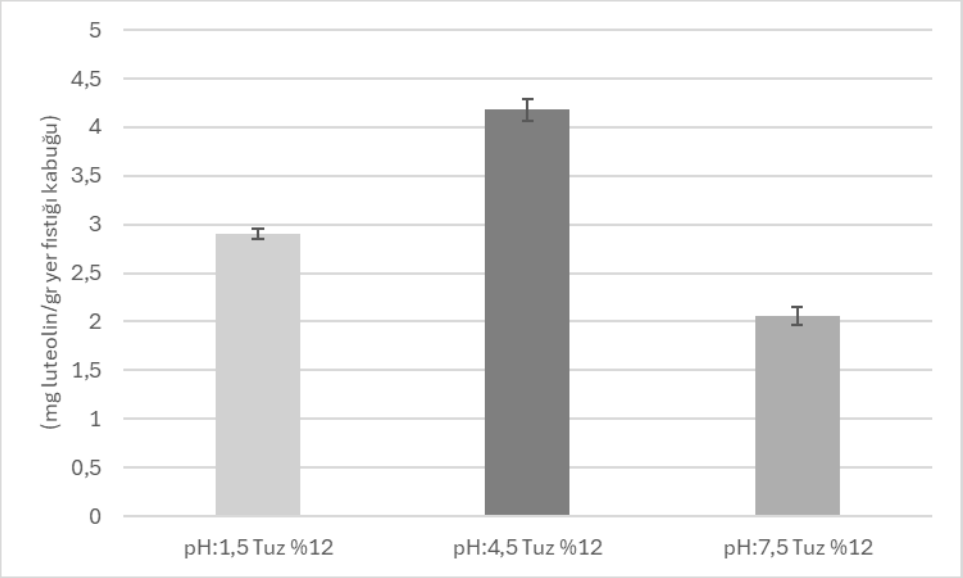
pH ve Tuz Etkisi

Şekil 1'de, farklı tuz konsantrasyonlarının (%8, %10 ve %15) toplam fenolik bileşik miktarı üzerine etkisi, pH 2 koşullarında sabit tutulmak suretiyle değerlendirilmiştir. Deneysel bulgular, en yüksek toplam fenolik bileşik kazanımının %10 tuz konsantrasyonunda gerçekleştiğini göstermiştir. Bununla birlikte, tuz konsantrasyonu %10'u geçtiğinde, toplam fenolik madde miktarında belirgin şekilde azalma olmuştur. Benzer şekilde Ji vd. (2021) yaptıkları çalışmada tuz konsantrasyonunun %5'ten %10'a yükseltilmesiyle BNE veriminin iyileştiğini, ancak tuz konsantrasyonun %10'u geçtikten sonra verimin anlamlı değişiklikler göstermediğini bildirmiştir. Bu artışın, NaCl gibi elektrolitlerin misel sistemindeki misel sayısını artırarak faz ayrımını kolaylaştırmasından kaynaklandığı bildirilmiştir (El-Abbasi vd., 2014; Ji vd., 2021). More ve Arya (2019) ise tuzun düşük konsantrasyonlarda (%4-6) salting-out etkisiyle verimi arttırırken, yüksek tuz konsantrasyonunun (>%8) kritik faz ayrım sıcaklığını düşürerek biyoaktif bozunmaya ve verim kaybına yol açtığını rapor etmiştir. Araştırmacılar optimum performans için %6-8 NaCl aralığını önermiştir.



Şekil 1. Sabit pH'da tuz konsantrasyonunun toplam fenolik madde miktarına etkisi

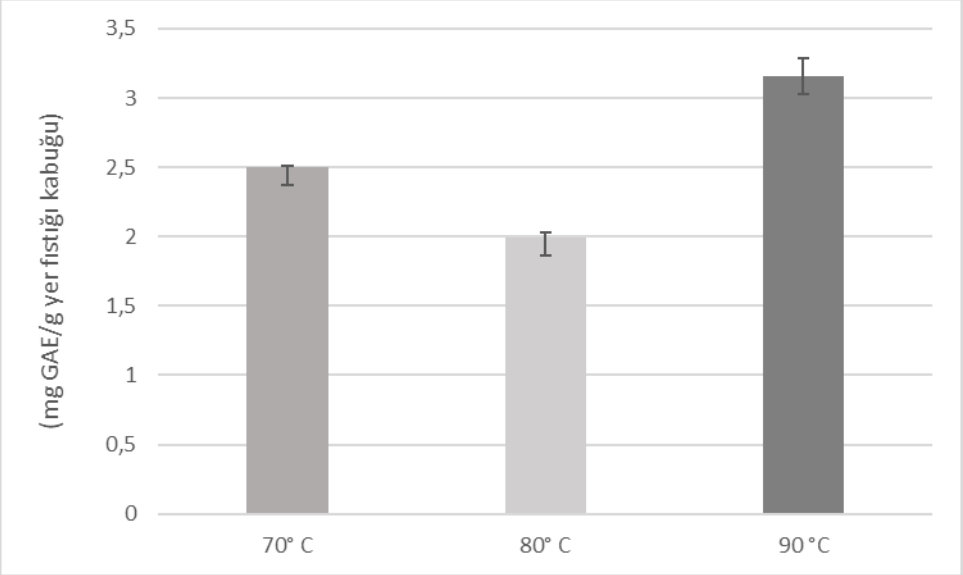
Şekil 2'de, pH parametresinin (pH 2, 4 ve 6) toplam fenolik bileşik miktarı üzerindeki etkisi değerlendirilmiş; bu süreçte tuz konsantrasyonu %8'de sabit tutulmuştur. Yapılan analizler, sabit tuz konsantrasyonunda en yüksek toplam fenolik bileşik kazanımının pH 4 koşulunda gerçekleştiğini ortaya koymuştur. Benzer şekilde More ve Arya (2019) pH 4'te toplam fenolik madde için %95 verim sağladığını bildirmiştir. pH değeri, BNE yönteminde önemli bir rol oynar. Düşük pH (asidik koşullar), fenolik ve flavonoid bileşiklerin yüksüz formda kalmasını sağlayarak surfaktan miselleri tarafından daha kolay tutulmalarına yardımcı olur. Benzer şekilde More ve Arya (2019), pH 4 gibi asidik koşullarda hem toplam fenolik madde hem de toplam flavonoid için yüksek geri kazanım oranları elde etmiştir. pH'nın 6'ya çıkarılmasıyla toplam fenolik madde miktarında belirgin bir azalma gerçekleştirmiştir. Bu durum Kiai vd. (2018) ile El-Abbassi vd. (2014)'nin de bildirdiği gibi, çözeltinin pH'ının artmasının fenollerin yüzey aktif madde fazından ayrışmasını artırarak biyoaktif bileşik kaybına yol açması ile açıklanabilir. Sonuç olarak, pH kontrolü, hedef bileşiklerin kimyasal stabilitesi ve surfaktan-misellerle etkileşimi açısından kritiktir ve yer fıstığı kabuklarının BNE'nunda en yüksek verim ve en düşük kayıp için asidik pH aralığı daha etkili olmuştur.



Şekil 2. Sabit tuz konsantrasyonunda pH'nın toplam fenolik madde miktarına etkisi

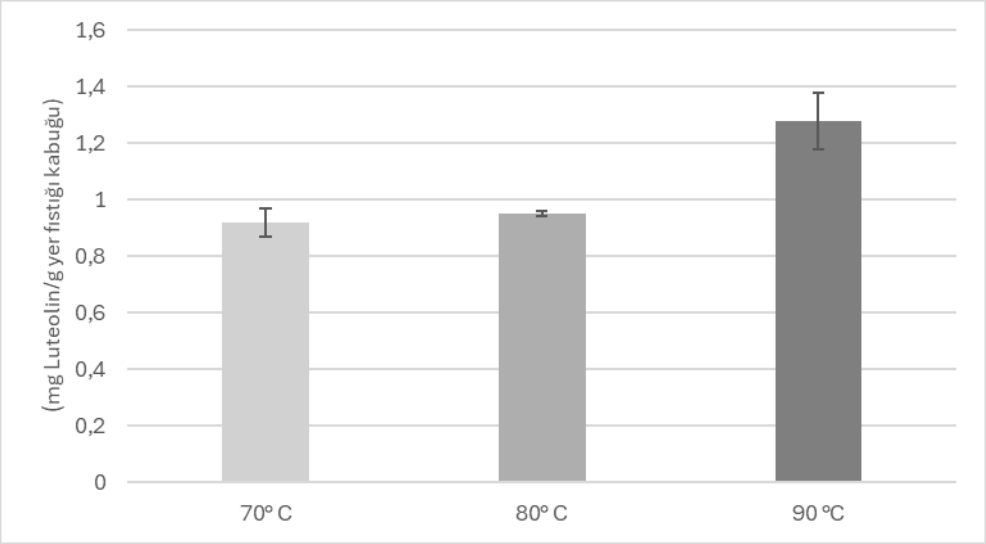
Şekil 3'de, farklı tuz konsantrasyonlarının (%6, %12 ve %18) toplam flavonoid bileşik miktarı üzerine etkisi, pH 4,5 koşullarında sabit tutulmak suretiyle değerlendirilmiştir. Deneysel bulgular, en yüksek toplam flavonoid bileşik kazanımının %12 tuz konsantrasyonunda gerçekleştiğini göstermiştir. Bununla birlikte, tuz konsantrasyonu %12'yi geçtiğinde, toplam flavonoid madde miktarında belirgin şekilde azalma olmuştur.

Şekil 3. Sabit pH'da tuz konsantrasyonunun toplam flavonoid madde miktarına etkisi



Şekil 4'de, pH parametresinin (pH 1,5 , 4,5 ve 7,5) toplam flavonoid bileşik miktarı üzerindeki etkisi değerlendirilmiş; bu süreçte tuz konsantrasyonu %12'de sabit tutulmuştur. Yapılan analizler, sabit tuz konsantrasyonunda en yüksek toplam flavonoid bileşik kazanımının pH 4,5 koşulunda gerçekleştiğini ortaya koymuştur. Benzer şekilde De Araújo Padilha ve arkadaşları camu-camu meyve atıklarından polifenol geri kazanımında bulutlanma noktası ekstraksiyonu yöntemini kullanmıştır. Çalışmada pH ve sodyum klorürün ekstraksiyon üzerindeki etkileri detaylı şekilde incelenerek, pH değeri 2–10 aralığında test edilmiş ve ekstraksiyon için en uygun pH aralığı araştırılmıştır. Ayrıca, %0–10 aralığında sodyum klorür konsantrasyonları değerlendirilmiş ve tuz ilavesinin toplam polifenol geri kazanımını anlamlı düzeyde azalttığı görülmüştür. Sonuç olarak, pH ayarlaması yapılmaksızın, %80 camu-camu ekstraktı, %7 Triton X-114 ve sodyum klorür içeren sistemle, 30 °C'de 3 saat süren ekstraksiyon sonucunda %95,71 oranında polifenol geri kazanımı elde edilmiştir.

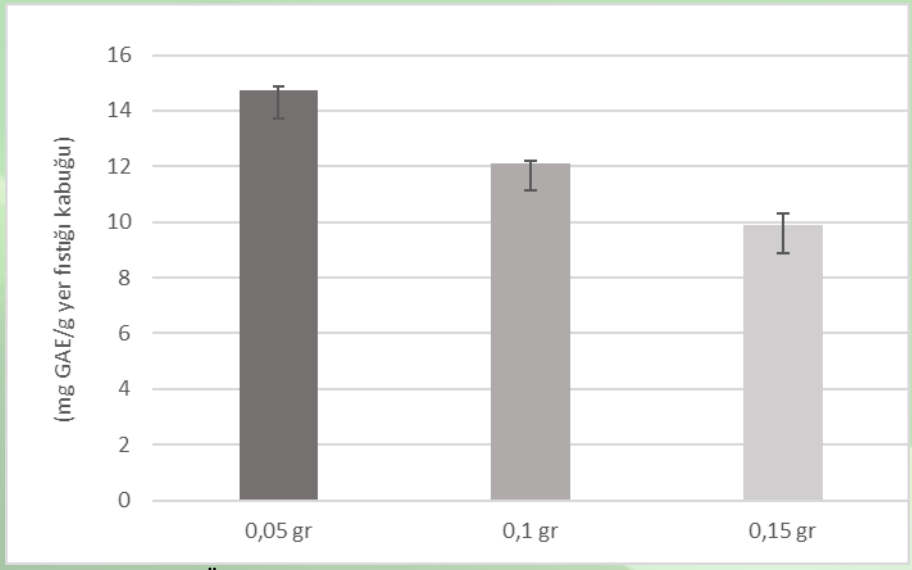
Şekil 4. Sabit tuz konsantrasyonunda pH'nın toplam flavonoid madde miktarına etkisi



Sıcaklık Etkisi

Şekil 5'te sıcaklık parametresi 70, 80 ve 90 °C olarak değerlendirilmiş; tuz konsantrasyonu ve pH sabit tutulmuştur. Yapılan analizler, en yüksek toplam fenolik madde miktarının 90 °C'de elde edildiğini göstermektedir. El-Abbassi ve arkadaşları (2014), yaptıkları çalışmada zeytin işleme atık suyundan polifenol elde etmek için bulutlanma noktası ekstraksiyonu yöntemini kullanmıştır. Ultrafiltrasyon ile berraklaştırılan örneklerde, %10 Triton X-100 ile 90 °C'de 30 dakikalık bulutlanma noktası ekstraksiyon işlemi sonucunda %66,5 verim elde edilmiştir. CPE yöntemi, düşük yüzey aktif madde tüketimi ve gıdalara doğrudan entegrasyon imkânı gibi avantajlarıyla öne çıkmaktadır.

Şekil 5. Sıcaklığın toplam fenolik madde miktarına etkisi



Şekil 6'da sıcaklık parametresi 70, 80 ve 90 °C olarak değerlendirilmiş; tuz konsantrasyonu ve pH sabit tutulmuştur. Yapılan analizler, en yüksek toplam fenolik madde miktarının 90 °C'de elde edildiğini göstermektedir. Benzer şekilde Mai ve arkadaşları(2020) yaptıkları çalışmada flavonoidlerin ekstraksiyon verimini etkileyen başlıca parametreler olan ekstraksiyon sıcaklığı (35–95 °C) ve süresi (5–25 dakika) incelenmiştir. Elde edilen bulgular, ekstraksiyon sıcaklığı 95 °C'ye ve süre 15 dakikaya kadar artırıldığında flavonoid veriminin anlamlı şekilde yükseldiğini göstermektedir. Ancak, daha uzun süreli ve yüksek sıcaklıklardaki ekstraksiyonlar, flavonoidlerin bozunmasına veya yapısal dönüşümüne neden olabileceğinden, optimum ekstraksiyon süresi 15 dakika olarak belirlenmiştir. Cihazın teknik sınırlamaları ve aşırı ısınmanın yol açabileceği zararlar göz önüne alınarak, sonraki deneylerde ekstraksiyon sıcaklığı 90 °C olarak belirlenmiştir.

Şekil 6. Sıcaklığın toplam flavonoid madde miktarına etkisi

Örnek Miktarının Etkisi

Şekil 7'de, örnek miktarının (0,05; 0,10 ve 0,15 g) biyoaktif bileşik kazanımı üzerindeki etkisi değerlendirilmiş; bu süreçte tuz konsantrasyonu ve pH değeri sabit tutulmuştur. Yapılan analizler sonucunda, en yüksek biyoaktif bileşik kazanımının 0,05 gram örnek miktarında elde edildiği belirlenmiştir. Bu durum, örnek miktarının artmasıyla birlikte sistemdeki çözünürlüğün sınırlanması ve kütle transferinin olumsuz etkilenmesi ile ilişkilendirilebilir. Katı/sıvı oranı arttıkça yer fıstığı kabuğundan su içerisinde fenolik madde çözünürlüğü doygunluğa ulaşır ve ekstraksiyon oranında düşüş meydana gelmektedir.

Şekil 7. Örnek miktarının toplam fenolik madde miktarına etkisi

Sonuç

Bu çalışmada yer fıstığı kabuğundan fenolik ve flavonoid bileşiklerin BNE yöntemi ile ekstraksiyonunda en yüksek fenolik bileşik miktarı %10 tuz konsantrasyonu ve pH 4 koşullarında elde edilirken en yüksek flavonoid bileşik miktarı %12 tuz konsantrasyonu ve pH 4,5 koşullarında elde edilmiştir. Sıcaklık parametresi için ise, 90 °C'de en yüksek fenolik ve flavonoid madde kazanımı sağlanmıştır. Örnek miktarı açısından ise, uygulanan BNE koşullarında 0,05 gram örnekle en fazla biyoaktif bileşik elde edilmiştir. Bu sonuçlar, BNE yöntemiyle yer fıstığı kabuğundan fenolik ve flavonoid bileşiklerin verimli bir şekilde elde edilebilmesi için işlem koşullarının dikkatle seçilmesi gerektiğini göstermektedir. Bulutlanma noktası ekstraksiyonu, yer fıstığı kabuklarından fenolik ve flavonoid bileşiklerin geri kazanımında etkili, düşük enerji tüketimli ve çevre dostu bir yöntem olarak öne çıkmaktadır. Bu yöntem, yer fıstığı kabuklarının değerlendirilerek hem ekonomik katma değer yaratılmasına hem de sürdürülebilir ve çevreye duyarlı üretim süreçlerinin geliştirilmesine katkı sağlayabilir.

Teşekkür

Çalışmanın yürütülmesinde desteklerinden dolayı TÜBİTAK'a (Türkiye Bilimsel ve Teknolojik Araştırma Kurumu) teşekkür ederiz (Proje No: 223O393).

Abstract

Deficiency of selenium might occur due to their low intake and impaired bioavailability. No data were available concerning the exact selenium requirements in camels. Selenium and sulphur have similar physical and chemical properties, and a number of studies indicate that increased dietary sulphur reduces the bioavailability of selenium. The present study was carried out on 12 young male and female clinically healthy dromedary camels (*Camelus dromedarius*), 2–3 years old were brought from Sodari area. Camels were housed collectively in one large pen at the animal housing of the Central Veterinary Research Laboratories, Soba, Sudan. They were left for four weeks for adaptation. The experiment was conducted in dry season. Animals were randomly divided into three groups of 4 animals each. The approximate mean weight is 185.28 kg. A control group, a group drenched daily with 4.4 mg of sodium selenite and a group drenched daily with a mixture of 4.4 mg of sodium selenite and 6 mg sodium sulphate anhydrous for three consecutive months. Blood samples were taken weekly and sera were analyzed. Selenium concentration was determined by using Inductively Coupled Plasma Spectrophotometer. Mean serum selenium levels in the control group were not significantly different at weeks 1, 3 and 8 to 12, whereas the values at weeks 2, 4 to 7 were significantly higher ($P<0.05$). In the group drenched with sodium selenite, significant differences ($P<0.05$) were shown. Low levels were observed at weeks 1, 2 and 3, whereas high levels were shown at weeks 11 and 12. Camels in the group drenched with the mixture showed significant differences ($P<0.05$). Low levels were observed at weeks 1 and 6, whereas high levels were observed at weeks 10, 11 and 12. It was concluded that camels are responsive to selenium supplementation. It could also be the mark of a greater sensitivity to toxicity.

Key words: *Selenium, dromedary, camel, Sulphur, serum.*

Introduction

Selenium (Se) received little attention from biologists for years but eventually was identified as the toxic principle that induced hair loss, lameness, hoof sloughing, and death in grazing livestock in South Dakota and Wyoming (Franke, 1934). Retrospectively, it was deduced that similar signs in horses observed by Marco Polo during his travels in China in the 13th century (Polo, 1926) and by Madison (1860) at Fort Randall, Nebraska Territory (a condition he called "alkali disease") were probably caused by Se toxicity.

The Se-deficiency problem in animal agriculture, as it existed before Se supplements could be legally used, has been reviewed (Ullrey, 1974). In some swine herds, mortality in growing pigs was 15 to 20% and morbidity was 25% or more. Reproductive efficiency was reduced and resistance to environmental stress and infectious disease was diminished. Comparable death losses and declines in productivity were observed in poultry and other livestock species. Selenium is an essential microelement for the prevention of a number of deficiency syndromes in a variety of species (Underwood, 1981). It is an antioxidant element. Its role in the body is not completely known. It is, however, involved in the absorption and/or retention of vitamin E. It is an integral component of glutathione peroxidase. Selenium, probably, has other essential functions in the enzymatic processes. In mammals, ingested Se-Met is absorbed in the small intestine via the Na^+-dependent neutral amino acid transport system (Vendeland et al., 1994). Higher animals are unable to synthesize Se-Met and only Se-Cys was detected in rats supplemented with Se as selenite (Tapiero et al., 2003).

The minimum daily allowance of selenium in most species is 0.1 ppm (mg/kg) on a dry matter (DM) basis (Maas, 1983). The requirement of selenium in ruminants is approximately 0.1 part per million (ppm) DM. The dietary Se requirements for camelids are probably similar to other ruminants (Fowler, 1986; Smith, 1989; Dart et al., 1996). An alfalfa hay based diet containing 0.2 ppm Se appeared to meet the Se requirement for llamas, based on glutathione peroxidase (GSH-Px) activity and the lack of clinical signs of selenium deficiency disease (Dart et al., 1996). In the Bolivian Altiplano, one of the nutrients most likely to be deficient for grazing llamas was Se (Espinoza et al., 1982). Although forage Se was deficient (0.06 ppm) in greater than 90% of samples, all llamas sampled were considered to have adequate liver Se concentrations. Iatrogenic Se toxicity has been reported in a llama (Farrar et al., 1992), and Se toxicosis is possible due to excessive supplementation, in animals grazing pastures contaminated with Se-accumulating plants, and in areas where soils are high in Se (Fowler, 1989). Dietary Se greater than 1.5 ppm may produce Se toxicosis, especially if this amount is fed for an extended time (Pugh, 1993).

Material and Methods

Animals

Twelve young male and female camels (*Camelus dromedarius*) 2-3 years old were brought from Sodari area, North Kordofan. Animals were grazing and browsing naturally in Sodari area, North Kordofan State. The weights of the animals ranged between 147.74 and 217.40 kg. In the present work body weights were estimated according to Schwartz, et al. (1983). The weights of the animals were estimated every month in the morning before feeding, watering and selenium supplementation. They were housed collectively in one large pen at the animal housing of the Central Veterinary Research Laboratories, Soba. They were fed on sorghum (Abu Sabeen) hey and provided with water ad. libitum. They were left for four weeks before the experiment commenced for adaptation. During this period they were treated with Ivermectin (Kepromec, Kepro B.V., Holland) at a dose rate 0.2 mg/kg. b. wt. (1 ml/50 kg. b. wt.). Before the start of the experiment all animals were examined clinically for their freedom from external and internal parasites. The experiment was conducted in dry season from 15 February 2009 to 15 June 2009.

Experimental work

The experiment (182 days) consisted of three phases:
Adaptation period (days 1-60). During this stage, the animals received the basal diet without any mineral supplementation to equilibrate their mineral status. They did not receive any selenium supplementation.
Supplementation period (days 61-151). Animals were randomly divided into three groups of 4 animals each. The approximate mean weight is 185.28 kg. Approximate mean weights of the animals in each group were 741.11 kg.

- ***Control group:*** didn't receive oral selenium.
- ***Group orally drenched with*** 4.4 mg of selenium daily in the form of sodium selenite (Oligoselen Vitamine E, COOPHAVET, ANCENIS Cedex, France).
- ***Group orally drenched with*** 4.4 mg of selenium daily in the form of of a mixture of sodium selenite and 6 mg sulphur in the form of sodium sulphate anhydrous (Na_2SO_4) (Blulux Laboratories Ltd., INDIA-121001).

The selenium and the mixture of selenium and sulphur were drenched at 9 o'clock am. daily.
Post-supplementation period (days 152-182). During this last phase of the experiment, selenium supplementation was discontinued. Animals received the basal diet only.

Blood samples

Blood samples were collected from the jugular vein in non-heparinized tubes (NH) at 9 o'clock am. daily, centrifuged, the sera were separated, transferred to the Departments of Biochemistry, Central Veterinary Research Laboratories, Soba, and stored at -80°C.

Laboratory analysis

Selenium was done in Animal Health Research Institute, Egypt by using ICP Spectrometer. Sera samples were digested by the use of Microwave method and run by ICP against known concentration of selenium**.** Quantification of selenium was performed by the standard addition method, using 11 point standard curve. AccuTraceTM Reference Standard solutions used were Quality Control Standard #1AccuStandard® and Laboratory Performance Check Standard AccuStandard®. The analysis of selenium required the digestion of the samples to destroy proteins and amino acids in order to release the molecules of Se related to proteins. The serum (2 ml) was mixed in the tubes of rotator's digester with 10 ml Nitric Acid (HNO_3) then 5 ml Perchloric Acid ($HClO_4$). The acids used in samples preparation were high purity grad. The tubes were placed in the rotator then introduced into Microwave digestion system using Milestone MLS-1200 MEGA, Italy. After cooling, digested sample was transferred to volumetric flask and stored in refrigerator until analysis. The same digestion protocol was followed for urine, and faecal sample. For selenium determination in different samples Inductively Coupled argon Plasma – Atomic Emission Spectrometer (ICP AES), Varian Vista MPX – CCD Simultaneous was used.

Statistical analysis

The data were introduced according to excel sheet and coded. The SPSS software version 10 was used for analyzing the data. One-way ANOVA was run. The separation of means when applicable was done using least significant difference (LSD), where P values higher than 0.05 were considered insignificant.

Results

The weekly mean values of serum selenium concentration in the group of camels orally dosed with 4.4 mg of sodium selenite daily for 12 weeks showed significant differences ($P<0.05$). The low levels were observed at weeks 1, 2 and 3 (35.39±2.43, 36.14±2.00 and 35.69±1.59 µg/l), respectively, whereas the high levels were

observed at weeks 11 and 12 (56.30±1.25 and 55.42±2.18 µg/l), respectively. The minimum level was at week 1 (35.39±2.43 µg/l), and the maximum level was at week 11 (56.30±1.25 µg/l). The weeks 4 to 6 recorded significantly higher (P<0.05) mean values than those at weeks 1 to 3, and significantly lower (P<0.05) mean values than those at weeks 7 to 12. The weeks 7 to 10 recorded significantly higher (P<0.05) mean values than those at weeks 1 to 6, and significantly lower (P<0.05) mean values than those at weeks 11 to 10 (Table 1 and Figure 1).

The weekly mean values of serum selenium concentration in the group of camels orally dosed with mixture of 4.4 mg of sodium selenite and 6 mg sulphur in form of sodium sulphate (Na_2SO_4) daily for 12 weeks showed significant differences (P<0.05). The low levels were observed at weeks 1 and 6 (45.39±1.85 and 46.68±1.89 µg/l), respectively, whereas the high levels were observed at weeks 10, 11 and 12 (67.23±3.87, 65.82±2.15 and 66.44±4.35 µg/l), respectively. The minimum level was at week 1 (45.39±1.85 µg/l), and the maximum level was at week 10 (67.23±3.87 µg/l). The weeks 2, 3, 5 and 7 recorded significantly higher (P<0.05) mean values than those at weeks 1 to 6, and significantly lower (P<0.05) mean values than those at weeks 8 to 12. The weeks 8 and 9 recorded significantly higher (P<0.05) mean values than those at weeks 1 to 3 and 5 to 7, and significantly lower (P<0.05) mean values than those at weeks 10 to 12 (Table 1 and Figure 1).

Table 1: Changes in serum selenium concentration and range in parenthesis (ng/ml) in camels supplemented with selenium and a mixture of selenium and sulphur.

Means in the same columns with different superscripts are significantly different at P<0.05. *n: Number of animals.

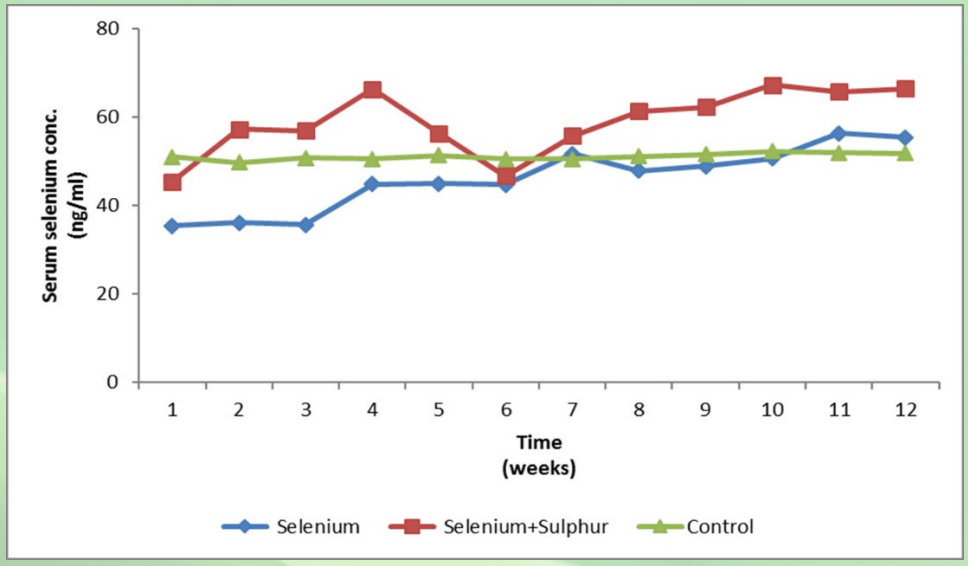

Figure 1: Weekly changes in serum selenium concentration in camels *(Camelus dromedarius)* orally suppleme

The weekly mean values of serum selenium concentration in the control group of camels were not significantly different at weeks 1, 3 and 8 to 12, whereas the values at weeks 2, 4 to 7 were significantly higher (P<0.05) (Table 1 and Figure 1).

Discussion

The mean concentration of blood/serum selenium reported in previous studies for large animals was around 100 ng/mL, a value considered as sufficient for the maintenance of suitable metabolic functions (Maas et al., 1990). In Saudi Arabia, serum Se values reported in young camels at the slaughterhouse varied between 5.3 and 131 ng/mL

with 30% of samples higher than 100 ng/mL (Barri & Al-Sultan, 2007). In recent experiments with different levels of Se supplementation, selenium content in serum for non-supplemented animals was on average 137.6 ± 18.7 ng/mL in non-pregnant, non-lactating camels (Seboussi et al., 2008), 109.3 ± 33.1 ng/mL in pregnant females, and 103.4 ± 28.7 ng/mL at milking period (Seboussi et al., 2009). Hamliri et al. (1990) observed in whole blood values between 109.1 and 117.8 ng/mL, Similar figures were recorded by Liu et al. (1994) in China, with concentrations varying from 97 to 112 ng/mL. Ma (1995) reported higher values: 274 to 288 ng/mL. In the United Arab Emirates (UAE), the mean value was 200 ± 90 ng/mL in animals with no Se supplementation (Seboussi et al., 2004). In small camelids such as llama (Herdt, 1995), the selenium concentration in serum ranged on average between 213 and 203 ng/mL depending on the physiological status. In Sudan, Abdel Rahim (2005) reported values in whole blood varying between 25 and 53 ng/mL. The analytical method used could also explain the observed differences. In Morocco, in dromedaries receiving probably a low Se basal diet, the plasma selenium concentration was quite lower, about 21 ng/mL (Bengoumi et al., 1998). In male adult camels in healthy conditions from Iran, the selenium concentration reported in serum was 12.6 ng/mL only (Nazif et al., 2009).
However, in most of the reported values, the selenium status of the diet was unknown even if Se supplementation was not distributed to the animals. Also, the analytical procedures were not described in all the cases and could differ between authors.

Acknowledgement
The authors extend their appreciation University of Al-Butana, Ministry of Higher Education and Scientific Research, Sudan for funding this work. Special thanks to the Central Veterinary Research Laboratories, Soba, and Animal Health Research Institute, Egypt for their help in samples preparation and analysis, respectively. Thanks were extended to Dr. Eltahir S, Shuiep for his great help in statistical analysis to the technician Rawda for her unlimited support.

Sürdürülebilir Hayvansal Üretim İçin Su Mercimeği Potansiyeli

Selin KIRIM[1*], Muhammed Talha İNCE[1]

[1]Nigde Omer Halisdemir University, Faculty of Agricultural Sciences and Technologies, Department of Animal Production and Technologies, 51240, Nigde, Türkiye

Özet

2050 yılına kadar 9 milyarın üstüne çıkması beklenen insan nüfusunun artışı iklim değişikliği ve kaynakların hızlı, bilinçsiz tüketilmesiyle birlikte, gıda sistemi üzerine insan kaynaklı baskı yaratacağı öngörülmektedir. Bu durum gelecek nesiller için besleyici gıdaların güvence altına alınmasını sağlayacak 'sürdürülebilir gıda sisteminin geliştirilmesini' zorunlu kılmaktadır. Bu sebeplerle hayvan beslemesi için alternatif ve sürdürülebilir bir protein kaynağı bulunmalıdır. Doğal kaynakların gelecek yıllarda tükenmesi tehlikesine karşı, artan yem maliyetleri nedeniyle özellikle ruminant hayvanlar için alternatif yem kaynaklarına ihtiyaç duyulacaktır. Su mercimeği (*Lemna minor)* yüksek protein içeriği, hızlı büyüme yeteneği ve sucul ortamlarda gelişebilmesiyle umut verici bir alternatif yem hammaddesi olarak öne çıkmaktadır. Su mercimekleri, su yüzeyinde yüzen ve boyutları 1.5 cm'ye kadar çıkan küçük bitkiler grubunu tanımlar. Su mercimeklerinin habitat gereksinimleri türler arasında farklılık gösterir ancak hepsi korunaklı, durgun suya ihtiyaç duyarlar. Bitki matının derinliği, bitkinin büyümesi için önemli bir sınırlayıcıdır. Su mercimeğinin dikkat çekici bir özelliği de muazzam bir üreme kapasitesine sahip olmasıdır. Elverişli koşullar altında, biyokütlelerini her 16 ila 48 saatte bir iki katına çıkardıkları bildirilmiştir. Su mercimeğinin alternatif yem hammaddesi olarak potansiyelini tam olarak gözlemleyebilmek için daha fazla araştırmaya ihtiyaç vardır. Diğer bir yandan su mercimeği temel amino asitleri içerir ve profili, geleneksel protein kaynaklarıyla karşılaştırılabilir yeterliliktedir. Ayrıca hızlı büyümesi, sık hasat imkânı sunarak sürdürülebilir, yenilenebilir ve ekonomik yem kaynağı sağlar. Geçmiş çalışmalarda su mercimeği yetiştirilmiş ve bitki %45 protein, %7 mineral, %37 karbonhidrat, %8 yağ ve %3 su içeriğine sahip olup, dokuz temel amino asit; demir, A, E ve B12 vitaminleri, omega 3, çinko, potasyum sağlamıştır. Bu projede, su mercimeğinin sindirilebilirliği ruminantlar üzerinde detaylı bir şekilde incelenecektir. Bu çalışmanın temel amacı, su mercimeğinin sindirilebilirliğini belirlemek ve ruminantlar için potansiyel bir yem kaynağı olarak kullanılabilirliğini araştırmaktır. Proje kapsamında su mercimeğinin sindirilebilirliği değerlendirilecektir.

Anahtar Kelimeler: *Su mercimeği (Lemna minor), Ruminant besleme, Alternatif yem kaynağı*

Evaluation of Some Element Contents in *Hypericum scabrum* L. from Kükürtlü Village (Erzurum)

Züleyha ASLAN ERGENEKON[1*], Meryem ŞENGÜL KÖSEOĞLU[1]

[1]Department of Biology, Faculty of Science, Atatürk University, Erzurum, Turkey

Abstract

Hypericum scabrum L. is a widely distributed plant in Turkey, known for its significant medicinal properties. This plant has been investigated for its potential as an accumulator in environmental pollution studies. In this study, the elemental contents of *H. scabrum* and surrounding soil samples from Kükürtlü Village, Erzurum, were analyzed to assess its capacity for element accumulation. The samples were processed following standard procedures for elemental analysis, and measurements were made using an ICP-OES device. The results revealed that *H. scabrum* contained high levels of potassium (K) and calcium (Ca), while calcium (Ca), iron (Fe), and magnesium (Mg) were the most concentrated elements in the soil. *H. scabrum* accumulated more potassium (K) than the soil, but other elements, such as copper (Cu), lead (Pb), nickel (Ni), zinc (Zn), and manganese (Mn), were found at lower levels. Although the plant's high uptake of macro-elements like potassium (K) may contribute to environmental nutrient recycling, its limited accumulation of certain heavy metals suggests that it has potential for mitigating environmental pollution, but it cannot be classified as a hyperaccumulator. Further studies should investigate the mechanisms of heavy metal uptake in *H. scabrum* and its potential for bioremediation in more detail.

Key Words: *Hypericum scabrum, element contents, Erzurum,* ICP-OES.

Kükürtlü Köyü (Erzurum)'nden Toplanan *Hypericum scabrum* L.'da Bazı Element İçeriklerinin Değerlendirilmesi

Özet

Hypericum scabrum L. Türkiye'de yaygın olarak bulunan ve önemli tıbbi özellikleri ile bilinen bir bitkidir. Bu bitki, çevre kirliliği çalışmalarında bir akümülatör olarak potansiyeli açısından araştırılmıştır. Bu çalışmada, Erzurum'un Kükürtlü Köyü'nden alınan *H. scabrum* ve çevresindeki toprak örneklerinin element içerikleri, element biriktirme kapasitesini değerlendirmek için analiz edilmiştir. Örnekler element analizi için standart prosedürler izlenerek işlenmiş ve ölçümler bir ICP-OES cihazı kullanılarak yapılmıştır. Sonuçlar, *H. scabrum*'un yüksek düzeyde potasyum (K) ve kalsiyum (Ca) içerdiğini, kalsiyum (Ca), demir (Fe) ve magnezyumun (Mg) ise topraktaki en yoğun elementler olduğunu ortaya koymuştur. *H. scabrum* topraktan daha fazla potasyum (K) biriktirmiş, ancak bakır (Cu), kurşun (Pb), nikel (Ni), çinko (Zn) ve manganez (Mn) gibi diğer elementler daha düşük seviyelerde bulunmuştur. Bitkinin potasyum (K) gibi makro elementleri yüksek oranda alması çevresel besin geri dönüşümüne katkıda bulunabilse de, bazı ağır metalleri sınırlı oranda biriktirmesi çevre kirliliğini azaltma potansiyeline sahip olduğunu, ancak hiperakümülatör olarak sınıflandırılamayacağını göstermektedir. *H. scabrum*'da ağır metal alım mekanizmaları ve biyoremediasyon potansiyeli daha ayrıntılı olarak araştırılmalıdır.

Anahtar Kelimeler: *Hypericum scabrum, element içeriği, Erzurum,* ICP-OES.

Introduction

The genus *Hypericum* Tourn. ex L., the largest genus of the Hypericaceae Juss. family, is represented by over 550 species worldwide (WFO, 2025). In Turkey, more than 100 species of this genus are found, with 48% of these species being endemic (Firat & Eroğlu, 2023). Members of *Hypericum*, which include trees, shrubs, annuals, and perennials, are widely distributed across various habitats, except for polar regions, tropical areas, and deserts (El-Chaghaby et al., 2024).

The material for this study, *Hypericum scabrum* L., has a wide distribution in Turkey and is naturally found in many regions, including Denizli, Kastamonu, Ankara, Erzurum, and Van (TÜBİVES, 2025). *H. scabrum* is a perennial plant that typically grows in dry and rocky slopes, open woodlands, and steppe habitats, at altitudes ranging from 750 to 3200 meters, and blooms between May and August (Peşin, 2007; Şerbetçi, 2002). A plant of significant medicinal value, *H. scabrum* has been used in traditional medicine to treat conditions such as heart, bladder, and intestinal disorders, rheumatism, jaundice, ulcers, gastritis, hemorrhoids, and constipation (Baytop, 1984). Its flowering branches are consumed in decoction form, while its fruits are used in infusions for stomach disorders (Kültür et al., 2018). In Turkey, it has been reported to be sold in markets for the treatment of eye diseases (styes) (Kocabaş et al., 2016). Recent studies have revealed that *H. scabrum* exhibits anti-inflammatory,

antioxidant, antifungal, and antidepressant effects, highlighting its potential for medicinal use (Abdollahi et al., 2012; Eslamı et al., 2011; Heshmati et al., 2018; Nalkıran Ergin et al., 2022; Şeker Karatoprak et al., 2019).
Industrial facilities are major sources of environmental pollution. As a result of production processes, heavy metals are released into the environment, with elements such as Pb, Ni, and Zn mixing into the atmosphere and soil, leading to severe environmental contamination. The accumulation of heavy metals in the soil can have toxic effects on organisms in the soil ecosystem, posing a threat to human health through the food chain. Heavy metal concentrations in soil typically range from 1 to 100,000 mg/kg, and when present at high levels, they disrupt the biological balance of the soil ecosystem, leading to reduced agricultural productivity and damage to ecosystems (Hayta & Avcil, 2019).

Previous studies have suggested that certain *Hypericum* species may exhibit potential accumulator properties with respect to heavy metal accumulation (Ayan et al., 2010; Colak et al., 2020). In one study, the heavy metal contents of soil samples around the Bitlis Solid Waste Integrated Disposal Facility were analyzed, revealing a high accumulation of metals, particularly Zn, Pb, Fe, and Cu. As a result, it was indicated that *H. scabrum* could potentially act as an accumulator for specific heavy metals (Hayta & Avcil, 2019). However, further research is needed to understand the tolerance mechanisms of this species to heavy metals and to determine whether it qualifies as a hyperaccumulator. This study aims to evaluate the elemental content of *H. scabrum* by analysing the concentrations of various elements in plants collected from an area near a cement factory and in soil samples taken from the same area.

Materials and Methods

Plant and soil samples were collected from Kükürtlü Village (Aşkale, Erzurum) (Table 1, Figure 1).

Table 1. Locality Information of Collected Plant and Soil Samples

Locality	Altitude	Coordinate
Kükürtlü Village, Aşkale, Erzurum	2006 m	39º51'34"N-40º36'11"E

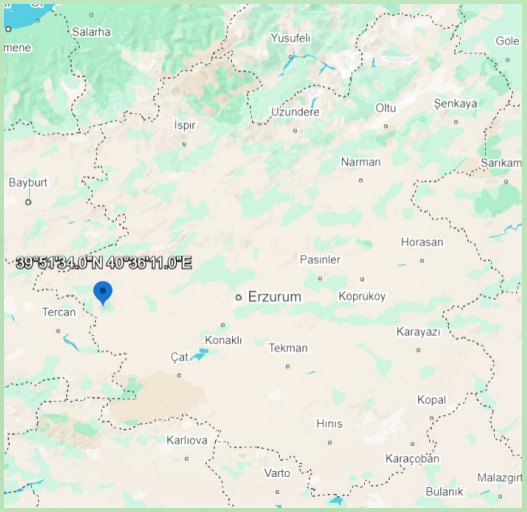

Figure 1. Location of the Plant and Soil Sample Collection Area (Google Earth)

The plant samples were carefully placed in polyethylene bags for preservation. Additionally, soil samples were also collected from the areas where the plants were gathered (Figure 1). To prevent microbial degradation of the plant material and to establish a fixed reference value based on dry weight, all samples were dried in an oven at 80 °C for 24 hours. To ensure the homogeneous distribution of metal content in the samples, plant samples were ground using a micro mill and passed through sieves of specific sizes to prepare them for analysis. The soil samples were collected using a stainless steel auger, air-dried, and then sieved through a 2 mm mesh. The homogenized soil samples were placed in transparent paper bags for preservation during the analysis process. Heavy metal analyses were carried out according to the method described by Aksoy et al. (2005), and the measurements were performed using a Varian Inductively Coupled Plasma Optical Emission Spectrometer (ICP-OES). The accuracy and measurement stability of the device were evaluated by controlling internal standard contamination during digestion and analytical procedures for each sample.
Data for various parameters were subjected to one-way analysis of variance (ANOVA) using SPSS version 22.

Results and Discussion

In this study, the element contents of *H. scabrum* collected from Kükürtlü Village (Aşkale, Erzurum) and the soil samples from the same site were analyzed. The obtained results are presented in Table 2.

Table 2. Detected Element Concentrations in Plant and Soil Samples

Elements	Plant (mg/kg)	Soil (mg/kg)
Ca	4123.2 (±201.53)	72200 (±2633.27)
Cu	4.05 (±0.09)	36,248 (±31.94)
Fe	18.22 (±4.14)	126448.5 (±45497.37)
K	9725.05 (±13.47)	5253.15 (±96.95)
Mg	725.04 (±208.95)	21710.5 (±5974.345)
Mn	7.27 (±0.07)	3749.25 (±137.67)
Na	94.70 (±48.81)	3299.4 (±82.73)
Ni	1.14 (±0.05)	156.70 (±82.73)
Pb	4.10 (±4.16)	203.02
Zn	20.99	362.47

Element Concentrations in *Hypericum scabrum* and Soil

The analyses revealed that the elements found at the highest concentrations in *H. scabrum* were potassium (K: 9725.05 mg/kg), calcium (Ca: 4123.2 mg/kg), and magnesium (Mg: 725.04 mg/kg). In contrast, soil samples showed the highest levels of Ca (72,200 mg/kg), iron (Fe: 126,448.5 mg/kg), and Mg (14,761.13 mg/kg). These findings offer important insights into the uptake and bioavailability of elements from soil to plant tissues.

When comparing *H. scabrum* and soil samples, it was observed that K was present at a higher concentration in the plant (9725.05 mg/kg) than in the soil (5253.15 mg/kg). Although K is a macronutrient and not classified as a heavy metal, this suggests that *H. scabrum* has a strong ability to absorb K, which may contribute to nutrient cycling within the ecosystem. In contrast, the accumulation of other elements such as Ca, Cu, Fe, Mg, Mn, Na, Ni, Pb, and Zn in the plant was relatively limited.

Accumulation of Potentially Toxic Elements

From an environmental perspective, the plant samples contained low levels of potentially toxic metals such as Cu (4.05 mg/kg), Pb (4.10 mg/kg), and Ni (1.14 mg/kg). However, the soil samples showed relatively high concentrations of Pb (203.02 mg/kg) and Ni (156.70 mg/kg), suggesting that these elements have accumulated in the area.

These results point to the limited ability of *H. scabrum* to uptake and store potentially hazardous metals, despite their elevated presence in the soil.

Hyperaccumulation Potential of *Hypericum scabrum*

Hyperaccumulator plants are defined by their ability to accumulate certain heavy metals in their tissues at 10–100 times the concentration found in the surrounding soil. According to the literature, threshold values for hyperaccumulation vary by metal. For example, Cu, Ni, and Pb must exceed 1,000 mg/kg to qualify as hyperaccumulators (Farooqi et al., 2022), while Zn and Mn require levels above 10,000 mg/kg.

The low accumulation levels of Cu, Ni, Pb, Zn, and Mn in *H. scabrum* indicate that it does not meet the criteria to be classified as a hyperaccumulator for these elements.

Ecological Implications and Future Research

Despite its limited uptake of heavy metals, *H. scabrum* showed a notably high uptake of potassium (K), an essential macronutrient. Although K is not considered a heavy metal, its elevated concentration in plant tissue compared to soil suggests that *H. scabrum* may play a role in nutrient cycling and ecosystem function.

Overall, the findings of this study suggest that *H. scabrum* absorbs certain elements in limited amounts and cannot be considered a hyperaccumulator. Further research is recommended to better understand its elemental uptake mechanisms, evaluate its potential role in environmental monitoring or phytoremediation, and examine its responses under varying ecological conditions.

Sustainable Irrigation Strategies for Enhancing Hass Avocado Yield in Arid Region of Tacna, Peru

Francisco Condori Tintaya[1*], Tefide Kızıldeniz[2], Oscar Fernandez Cutire[1], Junior Miranda Gutierrez[1], Yhudit Marili Mamani Llaca[1]

[1] Facultad de Ciencias Agropecuarias, Universidad Nacional Jorge Basadre G., Tacna, Peru
[2] Biosystem Engineering Department, Faculty of Agricultural Sciences and Technologies, Nigde Omer Halisdemir University, Niğde, Türkiye

Abstract

Hass avocado production in the Tacna region of Peru faces challenges related to irrigation efficiency and water availability. Efficient water management is essential for improving tree growth, fruit yield, and economic sustainability. This study aims to evaluate the relationship between irrigation efficiency, soil moisture levels, and avocado productivity to identify key factors influencing sustainable production. A comparative analysis approach was used to assess soil moisture, irrigation efficiency, tree growth, and fruit yield across different regions. Data were collected through field measurements, including soil moisture at various depths, irrigation system performance, and tree development indicators such as height and stem diameter. Regions with higher irrigation efficiency demonstrated better tree growth and higher fruit yields. The tallest trees and widest stem diameters were observed in areas with optimal water management, while inefficient irrigation systems led to lower productivity. Economic analysis indicated that high irrigation costs in water-scarce regions posed financial challenges, but improved irrigation techniques enhanced profitability. Climate change and water scarcity were identified as major risks, emphasizing the need for precision irrigation and sustainable water management practices. Optimized irrigation and soil moisture management significantly improve avocado production. To ensure long-term sustainability, modern irrigation systems and efficient water use strategies should be prioritized in water-scarce regions.

Key words: Hass avocado, irrigation efficiency, soil moisture, fruit yield, water management, sustainable agriculture, precision irrigation.

Abstract

The present study aimed to evaluate the biochemical and physiological characteristics, as well as the technological and probiotic properties of specific autochthonous Lactobacillus isolates. Initially, we confirmed the identification of these bacteria as belonging to the Lactobacillus genus by examining their macroscopic characteristics, conducting the catalase test, and performing Gram staining. Subsequently, we analyzed their biochemical and physiological traits, followed by an assessment of their technological properties. To evaluate their probiotic potential, we tested several of these isolates for antibacterial activity against a pathogenic strain of *Staphylococcus aureus* isolated from a urine sample of a patient with a urinary tract infection. The results indicated that most isolates are homofermentative and demonstrate the ability to thrive under challenging conditions. Additionally, the Lactobacillus strains exhibited strong acidifying, proteolytic, and lipolytic activities. They also produced flavors and exopolysaccharides (EPS), along with significant antibacterial properties. In conclusion, the Lactobacillus isolates assessed exhibited promising technological attributes that could be valuable in the food industry, particularly in dairy applications. Furthermore, their potential use in probiotic treatments, specifically for urinary tract infections, could provide a viable alternative to traditional antibiotic therapies.

Key Words: *Antibacterial activity, Lactic acid bacteria, Lactobacillus, probiotic effects, technological skills.*

Abstract

Controlling gene expression is critical for improving resistance against biotic and abiotic stress factors. The introduction of expression vectors encoding artificial miRNA or larger hairpin RNA to crops has proven to be effective for higher crop yield and quality by silencing the target gene via the RNA interference (RNAi) mechanism. Similarly, CRISPR/Cas-based genome editing tools have been employed to rewire the transcriptome by deleting genes or regulatory elements for improved crop plants. The expression of RNAi inducers, Cas endonucleases, and guide RNAs all rely on the delivery of expression cassettes via agrobacterium-mediated plant transformation. However, legal regulations, negative public perception, and lengthy and laborious tissue culture requirements restrict the use of agrobacterium-mediated transformation of crop plants. In animal systems ribonucleoproteins (RNP) and RNAs are commonly used to circumvent the use of DNA and tissue culture to induce gene silencing or genome editing *in vivo*. However, cell wall appears as a major barrier preventing the delivery of RNP and RNA molecules into the plant cells. We developed the high-pressure spraying technique (HPST), which successfully delivered sRNAs, mRNAs, and RNP molecules into plant cells *in planta*. In addition, the use of carbon-based nanoparticles, such as carbon dots, improves the uptake efficiency. The delivery of these molecules led to DNA- and tissue culture-free genome editing methods, new methods in epigenetic plant breeding, and substantially faster applications of gene deletions via CRISPR/Cas. In this presentation, the power and the limitations of HPST for RNAi and gene editing will be discussed.

Key Words: *CRISPR/Cas, RNAi, Genome Editing, RNA delivery, Plant Breeding*

Bridging the Digital Divide: An Assessment of Agricultural Extension Personnel's Usage of Digital Technology in Ondo State, Nigeria

T. F. Ojo[1*] and B. F. Balogun[1],

[1]Department of Agricultural Extension and Rural Development, Faculty of Agriculture
Obafemi Awolowo University, Ile-Ife, Osun State, Nigeria
Email: tfojo@oauife.edu.ng
Email: folayemibukola2@gmail.com

Abstract

This study assessed the utilization of digital technologies by public agricultural extension agents in Ondo State, Nigeria, for disseminating agricultural information. Data were collected from all (60) the extension personnel working with Ondo State Agricultural Development Programme using a structured questionnaire. Data analysis was carried out using descriptive statistics (frequency distributions, means, percentages) and inferential statistics (Chi-square tests, Pearson Product Moment Correlation) to test the study's hypotheses. The results revealed that mobile phone (100%), social media platform (98.3%), e-mail and SMS messaging tools (98.3%) were most available digital tools. Social media platform ($\bar{x}$ = 6.97) and television and radio broadcast ($\bar{x}$ = 6.97) were mostly utilised digital tools by the extension personnel for extension service delivery. The majority (66.7%) of the respondents had high knowledge in the use of digital technology for their extension work. Unstable power supply ($\bar{x}$ =1.98, high cost of Information Technology gadgets ($\bar{x}$ =1.83) and inadequate income to undertake digital technology training ($\bar{x}$ =1.78) were major constraints to the utilization of digital technology. Also, significant relationship existed between respondents' knowledge of digital technology (r=0.660) and the usage of digital technology (r=0.660). The study concluded that majority of the extension personnel utilised digital tools at high level for documentation, dissemination and information gathering purposes. To enhance the effectiveness of digital technology in agricultural extension services, it is recommended to stabilize power supply and provide continuous training to improve digital literacy among extension agents.

The role and potential of in silico studies in medicinal plant research

Ezgi Aksakallı[1], Müberra Koşar[1], Fatih Demirci[2]

[1]Department of Pharmacognosy, Faculty of Pharmacy, Eastern Mediterranean University, Famagusta, Cyprus
[2] Department of Pharmacognosy, Faculty of Pharmacy, Anadolu University, Eskişehir, Turkiye

Abstract

In silico studies, which have become increasingly widespread, are a crucial tool in overcoming the limitations of laboratory facilities, the high costs of chemicals, and the equipment and time requirements encountered in medicinal plant research. These studies generate data by analyzing the chemical structures of target molecules and enzymes, utilizing various online servers, computational, and visualization tools. The data generated can support, predict, or validate laboratory operations. Based on structure-activity relationships and prior clinical and preclinical data, *in silico* studies offer valuable predictions. Online resources help ascertain the physicochemical and pharmacokinetic characteristics of molecules. Interaction analyses are performed by calculating binding energies and the stabilities of molecules. Furthermore, a variety of computational techniques are employed to predict biological activities. *In silico* predictions are generally consistent with data obtained from previous clinical and preclinical studies, playing a crucial role in medicinal plant research. The implementation of such studies should be promoted, as they contribute to cost reduction and time efficiency. This study presents several examples to support the wider use of *in silico* studies in medicinal plant research.

Key Words: *In silico, Binding energy, Molecular docking, ADME, Medicinal plants*

In siliko çalışmaların tıbbi bitki araştırmalarındaki yeri ve potansiyeli

Ezgi Aksakallı[1], Müberra Koşar[1], Fatih Demirci[2]

[1]Farmakognozi Anabilim Dalı, Eczacılık Fakültesi,Doğu Akdeniz Üniversitesi, Mağusa, KKTC
[2] Farmakognozi Anabilim Dalı, Eczacılık Fakültesi, Anadolu Üniversitesi, Eskişehir, Türkiye

Özet

Günümüzde oldukça yaygınlaşan *in siliko* çalışmalar, tıbbi bitki araştırmalarında kısıtlayıcı faktör olarak karşımıza çıkan laboratuvar altyapısındaki sınırlamalar, yüksek kimyasal maliyetleri, zaman yönetimi ve gerekli ekipman gereksinimlerini aşmak için önemli bir araçtır. Bu çalışmalar, hedef molekül ve enzimlerin kimyasal yapılarının yanı sıra çeşitli hesaplama ve görselleştirme yazılımları ve çevrimiçi sunucular kullanarak veri üretir ve üretilen veriler laboratuvar faaliyetlerini desteklemek, tahmin etmek ya da doğrulamak amacıyla kullanılabilir. *In siliko* çalışmalar, önceki klinik ve klinik öncesi verilerle yapı-aktivite ilişkileri üzerinden tahminler yapmaktadır. Moleküllerin fizikokimyasal ve farmakokinetik özellikleri çevrimiçi araçlarla belirlenmektedir. Etkileşim analizleri, moleküllerin bağlanma enerjileri ve kararlılıkları hesaplanarak yapılmaktadır. Ayrıca, biyolojik aktiviteleri tahmin etmek için, çeşitli hesaplamalı yöntemler kullanılmaktadır. *In siliko* tahminler, daha önceki klinik ve klinik öncesi çalışmalardan elde edilen verilerle çoğunlukla uyumlu olup, tıbbi bitki araştırmalarında önemli bir rol oynamaktadır. Bu tür çalışmaların kullanımı, araştırma maliyetlerini düşürme ve zaman kazandırma açısından teşvik edilmelidir. Bu çalışmada, in silico çalışmalarının tıbbi bitki araştırmalarında daha yaygın bir şekilde kullanılmasını desteklemek amacıyla bazı örnekler sunulmaktadır.

Anahtar Kelimeler: *in siliko, bağlanma enerjisi, moleküler kenetleme, ADME, tıbbi bitkiler*

Cardioprotective Effects of *Crocus sativus* L. Against Doxorubicin-Induced Cardiotoxicity: A Review of Antioxidant and Anti-Apoptotic Mechanisms

Nardin Sedghizadeh [1], Emre Hamurtekin[2], Ezgi Aksakallı[3]

[1,2] Department of Pharmacology, Faculty of Pharmacy, Eastern Mediterranean University, Famagusta, Cyprus
[3]Department of Pharmacognosy, Faculty of Pharmacy, Eastern Mediterranean University, Famagusta, Cyprus

Abstract

Doxorubicin is a commonly utilized chemotherapeutic agent effective against a wide range of cancers. Nonetheless, its clinical utilization is considerably constrained by dose-dependent cardiotoxicity, potentially leading to irreversible cardiac injury and heart failure. The mechanisms of doxorubicin-induced cardiotoxicity are intricate and multifaceted, encompassing oxidative stress, mitochondrial dysfunction, apoptosis, and disruptions in calcium homeostasis.

In recent years, there has been a growing focus on natural compounds with cardioprotective properties. Crocus sativus (saffron) and its active components, notably crocin and safranal, have exhibited encouraging antioxidant, anti-inflammatory, and anti-apoptotic effects in multiple preclinical models. Numerous studies indicate that Crocus sativus may mitigate doxorubicin-induced cardiac damage by regulating redox balance, inhibiting apoptotic signaling pathways, and maintaining mitochondrial function.

This review aims to provide a comprehensive examination of the existing evidence regarding the cardioprotective properties of Crocus sativus and its bioactive constituents in relation to doxorubicin-induced cardiotoxicity. The review examines the molecular mechanisms involved, underscores the limitations of existing studies, and delineates future research directions and potential clinical applications.

Key Words: Doxorubicin, Cardiotoxicity, Crocus sativus , Natural cardioprotective agent, Oxidative stress Chemotherapy-induced cardiotoxicity

Doksorubisin Kaynaklı Kardiyotoksisiteye Karşı *Crocus sativus* L'un Kardiyoprotektif Etkileri: Antioksidan ve Antiapoptotik Mekanizmaların Derlemesi

Nardin Sedghizadeh [1], Emre Hamurtekin[2], Ezgi Aksakallı[3]

[1,2]Farmakoloji Anabilim Dalı, Eczacılık Fakültesi,Doğu Akdeniz Üniversitesi, Mağusa, KKTC
[3]Farmakognozi Anabilim Dalı, Eczacılık Fakültesi,Doğu Akdeniz Üniversitesi, Mağusa, KKTC

Özet

Doksorubisin, birçok kansere karşı etkili, yaygın olarak kullanılan bir kemoterapötik ajandır. Bununla birlikte, klinik kullanımı, potansiyel olarak geri döndürülemez kalp hasarına ve kalp yetmezliğine yol açan doza bağlı kardiyotoksisite ile önemli ölçüde sınırlıdır. Doksorubisin kaynaklı kardiyotoksisitenin mekanizmaları karmaşık ve çok yönlüdür ve oksidatif stres, mitokondriyal disfonksiyon, apoptoz ve kalsiyum homeostazındaki bozulmaları kapsar.

Son yıllarda, kardiyoprotektif özelliklere sahip doğal bileşiklere artan bir odaklanma olmuştur. *Crocus sativus* (safran) ve aktif bileşenleri, özellikle krosin ve safranal, birden fazla klinik öncesi modelde cesaret verici antioksidan, anti-inflamatuar ve anti-apoptotik etkiler sergilemiştir. Literatürde yer alan birçok çalışma, *Crocus sativus*'un redoks dengesini düzenleyerek, apoptotik sinyal yollarını inhibe ederek ve mitokondriyal işlevi koruyarak doksorubisin kaynaklı kardiyak hasarı hafifletebileceğini göstermektedir.

Bu çalışmada, *Crocus sativus*'un kardiyoprotektif özelliklerinin yanı sıra doksorubisin kaynaklı kardiyotoksisite ile ilişkili biyoaktif bileşenlerine dair mevcut kanıtların moleküler mekanizmaları incelenecek, mevcut çalışmaların sınırlamalarını vurgulanarak, gelecekteki araştırma yönlerini ve potansiyel klinik uygulamaları sunulacaktır.

Anahtar Kelimeler: *Doksorubisin, Kardiyotoksisite , Crocus sativus , Doğal kardiyoprotektif ajan , Oksidatif stres ,Kemoterapiye bağlı kardiyotoksisite*

Phenolic Compounds Found in Citrus Species

Fatma Yenice[1], Zeynep Akşit[2]

[1]Food Engineering, Faculty of Engineering and Architecture, Erzincan Binali Yıldırım University, Erzincan, Türkiye
[2]Hotel, Restaurant and Service Department, Tourism and Hospitality Vocational School, Erzincan Binali Yıldırım University, Erzincan, Türkiye

Abstract

Citrus fruits contain many components that are beneficial for health, including minerals, vitamins, and dietary fibers. They are also the main sources of many bioactive compounds with disease-preventing properties, such as flavonoids and limonoids. Flavonoids are a group of pigments found in plants and are responsible for the coloration of flowers and fruits. Flavonoids are found in fruits and vegetables in our diet. The inedible parts of citrus fruits, such as the peel, juice, and pulp, are as rich in phenolic compounds as the edible parts of the fruit. Citrus peels and seeds are rich in phenolic acids and flavonoids, and the peels contain more flavonoids than the seeds. The waste parts of citrus fruits such as peel and seed are particularly rich in flavonoid and phenolic compounds, and these compounds have important health properties. Recycling of citrus waste, which is produced in millions of tons worldwide, has significant potential in terms of environment and economy. In particular, recycling of peels contributes to the prevention of chronic diseases as a natural antioxidant source, while extending the shelf life by reducing oxidation in foods. The phenolic and flavonoid content of citrus waste varies depending on the species, growing conditions and harvest time. The use of citrus waste in the food, cosmetics and pharmaceutical industries not only reduces environmental pollution, but also enables the development of value-added products in terms of health and nutrition.

Key words: *Citrus fruits, Phenolic compounds, Citrus waste*

Turunçgil Türlerinde Bulunan Fenolik Bileşikler

Özet

Turunçgiller mineraller, vitaminler ve diyet lifleri de dahi olmak üzere sağlık için yararlı birçok bileşeni içermektedir. Ayrıca flavonoidler ve limonoidler gibi hastalık önleyici özelliklere sahip birçok biyoaktif bileşenlerin başlıca kaynaklarıdır. Flavonoidler bitkilerde bulunan bir pigment grubu olup çiçek ile meyvelerin renklendirmesinden sorumludur. Flavonoidler diyetimizde bulunan meyve ve sebzelerde bulunurlar. Turunçgillerin yenmeyen kısımları da kabuk, meyvenin öz suyu ve posası gibi meyvenin yenilebilir kısımları kadar fenolik bileşikler açısından zengindir. Narenciye kabuğu ve çekirdekleri fenolik asitler ve flavonoidler bakımından oldukça zengin olup, kabuklar flavonoid içeriği açısından tohumlara göre daha fazla bileşik içerir. Turunçgillerin kabuk ve çekirdek gibi atık kısımları, özellikle flavonoid ve fenolik bileşikler bakımından oldukça zengindir ve bu bileşikler sağlık açısından önemli özelliklere sahiptir. Dünya çapında milyonlarca ton üretilen turunçgil atıklarının geri dönüştürülmesi, çevresel ve ekonomik açıdan önemli bir potansiyel taşımaktadır. Özellikle kabukların geri kazanımı, doğal antioksidan kaynağı olarak kronik hastalıkların önlenmesine katkı sağlarken, gıdalarda oksidasyonu azaltarak raf ömrünü uzatmaktadır. Turunçgil atıklarının fenolik ve flavonoid içeriği; tür, yetiştirme koşulları ve hasat zamanına bağlı olarak değişiklik göstermektedir. Gıda, kozmetik ve ilaç endüstrilerinde turunçgil atıklarının kullanımı, çevre kirliliğini azaltmakla kalmayıp, sağlık ve beslenme açısından katma değerli ürünlerin geliştirilmesine de olanak sağlamaktadır.

Anahtar kelimeler: *Narenciye, fenolik bileşikler, narenciye atıkları*

Giriş

Narenciye türleri, dünyada yaygın olarak üretilmekte ve tüketilmektedir. En çok bilinen narenciye türlerinden portakal (Citrus sinensis) zengin antioksidan içeriği ile öne çıkarken, limon (Citrus limon) yüksek C vitamini içeriği ile bilinmektedir (Yüksekdağ, 2014). Mandalina (Citrus reticulata) daha tatlı ve az ekşi iken, greyfurt (Citrus paradisi) ise buruk tat vermekle birlikte zengin vitamin profiline sahiptir (Bürün, 2021). Turunç (Citrus aurantium) acı bir tada sahiptir ve genellikle marmelat yapımında kullanılır. Bu çeşitlerin yanında, lime (Citrus aurantiifolia) özellikle tropik bölgelerde sıkça tüketilen bir türdür (Özdemir & Tunçer, 2021).

Dünyada 2020/21 yılında yaklaşık 98 milyon ton narenciye üretilmiş olup bunların 49 milyon tonu portakal, 33 milyon tonu mandalina, 8 milyon tonu limon, 7 milyon tonu greyfurttur. Dünya turunçgil üretiminin kıtalara göre dağılımında Asya kıtası %44,9 ile birinci sırada yer almakta, Amerika kıtası %34,7 ile ikinci, Afrika kıtası %12,2 ile üçüncü sırada yer almaktadır (Atlı ve Söyler, 2018). Türkiye de ise 2020 yılında yaklaşık 4,3 milyon ton

turunçgil üretilmiş olup, bu üretimin %36'sı mandalina, %31'i portakal, %27'si limon ve %5'i greyfurta ait olmuştur. Turunçgil üretiminde Akdeniz bölgesi önde gelmekte olup mandalina üretiminin %84'ü, portakal üretiminin %85'i, limon üretiminin %93'ü, greyfurt üretiminin %96'sı bu bölgede gerçekleşmektedir (Turunçgiller Ürün Raporu 2021-333 TEPGE).

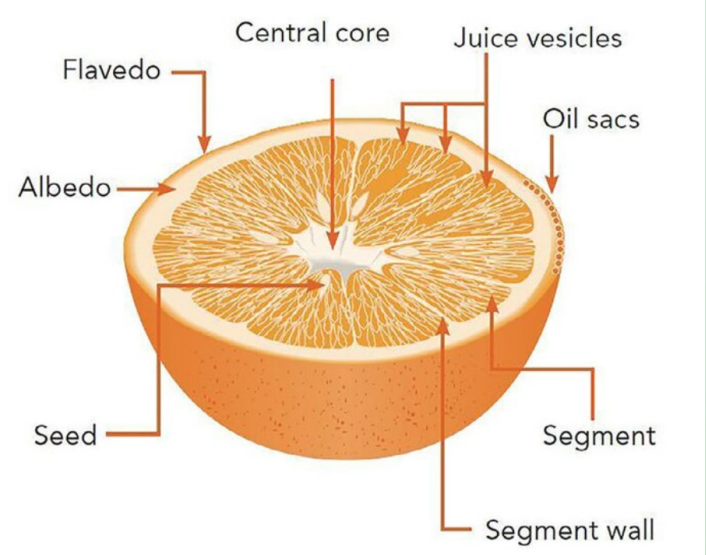
Turunçgiller, flavonoidler, fenolik bileşikler, askorbik asit, pektinler ve antioksidan maddeler gibi önemli biyoaktif bileşikleri bünyesinde barındırmaktadır (Fernández-López ve ark., 2005). Turunçgillerin bünyesinde barınan flavonoidler ve fenolik bileşikler; kalp hastalıkları riskini azaltmakta, bağışıklık sistemini güçlendirmekte, kanserojen hücrelerle savaşan antikorların üretimini desteklemekte, aynı zamanda antikanserojen, kolestrol düşürücü, antiinflamatuar ve antimikrobiyal etkiler göstermektedir (Zayed ve ark., 2021; Javanmardi ve ark., 2003; Elangovan ve ark., 1994; Friedman ve Levin, 2009). Narenciye meyvelerinin hem yenilebilen kısımları hem de özellikle kabuk gibi yenilmeyen bölümleri, zengin ve aktif bileşikler içermekte olup kabuklardaki yüksek flavonoid konsantrasyonu antimikrobiyal, antiviral ve antitrombotik gibi önemli biyolojik etkilere sahiptir. (Anagnostopoulou ve ark., 2006; Cook ve Samman, 1996). Flavonoidler, polifenolik yapıya sahip doğal bileşiklerdir ve meyve ile sebzelerin özellikle kabuklarında bulunurlar (Panche ve ark., 2016). Narenciye endüstrisinde kabuk ve çekirdek gibi atıkların geri dönüştürülmesi fenolik bileşiklerin için önemli bir kaynak oluşturabilir. Özellikle kabuklar, yenilebilir kısımlara kıyasla daha fazla fenolik bileşik içerir ve bu fark greyfurt, portakal, limon gibi türlerde belirgin şekilde görülür (Ma ve ark., 2009; Gorinstein ve ark., 2001). Gıda atıklarının geri kazanımı, çevresel sorunları azaltmanın yanında ekonomik faydalar da sunarak doğal kaynakların korunmasına yardımcı olur (Ajila ve ark., 2007; Hernandez-Carranze ve ark., 2016). Antioksidanlar açısından zengin gıdalar, kronik hastalık riskini azaltıp hücresel yaşlanmayı geciktirirken, gıdalara katılan antioksidanlar gıdalarda bozulmayı önleyerek raf ömrünü uzatır; turunçgiller ise önemli bir doğal antioksidan olan C vitamini bakımından oldukça zengindir (Boeing ve ark., 2012; Barden ve ark., 2016; Liu ve ark., 2012).

Turunçgiller mineraller, vitaminler ve diyet lifleri de dahi olmak üzere sağlık için yararlı birçok bileşeni içermektedir. Ayrıca flavonoidler ve limonoidler gibi hastalık önleyici özelliklere sahip birçok biyoaktif bileşenlerin başlıca kaynaklarıdır (Matheyambath ve ark., 2016). Flavonoidler bitkilerde bulunan bir pigment grubu olup çiçek ile meyvelerin renklendirmesinden sorumludur. Flavonoidler diyetimizde bulunan meyve ve sebzelerde bulunurlar (Macheix ve diğerleri, 1990). Turunçgillerin yenmeyen kısımları da kabuk, meyvenin öz suyu ve posası gibi meyvenin yenilebilir kısımları kadar fenolik bileşikler açısından zengindir (A.A. Damián ve ark., 2017; Mushtaq ve ark., 2014; Rodríguez ve ark., 2014). Narenciye kabuğu ve çekirdekleri fenolik asitler ve flavonoidler bakımından oldukça zengin olup, kabuklar flavonoid içeriği açısından tohumlara göre daha fazla bileşik içerir (Yusof ve ark.,1990). Turunçgillerin kabuk ve çekirdek gibi atık kısımları, özellikle flavonoid ve fenolik bileşikler bakımından oldukça zengindir ve bu bileşikler sağlık açısından önemli özelliklere sahiptir. Dünya çapında milyonlarca ton üretilen turunçgil atıklarının geri dönüştürülmesi, çevresel ve ekonomik açıdan önemli bir potansiyel taşımaktadır. Özellikle kabukların geri kazanımı, doğal antioksidan kaynağı olarak kronik hastalıkların önlenmesine katkı sağlarken, gıdalarda oksidasyonu azaltarak raf ömrünü uzatmaktadır. Turunçgil atıklarının fenolik ve flavonoid içeriği; tür, yetiştirme koşulları ve hasat zamanına bağlı olarak değişiklik göstermektedir. Gıda, kozmetik ve ilaç endüstrilerinde turunçgil atıklarının kullanımı, çevre kirliliğini azaltmakla kalmayıp, sağlık ve beslenme açısından katma değerli ürünlerin geliştirilmesine de olanak sağlamaktadır.

Turunçgiller ve Fenolik Bileşikler

Turunçgiller Geraniales takımının Rutaceae familyasının Aurantoideae alt-familyasına ait bir meyve grubudur (Antalya İl Tarım ve Orman Müdürlüğü, 2022) Birçok türü olmasına rağmen, ülkemizde en fazla tarımı yapılan turunçgiller sırasıyla, Citrus reticulata (mandalina), Citrus limon (limon), Citrus sinensis (portakal), ve Citrus paradisi (greyfurt)'dir (TÜİK, 2023).

Turunçgillerin ana bileşenleri; flavedo (dış kabuk), çekirdek (seed), meyve suyu kesecikleri (juice vesicles), albedo (flavedonun altındaki beyaz kısım), dilim (segment), dilim zarları (segment wall) gibi bölümlerden oluşmaktadır. Katmanlar incelendiğinde içeriğindeki bileşenler şu şekilde sıralanabilir



Flavedo (dış renkli kısım): flavonoidler ve esansiyel yağ (naringin ve limonen), pigmentler (karatenoidler), fenolleri içermektedir. Albedo (flavedonun altındaki beyaz kısım): protein, diyet, lifler, pektin, selüloz, neohesperidin içermektedir. Öz kalıntısı (meyve suyu ekstraksiyonundan sonra kalır): sitrik asit, folik asit, amino asit, selüloz içermektedir. Tohum: C vitamini, sterol, tokoferol, oleik asit, palmitik asit, limonoidler, eser mineraller içermektedir. (Chavan ve ark., 2018)

Turunçgiller; diğer meyvelerin bileşiminde yer almayan flavonon (hesperidin ve naringenin) ve karotenoid (kriptoksantin) bileşenlerinin ana kaynağıdır (Codoñer-Franch ve ark., 2010).

Meyvenin olgunlaşması esnasında meydana gelen çeşitli biyokimyasal ve fizyolojik değişimler yapıda yeni oluşumlara yol açar, örneğin; mandalinaların olgunlaşması sırasında karotenoid seviyeleri artar bu da rengin yeşilden koyu bir turuncuya kadar dönmesini sağlar. Aynı zamanda diğer biyoaktif bileşikler de değişir, bu durum meyvenin tadını ve asitliğini etkiler (Alquezar ve ark., 2008; Maduwanthi ve ark. 2019; Multari ve ark., 2020)

Narenciye bitkilerinden izole edilen ve tanımlanan 60'tan fazla flavonoid türü vardır. Narenciye kabuklarındaki flavonoidler, flavonon glikozitler (flavon C-glikozitler ve flavon O-glikozitler) ve polimetoksiflavonlar (PMF'ler)

olarak iki gruba ayrılmıştır (Zhang ve diğerleri, 2019). Flavonoidlerin temel yapısında bulunan benzoc–γ–piron (C6–C3–C6) glikozitleri birbirine bağlayarak oluşan flavon glikozitleri antikanser, nöroprotektif ve antiinflamatuar etkilere sahiptir (Musumeci ve ark., 2020; Okuyama ve ark., 2018). Hesperidin, turunçgil kabuklarında bol miktarda bulunan flavon O-glikozitlerine aittir. PMF'ler, C4 pozisyonunda bir karbonil grubu bulunan temel benzo-c-piron (15 karbonlu, C6–C3–C6) iskeletlerinde iki veya daha fazla metoksi grubu taşıyan flavonlardır. PMF'ler daha az polar ve yaklaşık düzlemsel yapıya sahiptir, bu da biyolojik membranlara yüksek geçirgenliğe yol açar ve kanda kolayca emilir (Gao ve ark., 2018). Metoksi gruplarının sayısı ve konumu, PMF'lerin biyolojik işlevleri üzerinde büyük bir etkiye sahiptir. Metoksi gruplarının artmasıyla, PMF'ler kanser hücrelerine yaklaşırken ve nüfuz ederken daha yüksek hidrofobisiteye sahip olur ve böylece daha güçlü biyolojik aktiviteye sahip olurlar (Walle, 2007). En yaygın olarak incelenen PMF'ler; tangeretin, nobiletin ve heptametoksiflavon ve bunların 5-hidroksile edilmiş PMF'leridir. Bazı hidroksillenmiş PMF'ler, PMF muadillerine göre daha güçlü anti-inflamatuar ve anti-kanser aktivitelerine sahiptir (Liu ve ark., 2021).

Şekil 1: Portakal meyvesinin genel bölümleri

(Adeniyi, A. G., Abdulkareem, S. A., Iwuozor, K. O., Ogunniyi, S., Abdulkareem, M. T., Emenike, E. C., & Sagboye, P. A. (2022). Effect of salt impregnation on the properties of orange albedo biochar. *Cleaner Chemical Engineering*, *3*, 100059.)

Flavonun dihidro türevleri ise flavanonlardır. En önemlileri naringenin, naringin, hesperidin ve hesperetin'dir. Naringin naringenin'in, hesperidin hesperetin'in glikozitidir. Greyfurt ve portakalda bol miktarda bulunurlar (Kökyar, 2012)

Turunçgil flavanonları glikozit veya aglikon formlarında bulunur. Aglikon formları arasında naringenin ve hesperetin en önemli flavononlardır. Glikozit formları arasında iki tip sınıflandırılır: neohesperidosidler ve rutinosidler (Gionfriddo ve ark.,1996; Macheix ve ark., 1990). Neohesperidosidler, flavanonlar, naringin, neohesperidin ve neoeriocitrin, neohesperidozlu bir flavanondan oluşurlar (ramnosil-a-1,2 glikoz) ve acı bir tada sahiptirler, rutinosidler (flavanonlar, hesperidin, nariru kalay ve didimin) ise bir flavanon ve bir disakkarit kalıntısı içerir. Flavanonlar genellikle diglikozit formunda bulunur ve turunçgillerin tipik tadını verirler (Macheix ve ark., 1990).

7-O-glikozilflavanonlar tüm turunçgillerde en bol bulunan flavonoidlerdir (Benavente ve ark., 1995; Lewinsohn ve ark., 1989). Neohesperidosid flavanonlar arasında naringin, neohesperidin ve neoeriositrin esas olarak bergamot, greyfurt ve acı portakal sularında bulunur. Rutinosid flavanonlar arasında hesperidin, narirutin ve didymin bergamot, portakal, mandalina ve limon sularında bulunur (Horowitz, 1986). Limon çekirdeği eriocitrin ve hesperidin, kabukları ise neoeriocitrin, naringin ve neohesperidin içermektedir. Kabukta neoeriocitrin ve naringinler benzer konsantrasyonda iken, çekirdekte; eriocitrin naringinden 40 kat daha fazla bulunmuştur (Tripoli ve ark., 2007). Bergamot çekirdeğinde naringin ve neohesperidin, ekşi portakal çekirdeğinde ise naringin tespit edilmiştir (Moulehi ve ark., 2012). Yapılan bazı çalışmalarda limon kabuğunun toplam fenolik içeriğinin, portakal ve greyfurt kabuklarından %15 daha fazla olduğu belirlenenirken (Gorinstein ve ark. 2001); greyfurt, limon ve portakal kabuklarının fenolik içeriğini inceleyen bazı çalışmalarda da greyfurt kabuğunda fenolik bileşik içeriği

daha yüksek bulunmuştur. İncelenen meyve kabuklarının fenolik içeriği farklılık göstermiş olup şu şekilde bir sonuca ulaşılmıştır: greyfurt 77,3 mg gallik asit eşdeğeri/g, limon 49,8 mg ve portakal 35,6 mg (Moulehi ve ark., 2012). Yine yapılan çalışmalarda bu kez greyfurt ve portakal kabuklarındaki toplam flavonoid içeriğinin limon kabuğuna göre daha yüksek olduğu görülmüştür. Kabukların flavonoid içeriği, greyfurt için 80,8 mg, portakal için 83,3 mg ve limon için 59,9 mg kateşin eşdeğeri/g olarak belirlenmiştir (Sir Elkhatim ve ark. 2018).
Yapılan çalışmalarda da görüldüğü gibi narenciye ürünlerindeki kabuk, pulp ve çekirdek gibi yan ürünlerin kimyasal yapısı ve antioksidan aktivitesi; narenciye çeşidine, yetiştirme koşullarına, iklime ve meyvenin hasat zamanına göre değişiklik göstermektedir (Karapınar ve Okuyan, 1982; Moulehi ve ark., 2012)
Tatlı portakal ve ekşi portakal flavonoid bileşikleri arasındaki farklar, tat profillerini etkileyen şeker türelerinden kaynaklanmaktadır. Tatlı portakallarda hesperidin ve narirutin, ekşi portakallarda ise neohesperidin ve naringin yoğun olarak bulunur (Bocco ve ark., 1998). Şekerlerden rutinoz (6-OaL-ramnosil-bD-glikoz), flavononlarlardan hesperidin ve narirutinin nötr tattan sorumludurlar ve tatlı portakallarda, mandalinalarda ve tangorlarda nispeten daha yüksek miktarlarda bulunurlar. Şeker neohesperidoz (2-OaL-ramnosil-bDglikoz), tangelolarda ve ekşi portakallarda yüksektir ve glikozitler neohesperidin ve naringine keskin veya acı bir tat verir (Peterson ve ark., 2006).
Çeşitli çalışmalar, bazı meyve çekirdeklerinin güçlü bir antioksidan aktiviteye sahip olduğunu göstermiştir. Narenciye meyvelerinde çekirdek ve kabuk bileşimleri her zaman aynı değildir. Örneğin, limon çekirdeği esas olarak eriositrin ve hesperidin içerirken, kabuk neoeriositrin, naringin ve neohesperidin açısından zengindir. Dahası, glikozit flavanon konsantrasyonları farklıdır; neoeriositrin ve naringin kabukta benzer konsantrasyonlara sahipken, çekirdekte eriositrin, naringinden 40 kat daha fazladır (Bocco ve ark., 1998). Neohesperidin, naringin ve neoeriocitrin büyük miktarlarda kabuktan elde edilir. Acı portakal çok ilginç bir neohesperidin ve naringin kaynağıdır; bu bileşikler tatlandırıcıların üretiminde faydalı olabilir. Bergamot tohumları, glikozlanmış flavanonlar, naringin ve neohesperidin'in en önemli kaynağıdır; limon eriocitrin ve hesperidin açısından zengindir. Diğer tüm turunçgil meyvelerinde az miktarda glikozlanmış naringin bulunur (Bocco ve ark., 1998; Yusof ve ark., 1990). Kabuk ve çekirdeklerin flavanon glikozil bileşimleri meyve sularınınkinden oldukça farklıdır. Naringin limon kabuğunda, limon çekirdeğinde ve mandalina çekirdeğinde bulunmuştur, ancak bu meyvelerin meyve sularında mevcut değildir (Mouly ve ark., 1995; Ooghe ve Detavernier, 1997).
Birkaç çeşitten elde edilen limon suyunda, glikozlanmış flavonoid miktarlarında çok az fark vardır. Eriocitrin, 6,8-di-C-b-glycosyldiosmin ve 6-C-b-glycosyldiosmin özellikle limon ve misket limonunda bol miktarda bulunurken, diğer turunçgillerde neredeyse hiç yoktur (Miyake ve ark., 1998). Polimetoksillenmiş favonlar (tangeretin, sinensetin, nobiletin, vb.) ve favanon glikozitleri (hesperidin, neohesperidin, narirutin, naringin, vb.) yalnızca turunçgillerde bulunur (M. Durand ve ark., 2015; Magwaza ve ark., 2016) . Hesperidin, neohesperidin, eriositrin, kuersetin, diosmin ve kaempferol, tatlı limonda temel fenolik bileşikler olarak bilinirken, rutin ve narirutin, minör bileşikler olarak bilinir. Kafeik, p-kumarik, sinapik, ferulik ve kloro-genik asit, tatlı limondaki en yaygın fenolik asitlerdir (Aludatt ve ark., 2017; Barreca ve ark., 2011; Hashemi ve ark., 2017; A.A. Damián ve ark., 2017; A. Fejzić ve ark., 2014) Kateşinler, lökoantosiyanin ve proantosiyaninler, diğer sebzelerde de bulunduğu için turunçgillere özgü bileşikler değildir (Tripoli ve ark., 2007).
Aşağıdaki tabloda portakal, mandalina, limon ve greyfurt meyve, kabuk ve çekirdeklerinde bulunan fenolik bileşikler verilmiştir.

Yapılan bir çalışmada mandalinanın kabuğunda toplam 28 fenolik bileşik tanımlanmıştır. Kabuk özlerinde, ana ürünler antosiyaninler, flavanonlar, flavanoller, flavonoller ve bir flavon (polimetoksile flavon sinensetin) dahil olmak üzere çoklu ikame desenlerine sahip flavonoidlerdi. Bunlar genellikle glikoz veya ramnoz veya arabinoz ile glikozillenmiş ve bazı durumlarda ayrıca diglikozillenmişti (rutin). İki fenolik asit (biri karşılık gelen aldehitle birlikte), bir dihidrokalkon (floretin) ve onun glikozillenmiş formu (floredzin) ve bir sinnamik asit (klorojenik asit) de bulundu. Polifenollere gelince, analiz kateşin-3-gallat (CG) ve epikateşin-3-gallat (EKG) ve tanen valoneik asit dilaktonun varlığını kanıtlanmıştır. Kabuğun fenolik bileşimi meyve olgunlaşma aşamasından güçlü bir şekilde etkilenmiştir. En ilginç aşama, en yüksek konsantrasyona ulaşan delfinidin-3-O glukozit, siyanidin-3-O-glukozit, delfinidin rutinozit, naringin, kuersetin-3-glukozit, rutin gibi bazı bileşikler için SRF gibi görünmektedir. (Costanzo ve ark., 2022)
Tohumlar arasında glikozile flavonların en ilginç kaynakları naringin ve neohesperidin açısından zengin bergamot; eriositrin ve hesperidin açısından zengin limon; ve naringin açısından zengin ekşi portakaldır. Diğer tüm türler çok az miktarda glikozile naringin içerir. Bu farklılıklar kullanılan meyvelerin çeşidine ve kökenine bağlı olabilir (Bocco ve ark., 1998).

Narenciye Atıklarının Kullanım Potansiyeli
Narenciye atıkları, değerli bileşenleri içeren yüksek organik madde konsantrasyonuna ve düşük pH değerine sahiptir (Zema ve ark., 2018). Sentetik antioksidanlar yerine doğal antioksidanların kullanımının önem kazanmasıyla birlikte, gıda işleme ve yan ürünlerinden antioksidan geri kazanımına yönelik çalışmalar artmıştır. Toplam meyve ağırlığının %50'sini oluşturan atıkların büyük bir kısmını narenciye endüstrisi üretmektedir.

Tablo 1. Portakal, limon, mandalina ve greyfurtun kabuk, meyve ve tohumlarında bulunan fenolik asitler ve flavonoidler

MEYVE	Bölge	Fenolik Asitler	Flavanoidler
PORTAKAL	Kabuk	p- kumarik asit (Wang ve ark. 2022) ferulik asit hekzozit ait, sinapik asit (Afifi ve ark., 2023)	sinensetin, narirutin, tetrametoksiflavon, nobiletin,hekzametoksiflavon (Guo ve ark., 2020) Hesperidin (Anagnostopoulou ve ark., 2006) Tangeretin ve nobiletin (Lu, Lee, Chu, Ho ve Sheen, 2019) Naringin, Limonin, Nomilin (Gou, 2014) apigenin, neohesperidin, naringin, isorhofolin, diosmin ve didymin (Anagnostopoulou ve ark., 2005)
	Tohum	Vanilik asit, kafeik asit, trans ferulik asit, p-kumarik asit (Falcinelli ve ark. 2020)	Eriocitrin, hesperidin, Didmin, Naringin, Narurutin (Berhow ve ark.,1998) Neoeriocitrin (Marini ve Balestireri, 1995)
	Meyve	ferulik asidi, p-kumarik asit, p-hidroksibenzoik asit (Fang ve ark. 2022) Klorojenik asit Kafeik asit (Hou ve ark. 2021; Xi ve ark. 2015)	Narirutin, Didmin (Forner-Giner ve ark. 2023) Naringin, Hesperidin, Epigallocatechin, Naftoresinol, Neohesperidin, Apigenin, Kuersetin, Rezorsinol, Kateşin, Rutin (Moulehi ve ark., 2012)
MANDALİNA	Kabuk	p-hidroksibenzoik asit, kafeik asit, vanilik asit, klorojenik asit, trans-sinamik asit (Anticona ve ark. 2022) gallik asit, ferulik asit ve p-kumarik asit (Gómez-Mejía ve ark. 2023)	Narirutin, hesperidin (Ma ve ark., 2008b) Nobiletin (Dou, 2019) Tangeretin, Sinensetin (Dou, 2019; Xu et al., 2019; Zhao et al., 2019) Limonin (Gou, 2014) Naringin, Naringenin, Apigenin, Kuersetin dihidrat, Rutin trihidrat, Kaempferol, (Anticona ve ark. 2022)
	Tohum	trans ferulik asit, p-kumarik asit, vanilik asit (Falcinelli ve ark. 2020)	hesperidin, naringin, narirutin ve tangeretin.
	Meyve	ferulik asidi, p-kumarik asit, p-hidroksibenzoik asit (Fang ve ark. 2022) Gallik asit, kafeik asit, klorejenik asit, vanilik asit, siringik asit, rosmanik asit, trans-2-Hydroxicinnamic acid (Moulehi ve ark., 2012)	Didymin, Eriocitrin, Hesperidin(Nogata ve ark. 1994) Epigallocatechin, Kateşin,Rutin,Kuersetin, Amentoflavon (Moulehi ve ark., 2012)
LİMON	Kabuk	gallik asit, ferulik asit ve p-kumarik asit (Gómez-Mejía ve ark. 2023) klorojenik asit, trans-ferulik asit (Alwazer ve ark., 2023)	Naringin (Büyükkurt ve ark., 2019; Patron- V´ azquez ve diğerleri, 2019) Nobiletin (Dou, 2019) Tangeretin (Dou, 2019; Xu et al., 2019; Zhao et al., 2019) Limonin (Gou, 2014) Narirutin (Chaves ve ark. 2022) Eriocitrin, neoeriocitrin, Neohesperidin, Luteolin, Isokuersitrin, Kuersetin galaktozit, Rutin, İzoramnetin, Rutinozit, Robinin, Mirisitrin (Rosa ve ark. 2023)
	Tohum	trans ferulik asit, ρ -kumarik asit, vanilik asit (Falcinelli ve ark. 2020) protokatekuik asit, ρ-hidroksibenzoik asit, siringik asit ve kafeik asit, sinapik asit (Dong ve ark., 2019)	Eriocitrin, hesperidin (Bocco, Cuvelier, Richard ve Berset, 1998).
	Meyve	Kafeik, p-kumarik, sinapik, ferulik ve klorogenik asit (Dong ve ark., 2019)	Hesperidin, Eriocitrin, diosmin, Cynaroside (Dong ve ark., 2019)
GREYFURT	Kabuk		Nobiletin (Dou, 2019) naringin (Büyükkurt ve ark., 2019; Patron- V´ azquez ve diğerleri, 2019) Limonin (Gou, 2014) Hesperidin, Eriocitrin, Diosmin, Sinarozit, Rutin(Dong ve ark., 2019) Didmin, Poncirin, Sinensetin (del Río ve ark. 2022)
	Tohum		Naringin(Büyükkurt ve ark., 2019; Patron- V´ azquez ve diğerleri, 2019) Nobiletin(Dou, 2019), Limonin (Gou, 2014),
	Meyve	protokatekuik, neoklorojenik asit, hidroksisinamik asitler ve ferulik asit (Cao ve ark. 2022) Klorojenik asit Kafeik asit (Hou ve ark. 2021; Xi ve ark. 2015)	Hesperidin, Neoeriocitrin, Neohesperidin (Deng ve ark. 2022) Narirutin, Naringin, Naringenin (Stabrauskiene ve ark. 2023) Cigranoside A-E, Bergamjuicin, Melitidin, Tangeretin, Heptametoksiflavon, Roifolin, Isokuersitrin (Deng ve ark. 2022)

Narenciye kabukları, doğal flavonoidler açısından oldukça zengin olduğu gibi, yenilebilir kısımlara oranla daha fazla fenolik bileşik içermektedir (Kökyar, 2012). Bu nedenle narenciye kabuklarındaki biyoaktif bileşiklerin potansiyeli, son yıllarda giderek artan bir ilgi görmüştür (Llorach ve ark., 2003; Manthey ve Grohmann, 2001). Narenciye atıkları, özellikle kabuk ve çekirdek kısımları biyolojik olarak aktif bileşikler açısından önemli bir potansiyele sahiptir. Bu atıklardan antioksidanlar, fenolik asitler ve flavonoidlerin geri kazanımı sayesinde, gıda, kozmetik ve ilaç sanayilerinde değerlendirme yapılabilir (Deng ve ark., 2012; Masuda ve ark., 2001). Ayrıca

antioksidanlar, gıda endüstrisinde raf ömrünü uzatmak ve oksidasyonu önlemek açısından kritik bir role sahiptir (Saito ve ark., 2004).

Gıda işleme sırasında ortaya çıkan atıkların etkin bir şekilde değerlendirilmesi yalnızca çevre kirliliğini önlemekle kalmaz, aynı zamanda katma değer yaratılması ve ürün çeşitlendirmesi açısından da büyük önem taşır. Atıkların değerlendirilmesi, ekonomik fayda sağlamanın yanı sıra, antioksidan ve diğer zenginleştirilmiş içeriklerin geri kazanımı sayesinde insan metabolizmasına girmesiyle sağlık ve beslenme açısından da ek faydalar sunmaktadır (Yağcı ve ark., 2006). Bitkisel atıkların geri dönüşümü, diyetlerde gıda takviyeleri, kozmetik ürünler ve sağlık odaklı ürünlerin üretimine yönelik çalışmalara odaklanmıştır. Narenciye atıklarından üretilen bu tür ürünlerin başlıca materyalleri sebze atıkları, meyve posası ve kabukları oluştururken, çekirdekler de son yıllarda bu alanda giderek popülerlik kazanmıştır (Peschel ve ark., 2006).

Sonuç

Turunçgiller, içerdiği fenolik bileşikler, flavonoidler ve antioksidanlar gibi biyoaktif maddelerle beslenme, sağlık ve endüstriyel alanlarda büyük bir öneme sahiptir. Meyvenin olgunlaşma süreci, bu bileşiklerin miktarı ve çeşitliliği üzerinde doğrudan etkili olup, renk, tat, asidite ve antioksidan aktivitede belirgin değişimlere yol açar. Fenolik bileşiklerin ve flavonoidlerin konsantrasyonu da olgunlaşma aşamasına bağlı olarak farklılık gösterir.

Narenciye atıklarının, özellikle kabuk ve çekirdek kısımlarının değerlendirilmesi ise sürdürülebilirlik açısından büyük bir potansiyel taşır. Bu atıklar, olgunlaşma süreçlerinde değişen fenolik bileşikler ve antioksidanların önemli bir kaynağı olarak gıda, kozmetik ve ilaç sanayinde kullanılabilir. Atıkların geri kazanımı, çevresel kirliliği azaltırken ekonomik katma değer sağlar ve doğal kaynakların korunmasına katkıda bulunur.

Sonuç olarak, turunçgillerin olgunlaşma aşamalarına bağlı olarak değişen biyoaktif bileşenlerinin takibi ve atık kısımlarının etkin değerlendirilmesi, sağlık, endüstri ve çevresel sürdürülebilirlik açısından önemli fırsatlar sunmaktadır. Narenciye türleri, zengin fenolik ve flavonoid içeriğiyla biyoaktif bileşiklerin önemli bir kaynağıdır. Yenilemeyen kısımların geri kazanımı, hem çevresel faydalar sağlayabilir hem de ekonomik açıdan cazip çözümler sunabilir. Gelecekte, bu atıkların etkin kullanımı için daha fazla çalışma yapılması gerekmektedir.

Abstract

Humans have consumed meat throughout history, either processed or fresh, as the main source of nutrition. In the modern meat industry, emulsion meat products play an important role among meat products. It is known that meat has been traditionally prepared in dough since ancient times. In later periods, it developed and industrial production became widespread. Salami and sausage constitute common emulsion meat products. Emulsification of meat products is the binding of fat and water with the help of emulsifiers and meat proteins. Sausage in general terms; It is produced by adding various additives to the dough obtained by emulsification process from beef, pork, buffalo, poultry and sheep meat and by-products of these meats, and filling it into natural or artificial casings. Sausage is a product that is vulnerable to spoilage due to both being a meat product and the water and fat content in its structure. Various antioxidants and additives such as nitrate-nitrite salts are commonly used to extend the shelf life of sausage. In addition, studies have shown that the shelf life of sausages is affected by factors such as the antioxidant and antimicrobial substances used, the heat treatment and packaging technique applied, moisture content, storage temperature and microbiological load.

Key words: *Food emulsions, Meat products, Sausage, Shelf life*

Sosis ve Raf Ömrü Çalışmaları

Özet

Et tarih boyunca insanlar tarafından işlenmiş veya taze bir şekilde ana beslenme kaynağı olarak tüketilmiştir. Modern et endüstrisinde, et ürünleri içerisinde emülsiyon et ürünleri önemli bir rol oynamaktadır. Çok eski tarihlerden beri etlerin geleneksel olarak hamur şeklinde hazırlandığı bilinmektedir. Sonraki dönemlerde gelişerek endüstriyel üretimleri yaygınlaşmıştır. Salam ve sosis yaygın emülsiyon et ürünlerini oluşturmaktadır. Et ürünlerinin emülsifikasyonu temel olarak emülgatörler ve et proteinlerinin yardımıyla yağ ve suyun birbirine bağlanmasının sağlanmasıdır. Genel anlamda sosis; sığır, domuz, manda, kanatlı ve koyun etleri ve bu etlerin yan ürünlerinden, emülsifikasyon işlemi uygulanmasıyla elde edilen hamurun içerisine çeşitli katkı maddeleri katılıp, doğal veya yapay kılıflara doldurularak üretilir. Sosisin hem et ürünü olması hem de yapısındaki su ve yağ içeriğinden dolayı bozulmaya karşı zayıf bir üründür. Sosisin raf ömrünü uzatmaya yönelik çeşitli antioksidanlar ve yaygın olarak nitrat-nitrit tuzları gibi katkı maddeleri kullanılmaktadır. Ayrıca yapılan çalışmalarda sosislerin raf ömrünün kullanılan antioksidan ve antimikrobiyal maddeler, uygulanan ısıl işlem ve ambalajlama tekniği, nem içeriği, depolama sıcaklığı ve mikrobiyolojik yük gibi faktörlerden etkilendiği belirtilmiştir.

Anahtar kelimeler: *Gıda emülsiyonları, Et ürünleri, Sosis, Raf ömrü*

Giriş

Kırmızı et ve et ürünlerinin tüketimi insanlık tarihinden uzun bir geçmişe sahiptir. Et ve et ürünleri bir besin ve mükemmel bir protein kaynağıdır. Türk Gıda Kodeksi Et Ürünleri Tebliği'ne göre; "Et; sığır, manda, koyun, keçi gibi büyük ve küçükbaş hayvanlar; tavuk, hindi, kaz, ördek, beç tavuğu gibi evcil kanatlı hayvanlar ile tavşan ve domuzdan elde edilen, insan tüketimine uygun olan tüm parçalar" olarak tanımlanmaktadır. Et dünya çapında büyük bir ekonomiyi kapsamaktadır. Et besin olarak taze veya işlenmiş olarak farklı şekilde tüketilmektedir. İşlenmiş et ürünleri, taze ete göre daha uzun raf ömrüne sahip gıdalar üretme ihtiyacından dolayı geliştirilmiştir (Melro vd., 2020). Teknolojinin ilerlemesi, insan nüfusunun artması, hazır gıdalara olan talebin büyümesi ve insanların güvenilir gıda endişesi et ürünlerinin endüstriyel ölçekte üretilmesine olanak sağlamıştır. Böylece et ürünlerinin işlenmesi kolaylaşmış ve işlenmiş et ürün yelpazesi genişlemiştir.

İşlem görmüş et ürünleri olarak en çok sucuk, salam, sosis, pastırma ve kavurma tüketilmektedir (Kara, 2012). Et hamurları, etlerin diğer bileşenlerle birlikte esas olarak su, yağ ve proteinden oluşan kaba bir dağılım oluşturacak şekilde doğranmasıyla oluşturulur (Andrés vd., 2006). Sosis ve salamların hazırlanmasında işlenecek et çok küçük parçalar haline getirildiği için üründe bağlama sorunu ortaya çıkar. Bu nedenle bu tür ürünlerde emülsifikasyon işlemi kullanılır.

Su içinde yağ (oil/water) emülsiyonları, sulu bir fazda dağılmış bir yağ fazından oluşan sistemlerdir (Dickinson, 2009). Bu tür emülsiyon ürünlerinde dağıtılan faz genellikle yağdır. Su ise sürekli faz olarak içerisinde tuzları ve proteinleri içermektedir (Ertaş, 1998). Emülsiyon et ürünlerinde, ısıl işlemin ardından dağılmış emülsiyon damlacıkları, işlem sonrası üründe dolgu maddesi görevi görür (Santhi vd., 2017). Hamurun işlenmesi için kullanılan termal işlem, yüksek viskoziteli ürünü, yağ parçacıklarıyla dolu bir protein jeli olarak görülebilen viskoelastik bir katıya dönüştürür (Andrés vd., 2006). Emülsiyon ürünlerinde yaygın olarak tuz, fosfatlar, nitrit, dekstroz ve emülgatörler kullanılır.

Et emülsiyonları gerçek emülsiyonlar değildir, ancak et ve yağ parçalarının iki fazlı sistem halinde homojen karışımı olduğundan emülsiyon olarak nitelendirilir. Et emülsiyonları denilince esas olarak su ve hayvansal yağların et proteinleri ve emülsifiye edici ajanlar yardımıyla bir arada tutulması sağlanmaktadır. Et emülsiyonlarında kullanılan emülgatörler, tuzlu suda çözünebilen miyofibriller proteinler ve suda çözünebilen sarkoplazmik proteinlerdir (Anar, 2012). Et proteinleri arasında miyofibriler proteinler emülsifikasyonda yüksek işlevselliğe sahiptir. Farklı türler farklı protein özelliklerine sahiptir ve bu farklılıklar etkileşim etkilerinden kaynaklanabilir (Zorba & Kurt, 2006). Farklı türdeki ürünlerde et emülsiyonunun yapısı ve stabilitesi üzerine çalışmalar yapılmış ve yapılmaya devam edilmektedir (Youssef & Barbut, 2009).

Sosis

Emülsiyon teknolojisiyle üretilen et ürünleri ülkemizde büyüklük ve şekil bakımından "salam" ve "sosis" olarak sınıflandırılırken, dünya gıda sanayisinde genel terim olarak "sausage" (sosis) kullanılmaktadır. Sosisin kökeni tam olarak bilinmemektedir. Sausage kelimesi Latince kökenli olup tuzlanmış ya da tuz ile korunmuş anlamına gelen salsus kelimesinden köken almaktadır ve parçalanmış ya da kıyılmış etin tuzlama ile korunması anlamında kullanılmıştır (Anar, 2010). Salsus kelimesi aynı zamanda et ve kanın çeşitli katkı maddeleriyle karıştırılıp hayvan midelerine doldurulması ile elde edilen ürünler anlamında kullanılmıştır (Küçükarslan, 2023).

Sosisler, sığır eti, domuz eti, kümes hayvanları veya av hayvanı etinin öğütülmesi, tuz ve diğer baharatlarla karıştırılması ve ardından bir kılıfa doldurulmasıyla üretilir (Mohan, 2014). Sosisler şekil olarak yarım küre uçlu silindir şeklinde tanımlanır. Sosis ve salam tipi et ürünleri için, dünyada, standart bir sınıflandırılmaya gidilmiştir. Sosisler türlerine göre UK (Birleşik Krallık) tarzı taze sosis, pişmiş, fermente edilmiş ve emülsiyon sosis olarak sınıflandırmaktadır. Sosisler ısıl işleme göre; Çiğ sosis (Raw sausage, Rohwurst), Pişirilmiş sosis (cooked sausage, Brühwurst, Kochwurst), tipik özellik ve farklılıklarına göre; Jelleştirilmiş sosisler (Sülze) ve tamamen ezilmiş kıyma halindeki ürünler (minced meat product, Hackfleisch) olarak sınıflandırılmıştır (Akbulut & Karagözlü,2012). Emülsiyon tipi sosislere Bologna, kokteyl, Frankfurts, karaciğer sosisi vb. olarak örnek verilebilir (Essien, 2003).

Sosis için kullanılan genel tanımlama, tuz, baharatlar ve diğer bileşenlerle birleştirilmiş, belirli şekil ve büyüklükte bir kılıf içine doldurulabilen öğütülmüş veya doğranmış et ürünü şeklinde yapılabilir. Et kaynağı ve baharatlar, malzemeler ve/veya hazırlama yöntemi değiştirilerek çok çeşitli sosisler üretilebilir (Mohan, 2014).

Sosis ve salam üretiminde temel olarak aynı hamur kullanılmaktadır. Farklı katkı maddeleri kullanılması, et ve yağın az veya çok kuterlenmesi ve dolum yapılan kılıfların boyut ve biçim bakımından farklı olmasından kaynaklanmaktadır (Akşit, 2018; Gökalp, 1999). Fermente sucuklar hava kurutulduğundan olgunlaşmaları sırasında fire vermeleri söz konusudur. Fakat haşlanarak hazırlanan salam ve sosislerde %30 oranında su (buz şeklinde) katılarak hazırlanmaktadır (Anar,2012).

Sosis üretimi için hammadde seçimi

Et ürünleri üretiminde kullanılan hammadde olan et ve yağın yanında kürleme maddeleri, baharatlar, lezzetlendiriciler, bağlayıcı maddeler ve su kullanılmaktadır. Başarılı bir et ürünü formülasyonu elde etmek için üretimde kullanılan hammaddelerin ve katkı maddeleri ve bileşimleri hakkında bilgi sahibi olunmalıdır. Ayrıca kullanılan kürleme maddeleri, bağlayıcı maddeler ve dolgu maddelerinin oranları yasal düzenlemeler çerçevesinde formüle edilmelidir (Anar, 2012).

A. Et

Et ürünleri üretiminde dana, sığır koyun ve domuz etlerinin yanı sıra koyun eti, kanatlı etleri ve diğer etler ile çeşitli iç organlar da kullanılmaktadır. Etler hayvan türlerine göre ve karkastan elde edildikleri bölgelere göre rutubet, protein, yağ miktarı, renk su ve yağ bağlama yetenekleri yönünden farklılık göstermektedir. Üretilecek et ürününe göre et seçiminin yapılması bu nedenlerden dolayı önemlidir. Haşlanmış et ürünleri üretiminde hammadde olarak etin yanında yenilebilir iç organlarda kullanılmaktadır. Böylece ekonomik bir üretim yapılabilmektedir. Emülsiyon tekniği ile üretilen et ürünlerinde su bağlama kapasitesi denince etin suyu bağlama yeteneği ve yağları emülsifiye edebilme özelliği anlaşılır. Koyun etinin su bağlama yeteneği oldukça yüksektir ancak tüketiciler tarafından çok tercih edilmediği için üretilen ürünün %10 ila %20 oranlarında kullanımı sınır kalmaktadır (Anar, 2012).

B. pH

Etlerin pH değeri ve kimyasal durumları et teknolojisinde önemli faktörler arasındadır. Sosis gibi ürünlerin üretilmesinde sıcak et yani ATP oranı yüksek, pH 6.0 olan etler tercih edilmelidir. Bu tür etler diğer etlere göre %50 daha fazla tuzlu suda eriyebilir protein ekstrakte edebilir (Anar, 2012).

C. Yağ

Yağ et ürünlerinde önemli bir lezzet kaynağıdır. Yağ doğrudan etin tadına, yumuşaklığına ve gevrekliğine katkıda bulunur. Yağ emülsiyonda da görev almakta ve üretim maliyetini düşürmektedir. Genellikle etin yağlı olma durumuna göre %16-18 oranında yağ kullanılmaktadır (Anar, 2012).

D. Su

Sosis gibi emülsiyon et ürünlerinde su et hamurunun %20-30 oranında bu veya soğuk su şeklinde ilave edilir. Su emülsiyonun homojen olarak dağılmasını, proteinleri çözerek emülsiyona katılmasını, et hamuruna akıcı özellik verilmesini ve işlem sırasında sıcaklığı düşük tutarak emülsiyonun stabilitesinin korumasını sağlamaktadır (Anar, 2012).

E. Tuz

Et ürünlerinde tuz önemli bir kürleme maddesidir. Sosislerde genellikle %2 oranında tuz kullanılmaktadır. Tuz etin tadının oluşmasında, bakteriostatik etkisiyle gıdanın korunmasında, et proteinlerinin çözülerek emülsiyona katılmasında ve hamurun su tutma kapasitesinin arttırılmasında oldukça önemli rol oynamaktadır (Anar, 2012).

F. Nitrit

Nitrit sosis üretiminde arzu edilen renk oluşumu, kürlenmiş et ürünlerine özgü tat oluşumu ve antimikrobiyal etkisinden dolayı kullanılmaktadır. Ancak nitritin toksik bir bileşik olarak vücutta birikmesinden dolayı kullanımı maksimum 150mg/kg oranında sınırlandırılmıştır (Anar, 2012).

G. Şeker

Sosislerde tuzun tadını nötralize etmek ve kürlenmiş ürünlerin tadını arttırmak amacıyla % 0.4-1 oranında kullanılır (Anar, 2012).

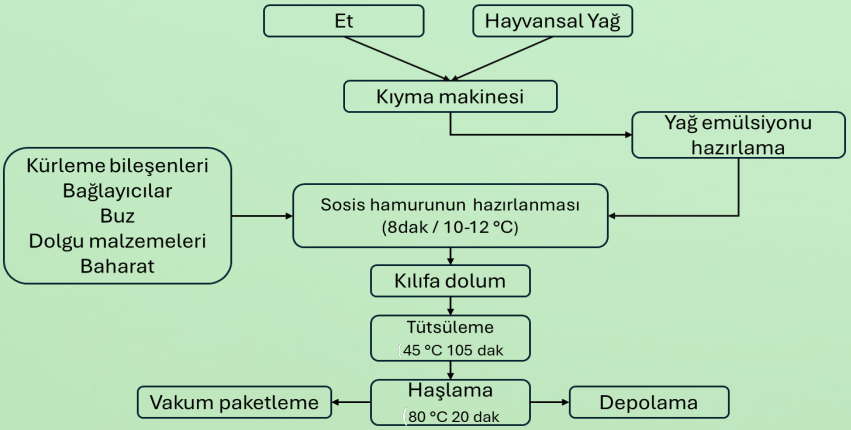
H. Bağlayıcı ve dolgu maddeleri

Bu maddeler sosis hamurunda emülsiyon oluştuktan sonra fazla suyun absorbe edilmesiyle istenilen kıvam ve tekstürün oluşmasını sağlar. Sosis üretiminde sosislerin haşlanması sırasında şekil bozukluklarını önlenmesi ve maaliyeti düşürmesi nedeniyle de kullanılmaktadır. Bu ürünler çoğunlukla hububat unları ve nişastalar, sebze unları ve nişastası son olarak süt ürünleri olarak sıralanabilir (Anar, 2012).

İ. Fosfat

Fosfatlar kas proteinini çözmek için en etkili katkı maddesidir ve genellikle toplam kütlenin kilogramı başına 3-5 g fosfat kullanılır. Emülsifiye edilmiş sosisler için öncelikle difosfatlar içeren özel fosfat karışımları mevcuttur ve doğrama veya karıştırma-emülsifikasyon sırasında protein üzerinde hızlı bir şekilde etki eder. Bu önemlidir çünkü bir emülsiyon oluşturmak yalnızca 7-12 dakika sürer ve ikincil bir işlemde yağ ve suyu emülsifiye etmek için önce proteinin etkinleştirilmesi gerekir. Fosfatlar her zaman kesme işleminin başında eklenir, böylece protein üzerinde en başından itibaren etki edebilirler (Feiner, 2006).

Sosis üretimi



Sosis, protein ve tuzlar gibi çözünmüş maddelerin çözeltileri, ilave sudaki daha büyük parçacıkların süspansiyonları, kas proteinlerinden yapılan jeller ve protein ve yağdan yapılmış bir jel içinde stabilize edilmiş kısmen sıvı halde bulunan yağ içeren emülsiyonlar dahil olmak üzere farklı sistemlerin oldukça karmaşık bir karışımıdır. Ürün, yağ veya su ayrımı olmadan ısıl işleme dayanabilen, sağlam doku ve iyi kavrama gösteren, homojen, ince kesilmiş, pürüzsüz dokulu bir ürün olmalıdır (Feiner, 2006).

Genel olarak pişmiş bir sosis, emülsiyonda hiçbir yağ parçacığı görünmeyecek sürede kesilmeli ve aynı zamanda mümkün olduğu kadar fazla proteini aktive edilmelidir. Kesme veya emülsifiye etme işlemi çok kısa olursa eksik kesme meydana gelir; bu durumda yağ yeterince ufalanmaz ve son üründe gözle görülür parçacıklar görülebilir. Kısa bir kesme işlemi, optimum miktarda proteini aktive etmez ve bu nedenle, ısıl işlem sırasında büyük yağ parçacıklarını kaplayan yalnızca ince bir aktive edilmiş protein tabakası kalır. Bu, ısıl işlem sırasında yağ ve suyun ayrılması riskinin artmasına neden olur. Aşırı kesme, sosis kütlesinin çok uzun süre kesilmesidir ve bu, emülsiyondaki sayısız çok küçük yağ parçacıkları nedeniyle çok büyük bir yağ yüzey alanıyla sonuçlanır (Feiner, 2006).

Sosis üretim aşamaları;

- Etin kıyma haline getirilmesi
- Tuz, Baharatlar, katkı maddeleri ve buzun ilave edilmesi
- Kuterde boyut küçültme (3-5 °C)
- Yağ ilavesi
- Bağlayıcı (süt tozu veya soya proteini)
- Hamur kuterleme (15 °C)
- Kalan buz ekleme ve kuterleme
- Bağlayıcı (nişasta)

- Askorbik asit
- Hamur dolum makinesi
- Kılıflara doldurulma
- Ön kurutma (58-60 °C 10-20 dk)
- Dumanlama (65 °C 30 dk)
- Haşlama (80 °C 20 dk)
- Soğutma
- Su püskürtme
- Sıcaklığın 5 °C'nin altına düşürülmesi
- Askıda bekletme (suyun süzülmesi için)
- Ambalajlama
- Depolama

Şekil.1. Sosis üretim prosesi şematik gösterimi

Sosislerde raf ömrünü etkileyen faktörler ve bu konudaki bazı çalışmalar

Et, içerdiği mikroorganizmaların gelişimini destekleyen yeterli besin maddeleri açısından zengin bir ortam sunar ve çok çabuk bozulur; özellikle kıyma, karıştırma veya kıyma işlemi sırasında kolayca kirlenebilecek artan bir yüzey alanı mikrobiyolojik büyüme için eşsiz bir alan sunar (Mahami, T. vd., 2012). Sosis, kırmızı ete göre daha uzun raf ömrüne sahiptir. Ancak bu özelliği, gıda güvenliği riskleri içermediği anlamına gelmemektedir. Et işlenmeden önce ve işlendikten sonra farklı tehlikeler içermekte, dolayısıyla karkas ve kıymada farklı risk türlerinin ele alınması gerekmektedir (Karadal & Ova, 2020;Prayson 2008).

Günümüzde üretilen tüm sosislerin yaklaşık %85'ini oluşturan pişmiş sosisler de dahil olmak üzere, tüketime hazır et ürünlerine yönelik tüketici ilgisi giderek artmaktadır (Bohaychuk vd., 2006). Sosis üretiminde kullanılan teknoloji türünün, etten, sosis kılıfından, baharatlardan ve diğer bileşenlerden, çevreden, ekipmandan ve işleme sırasında işleyicilerden sosislere erişim sağlayan mikrobiyal kirletici maddelerin türünü etkilediği bildirilmiştir. Sosislerin kalitesinin ve özellikle güvenliğinin özünde üretim süreçlerinin mikrobiyolojisine bağlı olduğu söylenmektedir (Mahami, T. vd., 2012).

Sosisler su geçirmez kılıflarda -1 ile 4 °C arasında depolanır. Her ne kadar mikrobiyolojik açıdan 4 °C güvenli kabul edilse de depolama sıcaklıkları çoğunlukla 2 °C' nin altındadır çünkü 4 °C' nin altındaki her bir derece raf ömrünü büyük ölçüde uzatır. Su geçirmez kılıflar genellikle ambalaj görevi de görür ve ikincil ambalajlamaya gerek kalmaz, bu da ambalaj ve işçilik maliyetlerinden tasarruf sağlar. Porsiyonlara ayrılmış pişmiş sosisler genellikle vakumla paketlenir ve kapatılmadan önce 0,98 bar veya daha fazla tam vakumun uygulanması gerekir. Vakumlu paketleme, *Pseudomonas spp*. gibi aerobik bozulmaya neden olan bakterilerin gelişimini ortadan kaldırır. -1 ila 2 °C arasındaki düşük saklama sıcaklıklarıyla birlikte ürünün raf ömrünü artırır (Feiner,2006).

İşlenmiş et ürünlerinin raf ömrü ve fiziko-kimyasal özellikleri, formülasyona ve üretim süreçlerine bağlıdır. Yüzyıllar boyunca dünyanın farklı yerlerinde raf ömrü ve koruma için çeşitli teknikler geliştirildi (Melro vd., 2020). Sosislerin raf ömrünü etkileyen faktörler arasında özellikle hamur hazırlama, haşlama, dilimleme ve paketleme adımları oldukça etkilidir. Haşlamadan depolama ve teslimata kadar olan üretim adımlarında malzemelerin kalitesi, işlenmesi ve paketlenmesine kadar her prosesin özenle yürütülmesi gerekmektedir. Pişirme adımı nihai sosis ürününün raf ömrünü belirleyen en önemli parametredir (Entrup., 2005). Pişmiş sosislerin su içeriği yüksektir ve çabuk bozulur. Nihai ürünün tazeliğini arttırmak için çeşitli antioksidanlar ve antimikrobiyal katkı maddelerinin seçimi ve kullanılması da raf ömrünü uzatan etkenler arasındadır.

Et ve et ürünlerinin işleme, depolama ve raf ömrü sırasında lipid oksidasyonu, renk, tat ve tekstürde kalite kayıpları ile sonuçlanabilir. Sosis gibi emülsiyon tipi et ürünlerinde, emülsiyon stabilitesinin zamanla bozulması son üründe yağ ve su fazının ayrılmasıyla kalite üzerinde olumsuz sonuçlar doğurabilir. Sosislerin emülsiyon stabilitesinin artırılması raf ömrüne direkt etki edeceğinden stabil emülsiyon oluşturulması bu tip gıdalar için çok önemlidir (Aksel Efe, 2019). Hem birincil hem de ikincil lipit oksidasyon ürünleri tat, renk ve dokudaki değişikliklerin yanı sıra besin kalitesinin düşmesine de neden olur. Antioksidan ve antimikrobiyal özelliklere sahip doğal bileşikler, et ürünlerinin lipit oksidasyon hızını ve kalitesini etkileyebilir. Bitki sekonder metabolitlerinin en yaygın grubu olan polifenollerin et ürünlerindeki oksidatif reaksiyonlara ve mikroplara karşı etkili olduğu bildirilmiştir (Kalem vd., 2018; Zhang vd., 2017).

Et veya kümes hayvanları gibi işlenmiş gıda ürünleri, özellikle vakumla paketlenmiş sosisler, depolama süresi boyunca sızıntı oluşumuyla karakterize edilir. Gıda ürününden sızan bu sıvı, paketlenmiş gıdanın mikrobiyal kalitesinin yanı sıra duyusal özellikleri üzerinde de olumsuz etkiye sahip olabilir. Bu bağlamda, dışarı atılan sıvı, patojenlerin veya bozulmaya neden olan mikroorganizmaların çoğalmasına izin verir, çünkü dışarı atılan bu sıvı, karbonhidratlar, proteinler ve yağlar gibi makro besinler ve mikro besinler, yiyeceklerden ayrılabilir mikro mineraller ve suda çözünen vitaminler gibi makro besinler açısından zengin bir ortam görevi görür. Görünümün bozulması, bakteriyel bozulma ve sızıntıların kaybı sosislerin depolanmasındaki temel problemlerdir (Narasimha Rao & Sachindra, 2002; Saimaiti & Gençcelep, 2020).

Saffle, 1968'de, et emülsiyonları üzerine yayınlanmış araştırma verilerinin neredeyse tamamı 1960'tan beri yazıldığını ve et emülsiyonu alanının, fiziksel kimya, biyokimya, lezzet kimyası veya gıda bilimi konularında güçlü bir geçmişe sahip kişiler tarafından yapılması gereken gelecekteki araştırmalar için verimli bir alan olduğunu bildirmiştir.

Novaković vd., 2021'de yapılan çalışmada raf ömrü boyunca sosislerin antioksidan direnci arttırma ve oksidatif stresi azaltmaya yönelik sosis formülasyonuna arı poleni eklenmiştir. Çalışmanın amacı, sosislere farklı polen tozu konsantrasyonlarının (0.0, 0.5, 1.0 ve 1.5 g/100 g) eklenmesi ile sosisin kalitesine zarar vermeden, depolama sırasındaki antioksidan potansiyeli ve oksidatif değişiklikler üzerinde bir etkisinin olup olmadığını belirlemektir. Çalışma kapsamınsa Frankfurter sosislerin soğukta muhafazası sonrasında, kullanılan polen miktarı arttırıldığında (1.0 ve 1.5 g/100 g) psikrotrofik bakteri popülasyonunda önemli (P <0.05) azalmalar elde edildiği bildirilmiştir. Sosislere polen katılarak antioksidan özellikler iyileştirilmiş. Kalite parametreleri açısından istatistiksel olarak anlamlı değişiklikler elde edilirken, ürünlerin duyusal özelliklerinde herhangi bir bozulma yaşanmadığı tespit edilmiştir. Ayrıca polen ilavesi sosislerin doku profili analizleri açısından değişikliğe neden olmadığı bildirilmiştir.

Akbulut & Kuleaşan, 2022 bu çalışmada, konserve hindi sosisi üretiminde ısıl işlem ve depolama süresinin bazı kalite özelliklerine etkisinin araştırmak üzere koruyucu katkı maddesi kullanmaksızın hindi etinden üretilen sosislere 118 °C'de 50 dakika sterilizasyon işlemi uygulamıştır. 4 aylık depolama süreci boyunca mikrobiyolojik bozulmanın önlenmesi ve genel kalitenin korunması amaçlanmıştır. Çalışmada kullanılan çiğ hindi etinin başlangıç bakteri yükü 4.33 log kob/g olarak tespit edilmiştir. Isıl işlem sonrasında raf ömrü boyunca sosis örneklerinde mikrobiyolojik bir gelişmenin tespit edilmediği bildirilmiştir. Oksidasyon derecesinin belirlendiği tiyobarbitürik asit (TBA) analizinde ise, hindi sosislerinde istatistiksel olarak fark görülmediği bildirilmiştir ($P > 0.05$).

Ahmad vd., 2010 yaptığı çalışmada sosisin kalitesi ve raf ömrü değerlendirmesi için manda etine %0, 15 ve 25 seviyelerinde soya proteini izolatının (SPI) eklenmesi araştırıldı. Sosisin kalitesi pH, nem içeriği, tiobarbitürik asit (TBA) sayısı, toplam plaka sayısı (TPC) ve maya ve küf sayısı, duyusal, özellikler ve enstrümantal renk ve doku ölçümleri ile değerlendirilmiştir. pH ve nem içeriğinin az da olsa etkilendiği, TBA sayısının ise etkilenmediği bildirilmiştir. Sosisin taze örneğinin TPC'si 3,7–4,3 log kob/g aralığında tespit edilmiştir. Sosis panelistler tarafından kabul edilebilir seviyede olduğu görülmüştür.

Adams vd., 1987'de İngiliz taze sosisinin düşük oksijen geçirgenliğine sahip bir filmde (Diolon) vakumla paketlenmesi ve geleneksel paketleme yöntemi ile kıyaslanması üzerine çalışma yapılmıştır. Çalışmada geleneksel paketlerdeki 6°C'de 9-14 gün olan raf ömrü, filmle kaplı vakum paketleme yapılan üründe 20 günün üzerine çıkarıldığı bildirilmiştir. 10 günlük depolamadan sonra, mayalar ve Brochothrix thermosphacta gibi önemli bozulmaya neden olan organizmaların sayıları, vakumlu paketlerde genellikle 2 log döngüsü daha düşük olduğu tespit edilmiştir. Gözlenen raf ömrünün uzaması, vakum paketlerinde bozulma florasının büyüme hızındaki azalmaya ve bunun sonucunda inhibitör sülfit seviyelerinin daha uzun süre korunmasına atfedilmiştir.

Cegielska-Radziejewska & Pikul, 2004 ele aldıkları çalışmanın amacı, sodyum laktat ilavesinin hem hava hem de azot atmosferinde paketlenmiş ve soğutulmuş koşullarda saklanan dilimlenmiş kanatlı sosislerinin raf ömrünün uzatılması üzerindeki etkisini araştırmaktır. Mikrobiyolojik incelemede toplam aerobik psikrotrofik bakteri sayısı ve laktik asit bakteri sayısı belirlenmiştir. Dilimlenmiş kanatlı eti sosisinin mikrobiyolojik ve duyusal kalitesi, sodyum laktat üretimi sırasında eklenmesine ve paketlemede kullanılan gazların (hava veya azot) bileşimine bağlı olduğu ifade edilmiştir. %1 ve %2 sodyum laktat içeren kümes hayvanı sosisi dilimleri, uygulanan gazlardan bağımsız olarak, değerlendirilen duyusal özelliklerin başlangıçtaki kalitesini daha uzun süre koruduğu görülmüştür. Sodyum laktat, buzdolabında depolama sırasında aerobik psikrotrofik bakterilerin ve laktik asit

bakterilerinin büyümesini engellediği tespit edilmiştir. %1 ve %2 sodyum laktat ilavesinin, hava atmosferinde paketlenmiş ve 5 ila 7 °C'de saklanan dilimlenmiş kanatlı sosislerinin raf ömrünü sırasıyla 3 veya 4 kat uzatabileceği sonucuna varılmıştır. Azot içinde paketlenmiş %2 sodyum laktat ile muamele edilmiş dilimlenmiş kümes hayvanı sosisi, en uzun (35 günlük) raf ömrüne sahip olduğu belirlenmiştir. Bu, dilimlenmiş kümes hayvanı sosisinin raf ömründe kontrole kıyasla yedi kat artış olduğu bulunmuştur.

Hashemi vd., 2023 çalışma kapsamında, farklı konsantrasyonlarda resveratrol (RES: %0,002 ve %0,004) veya timol (THY: %0,5 ve %1) içeren, biyolojik olarak parçalanabilen sodyum aljinat filmleri hazırlamış ve bunların bozulmaya bağlı mikrobiyal profil üzerindeki etkileri değerlendirilmiştir. 4°C'de 40 günlük depolama sırasında sığır mortadella sosisinde lipit oksidasyonu, duyusal özellikler ve Listeria monocytogenes'e karşı koruyucu etkileri araştırılmıştır. Çalışmada %1 THY (tek başına veya farklı RES konsantrasyonları ile birleştirilmiş) içeren sodyum aljinat filmlerle sarılmış numunelerin, depolama süresinin sonunda diğer deney gruplarına kıyasla daha düşük bakteri sayısı sergilediği tespit edilmiştir. %0,004 RES ve farklı THY konsantrasyonlarının kombinasyonunu içeren sodyum aljinat filmleri, diğer deney gruplarına göre daha yüksek antioksidan etkiler gösterdiği görülmüştür. %0,004 RES + %1 THY içeren sodyum aljinat filmi, tüm uygulamalar arasında en yüksek antimikrobiyal ve antioksidan aktiviteyi ve en yüksek duyusal skorları sergilediği tespit edilmiştir. Bu bulgulara göre, RES ve THY kombinasyonunu içeren sodyum aljinat filmin, et ürünleri endüstrisinde doğal koruyucularla birlikte aktif bir ambalaj malzemesi olarak potansiyel uygulamasına dikkat çekilmiştir.

Khorsandi vd., 2019 ele alınan çalışmada, doğal antimikrobiyaller olan nisin, tarçın esansiyel yağı (CEO), etilendiamintetraasetat (EDTA) ve bunların kombinasyonlarının, vakumlu ambalaj altında 10 °C'de 42 gün süreyle saklanan emülsiyon tipi pişmiş kürlenmiş sosisin raf ömrü üzerindeki etkisini araştırmayı amaçlamıştır. Tüm numuneler depolamanın 1, 14, 28, 35 ve 42. günlerinde toplam sayım, LAB sayımı, pH, duyusal özellikler ve objektif renk açısından incelenmiş. Sonuçlara göre, nisin ve CEO uygulamalarının sosislerin raf ömrünü sırasıyla 14 ve 7 gün artırdığını, N + C ve N + E + C uygulamalarının ise raf ömrünü sırasıyla 7 ve 14 günden fazla uzatmada etkili olmadığını bildirmiştir. EDTA tek başına LAB ve toplam bakteri üremesini inhibe etmede etkisiz olmasına rağmen, E + C ve N + E ile muamele edilen sosislerin raf ömrü 14 günden (kontrol numuneleri) 35 güne uzatıldığı belirtilmiştir.

Pedro & Ferreira, 2006 ileri dönük raf ömrü belirleme stratejisinin araştırıldığı çalışmada endüstrileşmiş gıda ürünlerinin raf ömrünün belirlenmesi için yeni bir yaklaşım olan Çok Değişkenli Hızlandırılmış Raf Ömrü Testi (MASLT) uygulayarak konsantre domates ürünün raf ömrünün hesaplanması amaçlanmıştır. Hızlandırılmış raf ömrü testi gerçek raf ömrünün 28 ay olduğu tahmin edilen tek konsantre endüstriyel domates ürününe başarıyla uygulanmıştır.

Silva vd., 2014 tarafından yapılan çalışma, iki paketleme formatının (vakumlu paketleme ve sarma usulü paketleme) 4 ± 1 °C'de 90 günlük bir süre boyunca depolanan kan, kalp, böbrek ve keçi eti parçalarıyla hazırlanan pişmiş sosisin raf ömrü üzerindeki etkisini araştırmıştır. Depolama süresi ve ambalaj türü, pişmiş sosisin kimyasal (pH, nem, protein ve TBARS sayısı), fiziksel (kesme kuvveti) ve mikrobiyal (küf ve maya) parametrelerini önemli ölçüde etkilediği ifade edilmiştir. Çalışma vakumlu paketlemenin, pişmiş keçi kanı sucuğunun mikrobiyolojik ve kimyasal özelliklerini, sarma usulü ambalajlamaya (63 gün) kıyasla daha uzun bir süre (41 gün) koruduğu ve kaliteli bakım için ürünün buzdolabında depolanmasına uygun bir alternatif olabileceğini bildirmiştir.

Sonuç

Bu çalışmada sosis hakkında genel bilgiler verilmiş ve raf ömrünü etkileyen faktörler açıklanmıştır. Emülsiyon et ürünlerinin raf ömrü üzerine birçok faktör etki etmekle birlikte bu faktörlerin olumsuz etkileri önlenerek veya minimize edilerek ürünlerin raf ömrü uzatılabilir. Sosis türü et emülsiyonlarının raf ömrü doğrudan hammadde seçimi ve işlem prosesi ile ilgilidir. Bu aşamalarda raf ömrü belirleme çalışmaları ve raf ömrüne etki eden faktörlerin dikkatli belirlenmesi gerekmektedir. İşlenmiş et ürünleri arasında sosis bozulmaya karşı nispeten zayıf bir ürün olmasından dolayı proses ve hammadde seçimi ile ilgili gelişmelerin yanında yeni paketleme stratejileri üzerinde çalışılmaktadır. Gelişmiş paketleme stratejileri ile ürünlerin raf ömrünü uzatmaya yönelik doğaldan uzak katkı maddesi kullanımı minimize edilebilir ve insanların sağlıklı gıdalara erişimi sağlanır.

Abstract

Fishes are susceptible to spoilage which occurred as a results of different factors including high level of temperature, weather, acidity, processing and storage methods and during transportation. This lead to a significant loss during storage of fresh fish samples. Spoilage of fish can be achieved through subjecting the fresh samples to smoking. Cold or hot smoking method to improve shelf-life. The main purpose of this review focused differentiate fish smoking method and the effect of wood biomass on the smoked fish product. The method involved processing and smoking raw fresh fish species with different fuel-wood species to ascertain the quality of the smoked products based on the chemical composition of the smoked fish, composition of the woods biomass and the volatile compounds; both beneficial such as color, aromatic and flavor improvement as well as he harmful effect such as polycyclic aromatic hydrocarbons (HAPs) which poise a severe health effect. Pyrolysis generated from Wood smoke consist of complex mixture of liquids, solid particles and gases (aerosol) due to incomplete burning, pyrolysis or combustion of the wood biomass such as; charcoal, wood chunk, sawdust, wood pellets etc. at an elevated temperatures with reduced oxygen level. Besides the main product of pyrolysis which is 'carbon dioxide and water', wood biomass contain approximately more than 200 different organic compounds identified to induce mild, acute or severe chronic health effects when accumulated in humans body. The nutritional composition of smoked fish samples includes; crude fibre, water content, protein, ash content, amino acids, minerals, phenols and biogenic amines. All the locally available woods species that impart desired colour and flavor also contain minimal level of 0.2 – 5.0 milligram of PAHs per cubic meter of air i.e. (0.2 – 5.0 mg/M^3) are recommended as safe, while at high concentration of 10 and 15 milligrams of PAHs per cubic meter of air is generally considered unsafe and could pose a chronic health challenge.

Heamatology and Serum Biochemistry of West African Dwarf Goats Fed Diets Containing Treated Rice Husk (RH) as a Replacement for Wheat Bran.

Afolayan Femi Opeyemi
Department of Agricultural Science Education, School of Vocational and Technical Education, Kwara State College of Education, Oro, Nigeria

Abstsract

The study was conducted to evaluate the effects of treated rice husk as a replacement for wheat bran on the haematology and serum biochemical parameters of West African Dwarf (WAD) goats. Twenty WAD goats were subjected to five dietary treatments in a completely randomized design with four goats per treatment. The treatments were 0% RH (T1), 25% RH (T2),50% RH (T3),75% RH (T4) and 100% RH (T5). The animals were fed at 5% of their body weight. Blood samples of 10 ml were collected at the end of the growth trial to analyze for haematology and biochemical components. Blood samples were taken before morning feeding via jugular vein puncture into two blood collection bottles. One containing an anticoagulant Disodium salt of ethylene diamine tetraacetic acid (EDTA) and the other with no anticoagulant from which serum was harvested for biochemical analysis. Packed Cell Volume (PCV), Haemoglobin (Hb), red blood cell (RBC) and total white Blood Cells (WBC) were determined. Mean Corpuscular volume (MCV), Mean Corpuscular haemoglobin (MCH) and Mean Corpuscular haemoglobin concentration (MCHC) was calculated from PCV, Hb and RBC. Serum biochemical parameters measured include glucose, total protein, albumin, blood urea nitrogen (BUN), aspartate aminotransferase (AST) and alanine aminotransferase (ALT) parameters were determined. Goat fed with diet T4 had better red blood cell, Pcv, hemoglobin, platelet, eosinophil and AST but high in cholesterol level. Goat on T2 had the highest Tp and better hemoglobin, Pcv, platelet lymphocytes, ALT and globulin content. The treated rice husk had positive impact on the blood parameters, the values are within the normal range for healthy goat. Hence, from this study, 25 – 50% treated rice husk replacement for wheat bran suggests suitable for better performance of WAD goats.

Comparative Analysis Of Growth Performance And Economic Benefits Of West African Dwarf Goat Fed With Diets Incorporation Treated Rice Husk As A Substitute For Wheat Bran

Afolayan Femi Opeyemi
Department of Agricultural Science Education, School of Vocational and Technical Education, Kwara State College of Education, Oro, Nigeria

Abstsract

The study was conducted to find out effects of treated rice husk as a replacement for wheat bran supplement on the growth performance of West African Dwarf (WAD) goats. Twenty (20) WAD goats were subjected to five dietary treatments in a Completely Randomized Design (CRD) with four (4) animals per treatment and each serving as a replicate. The treatments are: 0% RH (T1), 25% RH (T2), 50% RH (T3), 75% RH (T4) and 100% RH (T5). The animals were fed 5% of their body weight. The result showed that T2 and T1 are relatively high in crude protein, low in crude fiber, moderate in crude fat and high in carbohydrate. They equally had the lowest values of ADF, ADL and NDF among the treatments. The total weight gain (TWG), average daily weight gain (ADWG), total daily feed intake (TDFI) and feed conversion ratio (FCR) were all significantly ($P < 0.05$) influenced by the dietary treatments. The goat, T1 had the highest TWG, ADWG and TDFI values among the goats. The goat fed 25% RH replacement level (T2) converted and utilized feed better and had better growth performance comparable to goats fed T1. In conclusion, at 25% level of treated rice husk as replacement of wheat bran gave better growth performance in the goats. The result demonstrated the qualitative benefits and financial returns of using treated rice husk to replace wheat bran diets for WAD goats. Thus, the use of treated rice husk up to 50% in the diet of WAD goats is recommended for appreciable growth performance and better economic benefits.

Enhancing Egg Production Efficiency in Small-Scale Open Shed Layer Farms: A Smart Data Monitoring Case Study with 950 Birds

Md. Tabedar Rosul Noyon

Patuakhali Science and Technology University, Bangladesh

Abstract

Efficient management of egg production is essential for maximizing profitability in layer farming. Conventional monitoring methods often fail to detect early declines in productivity, leading to economic setbacks. This study investigates the use of a smart data-driven system to monitor egg production, identify low-yielding cages, and enhance farm management strategies.Utilizing Google Sheets and AppSheet, data from 950 layer hens housed in a cage system was systematically recorded and analyzed to detect production trends and abnormalities. A structured reporting system was developed to categorize underperforming cages on a weekly and monthly basis, with automated alerts for critical cases. Findings suggest that real-time data tracking enhances decision-making by allowing timely interventions such as feed optimization and health management.Additionally, the study highlights the impact of body weight on egg production, revealing that hens exceeding 2.0 kg tend to have lower productivity. Implementing strategies like controlled fasting and liver tonic supplementation contributed to improved egg yield.This research underscores the potential of technology-driven monitoring in enhancing farm efficiency, minimizing losses, and fostering sustainable poultry farming. Future advancements may include the integration of IoT-based automation for precise feed and environmental control.

Abstract

The present investigation was carried out to study some genetic diversity parameters i.e. the coefficient of variance, heritability and genetic advance for sixteen traits in common wheat. The trial included ten varieties used as phytogenetic material and parents of F1 individuals, whereas F2 individuals are obtained from self – fertilization of F1. The experimentation was conducted in randomized bloc design (RBD) with four replications. Measurements and data notations focused globally on direct and indirect yield components. Analysis of variance revealed significant differences among genotypes for all considered traits. The study showed wide amount of variability for all studied characters. We recorded high magnitude of both PCV and GCV for all the traits except of number of spikelets, spike length and number of grains in linear meter. Moreover, ECV had feeble values except of number of tillers and fertile tillers per plant and number of grains per plant. High values of broad sense heritability associated with high to medium magnitude of genetic advance as per cent of medium were recorded for all traits provided number of grains per plant and per linear meter.

Key words: *Common wheat, Morpho –phenologic traits, Genetic diversity, Heritability, Genetic gain.*

Introduction

On a worldwide scale, common wheat (Triticum aestivum L), among the cereals, is considered the most cultivated species feeding close to 40 % of the world's population. By their importance in Algerian menus and dishes, cereals in general and common wheat, in particular, occupy a significant part of the Utilized Agricultural Area, especially in the highlands where it has cohabited for a very long time and has become a profitable complement to sheep farming. Various methods and markers can be used to determine the genetic diversity of a species including morphological, biochemical, and molecular markers. Morphophysiological markers are widely used to study genetic diversity in plant species (Singh, G.P 1994; Mwirigi et al., 2009; Dhakar et al., 2012; Fikre et al., 2015; Seyoum and Sisay 2021). Determination of genetic variation in common wheat using morphological traits has been worldwide reported by many researchers (Gill & Brar 1977; Vavilov 1992; Williams et St Clair 1993; MacKey 1993; Zeven 1998; Firouzian et al., 2003; Lang et al., 2004; Garcia-Martinez et al., 2005; Sanchita et al., 2008; Salmi et Haddad 2015; Herison et al., 2018). Up till now, many studies dealt with botanic, morphophysiological and yield potential characterization of native common wheat varieties of Adrar region. However, little had been done in terms of genetic variability parameters studies of which it became a decisive factor for all reproduction program (Sanchita et al., 2008). Therefore, it is important to swipe widely in this direction for identifying the existing genetic capabilities of this local phytogenetic material in order to improve common wheat yield.

Materials and methods

The vegetal material for this trial comprises ten varieties used as parents of series of crossings, of which eight (08) are native to Adrar region, F1 individuals and F2 individuals. The trials were conducted in complete randomized bloc design with three (03) replications at local research station of National Institute of Agricultural Research. Sowing date is in December 29th 2023 distance between grains is 10 cm, while row are distanced every 18 cm. Adopted plot irrigation system is dripping and the frequency of irrigation is two to three times a week, depending on crop requirements and environmental conditions. The crop is conducted under standard technic itinerary and plot harvest was manually done at physiological maturity stage of the crop.

Studied traits:

The studied traits are as follows; tillers ability (Tal. P), Productive tillers (Tal. Ep), Plant height at maturity (H.T), number of grains per spike (Gr.E), number of pikelets per spike (Ept.T), number fertile spikelets per spike (Ept. Ft), spike length (L.E), spike density (D), Thousand grains weight (PMG), earliness to heading and yield (Yld).

Data analysis:

The collected data are subjected to analysis of variance where additive model suggested by Steel and Torrie (1980) is used

Yij = μ + gi + bj+ e(ij), where:
Yij = Observed value of genotype i on bloc j
μ = Trial mean
gi = Effect of genotype i
bj = Effect of bloc j
e(ij) = Residual of model
-The least significant difference (LSD) with p < 5 % was calculated following Steel and Torrie (1980)
LSD 5% = t 5, where:
-Phenotypic variance = $\delta_g^2 + \delta_e^2$ with δ_g^2 as genotypic variance
- Phenotypic, genotypic and environmental coefficient of variation was calculated according to Singh and Chaudhary (1985) formula.
GCV% =(δ_g^2 0.5 /$\bar{Y}$)*100 ; PCV% = (δ_P^2 0.5 /$\bar{Y}$)*100 ; ECV% =(δ_e^2 0.5 /$\bar{Y}$)*100
-$\bar{Y}$: is the studied trait mean.
For interpretation of parameters values we utilized Deshmukh et al.. (1986) scale.
-Broad sense heritability (h^2bs) was estimated as suggested by Falconer and McKay (1996)
h^2 (bs) = (δ_g^2 F2 – δ_g^2 F1) / δ_g^2 F2
For values interpretation, we employed the scale of Pramoda and Gangaprasad (2007).
-Genetic advance and genetic advance and GA as % of mean (GAM) were calculated according to Allard (1960):
GA: h^2 (bs) × $\sqrt{\sigma^2_p}$ × k. with
- $\sqrt{\sigma^2_p}$: Standard deviation of phenotypic variance of 2nd generation (F2)
K = Intensity of selection, the value of which is 2.06 when 5 percent of the individuals are selected from the population, as given by Lush. (1949).
GAM = (GA / $\bar{Y}$)*100.

Results and discussion:
Different variance sources, coefficient of variance and the least significant difference for all the sixteen characters are given in table 1. The analysis of variance revealed high significant differences between the genotypes means, resulting in significant effect of genotype for all considered characters (Table 1). Accordingly, the results showed substantial amount of genetic variability among genotypes studied, offering real possibilities of genotypes' improvement through hybridization and selection. Significant differences among genotypes for these traits were earlier mentioned for plant height (Sharma et al., 2020; Dragov et al., 2022), productivity tillering, spike length and number spikelets per spike (Dave et al., 2021; Chauhan et al., 2023; Kumawat et al., 2023), grains number per spike and grains weight per spike (Prasad et al., 2021; Ashebr Baye et al., (2020); Jalal A. Al-Tabbal et al., 2011)), thousand grains weight (Dragov et al., 2022; Sharma et al., 2020; Harshardhan et al., 2016). However, the mean square due to block was significant, only for two traits viz; plant height at maturity period and number of spikelets per spike.

Mean performance:
Regarding range as per cent of mean, it shows an important contrast of diversity among characters ranging from around 12.40 % for number of spikelets per spike to heading up to more than 88 % for mean rate of fertile tillers. High magnitude of diversity (> 20 %) was recorded for number of fertile tillers per plant, yield and number of grains per plant, spike length, tiller capacity, spike density, weight and number of spike grains. thousand grains weight and plant height, respectively. However, relatively low values were recorded for number of spikelets per spike. Indeed, high variability among this material for fourteen traits can constitute the base for a sound breeding program and select genotypes with desired traits for further improvement common wheat yield in such environmental conditions. Comparable findings have been in Harshwardhan et al., (2016); Prasad et al., (2021); Chauhan et al., (2023).
The main reference values (minimum, maximum and maximal) of the studied characters, Phenotypic, genotypic and environmental coefficient of variation, broad sense heritability, genetic gain and genetic advance as per cent of mean for sixteen traits are given in table 2.
A scale was established by Deshmukh et al (1968) regarding phenotypic and genotypic coefficient of variation (PCV, GCV) allow measuring the results extent. Accordingly, values were classified as high (> 20 %) moderate (10 to 20 %) and feeble (< 10 %). High to moderate magnitudes of GCV and PCV means that existing material has a wide range of polymorphisme indispensable for a promising program of selection.
However, low values of these parameters show that available variability rate is feeble within this material and the need to resume works of variability creation (recombination, gene mutation, chromosomal segregation…) followed by selection (Tiwari et al., 2012). Apart from the total number of tillers, fertile tillers and tillers to spike ratio, values of phenotypic coefficient of variation were slightly higher than genotypic coefficient of variation. Furthermore, environmental coefficient of variation values were generally feeble except of these traits, resulting in environment influence on the expression of characters was low for most of these studied characters.

Wolde et al., (2016), this is due to the genotype environment interaction. Abinasa et al., (2011), GCV and PCV values convergence shows a minor environmental effect on the expression of these traits and they are controlled by additive gene effects. However, wider difference between the values of GCV and PCV indicate non-additive genetic effects (Governed by dominance genes).

Among fourteen traits, eight possess high values (> 20 %) of phenotypic and genotypic coefficient of variation. It is about yield (48.55 and 45.27 %), number of tillers per plant (41.98 and 33.21 %), number of grains per plant (41.36 and 41.26 %), weight of spike grains (39.11 and 37.46 %), number of plant spikes (38.24 and 33.2 %), thousand grains weight (29.99 and 28.21 %), number of grains per spike (26.58 and 25.60 %), and number of grains per spikelet with 25.33 and 24.25 %, respectively. Additionally, two traits have moderate values (10 to 20 %), namely main spike length (11.67 and 10.02 %) and earliness to heading (10.76 and 10.65 %). Meanwhile, the magnitude of number of spikelets per spike was feeble (< 10 %). In terms of environmental coefficient of variation, its values were mostly feeble and exceptionally moderate to high. In fact, local environmental conditions have apparently significant effect on number of total and fertile plant tillers expression of which it stabilized during early advanced stages which coincides, to a large extent, with progressive resumption of high temperatures. Similar results were reported for the yield elements in early generations in Dragov et al., (2022). Moderate PCV and GCV values for the earliness to heading per main spike are in harmony with those obtained by Bendjama and Ramdani (2022). Feeble values of PCV and GCV for number of spikelets per spike are found (in late sown conditions) by Azimi et al., (2017). Indeed, high magnitude of GCV and PCV indicate existing real chance for selection of promising elite individuals for improvement of the traits.

Heritability is one of the crucial genetic variability parameters applied in breeding and selection for improving genotypes. According to Pramoda and Gangaprasad, (2007) scale, heritability values less than 0.4 (40 %) are considered feeble, average between 0.4 and 0.6 (40 to 60 %), high from 0.6 to 0.8 (60 to 80 %), and very high for

values above 0.8 (80 %). All traits were characterized by a high magnitude of heritability (> 0.80), except for spike length, which has high values of which number plant grains had the highest with 0.99 followed by plante height (0.95) , main spike density (0.94), number spike grains and earliness to heading (0.93), weight of grains per spikelet, weight of spike grains and earliness to heading (0.92), number of spikelets per spike (0.91), thousand weight grains (0.88), mean yield (0.83) and followed by spike length with 0.73. Nevertheless, Weak to moderate heritability values were obtained by Ahmad et al. (2023). According to Khan and Naqvi (2011), the direct selection on one single plant in early generations could be very effective for a character highly heritable. Present findings are comparable with Ali et al., (2008); Wolde et al., (2016), they also suggest that selection by the traits productivity tillers, plant height thousand grain weight can improve yield. Moreover, several researchers (Bhargava et al., 2003; Shukla et al., 2004) highlight the usage only of high heritability is not sufficient for selection and plant improvement programs, in early generation and must be associated with other genetic parameter especially genetic gain. Effectively, when high broad sense heritability values were supported by similar genetic advance magnitudes offer very solid real opportunities and consolidate such wheat improvement program.

According to Johnson et al., (1955) the estimates of genetic advance and genetic advance as percent of mean were classified as low < 10 %, moderate (10-20 %) and high (> 20). High to moderate genetic gain as percent of mean above 20 % associated with high values of heritability were reported for number of spikes per plant (64.71), number of tillers per plant (53.08 %), spike length (51.49 %), main spike density (48.44 %), thousand grains weight (29.08), number of spikelets per spike (25.92), number and weight of grains per spike. Moreover, Three traits possess mean GAM values i.e. yield (15.59 %),number of grains per spike (15.33 %) and plant height (12.63 %). However, two traits had weak values of genetic advance (<10%), namely number of grains per plant and earliness to heading. Moreover, these values have the same tendency as those of the above genetic parameters, except for heritability in the narrow sense. Furthermore, high heritability accompanied with low expected genetic advance signals influence of dominance genetic effects (Salman et al., 2014), which are suitable for heterosis breeding (Ilyas et al., 2019).

Within trial conditions, yield with both direct and indirect yield components traits, were characterized with high magnitude of genotypic parameters (genotypic and phenotypic coefficient of variation. heritability and genetic advance) and associated with relatively low environmental coefficient of variation except of spikes, tillers and tillers to spikes ration per plant. Consequently, direct selection during early generation based on phenotype is effective and would lead to a successful improving of these traits. For Mortez et al., (2018); Dragov et al., (2022), traits productivity, with high or medium genetic advance and high heritability, are controlled by several major genes with additive genetic action and effective selection is possible.

Conclusion

From the above results, it could be concluded that a high amount of genetic variability exists among these genotypes for almost the considered traits. The high magnitude of heritability of broad sense (> 60 %) was recorder for all traits except of density and length spike suggests a strong genetic effect for expression of the studied characters. Furthermore, substantial values of heritability associated with high to medium score of genetic gain as percent of mean (> 10 %) were noticed for nearly all studied traits, especially number of fertile tillers, plant height, number of spikelets per spike, thousand grains weight and yield grain. Consequently, all these mentioned traits expression are most likely governed by several additive genes, resulting in direct selection on individual plant in early generation lead potentially to a genetic improvement in common wheat grain yield.

Assessing the Effect of Cassava Flour as a Binding Agent in Chicken Sausages

Kaveesha Chamodi Walawege[1], Ruvini Mutucumarana[1], Marcus Andrew[2]

[1]Department of Livestock Production, Faculty of Agricultural Sciences, Sabaragamuwa University of Sri Lanka, Belihuloya, 70140, Sri Lanka.
[2] Maxies and Company (Pvt.) Ltd., Wennappuwa, Sri Lanka.

Abstract

Meat products are widely consumed globally, offering a valuable opportunity to enhance health benefits through improved formulations. The purpose of the present study was to assess how varying levels of cassava flour (CF) incorporation (0%, 50%, 75%, and 100%) as a binding agent affects the nutritional composition, physicochemical properties, and sensory appeal of chicken sausages. This study was conducted in a completely randomized design (CRD) evaluating four (04) treatments (Control: 0%, CF50: 50%, CF75: 75%, and CF100: 100% CF substitution from the conventional binder mixture). Each treatment replicated three times. Cassava flour and all four treatments were analyzed for proximate composition and physicochemical properties. Sensory attributes were evaluated in a 6-point hedonic scale. One-way ANOVA was used to analyze proximate and physicochemical data and the sensory scores were separated using unpaired t-test. Results showed that the Control, CF50 and CF75 exhibited the optimal nutritional profile recommended for sausages. Increasing CF incorporation ($P<0.05$) changed pH to become more acidic. The water holding capacity, cohesiveness, gumminess, chewiness, external redness (a*), yellowness (b*) and internal lightness (L*), a* and b* values were similar ($P>0.05$) across all four treatments. Unlike the treatments CF75% and CF100%, incorporation of CF at 50% (CF50) produced sausages with favorable folding test scores, extract release volume (ERV), springiness, and external L* and in comparable with the control. Resilience was higher in CF50 and CF100 than the control. Total CF substitution (CF100) increased moisture retention but reduced cooking yield with increased cooking loss ($P<0.05$). Total CF substitution resulted the lowest hardness ($P<0.05$). The results of the sensory evaluation revealed that CF50 was the most preferred sausage treatment by the panelists ($P<0.05$). The present study concluded that CF when substituted by 50% in the conventional binder mixture optimally enhances the proximate profiles, physicochemical properties and sensory attributes of chicken sausages.

Abstract

Frozen yoghurt is considered as a healthy alternative for ice cream due to its probiotic properties. Inulin and guar gum are well known soluble dietary fibers used as gelling and stabilizing agents in food processing along with their prebiotic properties. However, not that much of investigations have been performed to evaluate their applications in frozen yogurts, particularly their combination effect on physicochemical, probiotic and sensory properties of frozen yogurts. Individual (2.7% inulin and 0.3% guar gum) and combined (2.7% inulin with 0.3% guar gum) effects of inulin and guar gum on pH, titratable acidity, melting rate, overrun, survival ability of probiotics and sensory attributes of frozen yoghurt were investigated in freezing (-18 0C) storage for a period of 21 days. During the frozen storage, a reduction of pH and an increment of acidity were noticed for all the tested samples. This was more in samples treated with both dietary fibers. The overrun rate was increased in the presence of inulin and guar gum where guar gum had a greater impact. In freezing storage, probiotic bacteria, *Bifidobacterium* (BB-12) and *Lactobacillus acidophilus* (LA-5) showed greater survivability in the presences of inulin and guar gum. This was more prominenet when both dietary fibers were added. Frozen yoghurt with combination of soluble dietary fiber (0.3 % guar gum and 2.7 % inulin) had the most appealing sensory characteristics. It is evident from this study that inulin can be combined with guar gum appropriately to enhance quality attributes of frozen yoghurt including probiotic properties.

Key Words: *Frozen yoghurt1, guar gum2, inulin3, physicochemical properties4, probiotics5*

Introductıon

Frozen yoghurt has combining characteristics of yoghurt (acidic taste) and ice cream (cooling effect) (Tamime and Robinson, 2007). This fermented diary product contains probiotic bacteria and thus is considered as a health beneficial alternative dairy product for ice cream. The environment of frozen yoghurt is not favorable for the existence of bacteria due to the fact that certain stress related environment factors such as pH, acidity, redox potential, freezing, oxygen, sugar concentration and osmotic effects, hydrogen peroxide, antagonistic impact of co-cultures, and mechanical shearing can cause damage to the bacterial cell (Mohammadi, 2011). So, it is a challenge to maintain the viability of bacteria in frozen conditions to get potential benefits.

Inulin is a soluble dietary fiber consisting of non-digestible carbohydrate called fructans that occurs mainly in chicory roots. The wider applicability of inulin in food industry is attributed to its unique functionalities like gel-forming ability, fat replacing ability, limited solubility in water, thermal stability in short food processing steps, hygroscopic and act as humectants, caloric value, low glycemic index, and prebiotic properties (Soiab *et al*., 2016). It has been revealed that the addition of soluble dietary fibers like inulin and guar gum had a protective effect on probiotic bacteria in frozen yoghurt (Isik *et al*., 2011). In addition, fiber incorporation modified and improved the texture, sensory characteristics and shelf-life of frozen yoghurt (Rezaei et al., 2014). They further reported that the addition of inulin remarkably improved the viability of Lactobacillus acidophilus and Bifidobacterium lactis. Working on different ice cream formulations, Aykan et al., (2008) found that inulin provided better flavor and textural properties of ice cream. Guar gum also possesses excellent gelling thickening and emulsifying properties and thus is a widely used food hydrocolloids in food industry (Gupta and Variyar 2018). Rezaei et al., (2011) reported that guar gum significantly affect the viscosity, overrun and melting rate of frozen yoghurt. Soluble dietary fibers like inulin, guar gum are universally agreed-upon prebiotics (Carlson, 2018). However, little is known on their impact on frozen yoghurt, particularly their combine effects on probiotic, physicochemical and sensory attributes in frozen yoghurt.

The present work focused to develop probiotic frozen yoghurt by incorporating inulin and guar gum aiming to determine the individual and combined effects of these soluble dietary fibers on physicochemical, probiotic and sensory attributes of frozen yoghurt.

Materials and methods

Frozen yoghurt preparation

Preparation of yoghurt

Standardized milk with 2.5 % fat was heated up to 70 ^{0}C and then sugar, gelatin, Highland full cream milk powder with 40 % fat was added and mixed until it dissolved well. The mixture was pasteurized at 95^{0}C for 5 minutes. After that, the mixture was cooled to 43^{0}C and inoculated with probiotic yoghurt culture. Then the prepared mixture was incubated at 43^{0}C for 3 hours until the pH become 5.

Preparation frozen yoghurt base mix

Frozen yoghurt base mix was prepared by mixing skim milk, cream, sugar, glucose syrup according to the recipe given by the Milco Pvt Limited. Then mix was heated to 90 ºC for 15 seconds for pasteurization.

Preparation of frozen yoghurt

Frozen yoghurt was prepared by mixing 70 % of yoghurt with 30 % of frozen yoghurt base mix and this mix was kept in refrigerator (at 7^{0}C) for 15 hours for aging. Laboratory home ice cream maker machine was used for the target overrun of 80 percent to prepare frozen yoghurt. The frozen yoghurt was then packed in cartons and hardened and then stored at -18 ^{0}C for 21 days.

Inulin and guar gum treatment

Inulin and guar gum were added to the frozen yoghurt base mix. Four treatments were tested as T1 (only 3% inulin), T2 (only 0.3% guar gum), T3 (2.7% inulin and 0.3 % guar gum) and control (with no dietary fibers).

Determination of overrun

A fixed volume of the aged pre-mix and its volume expansion after frozen yoghurt preparation (freezing step) were measured and the overrun was calculated using the below equation.

$$\text{Overrun} = \frac{\text{(Volume of frozen yoghurt - Volume of mix used)}}{\text{(Volume of mix used)}} \times 100$$

Determination of titratable acidity pH

The acidity level of yoghurt sample was measured as the amount of lactic acid according to AOAC, (2000) by titrating with 0.1% NaOH in the presence of two drops of phenolphthalein and pH was measured in melted frozen yoghurt samples according to AOAC method, (2000) by using a pH meter (PH850-DP portable pH meter).

Melting Rate

The method described by Muzammil *et al*., (2015) was employed to estimate the melting rate. Frozen yoghurt (50 g) was placed on a sieve (0.5 mm) set on top of a beaker at 25 °C. The melted frozen yoghurt was collected in the beaker. The time of first dripping was noted and the weight of melted frozen yoghurt and the weight of the residual sample were obtained after 30 min. The melting rate was calculated by dividing the melted sample over the time (g/min). Melting rate was calculated after one week of frozen storage.

Microbiological properties

Enumeration of probiotic LABs were carried out to measure the bacterial survivability during frozen storage. The plate count technique on selective media (MRS and M17) was used after inoculation (starting level, 0 day) and after 21 days of frozen storage at -18 ^{0}C. Each sample was prepared following the methods provided by the International Dairy Federation (IDF, 2003). Enumeration of *Streptococcus* species was done on M17 agar by aerobic incubation at 37 ^{0}C for 48-72 h. Enumeration of *Bacillus* species was carried out on MRS agar after being adjusted to pH 5.4 by anaerobic incubation at 37 ^{0}C for 48-72 h as described by Almeida *et al.*, (2008).

Sensory properties

The sensory characteristics were measured using 15 trained and non-trained panelists for day 21 samples. The scores were allocated according to 5-point hedonic scale and the acidity, smoothness, yoghurt flavor, sweetness, freshness of samples was evaluated. Samples were ranked according to the overall acceptability.

Statistical analysis

Data were analyzed using SPSS univariate, Duncan's mean separation and LSD multiple comparison. Graphs were illustrated using Microsoft Excel 2010. The sensory evaluation data were analyzed in non-parametric Freidman test using SPSS statistics 26.0 version.

Results and discussion

pH and Titratable acidity

The change of titratable acidity and pH of frozen yoghurt samples are shown in Table 1. The acidity of all the tested samples was increased during the storage time while reducing the pH. The drop of pH is comparatively more prominent in samples treated only with inulin whereas the development of acidity (0.10) appeared to be the highest in sample treated with both dietary fibers at the end of storage time. Control sample showed the lowest development of acidity during frozen storage (0.083). According to the literature (Żbikowska et al., 2020, Rezaei et al., 2014, Aryana et al., 2007), the acidity is increased during the storage due to the lactic acid production by lactic acid bacteria utilizing prebiotics and thus high acid production shown in combined dietary fiber treated sample could imply that the use of both inulin and guar gum support the greater frozen storage survival and growth of probiotic bacteria. By performing the preliminary consumer preference and acceptance tests, some studies have

reported that consumers are most preferred the frozen yoghurts with pH range 4.3 to 5.3 and even in some cases 4.0 to 5.7 (Ionna *et al*., 1990, Isik *et al*., 2011). The pH range of the all the frozen yoghurt samples tested was in the consumer acceptable range.

Table 01:. pH and titratable acidity of frozen yoghurt incorporated with inulin and guar gum during frozen storage

	pH	
	Day 0	Day 21
Control	4.950±0.01a	4.817±0.005b (0.133
T1	4.970±0.01a	4.787±0.015b (0.183
T2	4.973±0.005a	4.830±0.01b (0.143
T3	4.980±0.01a	4.830±0.02b (0.150
	Titratable Acidity	
Control	0.677±0.005a	0.760±0.01b (0.0830
T1	0.677±0.005a	0.770±0.01b (0.093
T2	0.673±0.005a	0.767±0.005b (0.94
T3	0.667±0.005a	0.767±0.005b (0.10

Means in the same raw indicated by different letters are significantly different ($P < 0.05$)

Overrun and melting rate

The addition of inulin and guar gum increased the overrun of the frozen yoghurt where guar gum had much greater impact than inulin and when inulin was combined with guar gum the resulting overrun was higher than their individual impact (Table 2). The higher the overrun the lower the melting rate in frozen yoghurt. According to Sofjan and Hartel, (2004) higher overrun made ice creams with smaller initial air cell, due to the higher shear stresses during processing. Further they mentioned that lower overruns produced harder ice cream than that of higher overrun (120%) but they melted rapidly. It has been found the rate of overrun is increased in the presence of inulin in frozen yoghurt (Rezaei et al., 2014). Several studies observed the reduction of melting rate of frozen yoghurts and ice cream due to the added inulin (Xavier and Ramana 2021, Isik et al., 2011). Guar gum is commonly used in stabilizing ice cream and as a thickener in food applications due to its extremely high viscosity enhancement even at a very low concentration (≤1% w/v) in aqueous solutions (Gupta and Variyar 2018, Jagdish et al., 2015). Rezaei et al., (2011) also observed that gums like guar gum significantly alters the viscosity, melting rate and rate of overrun in frozen yoghurt.

Table 02: Melting rate and overrun in the inulin and guar gum added frozen yoghurt

	Melting rate (g/min)	**Overrun %**
Control	0.7300±0.010a	54.0967±1.035c
Treatment 1	0.7044±0.015b	56.0100±0.555b
Treatment 2	0.5156±0.005c	79.1733±0.259a
Treatment 3	0.5056±0.005c	79.2633±1.223a

Mean values with different letters shown in columns are significantly different ($P < 0.05$).As reported by Tamime and Robinson, (2007) overrun of frozen yoghurt should be in between the range of 50-60 % to consider as soft frozen yoghurt and 70-80 % overrun for hard frozen yoghurt. Each frozen yoghurt samples tested in this study falls within the above ranges in which control and Treatment 1 ranged 50-60 % while Treatment 2 and 3 ranged 70-80 %. According to Muse and Hartel, (2004) factors affecting on the melting rate of ice cream include destabilization of fat, the size of ice crystal and the consistency coefficient of the mix. As Xavier and Raman, (2021) reported, high water absorption capacity of soluble dietary fibers could cause a significant increase in melting time of ice cream. They further mentioned that soluble fibers enhanced the serum concentration of ice cream mixture resulting in increased viscosity and reduced melting rate. Dwórznicka et al., (2022) reported that the properties of ice cream produced with combination of soluble dietary fibers, especially, guar gum with another dietary fiber showed positive results in shortening of melting time. This claim is further confirmed from the results we observed in present study. The decreased meltdown rate offers ice cream with better melting resistance.

Probiotic bacteria count

Table 03: Colony forming units of probiotic bacteria (Lactobacillus acidophilus, Bifidobacterium, Streptococcus thermophilus) in inulin and guar gum added frozen yoghurt

Treatment	N	Day 0 1011 (cfu/g)	Day 21 108 (cfu/g)
Control	3	6.00 ±1.00a	09.00±1.00c
Treatment 1	3	7.00 ±1.00a	60.00±10.00b
Treatment 2	3	6.33 ±0.57a	66.66±5.77b
Treatment 3	3	6.66 ±1.52a	390.00±10.00a

Means in the same column indicated by different letters are significantly different ($p < 0.05$).

Probiotic counts in all freshly prepared samples were not significantly different (Table 03). However, from all the tested samples a significant reduction of probiotic counts was observed at the end of the storage time but to a different extent. Decomposition of bacteria counts could attribute to cold shock and osmotic pressure caused by freezing (Magariños et al., 2007). Rezaei et al., (2014) have also reported the reduction of number of lactic acid bacteria during cool storage. The highest remaining count after the 21 days of frozen storage was exhibited from treatment 3 (0.3 % guar gum+2.7 % inulin) followed by treatment 1 and 2 and the lowest from control sample. These results suggest that the inulin and guar gum significantly improve the survivability of probiotic bacteria in unfavorable environment existed in frozen storage and this is more in samples treated with both inulin and guar gum indicating that combine effect of inulin and guar gum provides a more favorable environment for probiotic bacteria than their individual counterparts. Inulin is one of the most commonly used prebiotics in dairy products (Żbikowska et al., 2020, Soukoulis et al., 2009). The decline rate of probiotic bacteria counts in inulin-containing frozen yoghurt samples showed lesser than the control sample (Rezaei et al., 2014, Isik et al., 2011). The recommended dose to receive the health benefits of the probiotic organisms, especially Bifidobacterium should be 106 cfu/g (FAO-WHO, 2003). In the present study, the total colony count of probiotic bacteria (Bifidobacterium and Lactobacillus acidophilus) remained after the frozen storage was higher than the above recommended value, particularly when both inulin and guar gum were added together. This is confirmed by the finding of Waitzberg et al., (2012) who found positive results when using prebiotic inulin- hydrolyzed guar gum mixture on the composition of intestinal microbiota. Further, they have mentioned that the combination of inulin and guar gum had an additional protective effect on gut microbiota by decreasing the number of pathological bacteria of the Clostridium genera.

Sensory analysis

Sensory characteristics, the taste, aroma, texture or color are the key quality attributes that play a crucial impact on consumer attraction. Keeping the appropriate sensory characteristics during the storage of frozen yoghurt is one of the most important things need to be maintained. Figure 1 , shows the results of Friedman's test analysis done for the different sensory attributes of 21 days stored samples. Acidity, smoothness, yoghurt flavor and sweetness were not significantly different among all the tested samples at the end of freezing storage time (21 days at -18 °C). But combination of inulin with guar gum had slightly higher sensory values of smoothness, sweetness and freshness than other treatments. The lowest sensory values of acidity and sweetness were noticed from control sample.

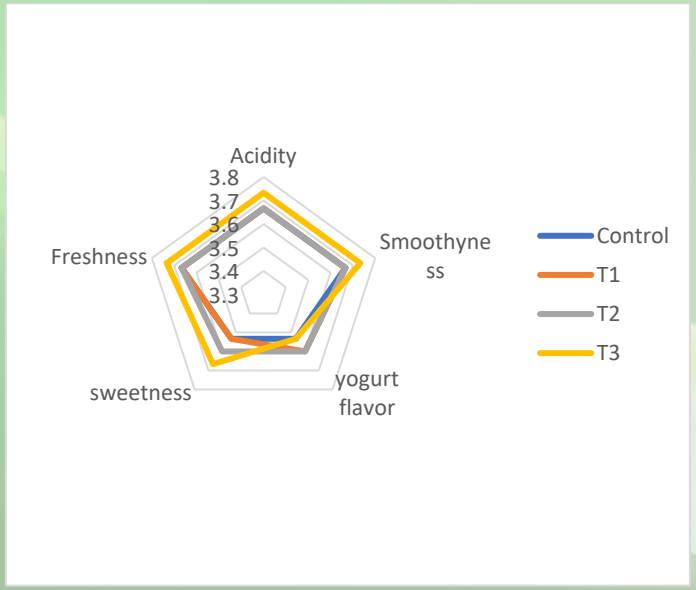

Figure 01: Sensory properties of frozen yoghurt prepared with inulin and guar gum at the end of day 21.

Dietary fiber can provide a wide range of functionalities to food especially in dairy products. They can modify and improve the texture and sensory characteristics of foods through their water-binding and gel-forming ability, fat mimetic, anti-sticking, anticlumping, texturizing and thickening ability (Soukoulis et al., 2009, Yangilar, 2013, Rezaei et al., 2014). According to Isik et al., (2011), except for the foamy melting attribute, adding inulin makes no significant difference in any of the sensory characteristics between tested frozen yoghurt samples. Akin, (2005) reported that inulin addition in (1% to 2%) had no impact on sensory attributes of frozen yoghurt. In contrast, Rezaei et al., (2014) mentioned that inulin improved the flavor, texture and total acceptance of frozen yoghurt. Guar gum is added to various dairy products due to its number of important functional properties (Gupta and Variyar, 2018). It has been reported that 0.2% of guar gum is sufficient to enhance the overall consumer acceptability of ice cream (Jagdish et al., 2015). The present study revealed that the inulin (2.7%) and guar gum (0.3%) together improved the yoghurt sweetness, freshness and smoothness during frozen storage showing combination effect has more impact on sensory attributes than individual effect of inulin and guar gum.

Conclusion

Inulin and guar gum significantly and positively alter probiotic, physicochemical and consumer acceptable qualities of frozen yoghurt where the combination effect of inulin and guar gum has more impact on the above properties of frozen yoghurt than their individual counterparts. It can be concluded that the soluble dietary fiber, inulin and guar gum in combination can be used as prebiotics in frozen yoghurts to improve probiotic bacteria viability with high consumer acceptable organoleptic properties. Further studies are required to optimize the combination effect of inulin and guar gum in a view of producing more heath beneficial and consumer acceptable frozen yoghurt.

Chemical Constituents Of Propolis Relevant To Its Use In Polymeric Formulations

Sheida Moradi[1]

Department of Pharmaceutical chemistry, Faculty of Pharmacy, International Final University, Kyrenia, Cyprus

Abstract

Propolis, a resinous substance collected by bees from plant sources, has gained increasing attention in pharmaceutical chemistry due to its rich composition of bioactive compounds and versatile therapeutic properties. This review aims to explore the key chemical constituents of propolis that contribute to its effectiveness in polymer-based drug delivery systems. Major compounds such as flavonoids, phenolic acids, terpenoids, and aromatic esters are identified as pivotal in providing antimicrobial, antioxidant, anti-inflammatory, and wound-healing activities. Advanced analytical techniques including HPLC, FTIR, and LC-MS have facilitated the precise profiling of these constituents in various types of propolis, with Brazilian red propolis being particularly well-characterized. The incorporation of propolis into natural and synthetic polymeric matrices—such as hydrogels, mucoadhesive gels, chitosanates, and collagen-based films—has shown enhanced physicochemical stability, controlled drug release profiles, and improved biocompatibility. Notably, polymeric systems loaded with propolis demonstrated significant antibacterial activity, thermostability, and antioxidant capacity, affirming their potential in topical and oral pharmaceutical applications. This review evaluates the structural and functional implications of propolis constituents in polymeric formulations, providing a basis for further development of bioactive delivery systems. Ultimately, this study reviews several chemical constituents of polymeric propolis and their relevance to pharmaceutical formulation and function.

Key Words: *propolis, polymer, chemical constituent, natural source*

Polimerik Formülasyonlarda Kullanımına Ilişkin Propolisin Kimyasal Bileşenleri

Sheida Moradi[1]

Eczacılık Kimyası Anabilim Dalı, Eczacılık Fakültesi, Uluslararası Final Üniversitesi, Girne, KKTC

Özet

Arıların bitkisel kaynaklardan topladığı reçinemsi bir madde olan propolis, içerdiği zengin biyolojik olarak aktif bileşenler ve çok yönlü terapötik özellikleri nedeniyle farmasötik kimya alanında giderek daha fazla ilgi görmektedir. Propolisin içeriğinde yer alan flavonoidler, fenolik asitler, terpenoidler ve aromatik esterler gibi başlıca bileşikler; antimikrobiyal, antioksidan, antienflamatuar ve yara iyileştirici aktiviteleriyle ön plana çıkmaktadır. HPLC, FTIR ve LC-MS gibi ileri düzey analitik teknikler, özellikle Brezilya kırmızı propolisi olmak üzere çeşitli propolis türlerinde bu bileşenlerin hassas şekilde tanımlanmasına olanak sağlamıştır. Propolisin polimer bazlı ilaç taşıyıcı sistemlerdeki etkinliğine katkı sağlayan temel kimyasal bileşenlerini inceleyen çok sayıda çalışma mevcuttur. Propolisin doğal ve sentetik polimerik matrislere—hidrojeller, mukoadeziv jeller, kitosanatlar ve kolajen bazlı filmler gibi—entegrasyonu; fizikokimyasal stabiliteyi, kontrollü ilaç salım profillerini ve biyouyumluluğu artırmıştır. Propolis yüklü polimerik sistemlerin belirgin antimikrobiyal aktivite, termal stabilite ve antioksidan kapasite sergilediği gözlemlenmiş, bu da onları topikal ve oral farmasötik uygulamalar için güçlü adaylar haline getirmiştir. Bu derleme, propolis bileşenlerinin polimerik formülasyonlardaki yapısal ve fonksiyonel rollerini değerlendirerek polimerik propolisin çeşitli kimyasal bileşenlerini ve bunların farmasötik formülasyon açısından önemini inceleyip, biyolojik olarak aktif taşıyıcı sistemlerin geliştirilmesi için bir temel sunmaktadır.

Anahtar Kelimeler: *propolis, polimer, kimyasal bileşen, doğal kaynak*

Abstract

There is limited information on the recovery of pectin from sweet potato starch extraction residues. Besides, the extraction parameters and raw material source affect the preferred functional properties of the pectin. Hence, the current study investigated the effect of temperature and extractant concentration on pectin yield, purity and characteristics. It was found that temperature and extractant concentration played an important role in influencing pectin yield and molecular weight (MW), and its side chain composition was mainly rhamnose, arabinose and galactose. In addition, it is worth noting that galactose was the main neutral sugar of the extracted pectin side chain, similar to citrus and apple pectin. The maximum pectin yield was realised with 90ºC and 0.05% SHMP, the pectin yield was 14%, and its degree of methoxylation and MW values were approximately 12% and 645kDa. The pectin possessed good antioxidant and ferrous ion chelation activity.

Pectin was extracted and further characterised from sweet potato starch pomace with combined sodium hydroxide and sodium hexametaphosphate. The chemical composition, molecular weight, degree of methoxylation, neutral sugar composition antioxidant capacity and iron chelation capacity were assessed. The extracted pectin had up to 72% galacturonic acid content, 14%yield, and 12% DM, which was confirmed by FTIR analysis. The pectin exhibited strong antioxidant capacity and high iron chelation activity.

Effect of Seed Priming Using Botanical Extracts on Germination of Okra (*Abelmoschus esculentus Var. Nancy)*

Tirth Narayan Yadav, Vijay Singh, Anita Bhandari, Abhisek Shrestha

College of Natural Resource Management, Bardibas
Corresponding author: tirth.naryan369@gmail.com

Abstracts

The germination in okra is poor due to its tough seed coats, undeveloped embryos, and adverse conditions which seems problematic in its cultivation. Seed priming is one of the best way to induce the seed germination and crop vigor in okra. Therefore, an experiment was conducted to evaluate the effects of seed priming on okra seeds using botanical extracts at College of Natural Resource Management, Bardibas, Mahottari, Nepal. Nancy (F_1) variety was taken to conduct the research using 6 different treatments i.e.(control, distilled water, 4% cow urine solution, 4% Moringa leaf extract solution, 4% Tulsi leaf extract solution and 4% Siris leaf extract solution) and 3 replications in Complete Randomized Design (CRD). The seeds were soaked for 15 hours in priming solution and dried at room temperature for 2 hours before sowing. The germination diversity parameter was recorded and analyzed through Genstat ver.2015. The results revealed that 4% Tulsi leaf extract solution shown highest germination % (83.33%), speed of germination (27.73 seeds/day), seedling length (23.63cm), dry weight (0.2990), seed vigor index 1 (1968cm) and seed vigor index 2 (24.84) followed by 4% Siris leaf extract solution with 75.56% germination, 23.48 seeds/day speed of germination, 22.51 cm length of seedling, dry weight of 0.2147, seed vigor index 1 (1705 cm) and seed vigor index 2 (16.24) as compared to control with (45.55 %) seed germination, (12.76 cm) seedling length, (0.088) dry seedling weight, SVI1 with 579 cm and SVI2 with (4.02). Seed priming with Tulsi leaf extract along with moringa and siris found to effective in improving seed germination and vigor in okra. So, this experiment should be conducted in farmer's field and larger plot for validation.

Nutrition-Focused Evaluation of Tomato Lines for Sustainable Food Systems In Bangladesh

AKM Quamruzzaman

Bangladesh Agricultural Research Institute, Bangladesh

Abstract

An evaluation trial was conducted on new tomato lines to study their yield, pest and disease resistance, quality attributes, and potential nutritional contributions at the experimental field of the Olericulture Division, Horticulture Research Centre (HRC), Bangladesh Agricultural Research Institute (BARI), Gazipur, during the winter season of 2023-24. Fruit yield varied significantly, ranging from 15.7 to 150.4 t/ha. The highest yields were obtained from the lines SLA 035 (150.40 t/ha), SLA 031 (126.54 t/ha), SLA 039 (107.23 t/ha), SLA 040 (111.33 t/ha), SLA 044 (98.91 t/ha), SLA 041 (87.40 t/ha), SLA 045 (86.16 t/ha), SLA 030 (84.70 t/ha), and SLA 043 (80.79 t/ha). These lines also demonstrated promising traits in terms of earliness, quantitative and qualitative characteristics, as well as resistance to late blight, TYLCV, bacterial wilt, leaf miner, and fruit borer infestations. Given Bangladesh's high prevalence of micronutrient deficiencies, particularly vitamin A and C, tomatoes serve as an important dietary source of antioxidants, vitamins, and minerals. The selected high-yielding and disease-resistant lines could enhance tomato production, ensuring better availability and affordability of nutrient-rich vegetables for the population. Further evaluation of their nutritional profiles, including lycopene, β-carotene, and ascorbic acid content, would be beneficial to confirm their potential in addressing malnutrition. These nine promising lines—SLA 035, SLA 031, SLA 039, SLA 040, SLA 044, SLA 041, SLA 045, SLA 030, and SLA 043—are recommended for further confirmation and potential release to improve both food security and nutritional outcomes in Bangladesh.

Advancing Tomato Hybrid Development: Yield Evaluation of Winter-Grown Hybrids in Bangladesh

AKM QUAMRUZZAMAN*, L. AKTER, MR ISLAM, S. AKTER and MH ISLAM

Olericulture Division, Horticulture Research Centre, Bangladesh Agricultural Research Institute, Gazipur-1701, Bangladesh
*Corresponding Email: akmqzs@gmail.com

Abstract

A field trial was conducted at the Olericulture Division of HRC, BARI, Gazipur during the 2023-24 winter season to evaluate eight tomato hybrids for yield performance, pest and disease resistance, and quality parameters. The study revealed significant variation in key traits including fruits per plant (36.0-155.0), individual fruit weight (14.5-90.0g), yield (up to 111.38 t/ha), fruit dimensions, TSS content, and resistance to TYLCV and leaf-sucking pests. The hybrids demonstrated maturity periods of 99-104 days to first harvest. Three hybrids showed exceptional performance: F_1 4601 (111.38 t/ha), F_1 1501 (103.85 t/ha), and F_1 1903 (100.22 t/ha) under Gazipur conditions. Based on comprehensive evaluation of yield attributes and resistance characteristics, F_1 4601 and F_1 1501 emerged as the most promising candidates for commercial release as new hybrid varieties. This study highlights the critical role of hybrid tomato development in Bangladesh's agricultural sector, where improved varieties can address key challenges of productivity constraints and pest pressures. The selected hybrids demonstrate the potential to significantly enhance tomato production efficiency, offering farmers higher yields with reduced input requirements. Their development aligns with national priorities to boost horticultural productivity through advanced breeding techniques, contributing to food security and economic growth in Bangladesh's rapidly evolving agricultural landscape. The successful performance of these hybrids underscores the importance of continued investment in hybrid vegetable breeding programs to meet the country's growing demand for high-quality, disease-resistant tomato varieties.

Productivity And Nutritional Potential Of Sweet Pepper Varieties In Bangladesh

L. AKTER, AKM QUAMRUZZAMAN*, MR KARIM, S. AKTER and MH ISLAM

Olericulture Division, Horticulture Research Centre, Bangladesh Agricultural Research Institute, Gazipur-1701, Bangladesh
*Corresponding Email: akmqzs@gmail.com

Abstract

An experiment was conducted at the central experimental farm of the Olericulture Division, HRC, BARI, Gazipur from October 2023 to April 2024 to evaluate four sweet pepper lines against the check variety BARI Mistimorich-2. The line CA 0043A showed the earliest harvestability (64.05 days), while CA 0046 produced the highest number of fruits/plant (9.43) and largest average fruit weight (106.32g). Yield performance ranged from 24.21 to 29.07 t/ha, with CA 0043A demonstrating superior productivity (29.07 t/ha). The selected line CA 0043A, characterized by red bell-shaped fruits, showed minimal pest infestation under protected cultivation and has been recommended for release as BARI Mistimorich-3. This development holds particular significance for Bangladesh's nutritional security, as sweet peppers are rich sources of vitamin C (ascorbic acid), vitamin A precursors (β-carotene), and antioxidants - critical nutrients for combating widespread micronutrient deficiencies. The high-yielding CA 0043A line presents opportunities to enhance year-round availability of nutrient-dense vegetables, particularly important for vulnerable populations. Its early maturity and protected cultivation compatibility address both productivity challenges and pesticide residue concerns. The release of this improved variety aligns with national efforts to diversify vegetable production and improve dietary quality, contributing directly to SDG targets on food security and nutrition. Further nutritional profiling of this line should be conducted to quantify its specific contributions to addressing vitamin deficiencies prevalent in Bangladesh.

ID: 636

Accelerating Sweet Pepper Improvement: Inbred Line Development For Bangladeshi Varieties

L. AKTER, AKM QUAMRUZZAMAN*, S. AKTER and MH ISLAM

Olericulture Division, Horticulture Research Centre, Bangladesh Agricultural Research Institute, Gazipur-1701, Bangladesh
*Corresponding Email: akmqzs@gmail.com

Abstract

An experiment was conducted during the 2023-24 winter season at the Olericulture Division, HRC, BARI to evaluate fourteen sweet pepper lines (CA0008-CA0020) against the check variety BARI Mistimorich-1, aiming to develop superior inbred lines for hybridization and quality varietal development. Significant variations were observed in all evaluated parameters, particularly in yield-related traits. The line CA0014 demonstrated exceptional earliness, requiring only 39.11 days to 50% flowering, while CA0020 produced marketable fruits earliest (57.70 days). CA0012 showed superior fruit productivity (17.44 fruits/plant), and CA0014 recorded the highest yield (11.90 kg/plot, equivalent to 42.50 t/ha). Based on comprehensive evaluation of earliness, fruit size, and yield performance, six promising lines (CA0011, CA0012, CA0014, CA0015, CA0016, and CA0018) were selected for advancement in hybridization programs and potential varietal release. This study contributes significantly to Bangladesh's sweet pepper improvement program by identifying high-performing inbred lines with desirable horticultural traits. The selected materials possess optimal characteristics for developing F_1 hybrids with enhanced productivity and quality attributes, addressing the growing demand for improved sweet pepper varieties in Bangladesh. The findings underscore the importance of systematic line evaluation in quality varietal development, which is crucial for meeting both farmer needs and consumer preferences in the domestic market. These advanced lines will form the genetic foundation for future breeding efforts aimed at developing superior sweet pepper varieties with improved yield potential, adaptability, and quality traits suitable for Bangladeshi agro-climatic conditions.

[3]Department of Plant Pathology, Sindh Agriculture University Tandojam, Pakistan.
[4]Sindh Horticulture Research Institute Mirpurkhas.

Abstract

The China rose, also known as *Hibiscus rosa-sinensis*, is a tropical flowering plant renowned for its large, vibrant blossoms. It is native to East Asia and thrives in warm climates. The propagation of China rose (*Hibiscus rosa-sinensis*) face several challenges, such as Rooting difficulty, inconsistent growth so that the present study investigates the effects of Moringa Leaf Extract (MLE) on the sprouting and growth responses of stem cuttings of Hibiscus rosa-sinensis L. (China Rose). Healthy, mature, and disease-free moringa leaves were carefully collected from near the Faculty of Crop Production Sindh Agriculture University, Tandojam. The leaves were washed under running water and then kept in a freezer for a day. Subsequently, the frozen leaves were crushed to extract juice with a locally made mortar and pestle. Moringa leaf extract was made with different concentrations, after which it was passed through a sieve before applying it to the cutting. The cuttings were 9 inches long and soaked for 5 hours in four different concentrations of MLE (10%, 20%, 30%, and 40%) they were planted in plastic bags filled with canal silt. the research utilized a Completely Randomized Design and assessed various growth parameters including sprouting percentage (%), number of sprouts per cutting, rooting percentage (%) fresh root biomass (g), dry biomass of roots (mg), fresh shoot biomass (g), Dry biomass of shoot (mg), Root Collar Diameter (mm). Results revealed that while sprouting percentages reached 100% at all MLE concentrations, the number of sprouts per cutting peaked at 10% MLE, indicating enhanced growth responses at this concentration. Furthermore, MLE significantly improved rooting percentages and biomass metrics, with optimal results observed at 10% concentration, while higher concentrations led to diminished effectiveness. The study concludes that MLE serves as a potent growth promoter for the propagation of China Rose, highlighting its potential in horticultural practices.

Key Words: Moringa leaf Extract (MLE)1, Sprouting2, Growth3, China rose3, Development5

Introduction

(Hibiscus rosa-sinensis L.), commonly known as the China Rose, is a species of flowering plant in the Malvaceae family.It is native to East Asia, but due to its aesthetic beauty, the plant has spread widely across the globe, particularly in tropical and subtropical regions(Magdalita et al., 2022). Revered for its striking, large flowers, Hibiscus rosa-sinensis has become a popular ornamental plant, cultivated for both aesthetic and medicinal purposes. The plant's cultural significance, ease of cultivation, and versatile applications make it an important species in both horticultural and traditional medicinal fields(Kosenkoet al., 2020).The China Rose is a shrub that typically grows between 1.5 and 2 meters in height, although some varieties can grow taller under optimal conditions. Its leaves are dark green, glossy, and elliptical, often with serrated edges. The flowers are the most striking feature of the plant, usually large, trumpet-shaped, and ranging in color from vibrant reds, pinks, and yellows to whites and purples. The flower has five petals and typically measures 4-5 inches in diameter. It has a prominent central stamen structure, adding to its ornamental appeal (Armitage, 2008).The plant blooms profusely throughout the year, particularly in warm climates. Hibiscus rosa-sinensis is not only important in ornamental gardening, but it also has ecological benefits. The plant attracts pollinators like bees and butterflies, playing a key role in supporting biodiversity in the ecosystems where it is found. In many tropical and subtropical regions, Hibiscus rosa-sinensis is often used in landscaping, parks, gardens, and as hedging plants due to its vibrant colors and hardy nature.In addition, it holds cultural significance in various parts of the world. In Hindu culture (Roy, 2013).

Propagation of *Hibiscus rosa-sinensis* is primarily carried out through stem cuttings, which is a common method for reproducing desirable traits such as flower color, size, and growth habits. However, the success of stem cutting propagation can be influenced by various factors, including hormonal treatments, environmental conditions, and nutrient availability Izadi et al., 2014).

Moringa oleifera, often referred to as the "miracle tree," has gained considerable attention for its rich nutritional content and medicinal properties. Moringa leaf extract (MLE), which is derived from the leaves of this plant, has demonstrated various beneficial effects in agricultural practices, including enhancing plant growth, improving root development, and promoting faster sprouting.(Mashamaite et al., 2022). Moringa is rich in growth hormones, vitamins, minerals, and antioxidants, which can potentially influence the physiological processes of plant cuttings and improve their success rate during propagation.The application of Moringa leaf extract (MLE) to stem cuttings of ornamental plants like *Hibiscus rosa-sinensis* could represent a valuable method for improving the rooting and growth performance of cuttings.

Materials and Methods

Study location

The experiment was carried out at the Nursery of the Department of Horticulture, Sindh Agriculture University (SAU), Tando Jam, within the agro-ecological environment of Tandojam, Sindh, Pakistan, during November-December 2024. The major aim of this research was to evaluate the effect of moringa leaf extract (MLE) on sprouting and growth responses of stem cuttings of china rose (hibiscus rosa- sinensis l.).

Preparation of Moringa Leaf Extract

Healthy, mature, and disease-free moringa leaves were carefully collected from near the Faculty of Crop Protection Sindh Agriculture University, Tandojam. The leaves were washed under running water and then kept in a freezer for a day. Subsequently, the frozen leaves were crushed to extract juice with a locally made mortar and pestle. Moringa leaf extract was made with different concentrations, after which it was passed through a sieve before applying it to the cuttings. Twenty cuttings of china rose were dipped with varying concentrations of moringa leaf extract (MLE), as per the treatments: (M_1= Control-no MLE), M_2 = 10% of MLE , M_3 = 20% of MLE , M_4 = 30% of MLE , M_5 = 40% of MLE. For each treatment, the cuttngs were immersed in the specific MLE solution for a period of 12 hours.

Results and Discussion

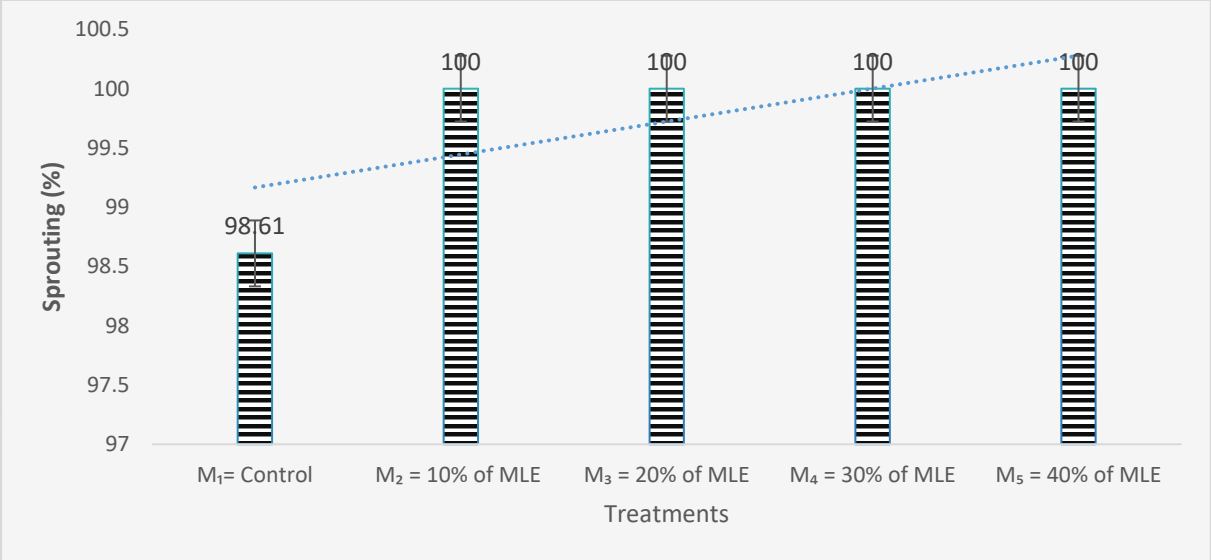

Figure no 1. Effect of Moringa Leaf Extract (MLE) on Sprouting % of china rose cuttings.

Sprouting %:

The sprouting percentages **of china rose** in response to different concentrations of Moringa Leaf Extract (MLE) and the findings are given in (Figure1)The sprouting percentage was **100%** at all concentrations of Moringa Leaf Extract (from 10% to 40%), demonstrating that Moringa Leaf Extract, even at higher concentrations, consistently promoted full sprouting. The control treatment showed slightly lower sprouting percentages, with **98.61% .**

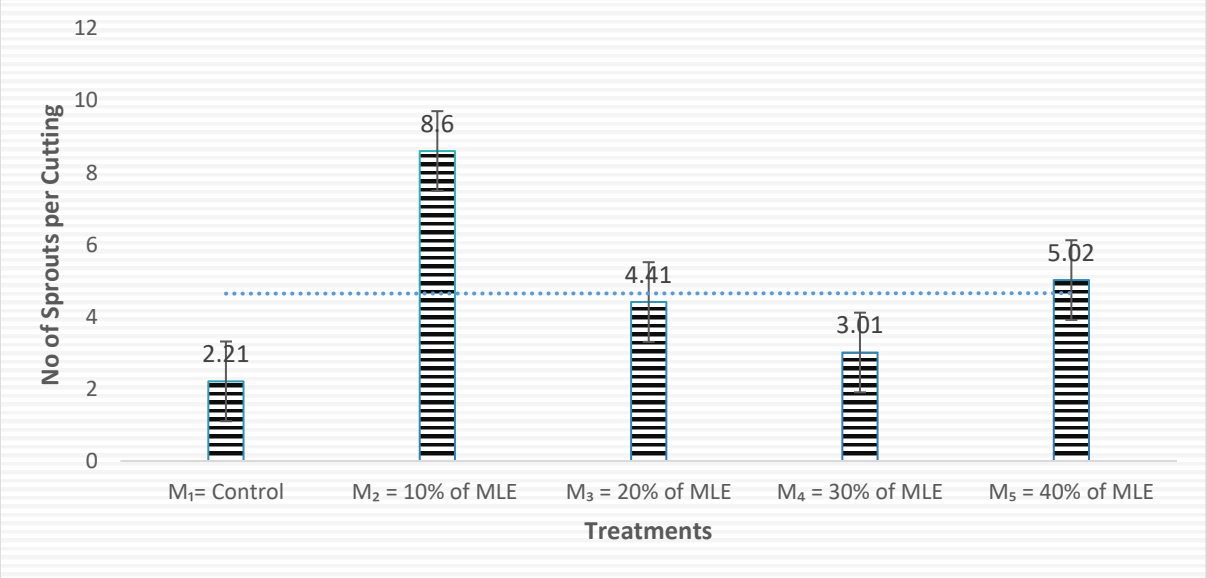

Figure no 2. Effect of Moringa Leaf Extract (MLE) on number of sprouts per cuttings of china rose cuttings.

Number of Sprouts Per Cutting:

The results regards the number of sprouts produced by stem cuttings of china rose varied in response to different concentrations of Moringa Leaf Extract (MLE) and the findings are given in (Figure2). In the control (M_1), the cuttings produced an average of 2.21 sprouts, This served as the baseline for the experiment. When the concentration of Moringa Leaf Extract was increased to 10% (M_2), the sprouting response was significantly higher. The cuttings produced the highest number of sprouts, with an average of 8.6. This indicated that 10% MLE was the most effective concentration for promoting sprouting. However, as the concentration increased further, the number of sprouts decreased. At 20% MLE (M_3), the cuttings produced 4.41 sprouts. showing a reduction in sprouting compared to the 10% concentration. Similarly, at 30% MLE (M_4), stem cuttings yielded 3.01 sprouts, This continued decline in sprouting suggests that higher concentrations of Moringa Leaf Extract were less effective at promoting growth. At the highest concentration of 40% MLE (M_5), Terminal cuttings produced 5.02 sprouts, still showing higher sprout numbers compared to the control group but lower than at the 10% concentration.

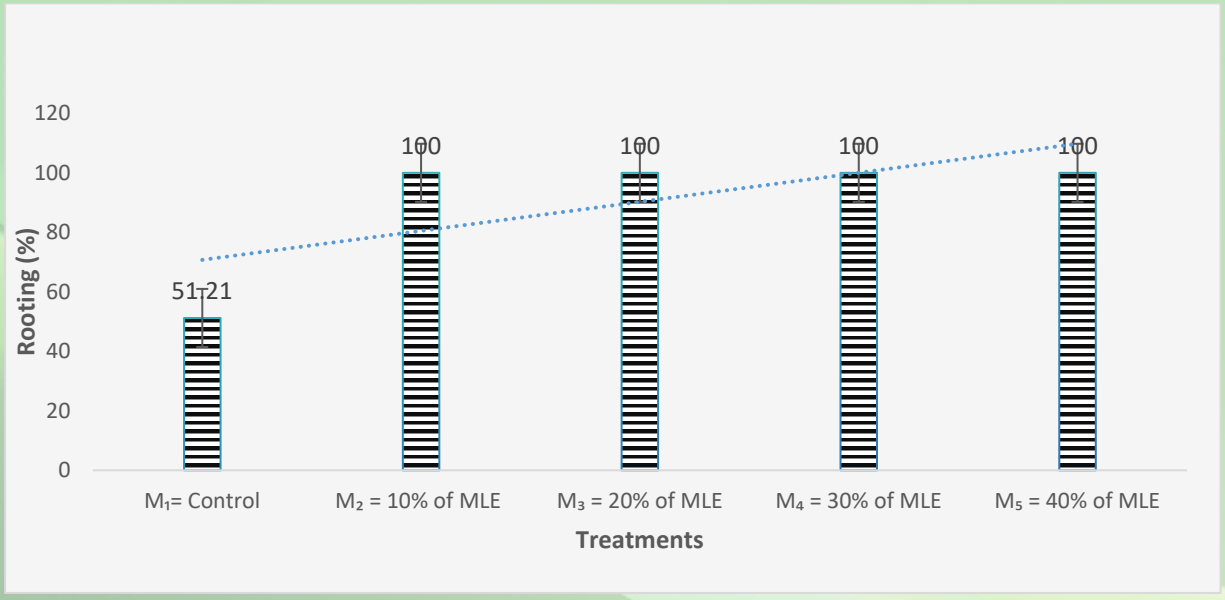

Figure no 3. Effect of Moringa Leaf Extract (MLE) on Rooting % of china rose cuttings.

Rooting percentages:

The rooting percentages stem **cuttings of china rose** in response to different concentrations of Moringa Leaf Extract (MLE) the findings are given in (Figure 4). In the **control group (M_1)**, **cuttings** had a rooting percentage of **51.21%**, indicating that rooting was limited without the use of Moringa Leaf Extract. When **10% Moringa Leaf Extract (M_2)** was applied, **cuttings** achieved **100% rooting**, showing a dramatic improvement. The same

100% rooting was observed at **20% (M3)**, **30% (M4)**, and **40% (M5)** concentrations, demonstrating that higher concentrations of Moringa Leaf Extract did not decrease rooting success.

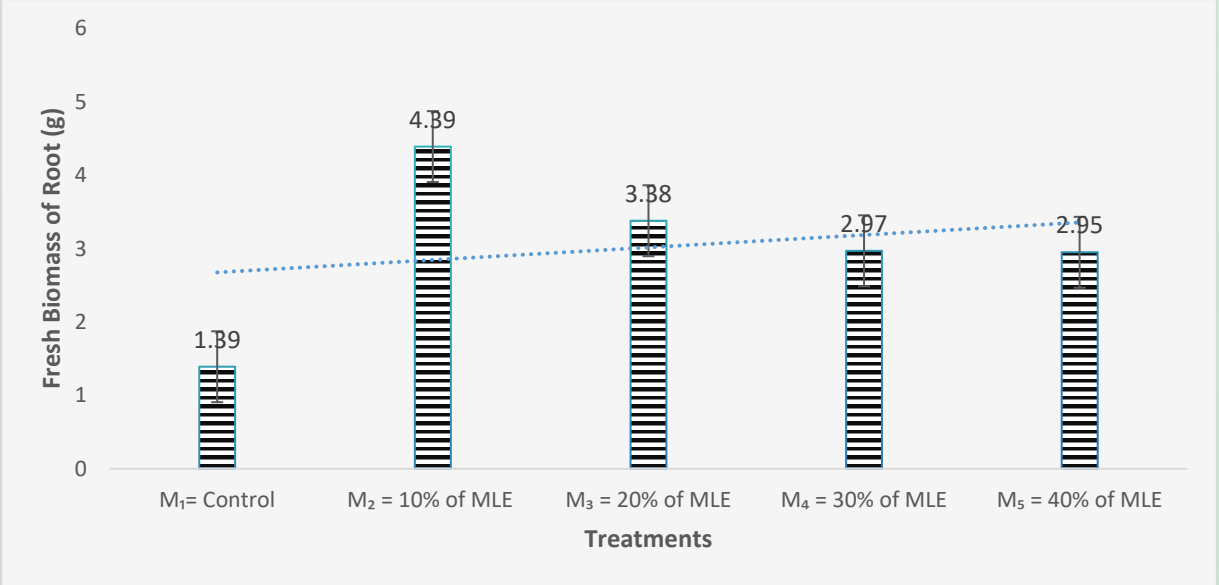

Figure no 4. Effect of Moringa Leaf Extract (MLE) on Fresh biomass of Root (g) of china rose cuttings.

Fresh Biomass of Roots (g):

The Results regards fresh biomass of roots in response to different concentrations of Moringa Leaf Extract (MLE), significant differences were observed in the stem cutting **of chna rose** the findings are given in (Figure 5). The control group (M_1) showed relatively low root biomass, with having **1.39,** establishing the baseline for the experiment.When **10% Moringa Leaf Extract (M_2)** was applied, cuttings experienced a considerable increase in root biomass. **cuttings** reached **4.39 grams**, This marked a substantial improvement compared to the control, indicating the effectiveness of the 10% MLE concentration in promoting root growth. At **20% Moringa Leaf Extract (M_3)**, the root biomass remained significantly higher than the control, with stem **cuttings** producing **3.38 grams.** While still an increase, the root biomass was somewhat lower than at the 10% concentration, suggesting a slight decline in effectiveness as the concentration of MLE increased.With **30% Moringa Leaf Extract (M_4)**, the fresh root biomass decreased further. **Terminal cuttings** produced **2.97 grams.** This decline in root biomass with increasing MLE concentration indicated that higher concentrations may not be as effective for root growth as the lower concentrations. At **40% Moringa Leaf Extract (M_5)**, **Terminal cuttings** produced **2.95 grams** of root biomass. While these values were still higher than the control group, they were lower than the biomass observed at the 10% and 20% concentrations, further suggesting that the optimal concentration for root biomass was at the lower levels of Moringa Leaf Extract.

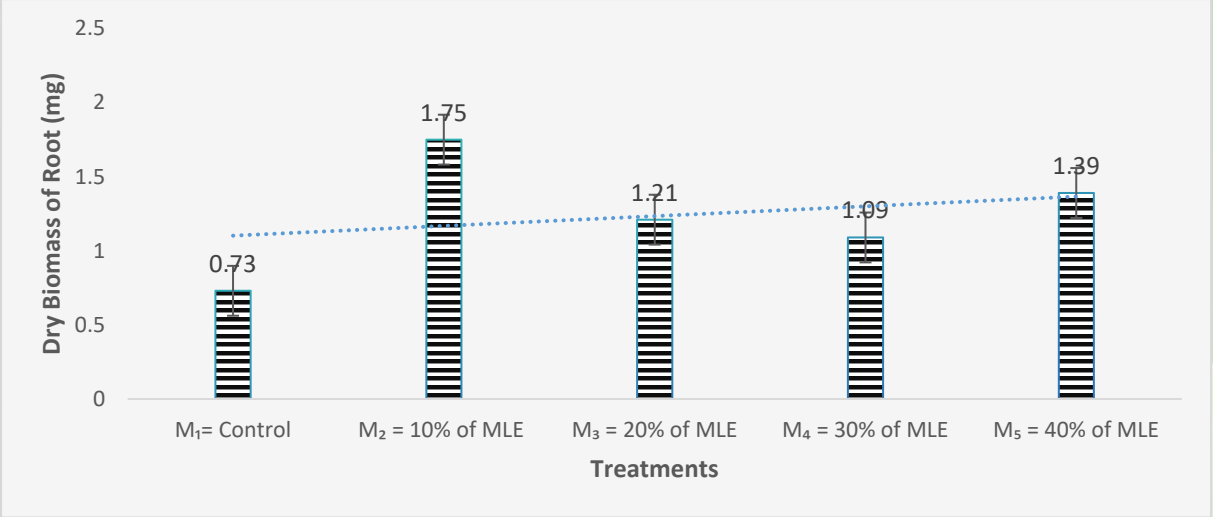

Figure no 5. Effect of Moringa Leaf Extract (MLE) on Dry biomass of Root (mg) of china rose cuttings.

Dry Biomass of Roots (mg):

The results regards the dry biomass of roots stem cutting **of china rose** in response to various concentrations of Moringa Leaf Extract (MLE) showed notable differences are given in (Figure 5). In the **control group (M_1)**, the dry root biomass was **0.73 mg**, These values served as the baseline for comparison. When **10% Moringa Leaf Extract (M_2)** was applied, stem **cuttings** experienced a significant increase in dry root biomass. **Terminal cuttings** produced **1.75 mg**, demonstrating the positive impact of Moringa Leaf Extract at this concentration.At **20% Moringa Leaf Extract (M_3)**, the dry biomass was **1.21 mg**, While both values were higher than the control, there was a slight reduction in biomass compared to the 10% concentration, suggesting a diminishing effect with higher concentrations.With **30% Moringa Leaf Extract (M_4)**, **Terminal cuttings** produced **1.09 mg**, Although these values were still higher than those in the control group, they were lower than those observed at the 10% and 20% concentrations, indicating that the effectiveness of the Moringa Leaf Extract began to decrease as the concentration increased.At **40% Moringa Leaf Extract (M_5)**, **Terminal cuttings** showed **1.39 mg**.

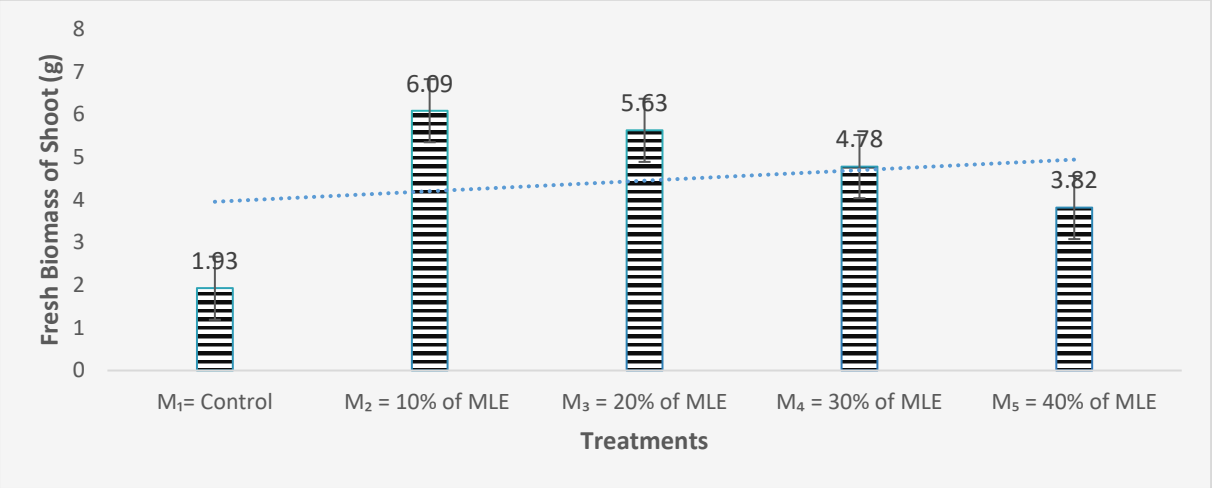

Figure no 6. Effect of Moringa Leaf Extract (MLE) on Fresh biomass of Shoot (g) of china rose cuttings.

Fresh Biomass of Shoot (g):

The results regards the fresh shoot biomass **of china rose** in response to different concentrations of Moringa Leaf Extract (MLE) the findings are given in (Figure 6). The outcomes clearly indicated an influence of MLE on shoot biomass, with the maximum biomass noted at the 10% MLE concentration (M_2). At this concentration, cuttings had a fresh biomass of 6. 09 g, This implies that Moringa leaf extract may greatly improve shoot growth. Though the 10% MLE level was most successful, more concentrations (20%, 30%, 40% MLE) resulted in a reduction in biomass for stem cutting. M_3 is 20% MLE; the biomass for terminal cuttings falls to 5. 63 g, Terminal cuttings' biomass dropped even more to 4. 78 g at 30% MLE (M_4), At the highest level of 40% MLE (M_5), though, biomass decreased once more; terminal cuttings had 3. 82 g.

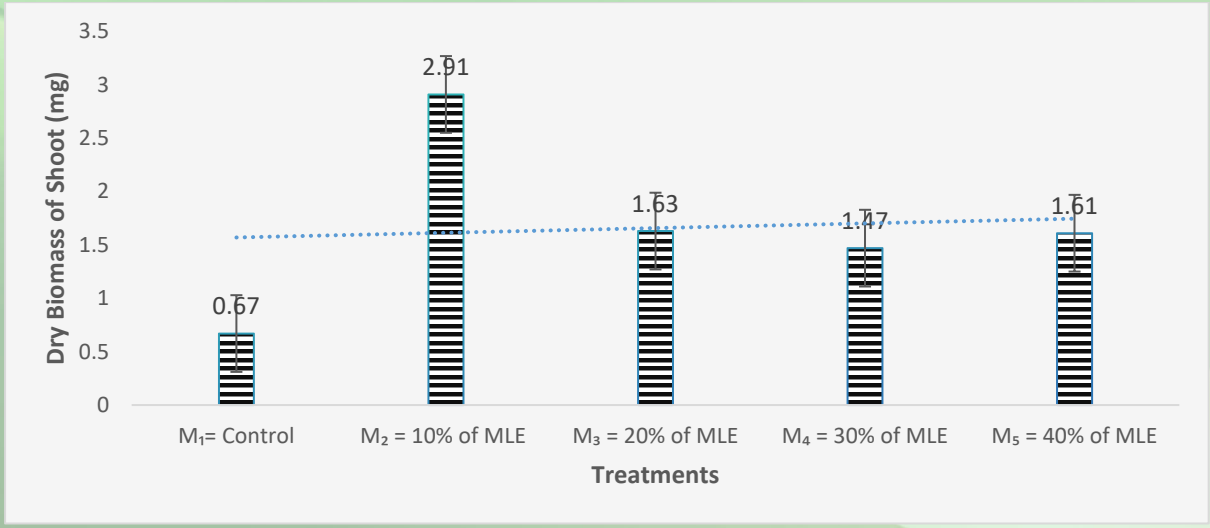

Figure no 7. Effect of Moringa Leaf Extract (MLE) on Dry biomass of Shoot (mg) of china rose cuttings.

Dry Biomass of Shoot (mg)

The results regards the Dry biomass of shoot of china rose in response to different concentrations of Moringa Leaf Extract (MLE) the findings are given in (Figure 7). Control treatment (M_1) yields 0. 67 mg terminal cut's Terminal cuttings' dry biomass rose significantly to 2. 91 mg after a 10% MLE (M_2) treatments, This suggests that terminal cuttings reacted more favorably to the 10% MLE concentration. By comparison, terminal cuttings saw a small decrease in dry biomass that dropped to 1. 47 mg at this level.With the highest 40 percent MLE (M_5), terminal cuts showed a small dry biomass rise to 1. 61 mg. This indicates that although higher MLE levels first raised biomass in sub terminal cuts, there was a reduced impact at the 40 percent level.

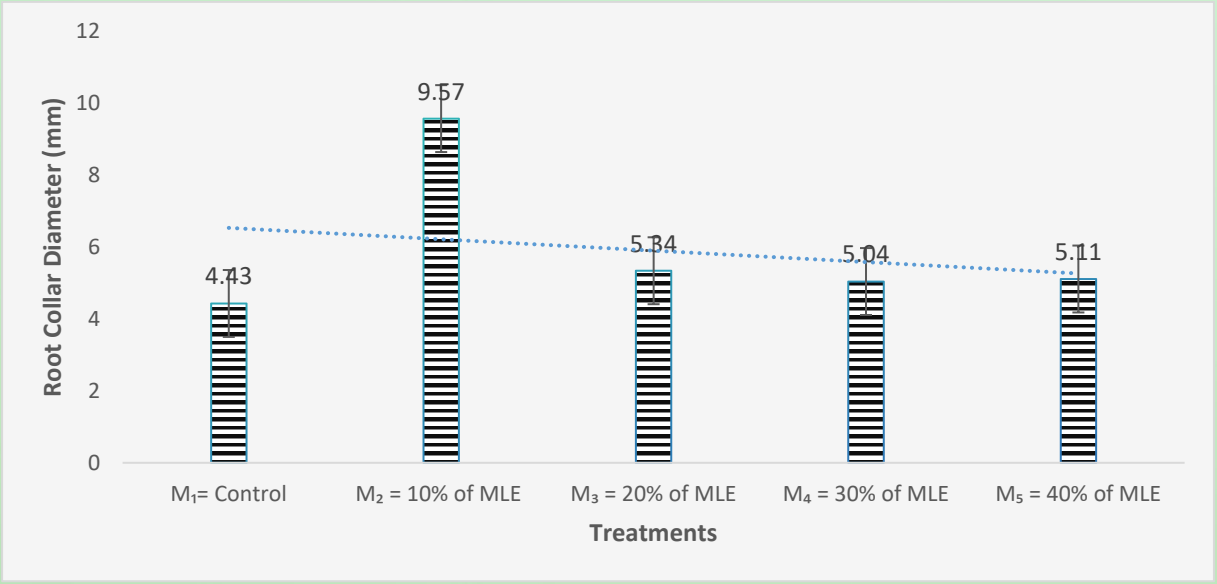

Figure no 8. Effect of Moringa Leaf Extract (MLE) on Root Collar Diameter (mm) of china rose cuttings.

The results regards Root Collar Diameter (RCD) of stem cutting of china rose treated with various concentrations of Moringa leaf extract (MLE)are shown in (figure 8). At the control level (M_1), the root collar diameter for terminal cuttings was 4.43 mm, On the application of 10% MLE (M_2), cuttings showed a significant increase in root collar diameter. Terminal cuttings showed a marked increase to 9.57 mm. This improvement is quite huge, and there is a huge positive effect in the development of the root collar by Moringa leaf extract at 10%. At the increasing concentration of 20% MLE (M_3), root collar diameter declined to 5.34 mm for terminal cuttings, Further reduction in root collar diameter for terminal cuttings was recorded by application of 30% MLE (M_4), and this came to be 5.04 mm while that of sub-terminal cuttings slightly decreased to 10.71 mm. This means higher concentrations of Moringa leaf extract did not show further improvement for terminal cuttings and only marginally affected the sub-terminal cuttings. At the highest concentration, 40% MLE (M_5), a slight increase to 5.11 mm in the terminal cuttings were observed. It indicates that though higher MLE concentrations failed to increase root collar diameter of the terminal cuttings positively.

Discussion

The current work sought to assess the effects of Moringa Leaf Extract (MLE) on sprouting and growth reactions of Hibiscus rosa-sinensis (China Rose) stem cuttings. Outcomes of this experiment indicate that MLE has a significant effect on promoting sprouting, rooting, and growth characteristics in China Rose cuttings with a different level of efficacy based on the concentration of MLE. The results of this research indicated that the percentage of sprouting of China Rose cuttings was 100% at all Moringa Leaf Extract concentrations, ranging from 10% to 40%, which indicates the high potential of MLE in promoting sprouting. These findings are in agreement with research that has indicated the positive impact of Moringa on seed germination and plant sprouting. Maishanu et al. (2017) showed that Moringa leaf extract was able to boost sprouting in several plant species owing to its high growth hormone content. The control treatment with the slightly lower percentage of sprouting (98.61%) also complements the positive effect of MLE on sprouting. This uniform sprouting response at all MLE concentrations indicates its function in inducing early growth processes irrespective of oncentration and implies that MLE may be a useful tool for enhancing China Rose propagation rates. The highest number of sprouts per cutting was achieved with the use of 10% MLE (M_2), where the cuttings averaged 8.6 sprouts, the highest across all treatments. This result is in line with other studies that have established the beneficial role of Moringa extract

on shoot growth and plant development (khan et al., 2020). The decrease in the number of sprouts with increasing MLE concentrations (20%, 30%, and 40%) may reflect a decreasing return at increased concentrations. This trend is consistent with the findings of khan et al. (2017), who hypothesized that elevated concentrations of plant growth regulators can cause phytotoxicity or decreased efficacy because of excess growth-promoting substance accumulation. So, a concentration of 10% MLE seems to be most effective for induction of sprouting and further shoot growth in China Rose.

The experiment proved that Moringa Leaf Extract greatly enhanced China Rose cutting rooting percentage with 100% rooting obtained on all concentrations, including the control. This aligns with Rajani et al. (2024) who found enhanced root growth in several plants exposed to Moringa leaf extract. Nevertheless, although MLE enhanced rooting at all concentrations, the similar percentages of uniform rooting across treatments indicate other factors, rather than MLE concentration, like environmental conditions and the inherent genetic makeup of the plant, could be involved in successful rooting. These findings suggest that MLE's influence on rooting can be less concentration-sensitive than its effect on sprouting since the rooting process tends to saturate at all the tested concentrations. The research noted drastic variation in the root and shoot biomass in accordance with the use of Moringa Leaf Extract. At 10% MLE, cuttings recorded the greatest fresh and dry biomass for roots and shoots. These findings agree with earlier research that noted the growth-promoting role of Moringa based on its high vitamin, mineral, and plant growth regulator content (Sonbarse et al., 2020). The enhancement of root and shoot biomass at reduced concentrations of MLE indicates improved overall growth and development, with the most effective being the 10% concentration.This is consistent with the fact that reduced levels of growth-stimulating substances are more effective in stimulating plant growth than elevated levels, which might bring about toxicity or compromise nutrient uptake efficiency (Bano et al., 2022).

The reduction of biomass at the higher concentrations (30% and 40%) may be an indication of the plant's reaction to excess growth promoter compounds. High levels of Moringa Leaf Extract might cause nutrient imbalance, cellular stress, or suppression of normal metabolic processes, which may result in reduced growth. These results indicate that, although Moringa Leaf Extract is a very effective plant growth promoter, the most suitable concentration for stimulating biomass accumulation in China Rose is approximately 10%.

The root collar diameter (RCD) improved considerably at the 10% MLE concentration, with the cuttings exhibiting a notable increase in RCD than the control group. This suggests that Moringa Leaf Extract can promote the structural growth of the roots, especially root collar development, which is an important consideration for root stability and nutrient absorption. But as the level of MLE intensified, the influence on root collar diameter decreased, especially at 20%, 30%, and 40% levels. This trend is consistent with what was recorded for biomass, where elevated levels of MLE yielded worse growth results.The growth-promoting properties of Moringa Leaf Extract noted in this study are due to its high concentration of growth hormones like cytokinins, auxins, and gibberellins that are responsible for cell division, root initiation, and shoot elongation (Basra et al., 2016).

Abstract

This study investigates the effect of varying levels of macro nutrients on the growth and development of spinach (Spinacia oleracea L.) using a Completely Randomized Design (CRD) with two varieties: Sindhi and English spinach. Conducted during 2024, the experiment utilized a total of six nutrient combinations, including control, NPK (3g/L, 4g/L, 5g/L), and Calcium Nitrate (1g/L), applied to two per pot across replicated treatments. Parameters such as seed germination percentage, germination index, plant height, leaf metrics, root characteristics, and chlorophyll content were assessed. Results indicated a significant enhancement in growth metrics with NPK (3g/L) plus Calcium Nitrate (1g/L), particularly for Sindhi spinach, where it exhibited a germination rate of 95.16% and an increase in chlorophyll to 64.86. Conversely, higher concentrations of NPK negatively affected germination and growth in both varieties, suggesting that balanced nutrient application is crucial for optimal spinach development. This investigation underscores the importance of macro nutrients in enhancing spinach yield, contributing valuable insights for growers aiming to maximize crop productivity.

Abstract

Pro vitamin A rich sources such as; cassava, Africa walnut and tigernut composite flour were used in the production of bread, where 100 % pro vitamin A rich cassava bread coded AP stands for (-ve control) sample HP had a formulation ratio of (90:5:5 %) while, sample IP produced from 100 % wheat flour serves as the positive control sample respectively. the pro vitamin A rich bread samples were analyzed for its proximate and phytochemicals properties. The results obtained for proximate composite of the bread samples had a moisture content ranged from (21.04 – 23.42 %), ash (1.55 - 3.45 %), crude fibre (2.33 - 2.96 %), crude fat (4.33 - 8.27%), crude protein (7.51 - 11.89 %) and carbohydrate (52.41 – 59.89 %) which showed that there was a significant difference among the samples coded HP, AP and IP at ($P<0.05$) level of probability ,which revealed that sample HP were significant in terms of ash, fiber, Fat and protein content and most highest in proximate composition with low moisture content compared with sample AP and IP respectively. The results the phytochemical properties of composite bread samples revealed that phenolic content had a mean value ranged from (803.89 - 905.70µg), tannin (107.60 - 147.65 µg), flavonoid content ranged from (201.78 - 339.85 µg), glycoside (1.83 – 1.83 %), alkaloid (3.23 - 3.54 %) and saponins (5.00 - 5.06 %) where sample HP had the highest mean value of phenol, tannin, flavonoids and glycoside, this properties could provide additional health benefits to the consumers. A bread prepared from a blends of Pro-vitamin A rich cassava, Africa walnut and tigernut flour could potentially be used to address protein-energy malnutrition and hence reduce the risk of vitamin A deficiency among vulnerable groups especially in developing countries.

Abstract

Common beans, being a nutritionally rich and widely consumed legume, require the evaluation of diverse genotypes to identify those with superior agronomic traits. This study aimed to evaluate the morphological variation among 16 common bean (*Phaseolus vulgaris* L.) genotypes collected from diverse regions of Azad Jammu and Kashmir and NARC Islamabad, Pakistan. The experiment was conducted on August 15, 2023, at the Vegetable Crop Research Program field in Islamabad. The 16 genotypes were replicated three times, resulting in a total of 48 plants, and arranged in a Randomized Complete Block Design (RCBD) to ensure uniformity and precision. Genotypes were assessed based on growth habit, leaf area, leaf shape, number of nodes, stem and flower color, number of flowers, days to flowering, days to fruit setting, and chlorophyll content. Analysis of variance (ANOVA) revealed significant differences among genotypes for most traits. Genotype AJKS8 (15) exhibited superior performance with the greatest plant height, highest number of nodes, and maximum flower production. In contrast, genotype 37753 (1) recorded the shortest height and smallest leaf area. All genotypes displayed ovate leaf shapes, with variation in stem and flower color, ranging from light green to dark stems and white to purple flowers. Genotype 37886 (10) flowered earliest, while genotype 37789 (11) showed the longest flowering duration. Least Significant Difference (LSD) analysis categorized genotypes into distinct groups, confirming considerable genetic diversity. These findings provide valuable insights for selecting high-performing landraces and contribute to future common bean breeding and improvement programs.

Abstract

Agriculture remains the backbone of Bangladesh's economy, with the vegetable sector critical for food and nutritional security. However, challenges like poor access to quality seeds, import dependency, and weak market linkages constrain productivity and farmer incomes. This paper presents a sustainable business model for community-based vegetable seed production, developed through a partnership between the Bangladesh Agricultural Research Institute (BARI), Sara Bangla Krishok Society (SBKS), and Dutch Bangla Bank PLC. The model engages smallholder farmers in quality seed production through a cooperative framework, thereby creating a comprehensive value chain that spans from cultivation to marketing. Implemented through the project "Community-Based Sustainable Vegetable Production," it involved 137 farmers cultivating 31 BARI-released varieties across 20.50 hectares, producing 16,923.7 kg of seeds with productivity reaching 927.78 kg/ha. The business model incorporates key components: (1) farmer capacity building through training and exchange visits, (2) quality assurance via BARI's technical supervision of seed processing and certification, and (3) financial support by Dutch Bangla Bank PLC and (4) market access through SBKS's network of 115 producer organizations serving 8,000+ farmers. Post-production activities—seed extraction, drying, quality testing (germination, purity, vigor), packaging, labeling, and storage—were rigorously supervised by BARI breeders. The SBKS cooperative network facilitated market linkages, distributing seeds to member farmers and institutional buyers like ActionAid Bangladesh and Udayankur Seba Sanstha (USS). This vertically integrated approach demonstrates strong commercial viability, with seeds marketed both to cooperative members and institutional buyers like ActionAid Bangladesh. The model reduces import dependence by 30-40% while increasing farmer incomes by 25-35%. Its scalability is evidenced by expansion across climate-vulnerable Barind and coastal regions. The business model offers a sustainable solution to Bangladesh's seed security challenges, combining farmer empowerment with market-oriented production. Policy support for scaling this model could transform Bangladesh's vegetable seed sector while contributing to SDGs 1, 2, and 8.

Selection of High-Yielding Watermelon Lines for Enhanced Food and Nutritional Security in Bangladesh

AKM QUAMRUZZAMAN*, L. AKTER, MR ISLAM, S. AKTER and MH ISLAM

Olericulture Division, Horticulture Research Centre, Bangladesh Agricultural Research Institute, Gazipur-1701, Bangladesh
*Corresponding Email: akmqzs@gmail.com

Abstract

This study evaluated 10 watermelon germplasm lines alongside check variety (BARI Tarmuj-1) at the Olericulture Division of HRC, BARI, Gazipur during February-May 2024 to identify superior genotypes for farmers' cultivation. Significant variations were observed in key agronomic and quality parameters among the tested lines. Vine length ranged from 4.0-5.10 m, while critical fruit quality traits showed substantial variation: flesh thickness (13.0-31.0 cm), rind thickness (1.7-2.5 cm), and total soluble solids (TSS) content (10.50-13.60%). Fruit yield per plant varied considerably (11.85-18.49 kg), with five promising lines outperforming the check variety: CL009D (18.49 kg), CL009B (18.36 kg), CL009C (18.10 kg), CL009A (17.32 kg), and CL008 (17.24 kg). The selected lines combine high yield potential with superior quality attributes, particularly the optimal flesh-to-rind ratio and elevated TSS content (>13%), indicating enhanced sweetness and nutritional value. These characteristics make them ideal for both fresh consumption and processing, addressing Bangladesh's growing demand for nutrient-dense fruits. The identification of these high-performing genotypes provides valuable breeding material for developing improved watermelon varieties that can boost productivity by 25-35% compared to existing varieties. This research contributes directly to food and nutritional security by offering farmers access to superior genetic material with better yield stability and quality. The selected lines demonstrate potential for climate resilience and market preference, aligning with national agricultural development goals. Further multilocation trials are recommended to validate performance across different agroecological zones before official release.

Effect of plant-derived additives on bioactive properties of fermented dairy products : A review

K.K.B.S. Rajapaksha[1*], M.A.L.S.S. Munasinghe[1], H.N.N. Dilrukshi[1], W.A.D. V. Weerathilake[1]

[1]Department of Livestock and Avian Sciences, Faculty of Livestock, Fisheries and Nutrition, Wayamba University of Sri Lanka, Makandura, Gonawila (NWP), Sri Lanka

Abstract

Food bioactives are compounds that exert physiological benefits promoting health and preventing effects of diseases in the human body through their antioxidant, antibacterial, anticancer, antidiabetic and analgesic properties. Plant-derived bioactive owing to the growing researcher's interest due to their abundance, low cost and wider acceptability. This growth is fuelled by technological innovations through the development of new products by fortifying plant-based sources. Fermented dairy products are of great importance due to their special characteristics, are an excellent matrix for the incorporation of ingredients and benefits on the hosts intestine and microbiome, immunomodulation and anti-allergenic effects. This review has extensively assessed the recent knowledge on the quantitative and qualitative enhancement of the nutritional value of fermented milk products by the enrichment of plant-based bioactive compounds. Fermented dairy products including yoghurt, curd, kefir, sour cream, cheese, buttermilk and drinking yoghurt have popularly fortified with different fruits, vegetables, herbs, spices, cereals and nuts. The findings of this review demonstrated that the bioactivity of fermented dairy products has increased with the incorporation of fruits, since they contain the majority of bioactive compounds such as carotenoids, polyphenols, dietary fibre and fatty acids. Fermented dairy products supplemented with herbs are typically high in polyphenols, fatty acids and carotenoids. It was also shown that spices enriched dairy products had more polyphenols, carotenoids and dietary fibre than unfortified dairy products. Nuts and oil crops, such as walnuts and hazelnuts have enhanced the fatty acid content of yoghurts. Taken together, these findings suggest that the role of bioactive compounds in promoting antioxidant, antimicrobial, antihyperglycemic, anti-inflammatory and antiradical effects. In future, it would be interesting to assess more studies on the synergetic effect between the natural bioactive compounds and fermented dairy products to enhance growing demand and potential health benefits.

Key Words: *Fermented Dairy Products1, Health Benefits2, Nutritional Value3, Plant-based Bioactives4*

Introduction

The consumption of fermented dairy products has seen a significant and steady increase over recent years, largely due to their enhanced digestibility, extended shelf life, improved nutritional and organoleptic properties, and the reduction of antinutritional compounds generated during fermentation. Certain strains of lactic acid bacteria are capable of metabolizing antinutritive components such as lactose and galactose, thereby offering protection against lactose intolerance and galactose accumulation (García-Burgos et al., 2020). Popular fermented dairy products include yogurt, curd, kefir, sour cream, cheese, buttermilk, and drinkable yogurt, all of which have been widely studied for their functional and health-promoting properties.

During fermentation, a variety of bioactive compounds such as vitamins, gamma-aminobutyric acid (GABA), bioactive peptides, bacteriocins, enzymes, conjugated linoleic acid (CLA), and exopolysaccharides are produced. These compounds have demonstrated potential roles in cancer prevention, blood pressure regulation, and type 2 diabetes management (Linares et al., 2017; Lee et al., 2020). Additionally, the increasing demand for fermented dairy products among individuals with lactose intolerance further highlights their functional appeal.

Despite the nutritional richness of fermented dairy products, some micronutrients such as zinc may be present in insufficient quantities (Jalal et al., 2016), and processing methods like heat treatment can degrade heat-sensitive nutrients. Moreover, fermentation may sometimes reduce antioxidant activity in products like yogurt (Dabija et al., 2018). As a result, fortification becomes essential to maintaining or enhancing the overall nutritional profile of these products.

The growing interest in functional foods—defined as those that provide health benefits beyond basic nutrition when consumed as part of a regular diet (Products & Foods, 1998)—has driven innovation in the dairy sector. With rising concerns over the negative effects of synthetic additives on the nervous and gastrointestinal systems, and their potential carcinogenic risks (Alenisan et al., 2017), researchers have turned their attention to natural plant-based additives rich in bioactive compounds.

Bioactive compounds—non-essential nutritional molecules present in small amounts—offer multiple health benefits, including antioxidant, antimicrobial, antidiabetic, anticancer, and analgesic effects (Septembre-Malaterre et al., 2017). These include phytosterols, polyphenols, unsaturated fatty acids, dietary fiber, and pigments such as carotenoids, anthocyanins, chlorophylls, and lycopene, commonly found in herbs, spices, fruits, vegetables, and green tea. Incorporating these compounds into dairy products can enhance both nutritional quality and product shelf life, while contributing positively to consumer health.

To effectively enrich dairy products with these bioactive compounds, a range of extraction and encapsulation techniques are employed, such as Soxhlet extraction, ultrasound-assisted extraction, supercritical fluid extraction, spray drying, coacervation, and freeze drying (Martins et al., 2017). However, challenges such as high dosage requirements, low bioavailability, unclear mechanisms of action, and limited availability of raw materials may arise. Advanced approaches involving biotechnology, nanotechnology, active packaging, and sustainable sourcing have been proposed to overcome these issues (Prakash et al., 2017).

Globally, the nutritional and therapeutic potential of natural sources has stimulated extensive research in this domain. Studies have shown that fortification with plant-based antioxidants can effectively reduce oxidation in dairy products with fewer adverse effects compared to synthetic additives (Alenisan et al., 2017). While essential oils have demonstrated positive antioxidant and antimicrobial properties, they may also affect sensory attributes negatively (Mishra et al., 2020). Similarly, the incorporation of grape extracts has improved antioxidant activity in dairy matrices but negatively impacted flavor (Kandylis et al., 2021).

Despite these advancements, research on the incorporation of tropical plant-based additives into fermented dairy products in Sri Lanka remains limited. The local application of such additives, which are rich in bioactive compounds, holds considerable potential for improving public health. Although antioxidant and antimicrobial properties have been well-documented, there is a notable lack of studies on the anti-tumor, anti-carcinogenic, anti-mutagenic, and immunomodulatory effects of these compounds when used in dairy product fortification (Prakash et al., 2017).

The primary aim of this review is to critically evaluate how natural additives rich in bioactive compounds can enhance the nutritional and functional quality of fermented dairy products, both quantitatively and qualitatively. Additionally, this review seeks to identify promising plant-based sources for fortification and to assess their impact on sensory, nutritional, and health-related attributes. A survey of Sri Lanka's dairy industry was also conducted to understand current practices and perceptions regarding the use of bioactive-rich natural additives in fermented dairy products. Ultimately, this article presents a comprehensive overview of fermented dairy products, the importance of fortification, the functional potential of plant-derived bioactive compounds, and the challenges and prospects in this emerging field

Materials and Methods

A comprehensive literature review was conducted using the Web of Science database to gather relevant studies aligned with the research objectives. A total of 291 articles were initially selected based on specific keywords related to fermented dairy products, fortification, and bioactive compounds. To maintain relevance and consistency, articles published before 2016 and those written in languages other than English were excluded.
Following a thorough screening process, 40 articles that met the inclusion criteria were selected for detailed review and analysis. The selected studies were assessed based on their contribution to understanding the nutritional, sensory, and health-related impacts of incorporating bioactive compound-rich natural additives into fermented dairy products.
Due to the extensive body of literature, the focus was narrowed to four major classes of bioactive compounds commonly studied in food fortification: polyphenols, carotenoids, dietary fiber, and polyunsaturated fatty acids. Similarly, among the wide range of fermented dairy products, cheese, yogurt, kefir, butter, and fermented milk were selected due to their global popularity and variation in formulation.
The selected articles were first qualitatively analyzed to understand the role and impact of each bioactive compound on nutritional enhancement, sensory attributes, and potential health benefits. Subsequently, the magnitude of observed effects was assessed and summarized, allowing for a more structured comparison of the outcomes across different studies.

Results and Discussion

Yogurt

Lactobacillus bulgaricus and *Streptococcus thermophilus* are the primary starter cultures used in the fermentation of cow's milk to produce yogurt. Yogurt is a rich source of minerals such as calcium, magnesium, phosphorus, and zinc, along with essential vitamins including B1, B2, B12, and D. It offers several health benefits, including enhanced lactose digestion, improved bioactive compound profiles, and increased bone mineral uptake (Gómez-Gallego et al., 2018).

Yogurt is particularly beneficial for individuals with lactose intolerance due to the partial hydrolysis of lactose by bacterial β-galactosidase. Furthermore, it plays a preventive role in various health conditions, including cancer, hypertension, and diarrhea, and supports gut microbiota balance. The unique flavor of yogurt is attributed to the volatile compounds produced by fermentative bacteria.

Yogurt can be categorized based on fat content, physical structure, and flavoring (Chandan, 2017):

Fat content: High-fat, reduced-fat, low-fat yogurt
Physical structure: Set yogurt, stirred yogurt
Flavorings: Plain yogurt, flavored yogurt

Figure 1. Classification of yogurts (Source: Chandan, 2017)

The general processing steps for yogurt production include standardization and fortification, homogenization (65°C, 1.8×10^4 kPa), heat treatment (85°C for 30 minutes), cooling to incubation temperature (42°C), and inoculation with the starter culture.

Figure 2. Flow diagram of yogurt processing (Source: Chandan, 2017)

The current study affirms that yogurt can be effectively enriched with bioactive compounds through natural additives (Jaster et al., 2018; Šeregelj et al., 2019, 2021a).

Cheese

Cheese is a versatile dairy product available in cooked and uncooked varieties. Over time, its nutritional value, texture, and flavor have improved. Cheese offers numerous health benefits, such as supporting bone and dental health, regulating blood pressure and cholesterol, and maintaining vascular and gut health (Martins et al., 2017).

Cheese can be made from various milk sources including cow, goat, sheep, and buffalo milk. Based on processing parameters, cheese is classified into several types (Hammam & Ahmed, 2019):

Processing method: Cheddar, cream cheese, cottage cheese
Composition: Salted, unsalted, high-fat, low-fat cheese
Maturation method: Acid-ripened, enzymatic ripened
Starter culture: Mold-ripened, bacteria-ripened cheese

The general processing steps for cheese involve standardization and pasteurization, inoculation with cultures, renneting, curd cutting, cooking (37°C–42°C for 40 minutes), salting, forming, pressing, and aging.

This study demonstrates that cheese can be successfully fortified with natural additives rich in bioactive compounds (Balabanova et al., 2020; Ghendov-Moşanu et al., 2020; Masmoudi et al., 2020).

Kefir

Kefir, an emerging functional dairy product, exists in two main forms: milk kefir and water kefir (Guzel-Seydim et al., 2021). It contains high levels of organic acids, sugars, esters, and alcohols, contributing to its distinct flavor and texture.

Kefir is produced by fermenting milk with kefir grains or lyophilized cultures that primarily consist of lactic acid bacteria and yeast. Nutritionally, kefir is abundant in B-complex vitamins (B1, B2, B6, B12), essential amino acids (e.g., phenylalanine, tyrosine, leucine, glycine), and minerals such as magnesium, potassium, and calcium (Vicenssuto & de Castro, 2020a).

Due to its probiotic, prebiotic, antibacterial, anti-inflammatory, and antioxidant activities, kefir offers protective effects against obesity, hypercholesterolemia, and cancer while promoting longevity. The study confirms that kefir can be effectively enriched with natural additives containing bioactive compounds (Vicenssuto & de Castro, 2020a, 2020b).

Butter

Butter typically contains 80–83% fat and up to 400 different fatty acids. It is widely used both as a spread and a cooking fat. Butter is produced by churning milk or cream, which disrupts fat globules and forms a water-in-oil emulsion, separating butter granules from buttermilk.

While cow milk is most commonly used, butter can also be derived from sheep, goat, and buffalo milk (Mehdizadeh et al., 2019). Chemically, butter is rich in fat, protein, milk sugars, and water. However, it is highly susceptible to spoilage through lipid oxidation and microbial contamination, requiring stringent storage conditions (El-Hadad & Tikhomirova, 2018).

This study supports that butter can also be enriched successfully with bioactive compounds via natural additives (Mehdizadeh et al., 2019; Vidanagamage et al., 2016).

Importance of Fortification of Fermented Dairy Products

Fermented dairy products are nutrient-dense, supplying protein, calcium, vitamins (especially B12 and riboflavin), and essential minerals. Individuals with lactose intolerance can tolerate fermented dairy due to bacterial conversion of lactose into lactic acid. Additionally, these products exhibit antibacterial, antitumor, and immunomodulatory properties (Savaiano & Levitt, 1984).

Fortification improves the nutritional profile of fermented dairy products, making them more functional and health-promoting. Moreover, the matrix properties of dairy products (texture, composition, and pH) play a crucial role in the efficiency and stability of added bioactive compounds.

Bioactive Compounds in Natural Sources

Bioactive compounds are secondary plant metabolites that contribute to a plant's adaptability and survival, though not directly involved in growth or reproduction. These compounds include phenolics, alkaloids, terpenes, and phytosterols (Galanakis & Drago, 2022).

Phenolic compounds, in particular, are further classified into flavonoids and non-flavonoids (Kamiloglu et al., 2021).

Figure 5. Classification of bioactive compounds (Source: Khezerlou & Jafari, 2020)

Extraction methods for these compounds include conventional techniques like Soxhlet and hydrodistillation, and advanced methods such as ultrasound-assisted extraction (UAE), microwave-assisted extraction (MAE), supercritical fluid extraction (SFE), pressurized liquid extraction (PLE), and pulsed electric field extraction (PEF).

Phenolic Compounds: Abundance, Bioactivity, and Application in Functional Foods

Phenolic compounds represent the most abundant class of secondary metabolites in plants, characterized by the presence of one or more hydroxyl groups attached to aromatic rings (Ayad & Akkal, 2019). These compounds are widely distributed among various plant species and are classified into several subgroups, including flavonoids, phenolic acids, lignans, stilbenes, and tannins.

Phenolics are known for their diverse biological activities. One of their notable functions is their anti-inflammatory property, which contributes significantly to the prevention of cardiovascular diseases. This effect is primarily exerted through the inhibition of platelet aggregation and modulation of smooth muscle cell activity (Guasch-Ferré et al., 2017). Furthermore, phenolics exhibit antidiabetic effects by enhancing glucose uptake in peripheral tissues and reducing insulin resistance through improved insulin sensitivity (LS & NJA, 2016). Their anti-obesity potential is associated with the suppression of adipocyte proliferation, stimulation of lipolysis, appetite regulation, and reduction of inflammation in adipose tissue (LS & NJA, 2016).

The anticancer potential of phenolic compounds is also well documented. They exert protective effects by scavenging free radicals, inducing detoxifying enzymes involved in xenobiotic metabolism, regulating gene expression, and modulating several signaling pathways involved in DNA repair, apoptosis, and cell invasion (Lutz et al., 2019; Yen et al., 2020).

Recent research has explored the functional properties of phenolics in food systems. Masmoudi et al. (2020) reported that the addition of 30% strawberry pulp to a food matrix resulted in a significant increase in anthocyanin content by 2.99 mg/100 g, along with enhanced antioxidant activity measured by DPPH (9.19 mg GAE/mL) and ABTS (0.38 mg GAE/mL) assays. Although a decrease in anthocyanin content was observed during storage, the antioxidant activity remained relatively stable.

In a comparative study, Muniandy (2016) found that yoghurt enriched with green tea exhibited the highest total phenolic content (526.34 mg GAE/mL) compared to those enriched with white tea (394.12 mg GAE/mL) and black tea (294.67 mg GAE/mL), likely due to the higher catechin and epicatechin content in green tea. However, storage over two weeks led to a significant decline in phenolic content across all samples. Antioxidant activity, evaluated by DPPH RSA and FRAP, was highest in green tea yoghurt, while black tea yoghurt showed superior antioxidant potential in the FIC assay. These variations may reflect the differences in primary and secondary antioxidant capacity measured by these methods.

Josipović et al. (2015) demonstrated that the addition of dried dill significantly increased the phenolic content of cheese to 37.8 mg GAE/100 g, surpassing that of cheese fortified with parsley, pepper, garlic, or rosemary. However, this increase in phenolic content did not correspond with a higher antioxidant effect. The discrepancy was attributed to several factors, including pH, temperature, phenolic structure, amino acid composition, and potential interactions between phenolics and proteins. Additionally, the capacity of certain reagents to react with non-phenolic compounds may influence the accuracy of antioxidant measurements.

Vidanagamage et al. (2016) investigated the incorporation of cinnamon extract into butter and observed an increase in total phenolic content to 135.62 µg GAE/mg and antioxidant activity to 38.73%, highlighting the potential of spice extracts in enhancing the functional properties of dairy products.

Kabakcı et al. (2020) examined kefir enriched with anthocyanin-rich fruit juices and found that the addition of 25% black mulberry juice led to the highest anthocyanin content (404.5 mg/L) compared to pomegranate, strawberry, and black carrot juices. However, anthocyanin degradation and co-pigmentation during storage led to a significant reduction (32.1%) in anthocyanin content. The antioxidant effect was associated with the anthocyanin content of black mulberry, although no notable antimicrobial activity was detected.

Contradictory findings were reported by Kiros et al. (2016), who found no increase in phenolic content in carrot juice-enriched yoghurt compared to the control, contrary to results by Pandey et al. (2021). In fact, a slight decrease from 37 mg GAE/kg in the control to 35.75 mg GAE/kg in the fortified sample was recorded. Possible explanations include differences in carrot varieties, agronomic practices, storage conditions, and processing techniques used prior to analysis.

Carotenoids

Carotenoids are lipid-soluble secondary metabolites widely distributed in nature, especially in plants, where they play essential roles in photosynthesis and photoprotection. From a nutritional perspective, carotenoids are recognized for their health-promoting properties, including provitamin A activity, antioxidant potential, and disease-preventive roles (Karpioski et al., 2022).

Structurally, carotenoids are composed of isoprene units forming C40 terpenoids, and they are typically classified into two main groups: carotenes (hydrocarbon carotenoids, such as α-carotene, β-carotene, and lycopene) and xanthophylls (oxygenated carotenoids, including lutein and bixin). Carotenes are characterized by non-polar structures, while xanthophylls contain polar groups, making them more reactive to oxidation. Among these, lycopene has the simplest linear structure, whereas α- and β-carotenes possess cyclic ends. The differentiation between α- and β-carotene arises from the position of the double bond in the cyclic group (Karpioski et al., 2022).

Carotenoids play crucial roles in quenching singlet oxygen and scavenging reactive oxygen species (ROS), attributed to the conjugated double bonds in their polyene chain. This ability to deactivate ROS stems from mechanisms such as triplet–triplet energy transfer, electron transfer, hydrogen atom donation, and radical adduct formation (Karpioski et al., 2022). Furthermore, carotenoids' antioxidant activity is directly proportional to the number of conjugated double bonds in their structure (Zakynthinos & Varzakas, 2016).

In addition to antioxidant capacity, carotenoids exhibit anti-inflammatory and antimicrobial activities. They interact with the NF-κB pathway, inhibiting its nuclear translocation and consequently reducing the expression of inflammatory cytokines such as interleukin-8 and prostaglandin E2 (Kaulmann & Bohn, 2014). Moreover, carotenoids have been reported to interfere with efflux pump activity in bacteria by disrupting ATP hydrolysis, altering membrane permeability, and increasing intracellular ROS production, thereby exerting antibacterial effects (Zakynthinos & Varzakas, 2016).

Carotenoids also contribute to cancer prevention by modulating signaling pathways associated with apoptosis, cell cycle arrest, and metastasis. Their chemopreventive roles include inhibition of tumor cell proliferation and enhancement of programmed cell death (Niranjana et al., 2015).

Numerous studies have explored the fortification of fermented dairy products with carotenoid-rich sources to enhance their functional properties. Kiros et al. (2016) reported that yogurt fortified with carrot or carrot oil demonstrated significantly higher carotenoid content and antioxidant activity compared to the control. Specifically, the addition of carrot oil resulted in a carotenoid concentration of 10.26 mg/kg in fresh yogurt. Similarly, a study by Balabanova et al. (2020) evaluated the impact of incorporating different pepper varieties into yogurt. Among them, yogurt enriched with *Kurtovska Kapia* showed the highest carotenoid content (570.02 µg/100g), exceeding the levels found with other varieties such as *Doux Marconi Geonet* and *Balgarian Ratunt*.

These findings highlight the potential of carotenoid fortification in enhancing the health-promoting properties of dairy products, making them valuable functional foods in modern diets.

Dietary Fiber

Dietary fiber refers to the indigestible portion of plant-derived carbohydrates, primarily in the form of polysaccharides, that escapes enzymatic digestion in the human small intestine. These fibers are broadly classified based on their water solubility into two major types: soluble and insoluble fibers. Soluble dietary fibers include pectin, gums, mucilage, fructans, and specific types of resistant starches, which are commonly found in fruits, vegetables, oats, and barley. In contrast, insoluble fibers such as lignin, cellulose, and hemicellulose are mainly sourced from whole grains, nuts, seeds, and vegetables (Soliman, 2019).

The inclusion of dietary fiber in daily intake has been associated with a reduction in the risk and severity of a range of health disorders, including constipation, diverticulosis, colorectal cancer, type 2 diabetes, obesity, cardiovascular diseases, and gallstones. Moreover, increased fiber intake has been linked to a reduction in serum cholesterol and blood pressure levels (Li & Komarek, 2017).

An increasing body of research has focused on the enrichment of dairy products with plant-derived dietary fiber sources. Issar, Sharma, and Gupta (2017) reported that the incorporation of 5% apple pomace fiber into acidophilus yogurt resulted in an acceptable sensory profile and enhanced fiber content, making it a suitable approach for

developing fiber-enriched fermented dairy products. Similarly, Kurt and Atalar (2018) demonstrated that the addition of quince seed-derived dietary fibers significantly increased the viscosity of yogurt, from 0.266 to 0.317 Pa·s, potentially improving the textural attributes and functional value of the product.

Fatty Acids

Fatty acids (FAs) are fundamental lipid components classified based on their saturation level. Saturated fatty acids (SFAs), such as palmitic acid (C16:0), stearic acid (C18:0), myristic acid (C14:0), and lauric acid (C12:0), are characterized by the absence of double bonds in their hydrocarbon chains. Unsaturated fatty acids (UFAs), which include monounsaturated (MUFAs) and polyunsaturated fatty acids (PUFAs), are distinguished by the presence of one or more double bonds (Karaguzel et al., 2019). Notably, oleic acid (C18:1), linoleic acid (LA, C18:2, omega-6), and alpha-linolenic acid (ALA, C18:3, omega-3) are the predominant UFAs found in plant sources.

PUFAs, particularly omega-3 fatty acids like ALA, eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA), are recognized for their beneficial effects in preventing cardiovascular diseases, modulating inflammation, and supporting neurological development (Dal Bello et al., 2017). Conversely, a disproportionate intake of omega-6 PUFAs, especially in the absence of adequate omega-3s, has been associated with adverse health outcomes (Shrestha et al., 2020).

In recent years, extensive research has focused on the fortification of dairy products with plant-derived oils rich in essential fatty acids. Ozturkoglu-Budak et al. (2016) observed that yogurt enriched with walnuts exhibited a significant increase in total fatty acid content (69.54 g/100 g) compared to variants fortified with hazelnuts, almonds, or pistachios. This enhancement was attributed to the high EPA and DHA content in walnuts, which also contributed to lower stiffness development during storage.

Similarly, Van Nieuwenhove et al. (2019a) demonstrated that yogurt fortified with pomegranate seed powder exhibited a 1.8-fold increase in conjugated linolenic acid (CLnA) compared to yogurt fortified with Jacaranda seed. The addition of these plant powders did not adversely affect the pH or sensory properties of the yogurts, even after 28 days of storage (Van Nieuwenhove et al., 2019b).

Dal Bello et al. (2017) reported that cheese samples fortified with blackcurrant oil presented the highest omega-6 PUFA levels (12.21 mg/g) on day one, surpassing samples fortified with raspberry, flaxseed, camelina sativa, and echium oils. The greatest omega-3 content (4.43 mg/g) was recorded in cheeses fortified with camelina oil. Interestingly, flaxseed oil-fortified cheeses exhibited a significant decrease in omega-3 content after three days of ripening. No significant differences were found in protein, moisture, ash content, or pH among control and fortified cheeses. Among the oil treatments, the combinations of flaxseed and raspberry oils were found to be the most favorable in terms of fatty acid composition and consumer acceptance.

Table 01 - Natural sources rich in bioactive compoubds

Natural Source	Examples	Phenolic Compund	Reference
Herbs	Red ginseng	Polyphenols	(H. Park et al., 2018)
	Sea buckthorn	Carotenoids	(Ghendov-Moşanu et al., 2020)
Spices	Turmeric	Carotenoids	Hasneen et al., 2020)
	Ginger	Phenolics	(Ahmed et al., 2021a)
	Dried curry leaves	Phenolics	(Weragama et al., 2021)
	Pepper	Carotenoids	(Balabanova et al., 2020)
	Cinnamon	Phenolics	(Vidanagamage et al., 2016)
	Strawberry	Phenolics	(Jaster et al., 2018)
	Passion	Phenolics	(Ning et al., 2021)
	Pomegranate	Phenolics	(Van Nieuwenhove et al., 2019b)
	Mango	Carotenoids	(Vicenssuto & de Castro, 2020a)
Vegetables	Carrot	Carotenoids	(Kiros et al., 2016)
	Spinach	Phenolics	(Göksel Saraç & Dogan, 2016)
Nuts and oil crops	Walnut	Fatty acids	(Ozturkoglu-Budak et al., 2016)
	Hazelnut	Fatty acids	(Ozturkoglu-Budak et al., 2016)
	Almond	Fatty acids	
Cereals	Black rice	Phenolics	(Khalil & Elkot, 2020)
	Wheat	Phenolics	(Çetinkaya & Öz, 2020)

Bioactive Compounds in Fermented Dairy Products

Fermented dairy products are rich sources of bioactive compounds, primarily produced through the metabolic activity of microorganisms such as lactic acid bacteria (LAB), yeasts, and molds. These microorganisms contribute to the synthesis of several functional metabolites, including exopolysaccharides (EPS), conjugated linoleic acid

(CLA), bioactive peptides, gamma-aminobutyric acid (GABA), galactooligosaccharides (GOS), and essential vitamins (Linares et al., 2017).

The vitamin profile of fermented dairy products is notably enhanced, especially in riboflavin and vitamin B12, which are synthesized during fermentation by specific strains of LAB. The consumption of such fortified products may contribute to reducing vitamin deficiencies in human populations (Savaiano & Levitt, 1984). Moreover, GABA is synthesized through the decarboxylation of glutamic acid by LAB and plays a vital role in human neurological function, contributing to the regulation of neurotransmission and stress responses (Santos-Espinosa et al., 2020).

Exopolysaccharides, also produced by starter cultures, are recognized for their dual functionality: enhancing textural attributes of fermented dairy products and promoting gut health by acting as prebiotic-like agents (Santos-Espinosa et al., 2020). In addition, bioactive peptides, typically composed of 2 to 20 amino acids, are generated via the proteolytic activities of microbial enzymes during fermentation. These peptides exert multiple physiological benefits, including antihypertensive, antioxidant, immunomodulatory, and antimicrobial effects, making them crucial targets in functional food research (Y. W. Park & Nam, 2015).

CLA, another key metabolite, exhibits strong antioxidant activity and is implicated in reducing the risk of chronic conditions such as cardiovascular disease, obesity, and certain cancers. Its inclusion in fermented dairy further enhances the health-promoting properties of these products, thereby supporting their role in maintaining a healthy lifestyle (Y. W. Park & Nam, 2015).

Collectively, these microbial-derived bioactive compounds not only improve the nutritional and functional quality of fermented dairy products but also underscore their potential in the prevention and management of various health disorders. This has spurred considerable scientific interest in optimizing fermentation conditions and microbial strains to enhance the bioavailability and efficacy of these compounds in functional dairy foods.

Natural sources of bioactive compounds used in fermented dairy products.

Health effect of fortification of fermented dairy products with bioactive rich natural compounds

Table 02a - quantitative evaluation of the effects of the bioactive compounds.

Dairy product	Natural Additive	Major bioactive ingredients	Experimental findings	Reference
Set yoghurt	Passion fruit juice (PFJ)	polyphenols	Total phenolic content (µg GAE/g) of set yoghurt increased from 1.69 to 11.4 with the addition of 2.5% PFJ. The antioxidant effect increased from 2.75% to 35.8% PFJ. (DPPH)	(Ning et al., 2021)
yoghurt	Red ginseng extract(RGE)	Polyphenols (ginseng saponins) Flavonoids	Total phenolic content (mg of GAE/100 g) and total flavonoid content (mg of GAE/100 g) of yogurt increased from 8.1 to 41.1 and from 8.4 to 18.7 with the addition of 2% red ginseng extract respectively. The antioxidant effect (µg/mL) of yoghurt increased from 5.8 - 13.1 to 18.7 - 41.1 with the addition of 2% red ginseng extract. (DPPH RSA)	(Park et al., 2018)
Probiotic yogurt	Green, black and white tea	Polyphenols	The highest total phenolic content (mg GAE/ml) recorded in green tea yoghurt (526.34). There was a significant reduction in TPC of all tea enriched yoghurts during storage. ($p<0.05$) The antioxidant activity of plain yoghurt (3-7%) increased into 83-97% with the addition of tea extracts ($p<0.05$)	(Muniandy et al., 2016)
yoghurt	Pomegranate seed (PS) and jacaranda seed (JS)	Fatty acids (conjugated linolenic acid) (CLnAS)	CLnAS of PS (62-63mg/100g) increased by 1.8-fold compare to JS yogurt. Highest antioxidant activity recorded in PS (61.55%). There was significantly decrease in antioxidant effect during 28 days.	(Van Nieuwenhove et al., 2019)

Table 02b - quantitative evaluation of the effects of the bioactive compounds.

Yoghurt	Walnut Hazelnut Almond Pistachio	Vitamins(folic acids, tocopherols) Minerals (selenium) Fatty acids	Highest folic acid amount (29.29 µg/100g) and fatty acid amount (69.54%) recorded in walnut enriched yoghurt. Highest Selenium (2.65 µg/100g) and ϒ-tocopherol (1.94 mg/100g) recorded in pistachio enriched yoghurt. Highest α-tocopherol content recorded in hazelnut enriched yoghurt (4.87 mg/100g). Almond enriched yoghurt had high protein (5.91wt/wt%) and walnut enriched yoghurt had high fat content(6.10wt/wt%). Lowest count of streptococci and L. *bulgaricus* recorded in walnut enriched yogurt.	(Ozturkoglu-Budak et al., 2016)
Dahi (Indian yoghurt)	Flax seed oi microcapsules	Fatty acids(α-linolenic acid)	A- linolenic acid (ALA) increased up to 10.62% with addition of 2% micro encapsulated flaxseed oil powder. ALA reduced (8.40) continuously during 15 days.	(Goyal et al., 2016)
Yoghurt	Carrot waste extract (CW)	Carotenoids	The highest beta-carotene bleaching antioxidant capacity(9.36 µmolTE/180g), reducing power(3.11 µmolTE/180g) recorded with 5CW beads enriched yoghurt. Highest antihyperglycemic activity(13.91%) and anti-inflammatory activity(15.27%) recorded with 5CW beads enriched yoghurt.	(Šeregelj et al., 2021)
Yoghurt	Seaweeds varieties (*Aacophyllum nodosum, fucus vesiculosus*)	Phenolics	Seaweed enriched yoghurts didn't exhibit cellular antioxidant activity.	(O'Sullivan et al., 2016)
Soft cheese	Clove Thyme Ginger	Phenolics (thymol, eugenol)	The minimum inhibitory concentration of clove, thyme and ginger essential oils was 0.001% for *S. aureas, E.coli, Ent. faecalis, P.aeruginosa, P.fluorascens, C. albicans, A. parasiticus* .	
Cream cheese	Dried curry leaves (DCL)	Phenolics	The highest phenolic content (193.33 mg GAE/100g) and highest antioxidant effect (lowest value of 0.06 IC_{50} (mg/ml) recorded with 0.25% DCL addition. Moisture and total solid content didn't significantly affect with DCL addition. Highest FRAP value (0.17Mm Fe(Ⅱ) was recorded with 0.25% DCL addition. Lowest fat level (33.01%) recorded with 0.25% DCL addition.	(Weragama et al., 2021)
Soft cheese	*Arbutus unedo L.* (AUL)	Phenolics Dietary fiber	Highest antioxidant effect recorded with 1g/L AUL extract and it decreased during 5days of storage period. (DPPH method) Fat and ash didn't significantly affect by AUL addition. Protein (46%) significantly increased by 1g/L AUL addition.	(Masmoudi et al., 2020)

Table 02b - quantitative evaluation of the effects of the bioactive compounds.

Processed cheese spread	Black rice powder(BRP)	Crude fiber phenolics	Highest total phenolic content (44.23 mg GAE/g) recorded by 6% BRP addition and it was reduced (36.62 mg GAE/g) gradually during 90days storage. Highest antioxidant scavenging activity 64.82% recorded 6% BRP addition and it was reduced (54.97) gradually during 90days storage. Dry matter and far were not significantly differed due to BRP addition. Protein (9.42%) was reduced by 6% BRP addition. Noticeable antimicrobial effect didn't recorded with BRP addition.	(Khalil & Elkot, 2020)
Labneh cheese	Pepper varieties Doux Marconi geonet, balgarian ratunt, kurtovska kapia, Doux Marconi geonet x kurtovska kapia, Doux	Phenolics Carotenoids Chlorophyll	The highest carotenoids (570.02 µg/100g), chlorophylls (960.29 µg/100g), total phenols (34.24GAE/100g), total flavonoids (0.05mg QE/100g) and antioxidant effect (28.95 Mm TE/100g) recorded with addition of kurtovska kapia variety. A slight decrease in phenols and flavonoids observed during storage. A significant difference for moisture, fat, total protein didn't recorded with addition of pepper.	(Balabanova et al., 2020)
Cream cheese	Sea buckthorn lipophilic extracts(SBLE)	Carotenoids polyphenols	28.89% antiradical activity recorded with addition of 2.5% SBLE. 11.95% fat level recorded with 2.5% SBLE addition. Total viable count(CFU/g)*2 reduced from 54 to 10 with 2.5% SBLE addition after 10 days storage.	(Ghendov-Moşanu et al., 2020)
Fresh cheese	Flaxseed oil(FS) *Camelina sativa* oil(CAM) Raspberry(RAS) *Echium plantagineum* oil(EC) Blackcurrent oil(BC)	Fatty acids(omega-3 FA and omega-6 FA)	Highest omega-6 FA (12.21mg/g) recorded with addition of BC oil. Highest omega-3 FA (4.43 mg/g) recorded with addition of CAM oil. Omega-3 FA (α-linolenic acid) in FS enriched cheese showed a significance difference during storage.($p<0.01$) Protein, moisture and ash didn't significantly differ with vegetable oil addition. Fat content increased (23.00%w/w) with the addition of RAS oil. Antimicrobial effect didn't show a significant difference among cheese samples.	(Dal Bello et al., 2017)
White cheese	Wheat germ (WG)	Fatty acids	High amount of poly unsaturated fatty (PUFA)acids and saturated fatty acids (SFA) recorded with 2% WG addition. SFA and PUFA increased significantly during 30 days storage.($p<0.05$) Highest percentage of fat (13.93), protein (18.09), dry matter(42.03) and salt(3.85) recorded with 2% WG addition. fat, protein, dry matter and salt content increased significantly during storage ($p<0.05$, $p<0.01$)	(Çetinkaya & Öz, 2020)
Butter	Olive pomace (OP) Olive mill waste water (OMWW)	Phenolics	Total mesophilic aerobic flora of butters enriched with 8mg of OMWW and 8mg of OP showed zero level. Antibacterial and antifungal effects showed with OMWW and OP addition for total coliforms, yeast and moulds and *Staphylococcus aureus*	(Mikdame et al., 2020)

Table 02c - quantitative evaluation of the effects of the bioactive compounds.

Butter	Cinnamon Extract(CE)	phenolics	Total phenolic content(µg GAE/mg) of 135.62 and antioxidant activity of 38.73% recorded in cinnamon enriched butter. Crude fat (82.12%), protein (0.76%), moisture (14.65%), CHO (0.08%), ash (2.39%) recorded with CE addition. Yeast and moulds weren't in cinnamon enriched yoghurt throughout the storage. Highest antimicrobial activity recorded in cinnamon enriched butter. (total plate count of $1.63*10^2$ CFU/g at 8th week).	(Vidanagamage et al., 2016)
Fermented milk	Pomegranate peel extract(PPE)	Phenolics	Significantly high total phenolic content and antioxidant activity recorded in fermented milk with PPE addition. The concentration below the 2% w/v didn't show an antimicrobial effect against *L. acidophilus*	(Chan et al., 2018)
Fermented milk	Grape marc (GM) Olive pomace (OP)	Phenolics	Highest total phenolics(98.5 µg GAE/g) level recorded with OP addition and it decreased by 28% during 50days storage.($p<0.05$) Highest antiradical power (ARP) (72.75%) recorded with OP addition and longer storage wasn't affected significantly on quantity of ARP. *S. thermophilus* count decreased not (statistically significant) during 14 days and the count was similar to control sample after 14 days *L. acidophilus* remained constant.	(Aliakbarian et al., 2015)
Kefir	Black mulberry juice(BMJ) Pomegranate juice(PJ) Strawberry juice(SJ) Black carrot juice(BCJ)	Phenolics (Anthocyanin)	Highest anthocyanin content(404.5 mg/L) and stability(32.1 weeks) recorded with 25% of BMJ addition. Antioxidant effects increased with 25% (1.8-4.8 times) compare to the plain kefir. Highest with BCJ addition-6.39). Highest antioxidant activity(6.39 mM Trolox/ml) recorded with 25% BCJ addition. Most decreased lactobacillus count showed in PJ 10% and 25% and SJ 25%. Lowest Lactococcus count recorded in PJ 25%.	(Kabakcı et al., 2020)
Kefir	Mango peel(MP)	Phenolics	21.35% increased antioxidant activity recorded in mango peel enriches kefir compared to the control kefir. Antioxidant activity increased 113%(13.81 µmol TE/g) compare the control by addition of MP.(DPPH RSA method) effect on antimicrobial effect against acidic bacteria and yeast.	(Vicenssuto & de Castro, 2020)

Commonly Found Effects of Bioactive Compounds

Antioxidant Effect

The antioxidant effect refers to the ability of a compound to mitigate or prevent the formation of oxidizable substances during metabolism, thereby minimizing damage to the body (Brainina et al., 2019). Oxidation is primarily driven by reactive oxygen species (ROS) such as superoxide ions, singlet oxygen, lipid peroxides, and hydroxyl radicals. Antioxidants, which are abundant in fruits and vegetables, play a key role in reducing oxidative stress caused by these ROS (Serafini & Peluso, 2016).

Bioactive compounds derived from natural sources act by converting ROS into non-radical species, disrupting autoxidative chain reactions, and lowering local oxygen concentrations (Hunyadi, 2019). Oxidative stress is a contributing factor to various chronic diseases including cancer, cardiovascular diseases, diabetes, age-related muscular degeneration, and ocular disorders.

In fermented dairy products, the DPPH Radical Scavenging Activity (RSA) method is commonly employed to assess antioxidant activity. DPPH, a purple-colored radical, becomes colorless upon receiving electrons from antioxidants. Other analytical methods used include ABTS, FRAP, and FIC assays. Natural antioxidants include phenolic compounds, carotenoids, and vitamins, which not only contribute to health benefits but also improve product shelf-life and quality (Wilson et al., 2017).

For example, Masmoudi et al. (2020) reported increased antioxidant activity in products supplemented with 30% spirulina powder (SP), with DPPH RSA and ABTS values reaching 9.19 mg GAE/mL and 0.38 mg GAE/mL, respectively. Muniandy (2016) found that green tea-enriched yogurt showed the highest antioxidant activity according to DPPH RSA and FRAP methods, while black tea-enriched yogurt performed best in the FIC method. This suggests that DPPH RSA and FRAP assess primary antioxidant activity, while FIC evaluates secondary antioxidant activity. However, antioxidant activity tends to decline during storage due to phenolic degradation.

Antimicrobial Effect

Microorganisms in food can alter its color, texture, odor, flavor, and safety. Bioactive compounds, especially phenolics, possess antimicrobial properties against both Gram-negative and Gram-positive bacteria due to the presence of functional groups like hydroxyls (Khameneh et al., 2019). These compounds are found naturally in herbs, spices, fruits, vegetables, seeds, and leaves.

Phenolic compounds such as eugenol, thymol, carvacrol, vanillin, allicin, cinnamic aldehydes, and allyl isothiocyanate contribute significantly to the antimicrobial properties of herbs and spices (Ghendov-Moşanu et al., 2020; Ozturkoglu-Budak et al., 2016). Fatty acids and dietary fibers also play supporting roles (Khalil & Elkot, 2020; Mehdizadeh et al., 2019).

The mechanisms of antimicrobial activity include membrane disruption, pH reduction, and enzymatic inhibition. Microbial testing often targets yeasts, molds, coliforms, Streptococcus species, and psychrotrophs (Enab et al., 2012). A study by Ozturkoglu-Budak et al. (2016) found a positive correlation between plant-based fortification and antioxidant activity. Additionally, walnut-enriched yogurt showed the lowest counts of *Streptococcus* and *L. bulgaricus*.

Anti-Hyperglycemic Properties

Diabetes is one of the most prevalent non-communicable diseases globally. Bioactive compounds from natural sources like fruits, vegetables, herbs, and grains can lower blood glucose levels (Vinayagam et al., 2016). Phenolics are particularly effective, as they reduce insulin resistance, promote glucose uptake, increase glycogen synthesis, and inhibit carbohydrate-digesting enzymes such as α-glucosidase and α-amylase.

The efficacy of these compounds is often evaluated using α-glucosidase inhibition assays. Bioactives affect multiple organs, including the liver, pancreas, intestine, muscle, and adipose tissue. Šeregelj et al. (2021b) demonstrated that plant-based fortification correlates positively with anti-hyperglycemic activity. Kiros et al. (2016) found improved glycemic control in carrot juice-enriched products.

Anticarcinogenic Effect

Dietary habits play a significant role in the prevention of chronic illnesses, including various types of cancer. Epidemiological studies have linked high fruit, vegetable, and grain intake with reduced risks of heart disease, cancer, diabetes, Alzheimer's, and age-related decline (Subramaniam et al., 2019). The National Cancer Institute has recognized approximately 35 plant-based foods with potential anti-cancer properties, including garlic, soybeans, ginger, licorice root, and cruciferous vegetables such as broccoli and cabbage.

Oxidative stress, which damages macromolecules like DNA, proteins, and lipids, contributes to carcinogenesis and cardiovascular disease. Antioxidants, particularly phenolics and carotenoids from plants, mitigate this damage (Chandra et al., 2012). Rosemary, due to its phenolic hydroxyl groups, is a strong candidate for chemoprevention. Its bioactive compounds exhibit antimicrobial, antiviral, anti-inflammatory, and anticarcinogenic properties (Sereiti et al., 1999; Aherne et al., 2007; Moore et al., 2016).

Limitations

Extraction Method

Traditional extraction methods such as hydroalcoholic distillation, Soxhlet extraction, and maceration are commonly used to extract bioactive compounds. These methods often require high solvent volumes and long extraction times. In hydro distillation, high temperatures can degrade heat-sensitive compounds, potentially leading to inaccurate estimations (Ahmed et al., 2021b; Qiu et al., 2021; Ribeiro et al., 2016).

Soxhlet extraction, developed by Franz Rizz Von Soxhlet, uses solvents to extract oils and other bioactives but also exposes compounds to heat, risking degradation (Sasidharan et al., 2011). Maceration, on the other hand, avoids heat and better preserves thermolabile compounds, though it still demands considerable time and results in crude extracts that require further purification.

Emerging methods like enzyme-assisted extraction, supercritical fluid extraction, pressurized liquid extraction, ultrasound-assisted extraction, microwave-assisted extraction, and pulsed electric field extraction offer advantages in efficiency and selectivity but are cost-prohibitive for many research applications (Azmir et al., 2013).

Storage Effect

Storage is a critical factor in evaluating the effectiveness of bioactive compounds in fortified fermented dairy products. Over time, the efficacy of these compounds may diminish due to degradation or complex formation with milk proteins (Josipovid et al., 2015; Ozturkoglu-Budak et al., 2016). However, some studies have shown increased bioactivity post-storage, attributed to microbial breakdown and subsequent release of phenolics (Vicenssuto & de Castro, 2020a). Stabilization methods such as microencapsulation are being explored to preserve bioactivity during storage (Aramrueang et al., 2019).

Methodology of Investigation

The DPPH Radical Scavenging Assay is the most widely used method to assess antioxidant activity. In this assay, the purple DPPH radical is reduced to a colorless product by antioxidant compounds, typically measured at 515–528 nm. Additional techniques include the ABTS assay, Ferric Reducing Antioxidant Power (FRAP), and Ferric Ion Chelating (FIC) methods. Each method evaluates different aspects of antioxidant capacity, ranging from electron donation (DPPH, FRAP) to metal ion chelation (FIC), providing a comprehensive understanding of antioxidant potential

Conclusion

This review aimed to evaluate the effects of bioactive plant compounds on fermented dairy products. The findings highlight the significant potential of incorporating these compounds into products such as yogurt and cheese, which are widely consumed and therefore ideal vehicles for nutritional enhancement. Among the various sources, spices and fruits emerged as the most commonly used natural carriers of bioactive compounds, largely due to their favorable sensory properties. Furthermore, the antioxidant effects of these compounds have been extensively investigated, attributed to the high phenolic content present in many plant sources. Future research could focus on elucidating the specific interactions between bioactive compounds and fermented dairy matrices, which would help to better differentiate their functional and sensory effects.

Acknowledgements

The successful accomplishment of this study resulted by the guidance of Faculty of Livestock, Fisheries and Nutrition Wayamba University of Sri Lanka. I give my great full thank for my supervisors Mrs. M.A.L.S.S. Munasinghe for her brilliant supervision and guidance of me from the beginning of proposals writing to the submission of this dissertation & Mrs. H.N.N. Dilrukshi for the great advices given me to keep me on focus on the study. I would like to give my thank for Mr. W.A.D.V. Weerathilake, Head of the Department of Livestock Fisheries & Avian Sciences, for his great support during planning and developing my research

Abstract

Heat stress (HS) significantly impacts the welfare of broiler chickens, which play a vital role in the global meat industry. The effects of heat stress on the colon of chickens are not yet fully understood. This study aimed to determine whether the inclusion of zinc in the diet of heat-stressed broilers could enhance their ability to manage with heat stress. Specifically, we investigated the impact of organic zinc supplementation on colon histology and the expression of heat stress-related genes in broiler chickens. A total of 1024 Xueshan chickens were assigned to four experimental groups: control, heat stress (HS), 90 mg/kg zinc, and HS with 90 mg/kg zinc. The results demonstrated that zinc intake significantly improved villus height (VH) and the VH:crypt depth (CD) ratio in the colon compared to the HS group, while a decrease in crypt depth and villus width was observed in both zinc-supplemented groups. Additionally, zinc administration led to higher levels of GSH, CAT, and SOD along with reductions in MDA and ROS compared to the HS group. It also significantly enhanced the relative ATP levels and enzymatic activities of complexes I, III, and V as compared to the HS condition. Furthermore, the protein expression of TFRC, ACSL4, PRX, and LPCAT3 were notably reduced in the HS+Zn group relative to the HS group. Zinc intake also decreased the enrichment of transcriptional regulators SRC1, P300, and RORγ at the promoter regions of PRX, LPCAT3, and ACSL4. A significant reduction in histone active marks, including H3K27ac and H3K9ac were observed at the loci of LPCAT3 and ACSL4 in the HS+Zn group compared to the HS group. This research highlights the potential of organic zinc as a strategy for modulating the oxidative genes TFRC, ACSL4, PRX, and LPCAT3 in the colon of chickens through the regulation of nuclear receptor RORγ and histone modifications.

Key words: *Oxidative stress; histone modification; colon; zinc; broiler chicken*

The Place of Animal Production in the Agricultural Sector: Economic Contributions and Future Perspectives

Mutlu Bulut[1]

[1]Department of Animal Production and Technologies, Faculty of Agricultural Sciences and Technologies, Niğde Ömer Halisdemr uiversity, Niğde, Türkiye

Abstract

This study examines the place of animal production in the agricultural sector in Türkiye, its economic contributions and its potential for the future in a multifaceted manner. According to the research findings, the share of the agricultural sector in Türkiye's 1,118.25 billion dollars of GDP in 2023 will be approximately 6%, while the share of animal production in agricultural production will be around 35%. This rate remains below the 45% level in the European Union countries, offering significant potential that can be developed. In the study, data for the period 2018-2024 were analyzed, and fluctuations in the number of large and small cattle were detected. After the increasing trend in large cattle between 2018-2021, a decrease was observed and a partial recovery was observed in 2024, while in the number of small cattle, a decrease was observed after the peak in 2021 and a tendency to increase again in 2024. In poultry farming, especially in 2024, there was a 22% increase in meat chicken production, while there was a significant decrease of 15.5% in the number of egg chickens. As a result of the research, it is recommended that feed costs be reduced for the sustainable development of Türkiye's animal production sector, the productivity of local breeds be increased, systems to adapt to climate change be developed, the organization of small and medium-sized producers be supported, digital technologies be disseminated and value-added production be focused on. It is emphasized that long-term and predictable support policies should be implemented, holistic strategies should be developed to increase the share of animal production in the agricultural economy and bring it closer to EU standards.

Key Words: *Agricultural Production, Animal Production, Rural Development, Sustainable Agriculture*

Tarım Sektöründe Hayvansal Üretimin Yeri: Ekonomik Katkılar ve Geleceğe Yönelik Perspektifler

Özet

Bu çalışma, Türkiye'deki hayvansal üretimin tarım sektöründeki yerini, ekonomik katkılarını ve geleceğe yönelik potansiyelini çok yönlü olarak incelemektedir. Araştırma bulgularına göre, 2023 yılında Türkiye'nin 1.118,25 milyar dolarlık GSYİH'si içerisinde tarım sektörünün payı yaklaşık %6 olup, tarımsal üretimin içinde hayvansal üretimin payı %35 civarındadır. Bu oran, Avrupa Birliği ülkelerindeki %45 düzeyinin altında kalarak geliştirilebilecek önemli bir potansiyel sunmaktadır. Çalışmada 2018-2024 dönemi verileri analiz edilmiş, büyükbaş ve küçükbaş hayvan varlığında dalgalanmalar tespit edilmiştir. Büyükbaş hayvancılıkta 2018-2021 arası görülen artış eğiliminin ardından düşüş ve 2024'te kısmi toparlanma, küçükbaş hayvan varlığında ise 2021'deki zirvenin ardından düşüş ve 2024'te yeniden artış eğilimi gözlenmiştir. Kümes hayvancılığında özellikle 2024'te et tavuğu üretiminde %22'lik artış kaydedilirken, yumurta tavuğu sayısında %15,5'lik ciddi bir düşüş yaşanmıştır.
Araştırma sonucunda, Türkiye'nin hayvansal üretim sektörünün sürdürülebilir gelişimi için yem maliyetlerinin düşürülmesi, yerli ırkların verimliliklerinin artırılması, iklim değişikliğine uyum sağlayacak sistemlerin geliştirilmesi, küçük ve orta ölçekli üreticilerin örgütlenmesinin desteklenmesi, dijital teknolojilerin yaygınlaştırılması ve katma değerli üretime odaklanılması önerilmektedir. Uzun vadeli ve öngörülebilir destekleme politikalarının uygulanması, hayvansal üretimin tarımsal ekonomideki payının artırılması ve AB standartlarına yaklaştırılması için bütüncül stratejilerin geliştirilmesi gerektiği vurgulanmaktadır.

Anahtar Kelimeler: *Tarımsal Üretim, Hayvansal Üretim, Kırsal Kalkınma, Sürdürülebilir Tarım*

Giriş

Tarım sektörü, toplumların ekonomik, sosyal ve çevresel kalkınmasında temel bir rol üstlenmektedir. Bu sektör, yalnızca bitkisel üretimi değil, aynı zamanda hayvansal üretimi de kapsayarak geniş bir üretim yapısını içinde barındırmaktadır. Özellikle hayvansal üretim, hem gıda güvenliği hem de beslenme kalitesi açısından kritik öneme sahiptir. Hayvansal ürünler, temel protein, vitamin ve mineral kaynağı olmalarının yanı sıra, ekonomik anlamda

da istihdam ve gelir yaratma potansiyeliyle dikkat çekmektedir (FAO, 2023). Ayrıca hayvansal üretim, tarımsal üretimin sürekliliğini sağlamada ve kırsal nüfusun geçim kaynaklarını çeşitlendirmede kilit bir rol oynamaktadır. Bu yönüyle sektör, hem bireysel refahın artırılmasına hem de makro düzeyde ekonomik büyümeye katkı sunmaktadır.

Hayvansal üretim, sadece kırsal bölgelerde değil, şehirleşmeyle birlikte artan hayvansal gıda talebi nedeniyle ulusal düzeyde stratejik öncelik taşıyan bir alan haline gelmiştir. Et, süt, yumurta gibi hayvansal ürünler; bireylerin sağlıklı beslenmesini sağlamasının ötesinde, ihracat kalemleri arasında yer alarak ülke ekonomisine doğrudan katkı sunmaktadır (OECD, 2022a). Ayrıca hayvancılık faaliyetleri, yem bitkileri üretimi, veteriner hizmetleri, lojistik ve gıda işleme gibi birçok alt sektörle güçlü bir ilişki içerisinde olup, ekonomik çarpan etkisi yaratmaktadır (Turan, 2024).

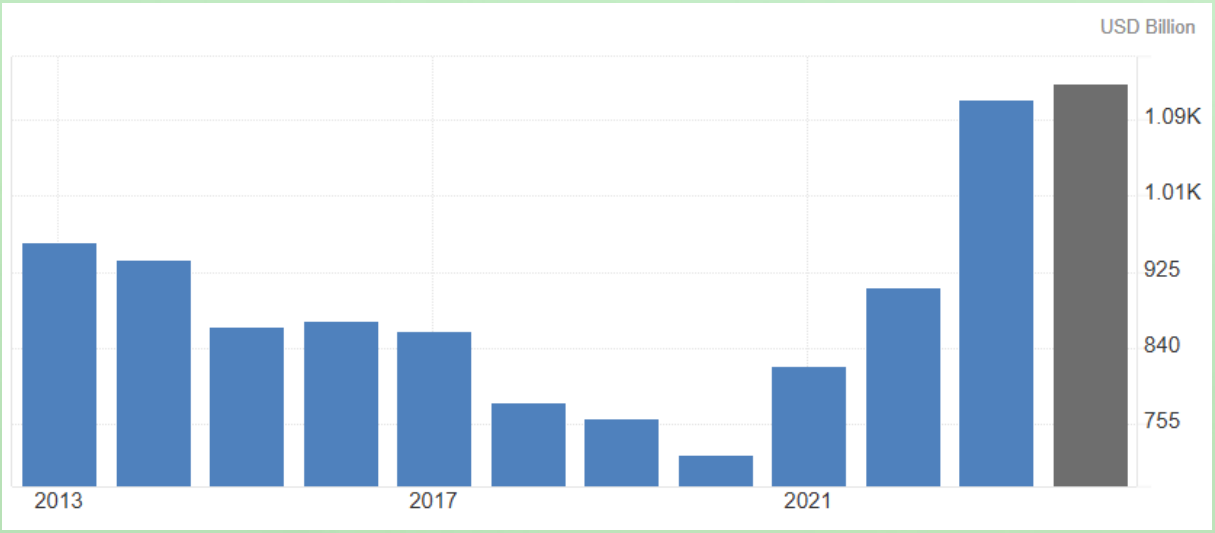
Bununla birlikte, hayvansal üretimin önemi yalnızca ekonomik katkılarla sınırlı değildir. Kırsal kalkınmanın sağlanmasında, tarımsal üretimin çeşitlendirilmesinde ve kırsalda göçün önlenmesinde de önemli bir rol üstlenmektedir. Özellikle küçük ölçekli işletmeler için hayvancılık, sürekli gelir sağlayan bir faaliyet alanı olması bakımından sosyal sürdürülebilirliğin anahtarıdır (Demir vd., 2016). Bu yönüyle hayvansal üretim, sadece ekonomik değil, aynı zamanda sosyo-kültürel bir işlev de görmektedir. Hayvancılık faaliyetleri, kadınların ve gençlerin üretim sürecine aktif katılımını destekleyerek toplumsal cinsiyet eşitliği ve kuşaklar arası işbirliği açısından da olumlu etkiler yaratmaktadır. Ayrıca, geleneksel hayvancılık kültürünün korunması, kırsal kimliğin yaşatılması ve yerel festivaller gibi kültürel etkinliklerin sürdürülmesinde de belirleyici rol oynamaktadır.

Ancak, iklim değişikliği, yem maliyetlerindeki artış, arazi kullanımı baskıları ve hayvancılığın çevresel etkileri gibi küresel ve yerel düzeyde yaşanan bazı sorunlar, hayvansal üretimin sürdürülebilirliğini tehdit etmektedir (Steinfeld vd., 2006). Bu durum, hayvansal üretimin geleceğini yeniden düşünmeyi ve politika yapıcıların sektöre yönelik uzun vadeli stratejiler geliştirmesini zorunlu kılmaktadır. Aynı zamanda yeni teknolojilerin, verimlilik artırıcı yöntemlerin ve çevre dostu uygulamaların entegrasyonu, sektörün dönüşüm sürecinde kilit rol oynamaktadır (Karaman, 2018).

Bu çalışma, tarım sektörünün önemli bir alt bileşeni olan hayvansal üretimin mevcut yerini, ekonomik katkılarını ve geleceğe yönelik potansiyelini çok yönlü olarak ele almayı amaçlamaktadır. Çalışma kapsamında, hayvansal üretimin tarımsal ekonomi içerisindeki stratejik rolü değerlendirilerek, hem ulusal hem de küresel gelişmeler ışığında sektörün güçlü ve zayıf yönleri analiz edilecektir. Böylece hem akademik literatüre katkı sunmak hem de sektörel gelişim için politika yapıcılara yol gösterici öneriler geliştirmek hedeflenmektedir.

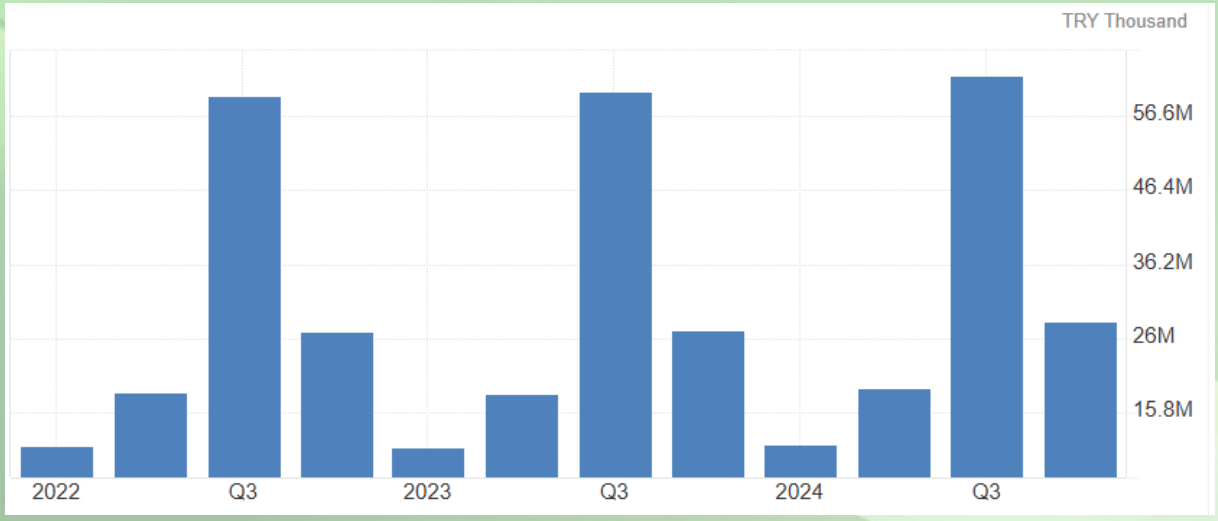
Materyal ve Yöntem

Bu çalışmada, Türkiye'deki hayvansal üretimin tarım sektöründeki yeri, ekonomik katkıları ve geleceğe yönelik perspektiflerinin analizi için ikincil veri kaynakları kullanılmıştır. Araştırmanın temel veri kaynakları Dünya Bankası (World Bank), Birleşmiş Milletler Gıda ve Tarım Örgütü (FAO) ve Türkiye İstatistik Kurumu (TÜİK) tarafından sağlanan resmi istatistiklerden oluşmaktadır.



Araştırma kapsamında, söz konusu kurumların veri tabanlarından elde edilen zaman serisi verileri değerlendirilmiş ve analiz edilmiştir. Çalışmada büyükbaş hayvan varlığı (sığır, manda), küçükbaş hayvan varlığı (koyun, keçi) ve kümes hayvancılığı (et tavuğu, yumurta tavuğu, hindi, kaz, ördek) verilerini içeren kapsamlı bir hayvansal üretim analizi gerçekleştirilmiştir.

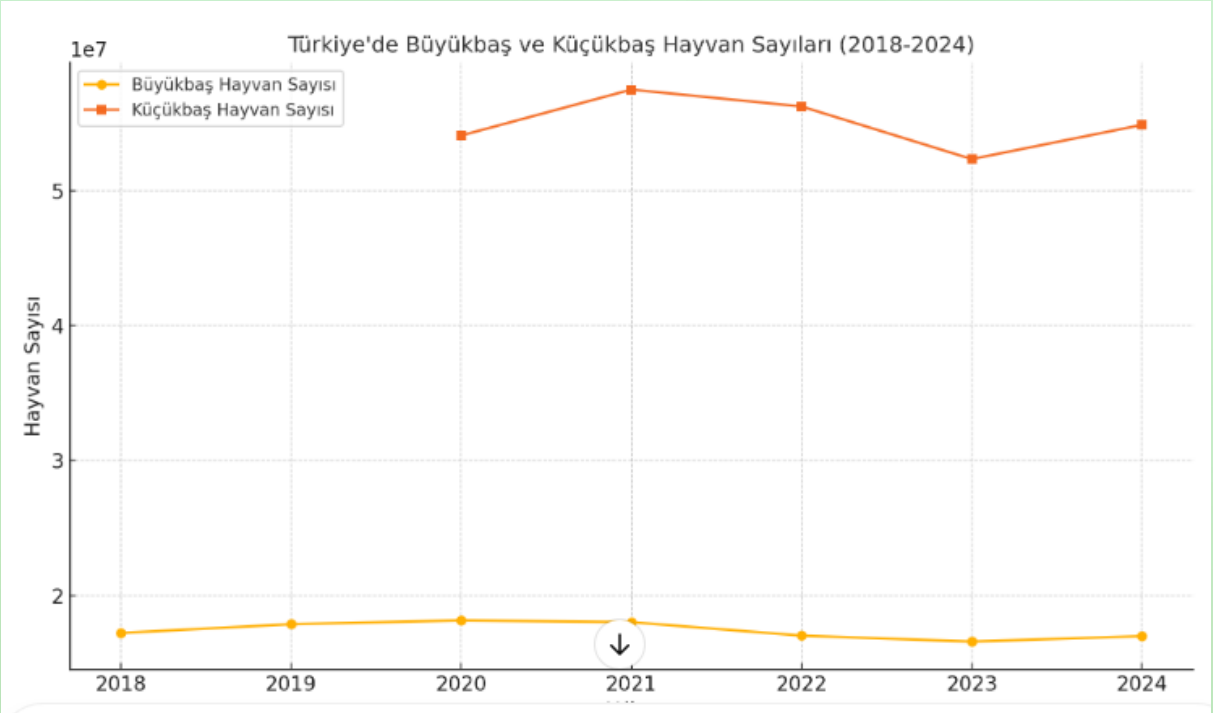
Metodolojik açıdan çalışmada, elde edilen verilerin betimsel analizi yapılmış ve zaman içerisindeki değişim eğilimleri değerlendirilmiştir. Büyükbaş, küçükbaş ve kanatlı hayvan varlığının yıllara göre gösterdiği dalgalanmalar, artış ve azalış trendleri incelenmiş ve bu değişimlerin olası nedenleri tartışılmıştır. Ayrıca, söz konusu verilerin Türkiye ekonomisine katkıları, tarımsal hasıla içindeki payları, et ve süt üretimi açısından önemi ve gıda güvenliğine etkileri yorumlanmıştır.



Bulgular ve Tartışma

Araştırma kapsamında incelenen TÜİK, Dünya Bankası ve FAO verilerinden hareketle, Türkiye'de tarımsal üretim ve özelde hayvansal üretimin ekonomik boyutu, yapısal özellikleri ve gelişim eğilimleri analiz edilmiştir. Elde edilen bulgular, Türkiye'nin 2023 yılında 1.118,25 milyar dolarlık GSYİH'si içerisinde tarım sektörünün %6'lık bir paya sahip olduğunu ve tarımsal üretimin içerisinde hayvansal üretimin %35 düzeyinde seyrettiğini göstermektedir. Büyükbaş hayvan varlığında 2018-2021 döneminde gözlenen artış trendinin ardından yaşanan düşüş ve 2024'teki kısmi toparlanma, küçükbaş hayvan sayılarında 2021'deki zirve noktasının ardından 2023'te yaşanan düşüş ve 2024'te gözlenen yeniden artış eğilimi, ve kümes hayvancılığında özellikle et tavuğu üretiminde 2024'te kaydedilen ciddi artış, hayvansal üretim sektörünün dinamik yapısını ortaya koymaktadır. Bu veriler ışığında, hayvansal üretimin ekonomik katkıları, gelişim potansiyeli ve karşılaştığı zorluklar aşağıda detaylı olarak sunulmaktadır.

Türkiye'nin hayvansal üretim sektörü, ulusal ekonomide kritik bir konuma sahiptir. Dünya Bankası verilerine göre, 2023 yılında Türkiye'nin 1.118,25 milyar dolarlık GSYİH'si (Şekil 1) içerisinde tarım sektörünün payı yaklaşık %6'dır ve bu tarımsal üretimin içerisinde hayvansal üretimin payı %35 civarındadır. Bu oran, Avrupa Birliği ülkelerindeki %45 düzeyinin altında kalarak, geliştirilebilecek önemli bir potansiyel olduğunu göstermektedir. 2024 yılının üçüncü çeyreğinde tarımsal GSYİH 62.039.644 bin TL ile rekor seviyeye ulaşmış, ancak dördüncü çeyrekte 28.375.071 bin TL'ye gerileyerek belirgin bir dalgalanma sergilemiştir. 1998-2024 döneminde tarımsal GSYİH ortalaması 22.774.874,69 bin TL olarak gerçekleşmiş, bu da tarım ve hayvancılık sektörünün ekonomideki istikrarlı ama dalgalı seyrinin bir göstergesidir (Şekil 2). Türkiye'de hayvansal üretim sektörünün GSYİH içindeki payının, Avrupa Birliği ülkeleri ortalamasının (%45) altında kalması, bu alanda hâlen değerlendirilmeyi bekleyen önemli bir büyüme potansiyeli olduğunu göstermektedir (European Commission, 2023). 2024 yılı üçüncü çeyreğinde tarımsal GSYİH'nin rekor seviyeye ulaşması, uygun üretim ve yatırım koşulları sağlandığında sektörün ekonomiye ciddi katkılar sunabileceğini ortaya koymaktadır. Ancak dördüncü çeyrekte yaşanan keskin düşüş, tarım ve hayvancılık sektörünün iklimsel, yapısal ve piyasa koşullarına oldukça duyarlı olduğunu göstermektedir. Literatürde de benzer şekilde, tarım sektörünün mevsimsellik ve iklim değişkenliği nedeniyle ekonomik performansında dalgalanmalar yaşadığı vurgulanmaktadır (OECD, 2021). Türkiye'de hayvansal üretimin sürdürülebilirliği, yatırım ortamının güçlendirilmesi, üreticilerin desteklenmesi ve altyapının dijitalleşmesiyle doğrudan ilişkilidir (FAO, 2022). Bu bağlamda, istikrarlı büyümenin sağlanabilmesi için yalnızca üretim hacmi değil, aynı zamanda üretim kalitesi, lojistik ve pazarlama altyapısının da güçlendirilmesi gerektiği söylenebilir.



Şekil 1. 2013-2024 Türkiye GSYİH Rakamları (Dünya Bankası, 2025)

Şekil 2. Tarımın Türkiye GSYİH İçerisindeki Payı (TÜİK, 2025a)

Büyükbaş hayvan varlığında 2018-2021 arasında görülen artış trendi (17,2 milyondan 18,1 milyona) sonrasında yaşanan düşüş ve 2024'teki kısmi toparlanma (16.986.259 baş), sektördeki hassasiyeti ortaya koymaktadır. Benzer şekilde, küçükbaş hayvan sayısının 2020'de 54,1 milyondan 2021'de 57,5 milyona yükselmesi, ardından 2023'te 52,3 milyona gerilemesi ve 2024'te 54.902.668'e toparlanması, sektörün ekonomik koşullara ve politika değişimlerine ne denli duyarlı olduğunu göstermektedir (Şekil 3). Bu dalgalanmalar, yem maliyetleri, iklim koşulları, destekleme politikaları ve pazar dinamikleri gibi faktörlerden doğrudan etkilenmektedir.

Şekil 3. 2018-2024 Türkiye Büyükbaş ve Küçükbaş Hayvancılık rakamları (TÜİK, 2025b)

Türkiye'nin hayvansal üretim sektöründe dikkat edilmesi gereken en önemli husus, tarımsal üretim içerisindeki %35'lik payın AB standartlarına yaklaştırılması için stratejik politikaların geliştirilmesidir. Bu artış, katma değeri yüksek ürünlerle ekonomiye daha fazla katkı sağlayacaktır. Ayrıca, yem maliyetlerinin düşürülmesi için yerli yem hammaddesi üretiminin teşvik edilmesi, yem bitkileri ekiliş alanlarının genişletilmesi ve alternatif protein kaynaklarının araştırılması zorunlu hale gelmiştir. Yerli ırkların verimliliklerinin artırılması ve adaptasyon kabiliyetlerinin güçlendirilmesi için kapsamlı ıslah programları uygulanması da sektörün sürdürülebilirliği açısından kritik önem taşımaktadır.

İklim değişikliğinin hayvan varlığı üzerindeki etkilerini azaltmak için kuraklığa dayanıklı üretim sistemleri ve su kaynaklarının verimli kullanımı teşvik edilmelidir. Küçük ve orta ölçekli üreticilerin kooperatifler ve üretici birlikleri altında örgütlenmesinin desteklenmesi, pazarlama kanallarına erişimlerini kolaylaştıracak ve değer zincirindeki paylarını artıracaktır. Hayvancılık işletmelerinde dijital teknolojilerin ve akıllı çiftlik sistemlerinin yaygınlaştırılması ile verimlilik artışı sağlanması, hastalık yönetiminin geliştirilmesi ve üretim maliyetlerinin düşürülmesi mümkün olacaktır. İklim değişikliğinin hayvan varlığı üzerindeki olumsuz etkilerinin azaltılması için kuraklığa dayanıklı yem bitkilerinin ve üretim sistemlerinin teşviki, literatürde giderek daha fazla önerilen bir stratejidir. Özellikle su kaynaklarının daha verimli kullanılması, hem üretimin sürdürülebilirliğini artırmakta hem de çevresel baskıyı azaltmaktadır (Thornton vd., 2009). Küçük ve orta ölçekli üreticilerin kooperatifler ve üretici birlikleri çatısı altında örgütlenmeleri, değer zincirinde daha etkin bir rol oynamalarını sağlamakta ve pazarlama süreçlerinde rekabet güçlerini artırmaktadır (Birner & Resnick, 2010). Bu yapılanmalar sayesinde çiftçiler, hem girdi temininde hem de ürün pazarlamasında daha güçlü bir pozisyon elde etmektedir. Öte yandan, hayvancılık işletmelerinde dijital teknolojilerin ve akıllı çiftlik sistemlerinin entegrasyonu ile üretim süreci daha verimli, izlenebilir ve maliyet etkin hâle gelmektedir. Sensör teknolojileri, uzaktan sağlık takibi ve otomatik yemleme sistemleri gibi uygulamalar sayesinde hem hayvan refahı artmakta hem de üreticiye anlık veri ile karar alma kolaylığı sağlanmaktadır (Wolfert vd., 2017). Ayrıca, dijitalleşme sayesinde erken hastalık teşhisi ve etkin sürü yönetimi gibi kritik konularda da önemli gelişmeler yaşanmaktadır. Bu bulgular, iklim değişikliği ve piyasa dalgalanmaları gibi dışsal şoklara karşı hayvansal üretim sistemlerinin daha dirençli hâle getirilmesi gerektiğini ortaya koymaktadır.

Hayvansal üretimdeki dalgalanmaların önüne geçmek için uzun vadeli, öngörülebilir ve sonuç odaklı destekleme politikalarının uygulanması elzemdir. Hayvancılık sektörünün kırsal istihdamdaki kritik rolü gözetilerek, genç

çiftçilerin sektörde kalmasını sağlayacak teşvikler ve eğitim programları geliştirilmelidir. Hayvansal ürünlerde katma değerli üretimin teşvik edilmesi ihracat potansiyelini artıracak, özellikle coğrafi işaretli yerel ürünlerin desteklenmesi rekabet avantajı sağlayacaktır. Hayvan sağlığı ve refahı standartlarının yükseltilmesi, antimikrobiyal direncin azaltılması ve çevresel etkilerin minimize edilmesi için bütüncül yaklaşımların benimsenmesi de sektörün geleceği için hayati önem taşımaktadır.

Türkiye'nin hayvansal üretim sektöründeki dalgalanmaların azaltılması ve istikrarlı büyümenin sağlanması, gıda güvenliği, kırsal kalkınma ve ekonomik istikrar açısından stratejik öneme sahiptir. GSYİH içindeki payı ve kırsal ekonomideki rolü düşünüldüğünde, hayvansal üretimin sürdürülebilir kalkınma hedefleriyle uyumlu biçimde geliştirilmesi, ulusal ekonomiye önemli katkılar sağlayacak ve Türkiye'nin bu alandaki rekabet gücünü artıracaktır.

Türkiye'de hayvansal üretimin önemli bileşenlerinden biri olan kümes hayvancılığı, özellikle et ve yumurta üretimi açısından stratejik bir konuma sahiptir. TÜİK verilerine göre, 2018–2024 döneminde kümes hayvanı varlığında dikkate değer değişimler yaşanmıştır.

Türkiye 2018-2024 Kümes Hayvanları Üretim Rakamları (2018-2024)

Yıl	Et tavuğu (milyon)	Yumurta Tavuğu (milyon)	Hindi (Milyon)	Kaz (Milyon)	Ördek (milyon)
2018	223,2	124,0	3,5	1,2	0,6
2019	226,1	122,4	3,4	1,3	0,6
2020	239,4	121,3	3,2	1,4	0,5
2021	233,1	118,6	3,1	1,4	0,5
2022	228,7	122,8	2,8	1,5	0,5
2023	221,7	129,1	3,4	1,5	0,5
2024	270,5	109,1	2,8	1,4	0,4

Kaynak: TÜİK, 2025c

Türkiye'de kümes hayvancılığı son yedi yılda dalgalı bir seyir izlemiştir. Et tavuğu üretimi 2018-2020 arasında yükseliş göstermiş, ardından 2020-2023 döneminde düşüşe geçmiş, ancak 2024'te %22'lik etkileyici bir artışla 270,5 milyon adede ulaşmıştır. Bu durum, beyaz et tüketimindeki artışa ve sektördeki yatırımların olumlu sonuçlarına işaret etmektedir. Buna karşın, yumurta tavuğu sayısında 2023'ten 2024'e kadar ciddi bir düşüş yaşanmış, %15,5'lik azalmayla 129,1 milyondan 109,1 milyona gerilemiştir. Bu düşüş, yem maliyetlerindeki artış, hastalık salgınları veya pazar koşullarındaki değişimlerden kaynaklanabilir ve acil müdahale gerektirmektedir.

Hindi üretimi 2018'den 2022'ye kadar genel bir düşüş eğilimi göstermiş, 2023'te kısa süreli bir toparlanma yaşansa da 2024'te tekrar 2,8 milyon adede gerilemiştir. Hindi eti, sağlıklı beslenme arayışında olan tüketiciler için önemli bir alternatif olduğundan, bu düşüş trendi tersine çevrilmelidir. Kaz üretimi 2018-2022 arasında hafif bir artış göstermiş, ancak son iki yılda 1,5 milyondan 1,4 milyona gerilemiştir. Ördek üretimi ise yedi yıllık süreçte 0,6 milyondan 0,4 milyona düşmüştür. Bu alternatif kümes hayvanları, ülke genelinde yaygın olmamakla birlikte, belirli bölgelerde ekonomik potansiyele sahiptir ve çeşitlendirme stratejisi açısından desteklenmelidir.

Türkiye'nin kümes hayvancılığı sektöründe öncelikli olarak yumurta tavukçuluğuna özel önem verilmesi gerekmektedir. 2024'teki keskin düşüş, temel protein kaynağı olan yumurta üretimini olumsuz etkileyebilir ve fiyatları yükseltebilir. Yem girdilerinin maliyetini düşürmeye yönelik politikalar, hastalıklarla mücadele programları ve küçük-orta ölçekli üreticilere finansal destek sağlanması bu alanda öncelikli adımlar olmalıdır. Bununla birlikte, hindi yetiştiriciliğinin canlandırılması da sektörel çeşitlilik açısından kritiktir. Hindi eti, düşük yağ ve yüksek protein içeriğiyle sağlıklı beslenme trendlerine uygun bir üründür, dolayısıyla üretiminin teşvik edilmesi hem iç pazar hem de ihracat potansiyeli açısından faydalı olacaktır. Türkiye'nin kümes hayvancılığı sektörü, hayvansal üretim içinde önemli bir yer tutmakta olup özellikle yumurta tavukçuluğu, temel protein kaynağı sunması açısından stratejik öneme sahiptir. Ancak 2024 yılında yaşanan üretim düşüşü, bu kaynağın sürdürülebilirliğini tehdit etmektedir. FAO (2023) verilerine göre, yumurta üretimindeki azalma hem fiyat dalgalanmalarına neden olmakta hem de kırılgan hanehalklarını doğrudan etkilemektedir. Bu bağlamda yem maliyetlerinin düşürülmesi, biyogüvenlik önlemlerinin artırılması ve üreticilere finansal destek sağlanması kritik müdahale alanlarıdır (OECD, 2022b).Öte yandan, Türkiye'de üretim hacmi görece düşük olan hindi yetiştiriciliği de önemli bir potansiyel barındırmaktadır. Hindi eti, düşük yağ ve yüksek protein içeriğiyle sağlıklı beslenme eğilimleriyle örtüşmekte ve bu da hem iç pazar hem de ihracat açısından yeni fırsatlar yaratmaktadır (Sipahi ve Cevger, 2010). Literatürde de belirtildiği gibi, hayvansal üretimde tür çeşitliliğinin artırılması, gıda güvencesi ve sektörün esnekliği açısından stratejik bir öneme sahiptir (FAO, 2020). Dolayısıyla hindi yetiştiriciliğinin desteklenmesi, Türkiye'nin kümes hayvancılığı sektöründe yapısal bir dönüşüm yaratabilir.

Et tavuğu üretimindeki 2024 artışının sürdürülebilirliği sağlanmalı, ancak bu büyümenin kalite ve hayvan sağlığından ödün vermeden gerçekleşmesi gözetilmelidir. Organik ve serbest gezen tavuk yetiştiriciliğine yönelik teşvikler, katma değerli ürünlerle sektörün rekabet gücünü artırabilir. Kaz ve ördek yetiştiriciliği gibi niş alanlarda bölgesel kalkınma projeleri desteklenerek, bu türlerin yetiştiricilik gelenekleri olan yörelerde ekonomik canlanma

sağlanabilir. Sonuç olarak, Türkiye'nin kümes hayvancılığında dengeli ve çeşitlendirilmiş bir üretim yapısına kavuşması, hem gıda güvenliği hem de kırsal kalkınma açısından stratejik önem taşımaktadır.

Sonuç

Türkiye'de tarım sektörü içerisinde hayvansal üretimin ekonomik katkıları ve geleceğe yönelik perspektiflerini analiz eden bu çalışmada, önemli bulgulara ulaşılmıştır. Hayvansal üretimin tarımsal ekonomi içerisindeki %35'lik payı, AB ülkelerindeki %45 oranının altında kalması, sektörün geliştirilmesi gereken önemli bir potansiyele sahip olduğunu göstermektedir. 2018-2024 dönemi verileri incelendiğinde, hem büyükbaş ve küçükbaş hayvan varlığında hem de kümes hayvancılığında dalgalanmaların yaşandığı, bu dalgalanmaların yem maliyetleri, iklim koşulları, hastalıklar ve politika değişikliklerinden kaynaklandığı görülmektedir.

Büyükbaş hayvancılıkta 2018-2021 arası görülen artış eğiliminin ardından 2022-2023'te yaşanan düşüş ve 2024'teki kısmi toparlanma, sektörün hassasiyetini ortaya koymaktadır. Benzer şekilde, küçükbaş hayvan varlığı 2021'de zirve yapmasına rağmen, sonraki yıllarda düşüş yaşamış ve 2024'te yeniden artış eğilimine girmiştir. Kümes hayvancılığında ise özellikle 2024 yılında et tavuğu üretiminde %22 artış kaydedilirken, yumurta tavuğu sayısında %15,5'lik ciddi bir düşüş yaşanmıştır. Bu durum, kümes hayvancılığı alt sektörlerinde dengesiz bir gelişim olduğunu göstermektedir.

Çalışma sonucunda, Türkiye'nin hayvansal üretim sektöründe sürdürülebilir kalkınma için bazı stratejik adımlar atılması gerektiği sonucuna varılmıştır. Öncelikle yem maliyetlerinin düşürülmesi için yerli hammadde üretiminin artırılması ve alternatif protein kaynaklarının araştırılması gerekmektedir. Yerli hayvan ırklarının verimliliklerinin artırılması ve adaptasyon kabiliyetlerinin güçlendirilmesi için ıslah programlarının yaygınlaştırılması önem arz etmektedir. İklim değişikliğinin etkilerine uyum sağlamak için kuraklığa dayanıklı üretim sistemleri ve verimli su kullanım yöntemleri geliştirilmelidir.

Ayrıca, küçük ve orta ölçekli üreticilerin kooperatifler ve üretici birlikleri altında örgütlenmesinin desteklenmesi, pazara erişimlerini kolaylaştıracak ve değer zincirindeki paylarını artıracaktır. Hayvancılık işletmelerinde dijital teknolojilerin ve akıllı çiftlik sistemlerinin yaygınlaştırılması, verimlilik artışı ve maliyet düşüşü sağlayacaktır.

Sektörde istikrarlı büyümenin sağlanması için uzun vadeli, öngörülebilir ve sonuç odaklı destekleme politikalarının uygulanması elzemdir. Genç çiftçilerin sektörde kalmasını teşvik edecek programlar geliştirilmeli, hayvansal ürünlerde katma değerli üretim desteklenmelidir. Özellikle coğrafi işaretli yerel ürünlerin teşvik edilmesi, rekabet avantajı sağlayacaktır.

Sonuç olarak, Türkiye'nin hayvansal üretim sektöründe dengeli, sürdürülebilir ve katma değerli üretime odaklanan bir gelişim stratejisi, hem gıda güvenliği hem de kırsal kalkınma hedeflerine katkı sağlayacaktır. Hayvansal üretimin GSYİH'deki payının artırılması ve AB standartlarına yaklaştırılması için bütüncül politikalar geliştirilmesi, Türkiye'nin bu alandaki rekabet gücünü artıracak ve sürdürülebilir bir hayvancılık sektörü için sağlam temelleri oluşturacaktır.

Abstract

The study analyzes maize farming productivity state transitions in Nigeria using data from the 2015 and 2018 General Household Survey-Panel to identify the socioeconomic and institutional factors influencing productivity development over time. Nigeria's national food security and rural livelihoods depend on maize, an essential staple crop. Maize farmers lag behind local competitors because their production system operations are insufficient. The study used Markov Chain analysis and multinomial logistic regression to analyze productivity category movement patterns and their corresponding determinants. Among the farmers from 2015, only 71.4 percent maintained productive status in 2018, while 28.6 percent left the category. A total of 79.2% of non-productive farmers transformed into productive groups between 2015 and 2018 based on Markov Chain analysis. In the long run, it is predicted that the majority of the farmers, 65%, will remain productive. The regression analysis confirmed that age, together with household size and sex, demonstrated statistical importance in the determination of productivity transitions. Older farmers and large households experienced increased chances of productive continuation and initiation, but men showed a reduced likelihood of exiting productivity. Despite many farmers transitioning into productive zones, limitations exist because of restricted credit access, minimal contact with extension services, and small production areas. Productivity, sustainability, and maize farmer resilience require specific interventions, including better extension programs, affordable credit, and cooperative membership enhancement. The research outcome makes valuable contributions to governmental authorities who aim to improve agricultural program results while promoting sustainable maize development in Nigeria.

Key Words: *Productivity Transition, Maize, Nigeria, General Household Survey, Markov Chain*

Introduction

Maize is the most significant cereal crop in sub-Saharan Africa, which is farmed by over 50% of the continent's population (FAO, 2006). It is the principal cereal crop in Nigeria and the principal cereal crop in West Africa (Ayedun, 2018). Maize (Zea mays), a staple crop, holds a significant position in Nigeria's agricultural economy, contributing to food security and livelihood for millions (Wossen *et al., 2023)*. As Africa's second-largest maize producer, Nigeria recorded an estimated 11 million metric tons of production in 2019, harvested from over 6.8 million hectares (Wossen *et al*., 2023). Despite its expansive cultivation, productivity levels have remained stagnant at approximately 1.7 tons per hectare, markedly lower than those of other leading African producers such as South Africa and Ethiopia, with 4.9 and 4.2 tons per hectare yields, respectively (PwC, 2021).

The productivity transition among Nigerian maize farmers is shaped by a complex interplay of factors, including technology adoption, resource allocation, and socioeconomic dynamics (Ibitola *et al.,* 2019). Recent studies highlight the critical role of improved maize varieties in bridging the productivity gap. For instance, adopting these varieties has been shown to enhance yields by up to 38.7%, driven primarily by technological advancements rather than improvements in managerial efficiency (Olasehinde *et al*., 2023). However, the persistent underutilization of efficient farming practices underscores the need for targeted interventions.

According to Mekonnen (2021), there has been extensive nationwide promotion toward advancing, propagating, and accepting enhanced crop varieties and fertilizer technology; still, the nation's agriculture industry is characterized by low productivity. Interventions seem important in raising the output level in a particular setting, but these increases are prone to inefficiency, particularly when the available technology is not used effectively. These issues are further compounded by climate variability and declining soil fertility, which disproportionately affect smallholder farmers who constitute the majority of maize producers in Nigeria (Ogbodo *et al.,* 2018). Addressing these challenges requires a multifaceted approach that includes improving access to agricultural inputs, promoting sustainable farming practices, and enhancing market linkages.

This study explores the dynamics of productivity transitions among maize farmers in Nigeria, examining the influence of socio-economic factors. Understanding these transitions is critical for formulating policies that improve maize yields, enhance the livelihoods of smallholder farmers, and contribute to national food security.

Materials and Methods

Study Area

The study was conducted in Nigeria, West Africa, at Latitude 9° 04' 39.90" N and Longitude 8° 40'. As of April 2025, the population of Nigeria is approximately 237 million 2025. 38.84" E, Africa's most populous nation and the sixth most populous country globally (Worldometer, 2025). The Federal Capital Territory, Abuja, and 36 states comprise the federal constitutional republic, the Federal Republic of Nigeria. The West African nation of Nigeria is bordered on land by the Republic of Benin to the west, by Chad and Cameron to the east, by Niger to the north, and by the Atlantic Ocean to the south. Nigeria is a 923,768 km³ nation in Africa. Nigeria has just two seasons, just like the rest of West Africa and other tropical regions. There are two of these: the rainy and the dry seasons. While the rainy season is greatly impacted by an air mass originating from the South Atlantic Ocean, popularly known as the South Western wind, the dry season is accompanied by an air mass packed with dust from the Sahara Desert, commonly known as Harmattan (Jeník & Hall, 1966). A brief and longer dry season comes between and after each peak in the two-fold rainfall maximum that the southern part of Nigeria experiences.

Data Source

The data for this study were obtained from the 2015 and 2018 Nigerian General Household Surveys (GHS). The GHS-Panel component in Nigeria is part of a regional initiative to improve agricultural statistics in Sub-Saharan Africa. The data was collected by the National Bureau of Statistics (NBS) in collaboration with the Federal Ministry of Agriculture and Rural Development (FMA&RD), National Food Reserve Agency (NFRA), World Bank (WB), and Bill and Melinda Gates Foundation (BMGF). The GHS-Panel aims to develop a leading paradigm for agricultural data collection, foster inter-institutional collaboration, and analyse welfare indicators and socioeconomic features. The 5,000-household GHS-Panel poll represents all households and geopolitical zones (urban and rural). A subset of the GHS sample homes is the GHS panel. The General Household Survey used a multi-stage stratified sample design. Nigeria's GHS sample includes 60 Enumeration Areas (EAs) or Primary Sampling Units (PSUs) from its 37 states, totalling 2220 EAs nationally. A survey of 456 respondents was used across all states and regions. Data on yield and household socioeconomic factors, including size, age, gender, marital status, education level, farm size, access to credit, and extension services, were gathered.

Analytical Technique

Markov Chain

The Markov chain model was used to determine the level of productivity transition among the maize farmers. The Markov model is converted into probability values of entering and exiting productivity by dividing each item by the corresponding row total to give the transition probability below.

X_{11} X_{21} (X_{12} X_{22})

Also, the vector of initial probability P (o) was obtained by dividing each column total by the total. Thereafter, we tried to see the proportion of households that will be in each category in the subsequent periods by using

$P(k) = P(o)\,Pk$

Where k is the period in seasons.

Long-term equilibrium (when the proportion of households entering productivity equals the proportion exiting it) was obtained by using

$eP = e$

$(e_1, e_2)\,(X_{11}\ X_{12}, X_{21}\ X_{22}) = (e_1, e_2)$

The solution to the above equation produced e_1 and e_2, the proportion of households that will be productive and at equilibrium in the long run.

Where e_1 = probability of households that will be productive at equilibrium

e_2 = probability of households that will be non-productive at equilibrium

Multinomial Logistics Regression

The multinomial logistics regression model was used to estimate the determinant of productivity transition among the maize farmers. Multinomial logistic regression was used to model nominal outcome variables, in which the log odds of the outcomes are modeled as a linear combination of the predictor variables. A multinomial logistic regression was performed to create a model of the relationship between the predictor variables and membership in the other groups. Multinomial logistic regression is the extension for the (binary) logistic regression when the categorical dependent outcome has more than two levels (Anderson & Rutkowski, 2008).

Following Adepoju (2012) and Ayantoye (2011), the multinomial logit regression model can be expressed explicitly as

$Y_0 = \alpha_0 + \beta_{10}X_1 + \beta_{20}X_2 + \ldots\ldots\ldots\ldots + \beta_{n0}X_n + \varepsilon_{i0}$ .....(1)

$Y_1 = \alpha_1 + \beta_{11}X_1 + \beta_{21}X_2 + \ldots\ldots\ldots\ldots + \beta_{n1}X_n + \varepsilon_{i0}$ .....(2)

$Y_2 = \alpha_2 + \beta_{12}X_1 + \beta_{22}X_2 + \ldots\ldots\ldots\ldots + \beta_{n}2_{Xn} + \varepsilon_{i0}$ .....(3)

$Y_3 = \alpha_3 + \beta_{13}X_1 + \beta_{23}X_2 + \ldots\ldots\ldots\ldots + \beta_{n}3_{Xn} + \varepsilon_{i0}$ .....(4)

Y_0 = those who entered productivity (which is the reference case)

Y_1 = those who are consistently productive

Y_2 = those who exited productivity

Y_3 = those who are always non-productive
$X_1 \ldots X_n$ represent the vector of the explanatory variables
$\beta_1 \ldots \beta_n$ represent the parameter coefficients.
ε_i = represents the independently distributed error terms
$\alpha_0 - \alpha_3$ = shows the intercept or constant terms.

Results and Discussion

This section discusses the socio-economic characteristics of the maize farmers. These include Sex, Age, Marital status, Education level, Household size, Credit access, Membership in cooperatives, etc. As shown in Table 1, 79.6% of the respondents were male, and 20.4% were female. The majority, approximately 64%, had only primary education. In comparison, about 76% of the respondents were married. In comparison, the majority of about 98% have no access to extension contact, while the majority of about 90% among the respondents have no access to credit. In contrast, the mean age of the respondents was 53 years, the average farm size cultivated for maize was 1.17 hectares, and the average household size was nine persons.

Table 1: Demographic characteristics of the respondents in the study area

Demographic variables	Frequency	Percentage	Mean
Sex			
Male	363	79.61	
Female	93	20.39	
Level of Education			
No education	29	6.36	
Primary	293	64.25	
Secondary	116	25.44	
Tertiary	18	3.95	
Marital status			
Unmarried	109	23.90	
Married	347	76.10	
Access to extension service			
Yes	11	2.41	
No	445	97.59	
Access to credit			
Yes	44	9.65	
No	412	90.35	
Age			53 years
<21	5	1.10	
21-30	13	2.85	
31-40	71	15.57	
41-50	111	24.34	
51-60	117	25.66	
>60	139	30.48	
Farm size			1.17 hectares

6-10	236	51.75	
>10	118	25.88	
Total	456	100.00	

Level of Productivity Transition among Maize Farmers

Table 2 shows the results of the transition matrix and their probabilities. The results are in line with the work of Baulch and McCulloch (2002). The results revealed that 71.4% of farmers who were productive in 2015 remained productive in 2018, while 28.6% of those who were productive in 2015 transitioned to non-productive in 2018. Also, 79.2% of non-productive people in 2015 transitioned to being productive in 2018, while 20.8% in 2015 remained non-productive in 2018.

Furthermore, the result showed that in the short run, the probability that a farmer will be productive is 77.1%, while the probability that a farmer will be non-productive is 22.8%.

In Equilibrium, i.e, the long run, the probability that a maize farmer will be productive in the long run is 65.0%, while the probability that the maize farmer will be non-productive in the long run is 35.0%. This shows that most maize farmers will be productive in the long run.

Table 2: Level of Productivity Transition among Maize Farmers

2015	2018		Total
	Productive	Non-Productive	
Productive	85 (71.4)	34(28.6)	119 (26.1)
Non-Productive	267 (79.2)	70 (20.8)	337 (73.9)
Total	352 (77.1)	104 (22.8)	456 (100)

Productivity Transitions Across Demographic Characteristics of the Maize Farmer

The section discusses productivity transitions among maize farmers based on demographic characteristics such as sex, age, education, marital status, and farm size. Key findings from Table 3 show that 81% of consistently productive farmers are male; 56% of those who exited productivity are female; 85% of new productive farmers are male; 73% of non-productive farmers are male. The majority of all the groups (always productive, exited, entered, non-productive) have primary education, ranging from 62% to 79%. 42% of consistently productive farmers are aged 51-60; 47% of those who exited productivity are aged 51-60 or above 60. In terms of marital status, 78% of consistently productive farmers are married; 56% of those who exited productivity are unmarried; 81% of new productive farmers are married; 69% of non-productive farmers are married Likewise, all groups have less than 1 hectare of land, ranging from 54% to 79%. Most farmers in all groups have 6-10 household members access. 97% of always productive and exited farmers lack access to extension agents, while 99% of those who entered productivity farmers lack access; 96% of non-productive farmers lack access. The majority of the farmers do not have access to credit, and this becomes evident in the groups as 95% of always productive farmers lack access; 82% of exited farmers lack access; and 90% of both new productive and non-productive farmers lack access.

Determinants of Productivity Transition among Maize Farmers

The multinomial logistics regression model was used to estimate the determinant of productivity transition among the maize farmers. As shown in the result, the P level of 0.00 ($P<0.005$) indicates that there is goodness of fit in the model. A unit increase in age will lead to a 0.1189 increase in being always productive compared to those entering productivity. It is significant at 10%. This indicates that an increase in age will contribute to an increase in 2015 and 2018 relative to entering productivity. A unit increase in household size will lead to a 0.0594 increase in being always productive compared to those entering productivity. It is significant at 5%. This means that an increase in household size will contribute to an increase in being productive in the years 2015 and 2018 relative to entering productivity. Tura *et al. (2010) agree* that household size significantly influences continued productivity among maize farmers. A unit increase in age will lead to a 0.3047 increase in exiting productivity compared to those entering productivity. It is significant at 10%. This indicates that an increase in age will contribute to increased existing productivity from 2015 to 2018 relative to entering productivity. A unit increase in household size will lead to a 0.0808 increase in exiting productivity compared to those entering productivity. It is significant at 5%. This means that an increase in household size will contribute to an increase in exiting productivity from 2015 to 2018 relative to entering productivity. Idris *et al.* (2015) *indicate that household size is a factor affecting the efficiency and productivity of maize farmers*. Being a male farmer will lead to a 2.2269 decrease in exiting productivity compared to being a female farmer relative to those entering productivity. It is significant at 1%. This means that being a male farmer will decrease exiting productivity compared to being a female farmer from 2015 to 2018 relative to entering productivity.

Being a male farmer will lead to a 0.7137 decrease in non-productivity compared to being a female farmer relative to those entering productivity. This is significant at 5%. This means that being a male farmer will decrease non-productivity compared to being a female farmer in 2015 and 2018 relative to entering productivity.

Conclusion

This study examined the productivity transitions among maize farmers in Nigeria, focusing on factors influencing their movement between productivity categories over time. The findings revealed that while a significant proportion of farmers (71.4%) remained consistently productive, 28.6% transitioned out of productivity due to limited access to credit, small farm sizes, and lack of support from extension services. Additionally, farmers who entered productivity between 2015 and 2018 showcased the positive impact of socioeconomic variables, including household size and education levels. However, the persistence of non-productivity among a minority of farmers highlights structural and operational challenges within the maize farming sector.

Recommendations

Based on the findings, policymakers should strengthen rural financial institutions to provide affordable credit facilities tailored to smallholder farmers. This intervention would mitigate financial constraints and enable farmers to invest in productivity-enhancing inputs and technologies. Expanding the network of extension agents is critical to disseminating knowledge about improved farming practices and technologies. This includes training programs that emphasize sustainable farming and resource management strategies. The study also recommended encouraging the formation of cooperatives, which can facilitate resource pooling, reduce operational costs, and enhance access to markets and financial resources. Such collaborative frameworks have been proven to improve productivity among smallholder farmers. The government and private sector must also invest in rural infrastructure, including roads and storage facilities, to reduce post-harvest losses and improve market access. By implementing these recommendations, productivity transitions among maize farmers in Nigeria can be significantly improved, fostering a more resilient and sustainable agricultural sector.

Bioecological and Faunistic Investigation of Insect Taxa in Patato Agricultural Areas and Surroundings of Derinkuyu District

Aysel KEKİLLİOĞLU [1], Ömer Eren BOSTAN [2]

[1] Dept. of Biology, Faculty of Arts and Sciences, Nevşehir Hacı Bektaş Veli University, Nevşehir, Turkey
[2] Dept. of Biology, Institute of Science, Nevşehir Hacı Bektaş Veli University, Nevşehir, Turkey

Abstract

Insects (Arthropoda: Insecta) are among the most important organisms of our planet in terms of biodiversity, ecological balance and economic effects. Our country has a rich insect fauna thanks to its location between the Asian and European continents, different climatic conditions and diverse vegetation. However, studies on insect diversity in Turkey are limited to certain regions, and there is a lack of taxonomic information on the insect fauna structure of arid and semiarid ecosystems and agricultural areas, especially in Central Anatolia. This research was conducted in the areas where potato farming is carried out and their surroundings in Derinkuyu district of Nevşehir province, which is located in the Central Anatolia Region and has great importance in terms of the regional economy, and aims to determine insect species diversity and ecological roles. Field studies were carried out between March and November 2022-2023. In the study, ecological and faunistic characteristics of Arthropoda: Insecta taxa were examined and the effects of environmental factors (temperature, humidity, precipitation) on insect populations were evaluated.

Abstract

According to the World Health Organization (WHO) data, cancer is one of the most common causes of death worldwide today. In this study, the cytotoxic effects of selenium nanoparticles (An-SeNP) obtained by green synthesis method on human liver cancer cell line (Hep-G2) were investigated. *Inula viscosa* L. (Andız grass) extract was used during the synthesis process and two different synthesis methods were applied. In both methods, 10 mM SeO_2 solution and andız extract were mixed at a ratio of 4:1 and kept in a magnetic heater at 65°C for 12 hours. In the first method, a red color change was observed in the mixture, 10 mL of the obtained An-SeNPs were used directly, and the remaining part was centrifuged to separate the nanoparticles. Centrifuged and uncentrifuged samples were used in cell cultures within 2 days. In the second method, the color in the mixture turned orange, then it was kept in the oven for 12 hours and stored in the dark at room temperature for 30 days. The An-SeNPs obtained in this method were used for cell studies without centrifugation. Synthesized nanoparticles were characterized by UV-vis spectrophotometer, Zeta potential and Scanning Electron Microscope (SEM). In order to evaluate cytotoxic effects, An-SeNPs at different concentrations were incubated with Hep-G2 cells for 24 hours and cell viability was determined by MTT test. It was determined that An-SeNPs showed significant cytotoxic effects on Hep-G2 cells in all three applications

Key words: *Green synthesis, selenium nanoparticles, Inula viscosa, Hep-G2, cytotoxicity, MTT*

Body Thermoregulatory Adaptations And Reproductive Potentials Of Yankassa Rams Fed Diets Containing Urea-Molasses Treated Cassava Peel Ensiled With Caged-Layer Droppings

Emmanuel Ugochukwu ANASO

Department of Animal Science, Federal University of Agriculture Mubi, Adamawa, Nigeria
Corresponding Author: Dr. Anaso, Emmanuel Ugochukwu; E-mail: dranasoeub@gmail.com

Abstract

This study was conducted to evaluate the physiological responses and reproductive performance of sheep fed diets containing urea-molasses treated cassava peels ensiled with caged layer droppings. The experiment took place at the Federal University of Agriculture Teaching and Research Farm, Adamawa. Twenty-one clinically healthy Yankassa breed of sheep, aged approximately 6 to 7 months, were used for the trial, which lasted for 63 days. Feed offered was measured daily. Statistical differences between mean values of the studied parameters were assessed using one-way repeated measures ANOVA. Thermoregulatory parameters—including heart rate, respiratory rate, earlobe temperature, and rectal temperature—showed no significant differences between treatment groups and the control group throughout the experimental period. Semen pH and abnormalities in sheep fed a diet with 25% replacement of urea-molasses treated cassava peels ensiled with caged layer droppings were not significantly different from the control group but were significantly better than those in the 50% replacement group. Conversely, reproductive parameters such as semen motility, live sperm percentage, semen concentration and volume, scrotal length, scrotal circumference, and libido were significantly improved in sheep fed the 50% replacement diet compared to the 25% replacement group, with no significant difference from the control. It can be concluded that the inclusion of urea-molasses treated cassava peels ensiled with caged layer droppings had no adverse effects on the thermoregulatory parameters of the sheep. Furthermore, the 50% replacement diet appears to be the most beneficial in terms of reproductive performance, falling within recommended nutritional standards for small ruminants.

Keywords; *Sheep nutrition, urea-molasses treated cassava peels, caged layer droppings, physiological responses, reproductive morphometrics,*

Introduction

The amount of animal protein consumed (4.5g/person/day) in the majority of emerging third-world nations, including Nigeria, is significantly less than the 35g daily recommended amount (FAO, 2001; Anaso et al. 2024c). Finding a new alternative method to stay competitive in the industry, improve performance while lowering production costs as much as possible, and provide consumers with high-quality protein is crucial to meeting the growing global demand for animal protein and preserving profitability (Anaso et al. 2021b; Anaso et al. 2024b; Anaso et al. 2025).

Anaso et al. (2023) assert that better nutrition can enhance livestock's reproductive and productive performance. Studies have been done to examine the effects of various feedstuffs on the reproductive performance and physiological response of cattle, with a small number focusing on goats and sheep. However, the exact mechanism by which feed affects ruminant reproductive performance and physiological response is still not fully scientifically proven (Anaso et al. 2024a; Anaso and Olafadehan 2025).

According to a study by Mohamed (2018), feeding Egyptian Barki ewes halophytic fodder shrubs (Atriplex, Acacia, and Cassava) did not pose any significant physiological risks or affect their ability to reproduce.

Despite having a low crude protein content and containing cyanogenic glycosides that are poisonous to livestock, cassava peels and other agroindustrial byproducts have been used to feed ruminant animals (Anaso et al., 2021a; Anaso et al., 2021b). However, they have undergone processing to maintain their nutritional value and lower the amount of cyanogenic glycosides and phytate (Oboh, 2006). To detoxify the cyanide concentration, a variety of processing techniques have been employed, including sun drying, ensiling, soaking, sun drying, and retting (Olafadehan, 2011). Molasses and poultry droppings have been utilized to increase the nutritional content of fibrous meals. Thus, ensiling the final product and treating it with caged-layer droppings and molasses can increase the nutritional content of cassava peels. This research focused on the thermoregulatory adaptations and reproductive potentials of Yankassa Rams fed complete diets containing caged layer droppings-molasses ensiled cassava peel as a substitute for corn bran.

Materials and Method

Study area

The research was conducted in Mubi town, the Northern Senatorial District of Adamawa State, Nigeria, at the Federal University of Agriculture Mubi Teaching and Research Farm's Monogastric Unit, the Morugo Agricultural/Research site was the study's location. Situated at the base of the Mandara Mountains, which divide

Nigeria from the Republic of Cameroun, Mubi is 1906 feet above sea level and falls between latitude 10.27 and longitude 13.28 (10.2801° N, 13.2774° E).

Source of feed ingredients and experimental animals

The cassava peels which were used for the experimental diet were obtained from selected farms during peeling of cassava in the post harvesting operation. Caged layer droppings were gotten from poultry farms within the university environment, while molasses and urea were gotten from Mubi Central market. The experimental rams were purchased from a nearby reputable animal farm Adamawa Nigeria.

Experimental animals, management and diets

Twenty one clinically healthy rams of Yankassa breed about 6 to 7 months with average initial body weight (BW) of 18.30 ± 0.46 kg were used for the experiment. The animals were ascertained to be healthy by a veterinary consultant, having vital parameters within normal ranges and showing no sign of disease. One week prior to the arrival of the animals, the surroundings and pens were thoroughly cleaned and disinfected with a strong antiseptic (morigad). On arrival, the rams were administered prophylactic treatment which included the intramuscular administration of oxytetracycline L.A. (Long acting) an antibiotic (1ml/10kg BW) against bacterial diseases. Ivomectin (0.5ml/25BW) was subcutaneously administered to the animals to protect them against endo-parasites inside the body cavity and ecto-parasites on the skin. Vitalyte was orally administered as anti-stress for a week in drinking water, before the animals were individually penned. Prior to isolation in their pen, they were allowed to adapt to their environment and the experimental diet for the period of one week before the commencement of experiment. The cages were cleaned thoroughly once a week.

Rams were weighed for their initial weight before starting feeding trials and they were randomized into three groups of similar body weight in completely randomized design (CRD). Experimental diets were fed to the animals and water given *ad libitum* through experimental period of 63 days.

100kg of dried cassava peel was collected, washed and allowed to wilt for 2 hours and mixed with 20kg of cage layers droppings and 10kg of molasses. It was allowed to for 30 days, then sundried for 3 days and grinded before taking to the laboratory for other analysis. The total amount of feeds offered daily and representative samples were on weekly basis and pooled together after the experiment. The quantity of feed provided and residue of each day was weighed to determine the feed intake of individual animal. The initial body weights of the goats were taken at commencement of the experiment and subsequently at 7 days interval in the morning before feeding.

Experimental diet

Three experimental diets were formulated with the inclusion of the three different types of supplement on cassava peel which include the cassava peel + molasses + cage layer droppings. T1 indicates 0% treated cassava peel replacement, T2 indicates 25% replacement of maize with treated cassava peel, and, T3 indicates the replacement of maize with 50% of treated cassava peel.

Table 1: Experimental diet with different inclusion level of treated cassava peel with urea-molasses ensiled with cage layer droppings on West Africa dwarf goat.

Ingredients (kg)	Treatment 1 0%replacmet of cassava peel	Treatment 2 25% replacement of cassava peel	Treatment 3 50% replacement of cassava peel

Collection of thermoregulatory parameters

Every goat's heart rate, respiration rate, and rectal temperature were recorded twice a week at 10:00 a.m. A digital thermometer was used to measure the rectal temperature. According to Anaso et al. (2024b) and Anaso and Alagbe (2025), the sensory tip was cleaned with an antiseptic, lubricated with petroleum jelly Vaseline, and then placed into the rectum of a single animal at the temperature display of constant "C L0" on the thermometer's mini digital screen. Following the digital thermometer's beeping alarm signal, the device was taken out of the rectum, and the recorded body temperature was noted. After the alert signal beeped and the temperature was recorded, the digital thermometer was taken out of the earlobe. Using the seconds hand on an analog wristwatch, the number of abdominal movements per minute was counted for one minute, and the counts were recorded in order to determine the respiratory rate. A stethoscope positioned at the left side of the ribs was used to measure the heart rate.

According to Olafadehan et al. (2023, Anaso et al., 2024b; Anaso and Alagbe, 2025), the loop dope sound was the typical heart sound because it signified a full heart beat for one minute using the seconds hand on an analog wristwatch.

Testicular and semen parameters

According to Bratte et al. (1999), Akpa et al. (2012), and Anaso et al. (2024b), scrotal length (SL) was measured in centimeters using a flexible measuring tape as the distance along the scrotum's caudal surface, from its site of attachment to the tip of the scrotum. After the testes are pushed firmly into the scrotum, the greatest diameter surrounding the pendulous scrotum is known as the scrotal circumference (SC) (Akpa et al., 2006). A measuring tape was used to convert it to centimeters (cm).

As described by Zemjanis (1970), an automatic electro ejaculator (Autojact, Neovet) with 12 V and 5 A was used to electroejaculate all of the bucks from each session. A series of 1-35 stimuli lasting between 30 and 5 minutes is then shown.

By directly measuring the millimeter graduation of the collection vial, the volume of the semen samples was assessed right away, and the result was expressed in milliliters (mL). By visualizing the consistency of the ejaculates, the semen's appearance was assessed and categorized as watery, thick, milky, creamy marble, and creamy. Every semen sample was smeared, allowed to air dry, labeled, and stored for additional analysis.

10 µL of semen was mixed with 1 mL of Tris dilution buffer (Hydroxymethylaminomethane) (3.0 g), sodium citrate (2.0 g), and fructose (1.0 g) to measure the progressive motility. After that, an optical microscope (100x magnification) was used to examine a 10 µL aliquot of the diluted semen sample that had been placed between a heated slide and coverslip (37ºC). A percentage was used to represent the progressive motility.

A hemocytometer crossed with microscopic grids was used to measure the spermatozoa concentration. Sperm cells were counted in five huge squares, each counting diagonally from top left to bottom right and from top right to bottom left (Rekwot et al., 1997; Anaso et al., 2024b). Formaldehyde was utilized as a dilution reagent before counting. Using an automated pipette, a drop of semen was extracted from each sample and diluted 1:100 with formaldehyde. After mounting the hemocytometer in the microscope, a drop of the solution was pipetted into the hemocytometer chamber using an absorbable tube and an O-no pette. The outcome was noted as the sample's concentration of sperm cells.

As soon as the semen sample was collected, a smear was made using eosin-nigrosin stain to assess the live to dead sperm ratio. Using an automated pipette, a diluted drop of semen was put on a sanitized glass slide. On the slide next to the semen was a drop of the eosin-nigrosin solution. To ensure that the two samples were evenly mixed, the slide was gently turned in a circular motion. To create a thin smear on the first slide, a quarter of the portion of another clean slide was put on top of the first sample, and the two slides were carefully and gradually separated. After letting it dry, this was labeled. Each sample was then put on a microscope to count the number of living and dead sperm cells. The idea is that although active sperm cells reject the dye and stay unstained, dead sperm cells accept it and seem stained. Hancock (1951) created the aforesaid approach.

Chemical analysis

The proximate analysis of the formulated diet was done using the standard procedures recommended by association of official and analytical chemists (AOAC).

Statistical analysis

The obtained feed and nutrient intake, hematological, biochemical, semen characteristics and thermoregulation data were subjected to analysis of variance (ANOVA) in completely randomized design using the SPSS (23.0). Duncan multiple range test (DMRT) of same software was used to test the significant difference between the means at ($p \leq 0.05$ level of significance.

The statistical model is shown below

$Yij = \mu + ti + ei$

Where:

Yij = the general response to the specific parameter under investigation,

μ, the general mean peculiar to each observation,

ti = the fixed effect of the dietary treatment on the observed parameters and

ei = the random error term for each estimate

Results and Discussions

Body thermoregulation of the experimental animals

Table 2 shows body thermoregulation of experimental animals.

All the vital signs (RT, HR and RR) were not ($P>0.05$) affected by diets and were within the reference ranges of 38.5 – 39.7°C, 70 – 90 bpm and 16 – 34 cpm for RT, HR and RR respectively for healthy sheep (Merck Veterinary Manual, 2010). The results indicate the diets did not compromise normal sheep's vital signs. Generally, normal vital signs of an animal depend on recent activity, feed and water consumptions and the physiological state of the animals (Olafadehan et al. 2023; Anaso et al. 2024b; Anaso and Alagbe, 2025). The normal values obtained for the vital signs are a confirmation of the fact that the diets did not affect the body physiology and health of the

animals, suggesting that that RPCP can safely be used as a feedstuff in the diets of sheep without posing any nutritional or health challenge because lower or higher values than the normal ranges indicate physiological or health problem.

Anaso et al. (2024b) reported that respiratory rate is practical and reliable measure of the heat load and stated that respiratory rate above 25 breath per minute in small ruminant is an indicator of heat stress.

Therefore, the result obtained for heart rate, respiratory rate and rectal temperature after feeding diet containing treated cassava peel with urea-molasses ensiled with cage later droppings showed no significant difference with that of the control diet and was therefore in agreement with research conducted by Kusuma et al. (2017) who reported a non-significant (P>0.05) difference in body thermoregulatory parameters in goat feed a varying protein level on their diet.

Table 2: Thermoregulatory adaptations of the experimental animals

Parameters	Control T 1	25% RPCP T 2	50% RPCP T 3	SEM
Rectal Temp (°C)	39.48	39.49	39.56	0.35
Heart rate (bpm)	83.71	84.00	83.66	0.18
Respiratory rate (cpm)	22.59	22.82	22.85	0.17

Means in the same row are statistically different at (P<0.05), T1 indicates 0% treated cassava peel replacement, T2 indicates 25% replacement of maize with treated cassava peel, and, T3 indicates the replacement of maize with 50% of treated cassava peel, SEM: indicate standard error of the mean

HR: Heart rate, RR: Respiratory rate, EL: Ear lobe temperature, RT: Rectal temperature, TRT: Treatment, RPCP; Replacement of treated cassava peel.

Semen quality and testicular parameters of experimental animals

Semen colour was the same (creamy) for the diets. Semen pH and abnormalities were higher ($p<0.05$) in 0 and 25% RPCP than in 50% RPCP. Sperm viability was affected ($p<0.05$) in the order: 50% RPCP > 25% RPCP > 0% RPCP. Semen volume, Semen concentration, progressive motility, live spermatozoa testosterone level, scrotal length and circumference, libido test (measured as the reaction time when exposed to female) followed the same trend and was significantly highest in the 50% replacement diet compared to the 25% replacement group, with no significant difference from the control.

Semen quality evaluation is crucial since adequate fertility in livestock depends on having high-quality semen (Anaso et al. 2023; Anaso et al. 2024a; Anaso et al. 2024d). Male reproductive efficiency is actually determined primarily by sexual activity and the quality of semen (Anaso, 2024). Semen volume, concentration, progressive motility, testosterone level of living spermatozoa, scrotal length and circumference, and libido all showed parallel results, suggesting that RPCP can be added to buck diets without adversely affecting these semen characteristics. Similar semen colors in the bucks are in line with previous research on goats and rams that observed a creamy color feature (Oyeyemi et al., 2011; Ososanyo et al., 2013; Anaso et al. 2024b). Creamy white semen frequently indicates good quality, blood stains and odd hues suggest poor quality or contamination, and translucent semen typically indicates low concentration. The pH of the semen fell within Osinowo's (2016) recommended range. Greater sperm and semen EV concentrations were found in the 50% RPCP, suggesting that the diet significantly influenced spermatogenesis and improved the nutritional status of the rams while they were fed this diet. The increased availability of nutrients for the spermatogenesis process resulting from increased enhanced feed and nutrient intake (especially protein intake) may be the cause of the improved nutritional status. Although not mentioned in this study, the diet may have also enhanced ruminal microbial growth and microbial protein production (Gado et al., 2009) and nutritional digestibility (Gado et al., 2015). Improved nutrient digestibility has been shown to support the nutrition of the seminal fluid and sertoli cells that nurse the germ cells (Anaso et al., 2024b). According to Osinowo (2016), strong, progressive motility is an essential measure of sperm viability and sperm level, which may be high or low. Anaso et al. (2023) explain that motile cells are usually innately viable and viability is crucial in determining non-motile cells that are alive or dead. Therefore, the increase in sperm concentration and volume of rams on 50% RPCP signals the possibility of high fertility during service or insemination (Oyeyemi and Okediran, 2007). Diets improved and affected spermatogenesis and sperm cell viability, according to the marginal influence of diets on sperm viability (Anaso et al. 2024b). Because low-quality or inadequate food has been connected to cases of low-live sperm count, it appears that RPCP is a nutritionally acceptable feedstuff that can be added in rams' diets up to 50% without impairing semen characteristics and fertility. (Anaso and others, 2023).

In rams given diets based on pineapple waste, the sperm abnormalities in all treatment groups did not exceed the previously documented acceptable limit (Ososanya et al., 2013). In general, low quality semen is indicated by high levels of sperm abnormalities. Thus, it may be concluded that the current study found no adverse effects of nutritional therapies on semen quality. The leydig cells of the testes produce testosterone, which is essential for spermatogenesis and masculine traits. Its vascular distribution throughout the body is a significant component in male desire (Sajjad et al., 2007; Sekoni et al., 2010; Anaso et al., 2024b). Although testosterone levels were higher

at 50% RPCP than at 0 and 25% RPCP, they were still within the 2.10–10.8 ng/mL range for small ruminants in Turkey (Polat et al., 2011; Delgadillo et al., 1999), indicating that the 50% RPCP threshold level had no effect on testosterone concentration in the current study. According to Cornwall (2009), low testosterone levels are the cause of poor sperm quality because testosterone has been found to be a crucial component in the production of superior quality semen due to its favorable connection with other semen features. Given that testosterone has been shown to increase male sexual behaviour, it is possible that the higher libido (lower reaction time to doses) in the 50% RPCP is related to testosterone levels. Generally, libido (sex drive) is an important component of male fertility.

Scrotal length and circumference are important indicators when observing animals for breeding soundness. Higher SC and SL of rams fed 50% RPCP diet indicate that the diet may improve the reproductive performance and breeding soundness of the bucks. Earlier studies (Azizunnesa et al., 2013) attributed increased scrotal circumference and growth rate to nutritional plane, implying that 50% RPCP diet is perhaps nutritionally superior to the other diets.

General findings from this study were similar to results presented by Anaso et al. (2024b) who evaluated the effect of substitution of *Pleurotus ostreatus* biodegraded sugarcane scrapings (BSS) for corn bran on the growth performance and reproductive potential of Kano Brown bucks and concluded that that up to 30% biodegraded sugarcane scrapings can be used in a complete diet for bucks without negatively impacting final body weight and semen quality.

Table 3: Semen quality and testicular parameters of experimental animals

Parameters	Control T 1	25% RPCP T 2	50% RPCP T 3	SEM
Semen colour	Creamy	Creamy	Creamy	
pH	6.56[a]	6.52[a]	6.21[b]	0.07
Ejaculatory volume, mL	0.24[b]	0.26[b]	0.38[a]	0.02
Progressive motility, %	74.59[b]	75.58[b]	85.49[a]	0.77
Sperm viability, %	78.67[c]	81.33[b]	88.00[a]	3.03
Sperm concentration, x 10^6	335.92[b]	354.96[b]	396.37[a]	8.40
Live spermatozoa, %	71.32[b]	73.11[b]	85.78[a]	1.20
Sperm abnormalities, %	16.39[a]	15.63[a]	10.03[b]	0.36
Testosterone, ng/mL	2.89[b]	3.26[b]	4.06[a]	0.22
Libido, seconds	12.21[b]	12.51[b]	15.92[a]	0.33
Scrotum length, cm	10.80[b]	11.01[b]	13.11[a]	0.46
Scrotum circumference, cm	17.45[b]	17.72[b]	18.66[a]	0.29

Means in the same row are statistically different at ($P<0.05$), T1 indicates 0% treated cassava peel replacement, T2 indicates 25% replacement of maize with treated cassava peel, and, T3 indicates the replacement of maize with 50% of treated cassava peel, SEM: indicate standard error of the mean

Conclusion

The result shows that animals fed with 25% and 50% replacement of urea-molasses treated cassava peel ensiled with caged layer droppings showed no significant difference in the heart rate, respiratory rate, earlobe temperature and rectal temperature when compared with that of the control diet. It can be concluded that the different treatments had no effect on the physiology of the animals. The result shows that animals fed with 50% replacement of urea-molasses treated cassava peel ensiled with caged layer droppings gave the highest semen motility, semen live, semen concentration, semen volume, scrotal length, scrotal circumference and libido. It can be concluded that the feed containing 50% replacement of urea-molasses treated cassava peel ensiled with caged layer droppings is best for the animals as it falls within general recommended ranges.

Recommendation

Based on the finding of this study, the feed containing 50% replacement of urea-molasses treated cassava peel ensiled with caged layer droppings is recommended for diet for ruminant as it does not have any side effect on the physiological response and reproductive performance of the animals.

Abstract

The present work was carried out to obtain essential oil from the sour orange peel (*Citrus aurantium*) which is rich in essential oil through steam distillation. Extraction using distilled water was the control treatment and other treatments were carried out by using 3%, 5%, and 7% $NaHCO_3$. This study determined the yield% of essential oil in four different treatments in freshly extracted essential oil. The Physico-chemical properties of essential oil were determined in freshly extracted essential oil .In performance, T3 (5% $NaHCO_3$) was the best yield% (w/w) with a value of 3.15%. According to this study, using $NaHCO_3$ for essential oil extraction from sour orange peel resulted in a higher essential oil yield than distilled water. The extracted essential oil in sour orange peel has distinct pale yellowish color with a fresh and tangy smell. T3 exhibited that distinct color and odor. Based on the yield% and Physico-chemical analysis, the essential oil extraction using 5% $NaHCO_3$ was the best treatments followed by treatment 4 (7% $NaHCO_3$), treatment 2 (3% $NaHCO_3$) and treatment 1.

Key Words: *Sour orange peel, Extraction, $NaHCO_3$, Essential oil*

Introduction

Fruits with nutraceutical and medicinal properties are gaining importance in the modern food industry. Among many fruit trees, Citrus is an extremely important bearing genus in this regard. It includes well-known species like orange, lime, mandarin, and lemon, as well as many other underutilized species. Oranges are among the most popular fruit in the world due to their pleasant taste (Nguyen *et al*., 2009), as well as their nutritional value. So, orange fruits have long been part of the human diet due to their nutritional and medicinal properties.

A large amount of wet solid waste is generated because of the widespread consumption of orange juice. Orange juice is one of the popular beverages today. About 50-60% of the processed fruits are converted into citrus peel, which is made up of peels, seeds, and membrane residues. Fruit waste is increasing dramatically as the production of processed fruit juice increases (Garg, 2017). Orange peels are discarded inside waste containers even in homes because people prefer the orange pulp for its juicy pulp and discard the peel because it does not taste as good as the pulp. Furthermore, citrus waste is disposed of in a variety of ways. Waste discharged into lakes may cause pollution and extinction of aquatic life, especially if the body of water is insufficient to dilute the waste properly (Sharma *et al*., 2017).

This waste is caused to pollute the environment if not properly handled. That waste may affect both economic and environmental problems such as high transportation costs, lack of dumping sites, and accumulation of high organic content material (Tripodo *et al*., 2008). As a result, it is critical to treat citrus waste in food industries and other areas in a systemic manner. By producing by-products from these wastes, they can be effectively disposed. This waste primarily consists of orange peels. The peels have numerous oil-producing glands that contain significant amounts of citrus oil (Lota *et al*., 2000). As a result, rather than discarding these peels as solid waste, they can be used to extract oil (Virot *et al*., 2008).

Citrus essential oils have gotten the most attention because of their broad-spectrum insecticidal, antibacterial, and antifungal properties, as well as their high yields, aromas, and flavors (Bora *et al*., 2020). Citrus fruits have a high nutritional value, as well as high levels of elemental bioactive compounds, such as phenols, flavonoids, limonoids, essential oils, and vitamins, particularly vitamin C and carotenoids, which have numerous health benefits. These components give this fruit its distinct flavor and aroma, resulting in a more balanced and tasty diet. Above all, citrus is beneficial in the treatment and prevention of many diseases.

Citrus fruits are high in essential oils as well as other nutrients like vitamin B9, vitamin C, potassium, flavonoids, coumarins, pectin, and dietary fibers (Bora *et al*., 2020). Citrus peel oil was chosen for extraction because it has a high potential for further commercialization. Essential oils are aromatic compound mixtures that are widely used in perfumes, food, pharmaceutical, and other industries. Essential oils are primarily composed of monoterpene hydrocarbons, sesquiterpenes, and their derivatives such as esters, alcohols, and aldehydes (Toan *et al*., 2020).

Citrus essential oil also has antibacterial, antifungal, and insecticidal properties (Burt, 2004). Essential oils from citrus peels are very complex matrices composed of many compounds of various chemical classes that are primarily separated into two parts: the volatile part and the non-volatile part. Essential oils are liquids that are clear and rarely colored, and they are soluble in organic solvents that have a lower density than water (Palazzolo *et al*., 2013).

All citrus trees belong to the genus Citrus, the family Rutaceae. Bitter ("sour") oranges refer to *Citrus aurantium* L. and are hybrid between *Citrus maxima* (Pomelo) and *Citrus reticulate* (Mandarin). This plant is native to southeastern Asia (Anwar *et al*., 2015). *Citrus aurantium* is a Latin name for bitter orange (Moonaz *et al*., 2010). Bitter orange is well-known for its use in the treatments of anxiety, lung, and prostate cancers, gastrointestinal diseases, and obesity. *Citrus aurantium* essential oils contain bioactive compounds with antimicrobial, antioxidant, anti-inflammatory, and anti-anxiety properties (Kacaniova *et al*., 2020).

Bitter orange consists of large amount of active constituents. Those active constituents can be found in bitter orange juice, flowers, seeds, leaves as well as peels. Active constituents in bitter oranges provide many biological effects, such as antioxidant, antimicrobial, anti-cancer, anti-diabetic, etc (Maksoud *et al*., 2021). Other than therapeutic applications, *Citrus aurantium* is used in the food production industry also. The food applications of bitter oranges are *Citrus aurantium* juices, wines, jams, canned fruits, and dried fruits. Those various applications of *Citrus aurantium* fulfill the better utilization of bitter orange and thus extend its industrial chain. The development of those value-added bitter orange products can partially overcome the defects of seasonality and the short life of fresh bitter oranges, and meet the nutritional requirements of novel fruit products from consumers (Liu *et al*., 2022).

The essential oil was extracted from citrus peel by using different methods such as steam or hydro distillation, maceration, solvent extraction, soxhlet extraction, cold pressing, supercritical fluid extraction, microwave-assisted extraction, etc. Those extraction methods can be divided into two types. They are traditional extraction methods (conventional methods) and non-conventional extraction methods. Conventional methods, which use organic solvents, necessitate long extraction time, large amount of energy, and other resources, posing as much of an environmental risk (Chemat *et al*., 2019) as the biodegradable properties of citrus waste already do. Because of the drawbacks of traditional extraction methods, the wide availability of citrus waste, and the emerging need to reduce environmental impact, there has been an increase in interest in the responsible management of this type of waste (Da *et al*., 2018). Furthermore, non-traditional technologies known as "green extraction methods" has gained importance. These are the most sustainable methods for obtaining bioactive compounds from citrus residues, allowing for better resource utilization. Their main advantages are improved performance, lower energy, time, and other resource expenditure, and the use of few or no organic solvents (Anticona *et al*., 2020).

Materials and Methods

Preparation of Sour Orange peel sample

The Sour Oranges were washed with clean water and peeled thinly. Thin outer peels were cut into small square shape cubes. Then those peels were ground into formed a fine particles of peels without drying.

Prepared Sour Orange peel sample transferred into the Extraction

Kjeldahl apparatus was used for the extraction of essential oil from sour orange peels fine particles.

Extraction of Essential oil with different treatments

The essential oil was extracted by using four different treatments. After the sample was transferred into the 500 ml flat bottom flask, the flask was connected to the Kjeldahl apparatus. 50ml graduated cylinder was used as the receiver. Then the mixture was distilled rapidly by heating it to 180ºC for 2 hours. The steam was generated from the boiling water (as the flask was heated) the volatile oil was extracted which was condensed as part of the steam into the distillation flask as it was passed through the cooling system.

T1 – Extraction with Distilled water (control): 150g sour orange peel particles + 250 ml distilled water
T2 – Extraction with 3% $NaHCO_3$: 150g sour orange peel particles + 7.5g $NaHCO_3$
T3 – Extraction with 5% $NaHCO_3$: 150g sour orange peel particles + 12.5g $NaHCO_3$
T4 – Extraction with 7% $NaHCO_3$: 150g sour orange peel particles + 17.5g $NaHCO_3$

Separation of Essential oil

The distillate (a mixture of oil and water) was poured into a separating funnel where the mixture separated into two layers. Then 10ml of n-hexane was added into the separating funnel and the stopper was placed. Then the separating funnel was shaken while releasing the pressure that may form in the funnel constantly. After that funnel was let into a stand for a 5 minutes for clear separation. The stopcock of the funnel was opened and the aqueous phase was drained into a 100ml Erlenmeyer flask. The stopcock was closed when the organic phase reaches it and it was recovered into a separate container. The process was repeated for twice using 5ml of n-hexane. Then needed to evaporate the hexane which in the beaker to isolate the oil using water bath. It was begun to evaporate at about 62.5 ºC. Finally, the thermometer was placed in the solution to monitor if it is hexane left or not. If the thermometer reached more than 80 ºC so then decide to stop evaporation. The extracted pure essential oil was placed in an airtight bottles.

Characterization of the Essential Oil

After the oil was extracted, it was characterized to ensure that the extracted liquid was indeed oil. The essential oil extracted from Sour Orange peels under optimal processing conditions was characterized by determining the physico-chemical properties.

Statistical Analysis

Each formulation was replicated in experiments and they were in Complete Random Design (CRD). Analysis of Variance (ANOVA) (α=0.05) and mean separation was done with Turkey's studentized test. Physio-chemical analysis and storage studies were done through Minitab 17 software statistical package

Results and Discussion

The Yield of Extracted Essential Oils from Sour Orange Peel Samples

Table 1 Yield % of freshly extracted essential oil samples

Treatment	Yield %(W/W)
T1	1.46 ± 0.22^{c}
T2	2.09 ± 0.01^{b}
T3	3.15 ± 0.04^{a}
T4	2.52 ± 0.04^{b}

The values are means of the triplicates ± standard error.
Means values with the same letters within the same column do not differ significantly at 5% level.

According to the results, essential oil yield % was high in the T3 (5 % $NaHCO_3$) treatment. The maximum essential yield was 3.15%. Mainly essential oil yield % was less in the first treatment which the extraction was done using distilled water. That yield was 1.46%. When the $NaHCO_3$ percentage was increased from 3% to 5%, the essential oil yield% also increased, but again at T4 (7% $NaHCO_3$), the oil yield % was decreased than T3.

Color

The color was determined by observing the samples visually. T1 (control) and T3 (5% $NaHCO_3$) essential oil samples were pale yellowish-white in color. T2 (3% $NaHCO_3$) and T4 (7% $NaHCO_3$) essential oil samples were pale reddish brown in color.

Odor

All treatments, T1, T2, T3, and T4 were given a fresh and tangy smell.

Solubility

In all treatments, T1, T2, T3, and T4 essential oil samples were insoluble in water.

Chemical Characteristics of Freshly Extracted Essential oil

The chemical characteristics of extracted essential oil such as saponification value, acid value, free fatty acid value, ester value, pH, and refractive index of the freshly extracted essential oil revealed there was significance difference between the treatments of essential oil at 5% level of significance.

Table 2 Chemical characteristics of freshly extracted essential oil samples

Treatment	Saponification value (mg KOH/g)	Acid value (mg KOH/g)	Free fatty acid content (mg KOH/g)	Ester value (mg KOH/g)	pH	Refractive index
T1	24.52±0.20^{d}	4.10±0.06^{a}	3.06±0.05^{a}	20.42±0.21^{d}	6.76±0.01^{c}	1.35±0.006^{a}
T2	41.54±0.17^{c}	3.87±0.03^{b}	2.43±0.07^{b}	37.67±0.14^{c}	6.97±0.07^{c}	1.25±0.006^{b}
T3	42.67±0.11^{b}	3.47±0.03^{c}	2.09±0.02^{c}	39.19±0.14^{b}	7.27±0.08^{b}	1.21±0.006^{c}
T4	44.57±0.21^{a}	3.07±0.04^{d}	1.94±0.003^{c}	41.49±0.21^{a}	8.12±0.003^{a}	1.02±0.006^{d}

The values are means of the triplicates ± standard error
Means values with the same letters within the same column do not differ significantly at 5% level.

While increasing the $NaHCO_3$ concentration from 3% to 7% for essential oil extraction, the saponification value of freshly extracted essential oil from sour orange peels was increased from 41.54 mg KOH/g to 44.57 mg KOH/g. when the $NaHCO_3$ concentration was raised from 3% to 7%, the acid value of the extracted essential oil decreased from 3.87 mg KOH/g to 3.07 mg KOH/g. According to the results, treatment 1, which extraction of essential oil using distilled water, contains the least mean ester value (20.42 mg KOH/g). The mean ester value of treatments 2, 3, and 4 were found as 37.67, 39.19, and 41.49 mg KOH/g respectively
According to the results, pH value (Figure 4.6) was high in T4 (7% $NaHCO_3$) essential oil. The highest mean pH value is 8.12. pH value was less in T1 (control) than in others. The least pH value is 6.76. pH value was increased, when increasing $NaHCO_3$ concentration from 3% to 7%. According to the results, mean value of refractive index was high in treatment 1 (control). The least refractive index was in treatment 4 (7% $NaHCO_3$).

Conclusion

The results of this particular study revealed that in the extraction of essential oil using steam distillation, the highest yield % of essential oil was obtained from T3 (5% $NaHCO_3$), 2 hours of distillation in sodium carbonate, therefore, the concentration of $NaHCO_3$ aids in the extraction of essential oil from the plant tissues of the sour orange peel. This research revealed that using $NaHCO_3$ for essential oil extraction, provided a higher yield than using distilled water. According to the results, the yield % was increased in the following manner. That is, T1<T2<T4<T3.Based on chemical characteristics, saponification value was increased according to T1<T2<T3<T4, 123.48mg KOH/g, 151.95mg KOH/g, 164.9mg KOH/g, 170.33 mg KOH/g respectively. Ester value was high in treatment 4 (7% $NaHCO_3$). Treatment 1 had the highest mean value for acid value and free fatty acid content than other treatments. Based on the Yield %, physical and chemical, the essential oil extraction using 5% $NaHCO_3$ was the best treatment compared to other treatments.

Abstract

Avocado is an important horticultural crop in Kenya and a key export fruit. The quality of avocado fruit is influenced by numerous environmental factors such as soil composition, elevation, rainfall, temperature, and sunlight exposure, alongside crop husbandry, postharvest handling, and geographical origin. Avocado samples from these regions were analysed for proximate composition, including ash, protein, lipid, fibre and carbohydrates, and fatty acid composition of extracted oils.

Findings revealed marginal variations across the regions. In terms of weight, samples from Nandi were the highest with 231.85 ± 0. 84g, followed by Kisii (219.52 ±0.59g), Muranga (165.02 ±0.94g) and Nakuru (149.20 ±1.35g), respectively. Moreover, samples from Murang'a recorded the lowest pulp yield (62.28%) and the highest seed proportion (23.08%), while other regions showed an insignificant difference in pulp content (71.33%) and seed (14.48%). The pulp content of Murang'a and Nandi regions exhibited the highest fat content at 68.26±3.18% (dwb) and 64.22±0.93% (dwb), followed by Kisii at 60.84±0.31 % (dwb). Nakuru had the lowest lipid content at 45.91% (dwb). Samples from Kisii had higher ash content (6.79% dwb), those from Murang'a had elevated fibre (4.46% dwb), while samples from Nakuru exhibited higher protein (7.63%dwb) and carbohydrate (36.61% dwb) levels. The fatty acid composition of avocados was in the range of oleic acid 55.1-60%, followed by Palmitic acid 22.1-23.8%, Linoleic was 18.8-21.1%, with saturated/unsaturated ratio in the range of 0.27-0.31, implying healthy fatty acid profiles for human nutrition for all the samples. Generally, the quality of the study samples was comparable to those traded globally in terms of nutrient profile.

Overall, Kenyan Hass avocados meet the required export quality in terms of size (calibre), pulp-to-seed and peel ratio was within acceptable limits, the nutritional composition of avocados and their lipid content is in line with those reported in key avocado-producing and exporting countries.

Keywords: *Hass avocado; proximate composition; Fatty Acid profile; lipid quality; Kenya*

Introduction

Avocado consumption has increased globally over the past years due to its recognised nutritional benefits, particularly its rich content of monounsaturated fatty acids (MUFAs), protein, vitamins, minerals, and dietary fibre (Acosta-Díaz et al., 2019; Carvajal-Zarrabal et al., 2014). The fruits are a good source of folate, potassium, healthy fats, and vitamins K, C, and E, and also contain small amounts of B vitamins and minerals, such as copper, phosphorus, magnesium, manganese, iron, and zinc (Ford et al., 2023). The monounsaturated fats in avocados, most of which are oleic acid, are good for heart health, fight inflammation, and may have anticancer properties (Carvalho & Velásquez, 2015; Méndez Hernández et al., 2023)

Kenya is a significant player in avocado production and export and is currently ranked 5th in avocado production after Mexico, Colombia, Peru and the Dominican Republic (FAO, 2024). In 2018, for instance, a total of 318,087,000 kgs of avocado fruit was produced in Kenya, with the Central region accounting for 54.4%, Eastern (9%), Western (3.3%), Rift Valley (7.4%), Nyanza (21%), Coast (2.9%) and Nairobi (2%). The major avocado-producing counties in Kenya are Murang'a (42%), Kiambu (11%), Kisii (7%), and Nyamira (5%), while Bomet, Embu, Meru and Bungoma account for 3% each (MoALFD, 2020). The country is ranked 6th in avocado export globally and 1st in Africa. Moreover, Kenya is ranked 3rd after Israel and Mexico among avocado exporters to the European market, with the Netherlands, U.A.E., France, UK, and Saudi Arabia being the five largest importers of Kenyan avocados (MoALFD, 2020).

The main avocado varieties grown in Kenya are Hass (20%) and Fuerte (80%) for the export market and Puebla, Duke and G6 for the domestic market (Mellado& Ferrari, 2019). Hass avocado is regarded as the most important in terms of cultivated area, geographical distribution and consumption(Cruz-lópez & Caamal-cauich, 2022; USDA, 2018). It is the most popular export variety because it enjoys a big market in Europe and other destinations compared to the other varieties (Kathula, 2021). Moreover, the variety has gained particular prominence due to

international demand fuelled by its perceived health benefits, unique flavour and extended shelf life (Nyakang'i et al., 2023).

While avocado export is key to Kenya, the sector faces myriad challenges; hence, many harvested fruits do not meet export quality standards. Approximately 45% of the fruits are not export quality and provide raw materials for oil extraction. Avocado oil processing is enjoying phenomenal growth in Kenya and provides a growing market opportunity for Grade 2 avocados unsuitable for export or sale in the domestic fresh fruit market (USAID, 2018). Domestic demand for Kenyan avocados accounts for more than 80% of total production, with the remainder exported as fresh fruits or processed and exported as crude oil (Kathula, 2021).

The quality of avocado fruit is influenced by numerous environmental factors, such as crop husbandry, postharvest handling, and geographical origin (Juan Camilo et al., 2019). Varied soil composition, elevation, rainfall, temperature, and sunlight exposure create distinct micro-environments influencing nutrient uptake by avocado trees, impacting the accumulation of essential nutrients, antioxidants, and bioactive compounds in the fruit (Kenbon Beyene, 2017; Ramírez-Gil et al., 2019). Such disparities can lead to differences in macronutrients, micronutrients, and antioxidants in avocados, with those grown in favourable environments offering enhanced nutritional quality and potential health advantages for consumers. Moreover, regional disparities may also influence the taste, flavour, and texture of fruits and can be attributed to differences in the composition of sugars, organic acids, and volatile compounds (Mccarthy & Considine, 2008). The sensory attributes and nutritional composition contribute to consumer preferences and market demand for avocados.

Previous research has delved into several aspects relating to avocados. For instance, a study in Egypt (Rozan et al., 2021) examined various avocado varieties' chemical composition, bioactive compounds, and antioxidant activity. Another study conducted in Malaysia focused on the proximate composition and physical properties of Thompson red avocado fruit (Tan et al., 2022). In Colombia, Henao-Rojas et al. (2019) explored the influence of different growing regions on avocado quality. In Kenya, research on the total phenolic content of avocado seeds was reported (Githinji et al., 2013), but studies profiling its nutritional composition are largely lacking despite Hass avocado's significance in the country. Furthermore, the influence of different growing regions on the nutritional composition of Hass avocado remains unexplored. Existing studies have suggested that climate and ecological variations, including geographical location and agricultural practices, can affect avocado composition, highlighting the necessity to evaluate this aspect concerning Hass avocados in Kenya.

Avocado is consumed in various forms in Kenya and globally, as puree salads, juice, seasoned with salt. Avocado pulp contains from 67 to 78% moisture, 13.5 to 24 % lipids, 0.8 to 4.8% carbohydrate, 1.0 to 3.0% protein, 0.8 to 1.5% ash, 1.4 to 3.0% fiber, and energy density between 140 and 228kcal (Duarte et al., 2016). Avocado

The country’s diverse regions exhibit significant geographical and climatic variations, which profoundly affect the growth of crops (Henao-Rojas et al., 2019; Kathula, 2021; Nyakang'I et al., 2023). This study aims to investigate and compare Hass avocados' nutritional composition and fatty acid profile from major producing regions in Kenya.

Materials and Methods

Study site

The study was conducted in Murang'a, Nakuru, Kisii, and Nandi Counties of Kenya. Among these, Murang'a County was the primary contributor to avocado production, accounting for 31% of the total value of Kenya's top 10 avocado-producing regions. This percentage represents the broader Central Kenya counties engaged in avocado cultivation. Kisii follows, with 6.8%, representing regions in Nyanza and South Rift involved in avocado production. Nakuru produced 6.8%, representing the avocado-producing counties in the Central Rift Valley.

Meanwhile, Nandi County contributes 2.7%, representing Western Kenya and North Rift in avocado cultivation. These counties lead in their regional avocado production in Kenya. Furthermore, the combined avocado production from these counties accounts for 47.9% of the national avocado production in value (MoALFD, 2020).

Study Design

A quantitative descriptive comparative study design was employed for the investigation. This design enabled the simultaneous collection and assessment of data across multiple distinct avocado growing areas within Kenya.

Sample collection

Representative samples of Hass avocado were collected from the study regions, with four avocado farms selected per county to represent each area. Only farms with Global GAP Certification were selected in the study. One hundred sixty (160) mature Hass avocados were randomly collected from different trees within the farms based on Codex standard 197-1995. The selection criteria ensured uniformity in maturity, size, and the absence of visible defects among the avocados. All samples were transported to Kenya Industrial Research and Development Institute (KIRDI) and Spectre Laboratories under controlled temperature and humidity conditions to maintain freshness and integrity. Ripening of the avocados was conducted at 20°C, and sample analyses were performed when the avocados ripened.

Sample preparation

The sample preparation involved cleaning and careful extraction of pulp, seed, and peel from the Hass avocado obtained from each region. The samples were carefully washed and then split to access the pulp, seed, and peel.

The peel, pulp and seeds were manually separated, with the seeds extracted and cleaned. Subsequently, each farm's pulp, seed, and peel were aggregated separately to form representative samples. The aggregated components were weighed and prepared for analysis. The fruit parts were cut into smaller pieces and dried in an oven dryer (Memmert, Germany) for three days at 45 ºC. The dried fruit parts (moisture content 9%) were ground into powder using a home blender (Waring MX1500XTX, USA). The powdered samples were stored in airtight plastic containers at -20 ºC until further analysis.

Mass and calibre of fruits

The whole fruits and fruit parts (peel, pulp, and seeds) were weighed using a digital balance (Shimadzu AUW220D, Japan), and the results were expressed as a percentage of total mass.

Proximate Composition Analysis

The proximate composition analysis was carried out to assess the nutrient content of the avocado samples. This analysis encompassed the quantification of essential components, including carbohydrates, proteins, calorific value, total ash content, fibre, and fats, employing established standard analytical methods outlined by the AOAC (Association of Official Analytical Chemists). Total ash content was assayed by placing the sample in a muffle furnace at 550°C for 8 hours (AOAC 942.05, 2012). The protein content was evaluated using the Kjeldahl method (N x 6.25) (AOAC 960.52, 2012), while crude fibre content was quantified following the AOAC method 2009.01, and fat content determined by solvent extraction method (AOAC 2003.06-2012) (AOAC, 2012). Carbohydrate content was obtained by difference, involving the subtraction of the combined weights of moisture, protein, fat, ash, and fibre from the total sample weight. The data obtained were expressed as percentages on a dry weight basis (dwb).

Fatty Acid Composition Analysis

Near-infrared (NIR) spectroscopy was employed to analyse lipid profiles. This method harnesses the near-infrared region of the electromagnetic spectrum, spanning approximately 700 to 2500 nanometres. By assessing the light interactions involving a sample, NIR reflectance spectra can swiftly unveil the material's properties without requiring sample modification. This approach is facilitated by the fact that NIR absorption bands, at wavelengths around 1600–1800 nm and 2100–2200 nm, correspond to distinct features in the molecule, specifically the straight carbon chain and double bonds, respectively.

Statistical Analysis

The data collected were analysed to obtain means and standard deviation for avocado samples from selected regions in Kenya. Analysis of variance (ANOVA), followed by a post-hoc test, was conducted to establish significant differences ($p < 0.05$) among samples from different regions. Data was analysed using GraphPad Prism 8 (GraphPad Software, Boston, MA-USA).

RESULTS AND DISCUSSION

Hass avocado calibre and weight of fruit and fruit parts from selected regions in Kenya

The weight of Hass avocado fruit samples exhibited varied results depending on the sampled region, as shown in Table 1 below. Fruit samples from Nandi were the heaviest with an average weight of 231.85 ± 0. 84g, followed by Kisii (219.52 ±0.59g), Muranga (165.02 ±0.94g) and Nakuru (149.20 ±1.35g), respectively. Based on calibre ranking, the Hass avocado samples from Murang'a had a calibre of 24, while Nakuru, Kisii and Nandi recorded values of 26, 18 and 16, respectively. This grading system is based on United Nations Economic Commission for Europe (UNECE) criteria for size (calibre) grading used by avocado producers and exporters, with European Union (EU) buyers preferring a calibre range of 16 (227g to 274g) to 20 (184g to 217g) (UNECE, 2019). Based on this criterion, samples from Nandi and Kisii fall within the acceptable range and hence qualify for export to Europe, while Muranga and Nakuru were not within the preferred levels.

Such variability in the weight of Hass avocado fruit has been observed in previous studies (Carvalho et al., 2014; López-Pimentel et al., 2022), where avocados from orchards in high-altitude areas had higher weights and sizes than those from lower-altitudes. Nandi and Kisii regions sit at higher altitudes (up to 2062mtrs and 2190mtrs, respectively) than Nakuru and Murang'a (1912mtrs and 1665.06mtrs, respectively). Other than altitude, factors such as soil fertility, climatic conditions and agricultural practices have also been attributed to variations in fruit sizes/weights (Henao-Rojas et al., 2019).

Table 1. Calibre and Mean weight of avocado fruit, peel, pulp and seed from selected regions in Kenya. Weight data indicates the Mean ±SD of triplicate samples.

County	Calibre	Fruit weight (g)	Pulp weight %)	Seed weight (%)	Peel weight (%)	Pulp/Seed
Muranga	24	165.02 ±0.94	62.71±0.43	22.83±0.23	13.75±0.23	2.75
Nakuru	26	149.20 ±1.35	70.87±0.24	14.32±0.22	15.41±0.26	4.95
Kisii	18	219.52 ±0.59	70.93±0.08%	16.02±0.11	13.38±0.14	4.43
Nandi	16	231.85 ± 0.84	72.66±0.16	13.61±0.175	14.00± 0.07	5.33

The percentage (%) pulp content of Hass avocado from Muranga, Nakuru, Kisii and Nandi were 62.71±0.43%, 70.87±0.24%,70.93±0.08%, and 72.66±0.16%, respectively, while the seeds accounted for 22.83±0.23%, 14.32±0.22%, 16.02±0.11%, and 13.61±0.18%, respectively. The proportion of peel, on the other hand, was 13.75±0.23%, 15.41±0.26%, 13.38±0.14%, and 14.00± 0.07%, respectively. From the results, fruits from Murang'a exhibited the lowest pulp percentage of 62.71±0.43%, compared to Nandi, which recorded the highest pulp percentage, 72.66±0.16%, while Nakuru and Kisii had no significant difference. The pulp percentage difference between the regions differed significantly ($p<0.05$), with Muranga recording a significantly lower value than the other counties. Conversely, Murang'a also showed the highest seed percentage, 22.83±0.23%, compared to the other regions, which were between 13.61±0.18and 16.02±0.11%. The seed percentage difference between the regions was significantly different ($p<0.05$). All the regions exhibited relatively similar peel percentages (Kisii 13.38±0.14%, Murang'a13.75±0.23%, Nandi 14.0±0.07%, and Nakuru 15.41±0.26 %, with samples from Nakuru being significantly higher than from the other regions ($p<0.05$). Murang'a origin avocados exhibited the lowest pulp and highest seed percentages, making them less desirable than those from Nandi, which had high pulp and low seed percentages. The observed differences can be attributed to environmental factors such as microclimate, soil fertility, climate conditions, and possibly agricultural practices specific to each region.

The present findings on pulp percentage largely fall within that was reported by (Alnasan et al., 2019), who found that Hass possesses a pulp content ranging from 67.96% to 85.3%, with Hass avocado having 67.96% in Hass, and Fortuna cultivars having 85.3% pulp content. Another study reported that avocado pulp represents between 52.9 and 81.3% of the fruit mass (Jimenez et al., 2021), while all the Hass avocados sampled in the present study fall within the range. Meanwhile, seed and skin/peel comprise about 33% of the total fruit weight (Dreher & Davenport, 2013). It was reported that, on average, an avocado fruit consists of the peel (7–15%), the pulp (65–73%), and stone (including the seed) (14–24%) (García-Vargas et al., 2020). It was reported that avocado fruits with lower seed and peel levels are most interesting for oil extraction due to their higher pulp yield (Domínguez et al., 2016). A study in Ethiopia by Tesfaye et al. (2022) established that the avocado seed represents 13–18% of the fruit, similar to our findings. Further, the seed and peel content of Hass are notably lower, making it suitable for various home consumption and guacamole and industrial applications like oil extraction. The pulp to seed ratio of avocados from Muranga, Nakuru, Kisii and Nandi were 2.75, 4.95, 4.43, and 5.33, respectively. The higher the pulp-to-seed ratio, the higher the avocado pulp yield. The distinctive proportions of seed, pulp, and peel in the Hass avocado contribute to its culinary versatility and commercial success, underscoring its significance in the avocado market. In a study reported on the Hass avocado from Ethiopia, it was established that the Hass avocado cultivar showed a greater flesh-to-seed ratio (13.57±10.43) and had a lower fruit weight (183.92±47.58g) (Kenbon Beyene, 2017).

Proximate composition of Hass avocado pulp from selected regions in Kenya

The results of the proximate composition of Hass avocado pulp are shown in **Hata! Başvuru kaynağı bulunamadı.** below. The data showed non-significant variation in the nutritional composition of the avocado pulp between the proximate parameters except for fats (% w/w) dwb and carbohydrates (% w/w) dwb. No statistically significant differences were observed at ($p < 0.05$) level. Avocados from Kisii exhibited the highest ash content of 6.79±0.53% (dwb), suggesting superior mineral content. Conversely, avocados from Nakuru demonstrated the highest protein and carbohydrate content at 7.63±0.85% (dwb) and 36.611±0.46% (dwb), respectively. In contrast, avocados from Murang'a displayed elevated fat and fibre levels, with values of 68.26±3.18% (dwb) and 4.46±0.32% (dwb), respectively.

Fat and carbohydrate content exhibited the highest levels among the proximate parameters analysed, a finding consistent with the established nutritional profile of Hass avocado (Jimenez et al., 2021). Notable parameter variations were observed among the regions, with statistically significant differences ($p < 0.05$) in lipids and carbohydrates. Specifically, Murang'a and Nandi regions exhibited the highest fat content at 68.26±3.18% (dwb) and 64.22±0.93% (dwb), respectively, whereas the lowest lipid content was reported in the Nakuru at 45.91% (dwb), and Kisii 60.84±0.31 % (dwb). Carbohydrate content for Murang'a had the lowest levels at 13.67±2.64% (dwb), contrasting with Nakuru, which displayed the highest at 36.61±0.46% (dwb). Kisii and Nandi regions reported intermediate carbohydrate levels at 21.49±0.31% (dwb) and 19.67±1.22% (dwb), respectively.

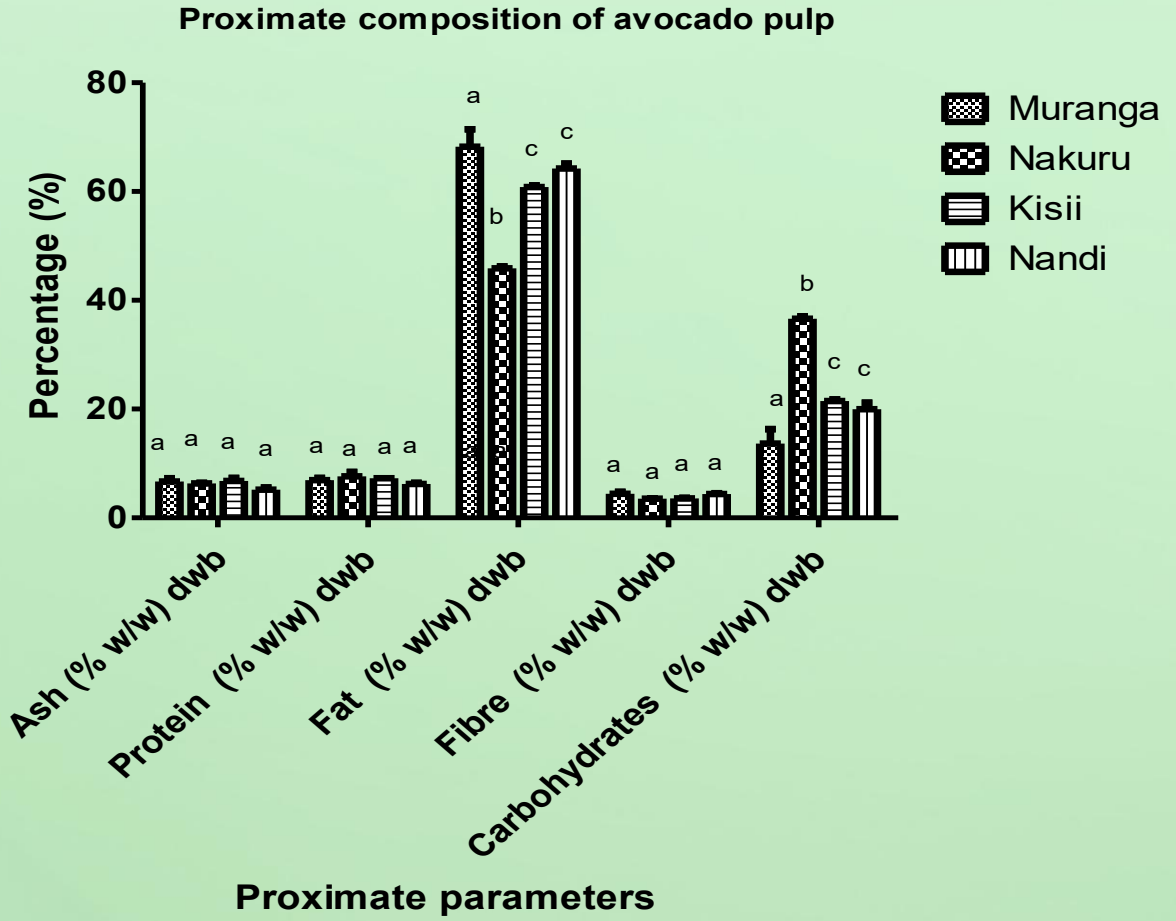

Figure 1.The Proximate composition of Hass avocado pulp. Each data point represents the mean±SD of triplicate samples. Bars with similar letters are not significantly different, while those with similar letters are significantly different at $p < 0.05$.

The avocado pulp contains high lipids content, which makes the pulp the portion of greatest interest. Avocados are among the fruits with the highest fibre content, including 75% insoluble and 25% soluble fibre (Araújo et al., 2020; Noorul et al., 2016). It was reported that the relative amount of pulp varies according to cultivar, from 67.96% in Hass to 85.3% in the Fortuna cultivar. The oil content may also vary widely (13.15% in Margarida to 25% in Hass) by soxhlet extraction and (7.9% in Margarida to 20% in Hass) by cold-centrifugal (Alnasan et al., 2019). A study on Mexican avocado pulp reported the following values: carbohydrates (4.2–5.6%), proteins (1.2–1.8%), dietary fibre(12.55–15.8%), and lipids (12– 16%) on a wet weight basis (Méndez-Zúñiga et al., 2019). Other studies report moisture content ranging from 67 to 78%, lipid content ranging from 12 to 24 %, carbohydrate content ranging from 0.8 to 4.8%, protein content ranging from 1.0 to 3.0%, ash content ranging from 0.8 to 1.5%, fibre content ranging from 1.4 to 3.0%, with energy of between 140 and 228 kcal per avocado on wet weight basis (Duarte et al., 2016).

Fatty Acid profile of Hass Avocado from selected regions in Kenya

The oleic content of Hass avocado was in the range of 55.1-60%, followed by Palmitic acid 22.1-23.8%, Linoleic was 18.8-21.1%, with only Nandi origin samples having trans fatty acid in negligible level of 2% as, while the Linolenic and stearic acids were largely below the detection limit per Figure 2 the results within the range of reported values for Mexican avocados (Méndez-Zúñiga et al., 2019). Moreover, the results largely conform to the proposed Codex Standard for avocado oil profile, which specifies that Palmitic acid C16:0 is 11.0–26.0%, Linoleic acid C18:2 (7.8–19.0%), Oleic acid C18:1(42.0–75.0%), and C18:3 Linolenic (0.5–2.1 %) (Green & Wang, 2023). A study on 68 avocado oil samples in the USA found the following values: C16:0 9.90–23.19%, C16:1 3.32–10.03%, C18:1 49.74–71.41%, and C18:2 9.25–22.46% (Green & Wang, 2023). According to a study by Méndez Hernández et al. (2023), the fatty acid profile of avocado is within the following arrange: oleic acid represents 50–60% of the total fatty acids, followed by palmitic (15–20%), palmitoleic (6–10%), linoleic (11–15%), and linolenic (1%) acids. Thus, monounsaturated fatty acids dominate the composition of avocado oil, especially oleic acid. A study to determine the effect of altitude on orchards of avocados found that the quantities of oleic acid decreased drastically at lower altitudes while the amounts of palmitoleic and linoleic

acids increased (Carvalho & Velásquez, 2015). Therefore, this can explain slight variations in amounts across the sampled regions. Another study found that exposure to the sun increased the proportion of the saturated fatty acid palmitic acid and decreased the proportion of monounsaturated fatty acid oleic acid (Woolf et al., 1999). Palmitic acid levels were the highest of the saturated fatty acids in all samples, ranging from 38.37% to 48.32% of the total lipid. The oleic acid content in all avocado cultivars was higher than those of other unsaturated fatty acids. It was further revealed that early and late-harvested fruits showed higher total lipid content than the rest (Teng et al., 2016). Moreover, a study of 12 native Mexican avocado accessions found that the primary saturated fatty acids in all the avocado accessions were palmitic acid (15.54-22.68%), monounsaturated fatty acids (oleic) (56.58-74.19%) while polyunsaturated fatty acids were linoleic (5.62-16.85%), and linolenic (0.63-2.85%) being the most abundant unsaturated fatty acids in all the accessions (Méndez-Zúñiga et al., 2019). Researchers in Colombia determined that at a higher elevation, the concentration of fatty acids in avocados increases (Ramírez-Gil et al., 2019).

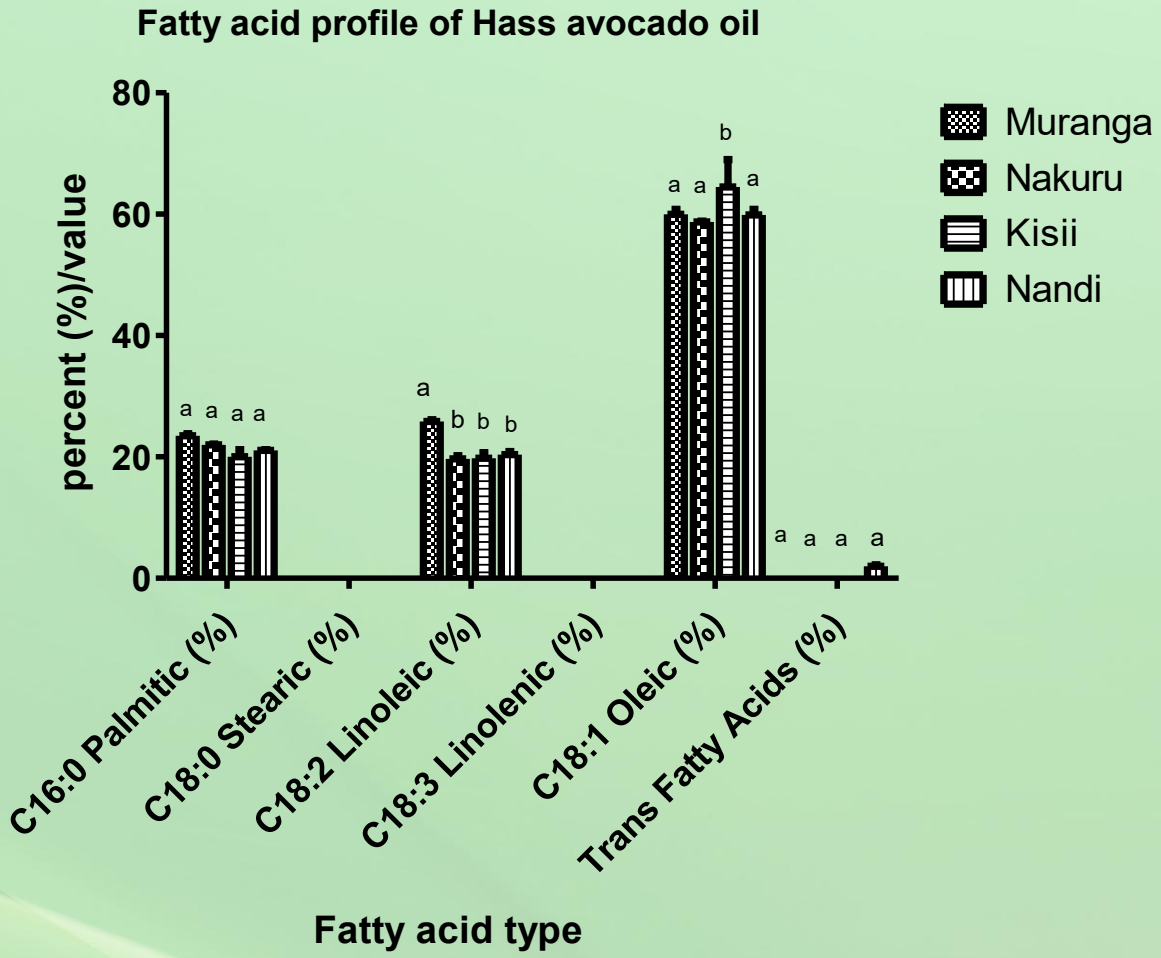

Figure 2. Fatty acid profile of Hass avocado oil. Each data point represents the mean±SD of triplicate samples. Bars with similar letters are not significantly different, while those with similar letters are significantly different at $p < 0.05$.

Previous publications reported Hass avocado pulp composition to be as follows: oleic acid (18:1n-9) (about 59%), Palmitic acid (16:0) (approximately 14%), linoleic acid (18:2n-6) is the predominant polyunsaturated fatty acid (approximately 11%) (Ford et al., 2023). The fatty acid profile is influenced by ripening, where during ripening at 20 ◦C, palmitic acid content decreases and polyunsaturated fatty acids increase, while monounsaturated fatty acids remain relatively unchanged. However, pre-harvest conditions may influence fatty acid profiles because lower growing temperatures shift the oil profile towards more oleic acid and less palmitic acid (Ferreyra et al., 2016; Ozdemir & Topuz, 2004). These regional fat and carbohydrate content disparities may be linked to origin, season, and production practices (Rodríguez et al., 2023).

It was reported that harvesting time affects the lipid content of avocado fruit. Early and late-harvested fruits showed higher total lipid content than others (Teng et al., 2016). The MUFAs essentially consist of Oleic acid, the predominant monounsaturated fat in avocado oil, making up approximately 60-70% of the total fatty acids. Oleic acid is a heart-healthy fat that has been associated with various health benefits. Meanwhile, for saturated fatty acids, palmitic acid is the primary saturated fat found in avocado oil, comprising around 15-20% of the total fatty

acids. Of the polyunsaturated fatty acids (PUFAs), Linoleic, an omega-6 fatty acid, is the primary constituent but occurs in low amounts in avocado oil. However, the exact proportion may vary. It is important to note that the specific fatty acid composition can differ slightly based on factors such as avocado variety and growing conditions. However, Hass avocados from Mexico, one of the major producers of avocados globally, generally exhibit a similar fatty acid profile (Rodríguez et al., 2023). Oil may be classified as hard or soft, depending on the ratio of saturated to unsaturated fatty acids. Soft oils are defined as liquid oils containing a very high percentage of unsaturated fatty acids, while hard oils contain high levels of saturated fatty acids (Naghshineh et al., 2010).

Table 2.The Fatty acid quality of Hass avocados from the four (4) main avocado-producing regions in Kenya.

Region	**Total saturated fatty acid**	**Total Saturated fatty acid**	**Saturated/Unsaturated fatty acid ratio**
Muranga	23.8	76.2	0.31
Nakuru	22.1	77.9	0.28
Kisii	21.2	78.8	0.27
Nandi	21.2	78.8	0.27
Average value			**0.28**

The desirable ratio is between 0.1-0.44, with lower values representing the best oil/fat quality. This signifies that the fatty acid profile of the Kenyan avocado is healthy, with samples from Kisii and Nandi having the best ratio. The values of Kenyan Hass avocado oil were within the range reported for various avocado-producing countries as per a study report on the saturated/unsaturated ratio reported that Australia 0.35, Mexico 0.29, New Zealand 0.26, USA 0.30, and Colombia 0.2 (Ramírez-Gil et al., 2019). The findings are within the ratios reported in avocados from Morocco, where Hass avocado oil was rich in oleic, palmitic, linoleic, and palmitoleic acids, while stearic acid was present in low amounts. The Reed variety had the highest amount of oleic acid (61.18%) among all studied varieties (Nasri et al., 2021). A previous study (Bob Bergh, 1992) reported that linoleic acid was slightly above 21%, which agrees with the present findings of Hass avocado of 26.1-21.8%. Increasing polyunsaturated (PUFA) intake lowers LDL-C and decreases heart disease risk; increased PUFA intake lowers LDL-C by increasing LDL receptor activity (Teng et al., 2016; Weschenfelder et al., 2015).

Conclusion

This is one of the pioneer studies on the nutritional profile of Hass avocados in Kenya. The study revealed that the size of Kenyan avocados and the pulp, seed, and peel content vary slightly but within recommended global ranges. These variations could be due to environmental variables, crop management practices, altitude, weather conditions, and soil conditions. The nutritional value equally points to the need to consume more avocados to meet body requirements of some nutrients. Kenyan Hass avocados meet the required export quality in terms of size (calibre), pulp-to-seed and peel ratio was within acceptable limits, the nutritional composition of avocados and their lipid content is in line with those reported in key avocado-producing and exporting countries. The fatty acid profile of the avocados is consistent with high quality lipids with high unsaturated fatty acid content. Continued emphasis on quality improvement, sustainability, and market access will help Kenya strengthen its position in the global avocado trade.

The avocado from Kenya meets the minimum 58% oil; hence, it is suitable for extraction of avocado oil. The fatty acid profile makes Kenyan avocados nutritionally suitable regarding unsaturated fatty acid content. The overall quality of Kenyan avocados conforms to and is similar to that of top global origin destinations like Mexico.

Extraction of Essential Oil from Sour Orange (*Citrus aurantium*) Peels and Evaluation of its Physico Chemical Characteristics

Anjela Oshadi Rodrigo [1], Thevagi Mahendran [2], Fathima Nuha Mohamed Ubaidullah[3]

[1]Eastern University Sri Lanka, Faculty of Agriculture, Department of Agricultural chemistry, Batticaloa, Sri Lanka
[2]Eastern University Sri Lanka, Faculty of Agriculture, Department of Agricultural chemistry, Batticaloa, Sri Lanka
[3]Eastern University Sri Lanka, Faculty of Agriculture, Department of Agricultural chemistry, Batticaloa, Sri Lanka

Abstract

The present work was carried out to obtain essential oil from the sour orange peel (*Citrus aurantium*) which is rich in essential oil through steam distillation. Extraction using distilled water was the control treatment and other treatments were carried out by using 3%, 5%, and 7% $NaHCO_3$. This study determined the yield% of essential oil in four different treatments in freshly extracted essential oil. The Physico-chemical properties of essential oil were determined in freshly extracted essential oil .In performance, T3 (5% $NaHCO_3$) was the best yield% (w/w) with a value of 3.15%. According to this study, using $NaHCO_3$ for essential oil extraction from sour orange peel resulted in a higher essential oil yield than distilled water. The extracted essential oil in sour orange peel has distinct pale yellowish color with a fresh and tangy smell. T3 exhibited that distinct color and odor. Based on the yield% and Physico-chemical analysis, the essential oil extraction using 5% $NaHCO_3$ was the best treatments followed by treatment 4 (7% $NaHCO_3$), treatment 2 (3% $NaHCO_3$) and treatment 1.

Key Words: *Sour orange peel, Extraction, $NaHCO_3$, Essential oil*

Farmer's Attitude Towards Rental Combine Harvester in Thakugaon District

Ariful Haque[1], Sadekur Rahman[2], and Rubayet Noman[3]

[1] Former MS Student, [2] Professor and [3] Assistant Professor, Department of Agricultural Extension, Hajee Mohammad Danesh Science and Technology University, Dinajpur, Bangladesh

Abstract

The main purpose of the study was to determine the attitude of the farmers towards combined harvester. The study was carried out at Thakurgaon Sadar upazila of Thakurgaon district under Rangpur division. Ninety-eight (98) farmers were selected as sample from an updated list of 300 farmers' who are rental user of combined harvester by following proper statistical techniques. Data were collected by a pre-tested interview schedule during 10 November to 10 December 2023. Simple and direct questions with different scales were used to obtain information. Pearson Co-efficient of Correlation (r) was computed to explore the relationships between the nine selected characteristics of the farmers and their attitude towards combined harvester. Just more than three-fourths (45.9 percent) of the respondents had moderately favourable attitude while (43.9 percent) of them had highly favourable attitude and only (10.0 percent) of them had lower favourable attitude towards combine harvester. Out of nine selected characteristics, four characteristics of the respondents such as education, farm size, social network and extension media contact had significant positive relationship with their attitude towards combine harvester, but age of the farmers had negative significant relationship with their attitude towards combine harvester. The remaining selected characteristics *e.g.* family size, annual income, level of mechanization experience and exposure to combine harvester technology did not show any significant relationship with their attitude towards combine harvester. Fragmented land & small farm size emerged as the most important constraints expressed by the farmers. The foremost suggestion cited by the farmers was organizing training program by government for the farmers on combine harvester. Increase of direct government and private investment was suggested by the farmers as the last suggestion.

Key words: *Attitude, Rental combined harvester and Farmers'*

Küresel Perspektiften Türkiye'ye: Tarım Ekonomisinde Yeşil Yaka Uygulamaları Üzerine Bir Derleme

Senem DOBUR[1] Bekir AYYILDIZ[2] Hilmi ERDAL[3]

[1]Tarım Ekonomisi Bölümü, Tokat Gaziosmanpaşa Üniversitesi, Tokat, Türkiye
[2]Tarım Ekonomisi Bölümü, Yozgat Bozok Universitesi, Yozgat, Türkiye
[3]Tarım Ekonomisi Bölümü, Tokat Gaziosmanpaşa Üniversitesi, Tokat, Türkiye

Özet

Küresel iklim değişikliği, doğal kaynakların tükenmesi ve çevresel bozulma gibi tehditler, tarım sektörünün sürdürülebilirlik ekseninde yeniden yapılandırılmasını zorunlu kılmıştır. Bu bağlamda ortaya çıkan "yeşil yaka" kavramı, çevresel etkileri minimize eden, doğa dostu üretim ve hizmetlerde çalışan bireyleri tanımlar. Tarım ekonomisi özelinde yeşil yakalı çalışanlar; organik tarım, su ve toprak kaynaklarının verimli yönetimi, yenilenebilir enerji kullanımı ve çevre koruma gibi alanlarda etkin roller üstlenmektedir.

Bu derleme çalışması, Türkiye ve dünyada tarım sektöründe yeşil yaka istihdamının mevcut durumu, gelişim süreci ve potansiyel etkilerini değerlendirmektedir. Uluslararası örneklerde yeşil ekonomi politikalarının tarımsal istihdamı artırdığı, kırsal kalkınmayı desteklediği ve çevresel sürdürülebilirliği güçlendirdiği görülmektedir. Türkiye'de ise yeşil ekonomi ile uyumlu politikaların yeni yeni şekillenmeye başladığı, ancak bu alanda stratejik planlamaya ve eğitim-eğitim destekli istihdam politikalarına ihtiyaç duyulduğu anlaşılmaktadır.

Çalışma sonucunda, yeşil yaka istihdamının artırılmasının hem çevresel hedeflerin gerçekleştirilmesi hem de ekonomik büyümenin sürdürülebilir temeller üzerine inşa edilmesi açısından kritik öneme sahip olduğu vurgulanmaktadır.

Abstract

Tea is the most consumed beverage in Bangladesh, and it has a great impact on the economy due to its export potential. The organoleptic quality of tea depends on different biochemical compounds and can be affected by physical factors. The objectives of the study were to assess the biochemical and physicochemical properties of black and green tea sourced from six major tea-growing regions of Bangladesh, their relationship with organoleptic properties, and how they are affected. Fifteen Black and green tea samples were collected from different tea-growing regions of Bangladesh. They were analyzed for moisture content, ash content, electrical conductivity, caffeine content, total polyphenol and total flavonoid contents in water and methanol extract, theaflavin, thearubigin, total colour, total brightness, and heavy metal contents. The moisture content of the samples ranged from 4.26% to 7.23%, caffeine content ranged from 2.15% to 3.81%, and Thearubigin-Theaflavin ratio ranged from 5.14 to 6.69. The total polyphenol content of black tea was found to be higher in water extract than in methanol extract, whereas total flavonoid content was found to be higher in methanol extract. In green tea samples, total polyphenol content, total flavonoid content, and caffeine content are found to be positively correlated with organoleptic properties, with a total correlation coefficient of 0.95, 0.97, and 0.96, respectively. In black tea samples, organoleptic properties are positively correlated with the Thearubigin-theaflavin ratio (0.76), caffeine content (0.74), and weakly correlated with total polyphenol (0.22) content and total flavonoid content (0.34). Moisture content is strongly negatively correlated with organoleptic attributes in both green tea (-1.0) and black tea (-0.91). These findings highlight the critical role of biochemical profiling, particularly thearubigin–theaflavin ratio, polyphenol content, in determining the organoleptic properties of Bangladeshi teas. Moisture content has a deteriorating effect on the sensory properties of tea, and it should be maintained properly during the processing and storage of tea.

Abstract

Rice plays crucial role in sustaining nutrition and sustaining livelihoods nutritional and livelihood globally but lack of high yielding and early maturing varieties cause problem in sustainable production. Thus, the study was conducted to evaluate the performance of early rice genotypes in Madhesh province, focusing on yield and yield attributing characters. The research was laid in randomized complete block design (RCBD) with two replications and twenty-four genotypes (2 check varieties Hardinath-1 & Hardinath-3) in CNRM Bardibas. Geographically, it is suited at altitude 26˚52'0''8North, longitude 85˚49'96'' East; 78 m above sea level, AFU. The planting distance between the rice plant was 20*20 cm with plant plot size:1.5x3=4.5 and the spacing between two plots consecutive plots was maintained 0.5 m. Key agronomic traits of growth, yield and yield attributes characters were recorded. Data was entered and tabulated using MS-Excel and analyzed using Gen-stat ver. 2015. Mean separation was done by DMRT at 5% level of significance. The results revealed that highest yield (6.87 t/ha) was achieved by the genotypes IR-18-A-2294, followed by IR-19-A-5000 (6.516 t/ha), NS-314(6.24 t/h), NS-278(6.26 t/h), Hardinath-3(6.24t/h) and least by NS-232(3.91t/h). Hardinath-1 (86.5 DAT) had early maturity followed by NS-201 (91 DAT), Hardinath-3 (94 DAT), IR-132T799(96DAT) & IR-132084-B-1191-1-2-B-12 (96 DAT) whereas late maturity was observed in NS-313 (104 DAT) and yields were 5.24 t/h, 5.14 t/h, 6.24 m/t, 5.37 t/h, 4.87 t/h & 5.98t/h respectively. Based on grain quality and yield, IR-19-A-5000, IR-18-A-2294 were found as high yielding genotypes respectively, while based on earliness and yield potential Hardinath-1, IR-132T799 and Hardinath-3 were found superior among tested. These results provide valuable insights into the selection and development of rice varieties adapted to the specific agro-ecological conditions of Nepal.

Keywords: *Earliness, Rice, Genotypes, Yield, Yield Attributes.*

Introduction

Rice (*Oryza sativa* L.,2n=2x=24) is essential to nutrition, livelihoods, and cultural activities, supporting more than half of the world's population and contributing significantly to global food security(Fukagawa & Ziska, 2019). Rice is a major staple food crop and ranks first in position in terms of production and productivity in Nepal(AITC, 2024; MoALD, 2024). Rice supplies nearly 20% of the economic to its agricultural GDP, and 7% of its overall GDP comes from rice, making it a vital crop in Nepal(Devkota et al., 2018). It is cultivated in an area of 1447789 hectares, yielding an average of 3.7 t/ha. where Mahottari District shares 3.00 % production of national production, located in Terai,is one of the productive locations for high rice production due to its suitable agro-climatic condition(AITC, 2024; MoALD, 2024).

Inconsistent yield due to poor soil, water scarcity, and pest susceptibility, raises concerns about its stability. A weak seed production and distribution system in Nepal limits farmers' access to quality rice seeds(Prasad et al., 2017). Insufficient research on early rice compatibility with farmer needs. This has made it necessary to concentrate on increasing productivity through agronomic development and genetic enhancement. Developing high-yielding, early-maturing rice varieties is necessary to address Nepal's food security concerns, particularly in the Terai region, which serves as the country's agricultural hub(Dhungana et al., 2022). The prevention of terminal drought and the ability to plant successive crops on schedule are two major advantages of early-maturing genotypes for cropping intensity optimization. Sustainable production is hampered by the lack of cultivars appropriate for Nepal's agroecological conditions(B. B. Adhikari et al., 2018). Grain yield is a complicated trait impacted by genotype-environment interactions, and finding improved genotypes for it requires a thorough assessment of yield-related traits(Liang et al., 2015).

The environment has a significant impact on rice grain production, which is a quantitative polygenic characteristic. When selecting germplasm based on the genetic variation available, it is important to consider the extent and significance of the relationship between yield and its components(B. N. Adhikari et al., 2018; Aditya & Bhartiya, 2013). The success of breeding programs depends on the population's level of genetic variability as well as the heritability of the targeted features. With new plant type attributes linked to crop productivity, several morphological features are crucial for increased rice production. The phonological traits of rice that are also linked to the yield potential of the many rice varieties in order to choose the best variations for further rice breeding(Aditya & Bhartiya, 2013). Thousand rice varieties that are well suited to the regional conditions have been developed through selection from the cultivated material many years ago. Under biotic and abiotic stress

conditions, several of those rice varieties have higher yield potential and superior quality traits(Amirova et al., 2024).Keeping in view in the above fact, present evaluation was done with objectives to determine appropriate high-yielding rice genotypes and earliness under the conditions of the Terai region and assess several rice genotypes for yield and yield characteristics.

Materials And Methods

Experimental site

The study was conducted during the 2024 monsoon season (June-October) at College of Natural Resources Management Bardibas (CNRMB) experimental farm in Bardibas, Mahottari District, Nepal, which is suited in the inner terai of Nepal. Geographically, it is suited at altitude 26˚52'0''8North, longitude 85˚49'96'' East; 78 m above sea level. The region receives an average annual rainfall 1200-1400 mm. The soil texture was found silty clay loam (alluvial deposits), pH was slightly acidic (5.6- 6.2) and nutrient status was low organic carbon (0.8-1.2%), moderate nitrogen (0.10-0.15%), deficient available phosphorus (<20 kg ha^{-1}), and high potassium content.

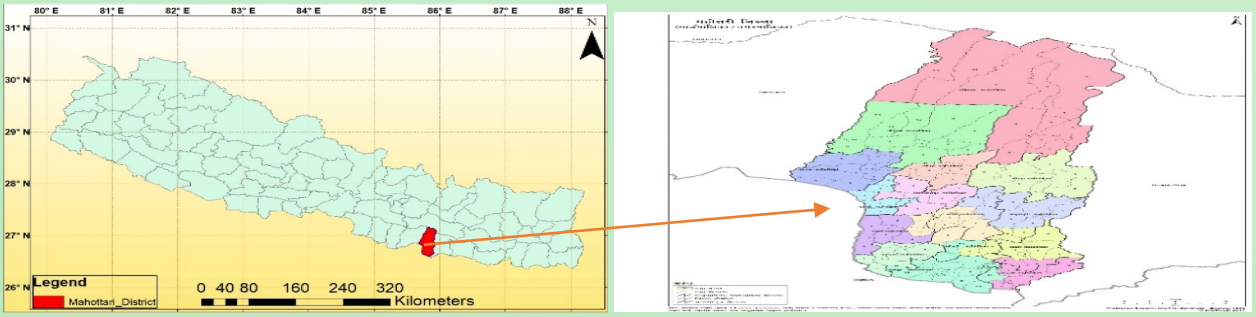

Figure 1: A map showing experimental site

Experimental design and crop management

The research was laid out in one factorial randomized complete block design (RCBD) with two replications and twenty-four genotypes (2 check varieties Hardinath-1 & Hardinath-3) in CNRM Bardibas, AFU. The planting distance between the rice plant was 20*20 cm with plant plot size:1.5x3=4.5 and the spacing between two plots consecutive plots was maintained 0.5 m. The experimental plots and dry seed bed were leveled and prepared using traditional practices. A raised nursery bed was conducted using the dry method of preparing nursery beds. The nursery seedlings of 21 days old were transplanted in June 2024.

The plot size was 4.5 m^2. The fertilizer were applied using urea diammonium phosphate (DAP),and muriate of potash (MOP) at rate of 120:40:40 N:P_2O_5: K_2O [nitrogen (N), phosphorus (P2O5), and potassium 67 68 (K2O)] ha-1(AITC, 2024). The full doses of P2O5 and K2O, along with half of the dose of N, were applied as the basal dose, and the remaining 50% of the nitrogenous fertilizer was applied into two split doses. The first one was used during tillering, and the second one was used after panicle initiation. Every other intercultural operation and mandatory practice package was completed as needed and in compliance with the recommended practices.

Plant materials

The rice genotypes were obtained from National Rice Research Program, Hardinath, Dhanusha, Nepal. The list of rice genotypes used in this experiment is given in **Table 1**.

Data Collection and statistical analysis

Panicle initiation 80%, days to maturity, plant height, test weight, filled grain per panicle, sterility percentage, biomass yield, harvest index, effective tillers were recorded. The grain yield at 12% moisture was calculated using the formula adopted (Shrestha et al., 2021). Data was entered and tabulated using MS-Excel and analyzed using Gen-stat ver. 2015. Key agronomic traits of growth, yield and yield attributes characters were processed to Analysis of Variance (ANOVA). The significant of the differences among the treatments of the rice varieties was estimated with the help of Duncan's Multiple Range Test (DMRT)at a 5% level of probability.

Results And Dıscussıon

Phenological characteristics

Panicle initiation 80%

the panicle emergence was highly varied with the genotypes at 1% level of significance (Table2).The result depicts that IR-132084-B-1191-1-3-B-5, IR-19-A-3197,NS-224 and NS-313 were found delayed in panicle initiation while in 71 (DAT). Hardinath-1 and NS-201showed earlines in panicle emergence. The days to panicle initiation may be influenced by factors such as water and soil conditions, planting and sowing techniques, and its early maturing genetic ability and translation time(Ashfaq, 2012; Hussain et al., 2005).

F-test	<0.001(***)	<0.001(***)	<0.001(***)
CV%	1.8	0.9	6.1
LSD (0.05)	2.508	1.913	15.44
Grand Mean	65.94	97.62	121.5

LSD= Least significant Difference, CV= Coefficient of Variation, * = significant at (P<0.05), ** = significant at (P<0.01), *** = significant at (P<0.001), NS= Non-Significant. DAT- Days after transplanting.

Genotype genetic diversity may be one of the cause of the variation in panicle initiation(Khalil et al., 2009).Similarly, genetic composition of the foreign lines and genotypic environmental interaction may be the cause of the variation in days to panicle initiation(Marwat, 2002).

Days to maturity

The days to maturity of the examined rice genotypes varied significantly at 1% level of significance (Table 2). The results indicated that NS-313had the highest number of days to maturity 104 (DAT), followed by NS-188in 102 (DAT). The Hardinath-1 genotype was showed earlier in maturity (86 DAT),followed byNS-201(91 DAT).Variation in marturity depend upon the panicle emergence and availability of resource at that time. Maturity of different genotypes may varied due to genetic and environment interaction(Karim et al., 2007).

Plant Height (cm)

The plant height was significantly influenced by genotypic variation at 1% level of significance. (Table 2). IR-18-A-2294 had highest plant height of 147.7 cm followed by NS-313 (141.6cm). The shortest plant height was observed in IR-13C121 (94 cm). followed by IR-19-A-5000 (108.1cm).It has been determined that the climatic requirements of each genotype of rice are distinct, which may account for the variance in plant height among these genotypes(Rabbani et al., 2010).

Yield and Yield Attributing Characteristics:

1000 grain weight (gram)

Difference in 1000 grain weight was significant to various genotypes (Table 3).Thousand grain weight of tested ranged from (20.75-29.24).IR-18-A-2294 shown the highest grain weight of 29.24gm, followed by IR-127153-2-3-5-1-B-B (28.57 gm). And lowest was shown in NR-2312-59-1-3-1-1 (20.75 gm) followed by Hardinath-1 (21.24 gm).Several traits showed highly significant variance, and these attributes were controlled by genotypic differences across the tested genotypes(Tahir et al., 2002).

Panicle Length (cm)

The panicle length was observed significant difference in the panicle length among the observed genotypes(Table 3). Longest panicle length was observed on NS-313 (30.19 cm), followed by IR-18-A-2294 (30.01 cm) and shortest panicle length was observed on NR-2312-59-1-3-1-1 (19.85 cm), followed by R-19-A-5000 (23.12 cm). Different rice genotypes may differ in their genetic composition, which could account for the variance in panicle length(Sultana et al., 2014). The genetic variability for several traits in ten rice genotypes, and he found that these traits were controlled by genetics and could be used to choose a desired characteristic of rice(Cha-um et al., n.d.; Tahir et al., 2002).

Filled Grain per Panicle

The number of filled grain per panicle of different genotypes of rice was shown significantly difference under this experiment (Table 3). The highest number was observed in NS-201 (135.8), followed by IR-18-A-2294 (131.6). And lowest number was observed by NS-224 (68.9), followed by IR-12C170 (74.9). The variance was shown due to panicle length, days to maturity and traits among genotypes(Karim et al., 2014). The length of the panicles and the configuration of their spikelets determine the amount of grain per panicle(Balasubramanian et al., 2006; Zhao et al., 2020).

Sterility percentage

Analysis of various genotypes indicates that the differences in sterility percentages amongst the genotypes are statically significant, as presented in Table 3. The genotypes IR-12C170 exhibited the highest sterility percentages at 43.60%, followed by IR-127153-2-3-5-1-B-B at 41.27%. Conversely, the lowest sterility percentage was observed in NS-313 at 13.9%, followed by NS-201 at14.20%. The component of variation for Sterility percentage was due to A lack of boron, which is essential for the growth of pollen tubes, varies by genotype, and drought stress interferes with the uptake of nutrients and water, which impacts spikelet development.(Ali et al., 2013).

Biomass Yield (ton ha^{-1})

The biomass production of the several rice genotype was non-significant (Table 4). The maximum biomass production 32.44 t/ha, was obtained by the genotype NR-2312-59-1-3-1-1, followed by IR-18-A-2294 which yielded 30.01 t/ha. Conversely, And lowest production 21.28 t/ha, was obtained by the genotype IR-132084-B-1191-1-2-B-12, followed by Hardinath-1 which yield 21.82 28 t/ha).These differences suggest that both genetic factors and breeding history contribute to biomass yield variations among rice genotypes(Chen et al., 2008; Jahn et al., 2011).

Harvesting Index

The research revealed that the harvesting index of different genotypes of rice significant difference relation among them (Table 4). The mean harvesting index of different rice genotypes was highest in IR-19-A-5000 (28.40), followed by IR-19-A-4494 (25.11). And lowest was IR-12C170 (13.5), followed by NS-232 (15.14). The variation in harvesting index could be attributed to genetic background plays a significant role in determining harvesting index.(Cui et al., 2000)

Figure 2: A Panicle initiation stage of rice B. Maturity stage of rice C. Layout of rice experiment conducted in CNRM Bardibas

Grain Yield (ton ha^{-1})

When evaluating the grain yield of the tested rice genotypes against the standard (2 check varieties (Hardinath-1 & Hardinath-3), the majority of them were found to be better and significant (Table 4). The results revealed that highest yield (6.87 t/ha) was achieved by the genotypes IR-18-A-2294, followed by IR-19-A-5000 (6.516 t/ha), NS-314(6.24 t/h), NS-278(6.26 t/h), Hardinath-3(6.24t/h) respectively and least by NS-232 (3.91 t/h), followed by IR-12C170 (3.983 t/h).As breeding materials for confirmation, these superior rice genotypes over the standard check in terms of grain yield might be examined further.(AITC, 2024; Pervaiz et al., n.d.)

Conclusion

A rice breeding program's main objective is to evaluate the genotypes of rice for a particular region or niche. The finding of this study showed that based on grain quality and yield, IR-19-A-5000, IR-18-A-2294 were found as high yielding genotypes respectively, while based on earliness and yielding potential Hardinath-1, IR-132T799 and Hardinath-3 were found superior among tested.

Abstract

Bread waste is a critical issue in North Africa, exacerbated by bread subsidies and cultural consumption patterns. This study explores household bread storage, wastage, and management practices in Algeria, analyzing their associations with sociodemographic variables.

An online survey was performed on 316 respondents (62.8% female, 70% aged from 25 to 60 years old) from September, 2023 to December, 2023. The questionnaire asked questions to determine bread storage and management practices and bread wastage levels, as well as socio-demographic characteristics of respondents. Data analysis was based on percentages and Chi-square tests, using SPSS v25 software.

Findings of Algerian households revealed that bread is primarily stored in freezers (83.8%) and at room temperature (76.5%), with plastic bags being the most common storage medium (47.5%). Bread is typically stored for two days (46.1%), with storage duration significantly associated with age and marital status ($p < 0.05$). Notably, 55.8% of respondents reported discarding stored bread, with this behavior significantly linked to gender, age, and marital status ($p < 0.05$).

Bread management strategies in Algeria include reuse in meals (87.0%), reheating (82.5%), and feeding to animals (83.1%). These practices were significantly influenced by gender, household size, and education level ($p < 0.05$). Furthermore, ethical and religious considerations were the primary motivations for reducing bread waste, cited by 47.9% and 36.6% of respondents, respectively. However, environmental and economic concerns were less prominent motivations, indicating a gap in awareness of the broader implications of bread waste.

Policy recommendations from respondents highlighted the need for educational campaigns (38.8%), quality improvements for enhanced preservation (31.1%), and adjustments to bread subsidies (21.4%) to better reflect production costs. These findings emphasize the importance of culturally tailored interventions that address specific demographic behaviors and motivations to effectively mitigate bread waste in Algeria.

Key Words: *bread waste, Algeria, storage practices, sociocultural factors, food sustainability, policy recommendations*

Correspondence: raedsalem8882001@gmail.com

Abstract

One of the most important goals is producing healthy food to eliminate the harmful effects of pesticide residues in plant foods such as grains, vegetables and fruits. There is no doubt that applying good farming practices such as relying on biological pest control and plant growth regulators to achieve the goal of eliminating the dangers of pesticides residues to human health. This is proven by our study using GC-MSMS and LC-MSMS through a full scan of samples of fresh Strawberry fruits (Fragaria × anannasa Duch) var 'Sensation' from the private agricultural field were obtained from badr district, el Beheira Governorate, Egypt. All of which were proven by analysis to be free of the pesticide residues. The results showed that 28-Homobrassinolide at 0.05 mg/l in a greatest decrease in concentrations of pesticide residues (imidacloprid, fenpyroximate, difenoconazole, azoxystrobin, fludioxonil and Lambda-cyhalothrin). Overall, 28-Homobrassinolide at 0.05 mg/l improved detoxification of pesticide residues from fresh strawberry fruits.

Key Words: *Pesticide residues, Strawberries, GC-MSMS, LC-MSMS, 28-Homobrassinolide.*

Introduction

Strawberry (Fragaria × ananassa) known as false fruit is grown in temperate, tropical and subtropical regions of the world and is a member of the Rosaceae family (Trejo-Téllez & Gómez-Merino, 2014). Its excellent flavour, taste and nutritional value made (Rajwana et al., 2017). Strawberry (Fragaria × ananassa Duch.) Is a vital and economical fruit crop that can be grown in a wide range of environments. Customers attracted to its appealing to flavour and aroma, its broad acceptance as a preferred fruit (Lewers et al., 2020; Fecka et al., 2021).

Pesticides known as Toxic chemicals are frequently employed to manage diseases, weeds and pests in order to guarantee crop quality and productivity (Collotta et al., 2013). Because of their negative impact on ecosystems, pesticide residues are now more widely acknowledged as pollutants in the environment (Song et al., 2007). Brassinosteroids (BRs) diversified class of steroid phytohormones (polyhydroxysteroids), (BRs) have a wide range of biological roles (Nolan et al., 2020; Qiao et al., 2022). BRs play important roles in development, plant growth, adaptation to environmental stress and fruit quality (Siddiqi & Husen, 2021; Zhang & Yang, 2021; shehata, 2024). In various types of crops, such as cucumber, mustard, tomato (Lycopersicon esculentum), strawberry (Fragaria ananassa), grapes, and tea (Camellia sinensis), exogenous application of the BR analogue 24-epibrassinolide (EBR) decreased pesticide residues (Sharma et al., 2019; Wang et al., 2017; Xia et al., 2006, 2009; Zhou., 2015). The objectives of this study were to use 28-Homobrassinolide as an exogenous spray to enhance detoxification of pesticide residues from fresh strawberry fruits. For growing healthy food free from any pesticide residues to protect humanity from potential illnesses.

Materials and Methods

Chemicals and Reagents

Certified reference material of GC-MSMS Pesticide combinations including 9 multi pesticide residue mixture as listed below.

GC Multiresidue Pesticide Standard - 185 components including,

Allidochlor, Dichlofluanid, Biphenyl, Mevinphos, 3,4-Dichloroaniline, Etridiazole, Pebulate, N-(2,4-Dimethylphenyl)Formamide ,Captafol, Methacrifos, Chloroneb, 2-Phenylphenol, Pentachlorobenzene, Tecnazene, Propachlor, Diphenylamine, 2,3,5,6-Tetrachloroaniline, Cycloate, Chlorpropham, Ethalfluralin, Trifulralin, Benfluralin, Sulfotep, Diallate , Phorate, Alpha -HCH, Diallate isomer, Hexachlorobenzene, Dichloran, Pentachloroanisole, Atrazine, Clomazone, Beta-HCH, Gamma-HCH(lindane), Terbuthylazine, Terbufos, Profluralin, Quintozene, Propyzamide, Disulfoton, Tefluthrin, Delta-HCH, Isazofos, Tri-allate, Chlorothalonil, Endosulfan-alpha, Prapanil, Dimethachlor, Acetochlor isomer, Vinclozolin, Chlorpyrifos-Methyl, Cypermethrin, Tolclofos-Methyl, Alachlor, Acetochlor, Heptachlor, Metalaxyl, Fonofos, Pentachlorobenzonitrile, Pyrimethanil, Diazinon, Etofenprox, Fluchloralin, Fenchlorphos, Prodiamina, Fenitrothion, Pirimiphos-methyl, Malathion, Methyl-Pentachlorophenyl sulfide, Dichlobenil, Metolachlor, Anthraquinone, Fenthion, Aldrin, Chlorpyrifos, Parathion, Triadimefon, 4,4-Dichlorobenzophenone, Chlorthal-dimethyl, Fenson, Diphenamid, Pirimiphos-ethyl, Bromophos-Methyl, Isopropalin, Cyprodinil, Isodrin, Metezachlor, Pendimethalin,

Penconazole, Chlozolinate, Bioallethrin, Fipronil, Heptachlor-exo-epoxide, Tolyfluanid, Chlorbenzilate, Bromfenvinphos-Ethyl, Quinalphosl, Triadimenol, Folpet, Procymidone, Chlorbenside, Bromophos-Ethyl, Cis-Chlordane, 2,4-DDE, Paclobutrazol, Cis-Tetrachlorvinphos, Fenamiphos, Endosulfan-beta, Flutriafol, Trans-Chloridane, Chlorfenvinphose, Flutolanil, Cis-Nonachlor , Iodofenphos, Prothiophos, Fludioxonil, Profenfos, Pretilachlor, Oxadiazon, 4,4-DDE, Oxyfluorfen, Myclobutanil, Dieldrin, Flusilazole, Bupirimate, 2,4-DDD, Fluazifop-P-butyl, Chlorfenapyr, Nitrofen, Chlorobezilate, Endrin, Endosulfan Ether, 4,4-DDD(TDE), Ethion, 2,4-DDT, Chlorthiophos, Trans-Nonachlor, Triazophose, Sulprofos, Enderin Aldehyde, Enderin ketone, Carfentrazone-Ethyl, 4,4-methoxychlor-olefin, Carbophenothion, Norflurazon, Edifenphose, Lenacil, 4,4-DDT, Endosulfan total, Hexazinone, o,p-Methoxychlor-olefin, Methoxychlor(DMTD), Propargite, Piperonyl butoxide, Resmethrin, Pyridaphenthion, Cis-Bifenthrin, Tetramethrin, Bromopropylate, Phosmet, EPN, Fenpropathrin, Tebufenpyrad, Phenothin, Phenothrin, Tetradifon, Pyriproxyfen, Azinophos-Methyl, Leptophos, Iambda-Cyhalothrin, Mirex, Pyrazophos, Fenarimol, Azinophose-Ethyl, Pyraclofos, Cis-Permethrine, Trans-Permethrin, Pyridaben, Coumaphos, Fluquinconazole, Cyfluthrin, Fenvalerate, Flucythrinate, isomerFlucythrinate and Fluridone.

LC Multiresidue Pesticide Standard - 45 components including:

Rotenone, Spirodiclofen, azoxystrobin, Flufenoxuron, Indoxacarb, Chlorfluazuron, Linuron, Carbofuran, Bendiocarb, Mevinphors, Ametryn, Dimethoate, Carboxin, 3-Hydroxycarbofuran, Dicrotophos, Primicarb, Forchlorfenuron, Clothianidin, Thiacloprid, imidacloprid, Dithofencarb, Chloroxuron, Thiamethoxam, Spiroxamine, Propham, Tricyclazole, Cycluron, Carbaryl, Thiabendazole, Promecarb, Propoxur, difenoconazole, Fenoxycarb, Diflubenzuron, Cyazofamid, Benalaxyl, Boscalid, Triflumeron, Propargite, Spiromesifen, Spirotetramat, fenpyroximate, Dimethomoroph, Spinosad, Spinetoram, and Emamectin benzoate were purchased from CAP- CHEM (Augsburg, Germany), with certified purity ranging from 97% to 99.9%. Acetonitrile, ammonia solution, sodium chloride, acetic acid, triphenylphosphate (TPP), and ethoprophos were obtained from chem- lab (Belgium), and QuEChERS extraction mix kit from CHROMABOND (Valencienner St. 11, 52355 Duren, Germany). All the organic solvents used were higher performance liquid chromatography (HPLC) grade.

Field experiment

The present study was carried out during in two successive 2023 and 2024 on strawberry (Fragaria X ananassa Duch) var "Sensation", grown under a drip irrigation system in a private field at badr district, el Beheira Governorate, Egypt. Soil texture was sandy and drip irrigation system was adopted. Strawberry plants had been under the standard agriculture practices throughout the seasons. Three replications were used for each treatment. The treatments included: control (tap water spray), 28-Homobrassinolide at (0.025 mg/l) and 28-Homobrassinolide at (0.05 mg/l). The non-ionic surfactant Top film at 0.05% (V/V) was added to all treatments to reduce the surface tension and to increase the contact angle of sprayed droplets. These treatments were arranged in Analysis of Variance (ANOVA) for Randomized Complete Block Design (RCBD).

Samples collection

Fresh strawberry fruits were picked at mid-December after 5 days of pre-harvest treatments, when bright red color (3/4 of surface showing red) at the same ripening stage. The fruits were selected based on the uniform color, same size and no pests, as well as the absence of blemishes or disease, with no physical damage. The samples included 1kg from fresh strawberry fruits for each replicate for pesticide residue analysis. The samples were collected from private field at badr district, el Beheira Governorate, Egypt. The sampling was performed in accordance with the general principles and methods of the European Commission (EC) directive 2002/63/EC for establishing MRLs in food commodities (EC, 2002). All the samples were placed in sterile polythene bags, in an ice box, to avoid contamination and deterioration, labeled, and transported to the laboratory for processing. The homogenized samples were analyzed immediately.

Sample Extraction and Clean-Up

The extraction and clean-up method used was based on QuEChERS (quick easy cheap effective rugged and safe) sample preparation method for pesticides (BS EN 15662:2018). An aliquot of 10 g of homogenized sample was placed in a 50 mL centrifuge, and 10 mL of acetonitrile was added. The mixture was vortexed for one minute, followed by adding 4 g of magnesium sulphate anhydrous, 1g trisodium citrate di hydrate, 0.5 g disodium hydrogen citrate and 1 g of sodium chloride. The clean-up was carried out by transferring 3 ml of supernatant into another tube containing 75 mg of primary and secondary amine (PSA), 75 mg of C18 Sorbent (for wheat) and 450 mg of magnesium sulphate. After agitation and centrifugation, the aliquots of the extract were reconstituted to 1.5 mL vial for gas chromatography (GC-MS/MS) (Mustapha et al., 2017).

Solutions and Standards

From Reference Standard pesticide mixtures (9 Mixture 100ppm each compound for GC-MS/MS and 10 mixtures 100ppm each compound for LC-MSMS), stock solutions (1 ppm) were prepared in acetonitrile for GC-MSMS and LC-MSMS analysis. Multi-residue working solutions containing pesticides analyzed by GC-MS/MS and LC-MSMS were prepared in acetonitrile at a concentration of 5 – 100 ppb for each pesticide to create calibration curves.

GC-MSMS Analysis

GC-MS/MS analysis was proceeding using a gas chromatography (GC-MSMS- TSQ9610 Mass Spectrometer, Thermofisher, USA), With Trace gold GC column TG-5MS, length 30 m, internal diameter 0.25mm, film 0.25µm and temperature -60 to 330/350°. Sample injection was performed in the splitless mode, with an injector temperature of 250 °C and an interface temperature of 280 °C. The temperature of the oven was programed from an initial value of 80 °C for 1 min, ramped to 160 °C at 10 °C min^{-1} for 2 min, and to 280 °C at 12 °C min^{-1} for 6 min. Helium was used as a carrier gas with a constant flow rate of 1.2 mL min^{-1}. Electron ionization was used at –70 eV in selective reaction monitoring (SRM) and full-scan modes between 50 m/z and 550 m/z for the detection of different analyses.

LC-MSMS Analysis

LC-MS/MS analysis was proceeding using a liquid chromatography (LC- MSMS-SCIEX QTRAP 4500, Canada), with Synergi 2.5µm fusion – RP100A, LC column 50*2 mm. C-18 analytical column. The sheath gas temperature was kept at 400 °C. Deionized water containing 0.1% formic acid and ammonium formate 5 mM (mobile phase A), and methanol and (5mM) ammonium formate dissolved in deionized water (95:5, v/v) containing 0.1% formic acid (mobile phase B) were used for the gradient program, which started with 100% A for 1 min and was linearly decrease to 0 % A and 100% B over 13 min. then decrease B to 0 % and 100% A over 6 min. The column temperature was kept at 40 °C, and the injection volume was 3µL with a constant flow rate of 0.4 mL_min^{-1}. For each compound, two multi reaction monitoring (MRM) transitions were monitored. The pesticides Propham, Tricyclazole, Cycluron, Carbaryl, Thiabendazole, Promecarb, Propoxur, Linuron, Carbofuran, Bendiocarb, Mevinphors, Ametryn, Dimethoate, Carboxin, 3-Hydroxycarbofuran, Dicrotophos, Primicarb, Forchlorfenuron, Clothianidin, Thiacloprid, Dithofencarb, Chloroxuron, Thiamethoxam, Spiroxamine, Fenoxycarb, Diflubenzuron, Cyazofamid, Benalaxyl, Boscalid, Triflumeron, Propargite, Spiromesifen, Spirotetramat, Dimethomoroph, Rotenone, Spirodiclofen, Flufenoxuron, Indoxacarb, Chlorfluazuron, Spinosad, Spinetoram, and Emamectin benzoate were analyzed with LC-MS/MS. The results of all investigated sample for above 42 pesticides were less than LOQ (5 ppb). The results indicate the safety of organic vegetables and fruits for human health because of no pesticide residue (Willer and Lernoud, 2017; Apaolaza et al., 2018).

Experimental

The analysis precured as shown in the standard method of Britch standard institute (BS EN 15662:2018). Multimethod for the determination of pesticide residues using GC- and LC-based analysis following acetonitrile (Thermofisher) extraction and clean-up by dispersive solid phase extraction (SPE). Modular QuEChERS-method.

Chromatography techniques

GC-MSMS Thermofisher TSQ9610 With Trace gold GC column TG-5MS, length 30 m, internal diameter 0.25mm, film 0.25µm and temperature -60 to 330/350° c. PrO-Analytical Centrifuges.

Data analysis

Statistical comparisons of differences were made by analysis of variance (ANOVA). To compare the means between different treatments concentrations and Pesticide Residues, the Least Significant Difference (LSD) test was conducted at the 0.05 level of probability, the differences between treatments concentrations and Pesticide Residues were designated by different letters. According to (Snedecor & Cochran, 1980). The data was analyzed using (SAS, 2009).

Results

Changes in pesticide residues (Imidacloprid, Fenpyroximate and Lambda-cyhalothrin) of "Sensation" Strawberry fruits in response to used applications of 28-Homobrassinolide were reported in (Table 1, Figure 1, Figure 2 and Figure 3). The data confirmed the previous trend that pesticide residues (Imidacloprid, Fenpyroximate and Lambda-cyhalothrin) were significantly decreased by two applications compared with control. Moreover, the greatest decrease in pesticide residues (Imidacloprid, Fenpyroximate and Lambda-cyhalothrin) were obtained with 28-Homobrassinolide at 0.05 mg/l in both seasons. The use of 28-Homobrassinolide with the lower concentration at 0.025 mg/l was able to cause a significant decrease in pesticide residues (Imidacloprid, Fenpyroximate and Lambda-cyhalothrin) as compared with control.

The influence of pre-harvest treatments of 28-Homobrassinolide on pesticide residues (Difenoconazole, Azoxystrobin and Fludioxonil) of "Sensation" Strawberry fruits whether high or low concentrations were reported in (table 2, Figure 4, Figure 5 and Figure 6). The data showed that pesticide residues Difenoconazole, Azoxystrobin and fludioxonil were disappeared from strawberry fruits samples when applied 28-Homobrassinolide (at 0.05 mg/l) in both seasons. When 28-Homobrassinolide was applied (at 0.025 mg/l), it gave low pesticide residues (Difenoconazole, Azoxystrobin and Fludioxonil) as compared with control.

Table 1. The effect of pre-harvest applications of various 28-Homobrassinolide concentration on Pesticide Residues (Imidacloprid, Fenpyroximate and Lambda-cyhalothrin) of "Sensation" Strawberry fruits during the two seasons 2023 and 2024.

Treatments	Pesticide Residues (active ingredient of pesticides)					
	Imidacloprid (mg/kg)		Fenpyroximate (mg/kg)		Lambda-cyhalothrin (mg/kg)	
	2023	2024	2023	2024	2023	2024
Control	0.023[a]	0.030[a]	0.111[a]	0.121[a]	0.041[a]	0.052[a]
28-Homobrassinolide at 0.025 mg/l	0.010[b]	0.020[a]	0.108[a]	0.100[a]	0.035[a]	0.048[b]
28-Homobrassinolide at 0.05 mg/l	0.005[b]	0.005[b]	0.051[b]	0.048[b]	0.006[b]	0.009[c]
LSD at 0.05	0.008	0.011	0.011	0.051	0.010	0.002

Values in each column when accompanied with similar letters, were not significantly different by using the least Significant Difference at 0.05 for comparing the means.

Table 2. The effect of pre-harvest applications of various 28-Homobrassinolide concentration on Pesticide Residues (Difenoconazole, Azoxystrobin and Fludioxonil) of "Sensation" Strawberry fruits during the two seasons 2023 and 2024.

Treatments	Pesticide Residues (active ingredient of pesticides)					
	Difenoconazole (mg/kg)		Azoxystrobin (mg/kg)		Fludioxonil (mg/kg)

Discussion

Brassinosteroids (BRs) have a wide range of biological roles (Nolan et al., 2020; Qiao et al., 2022). 28-Homobrassinolide (HBL) is gaining attention because of its high advantages, such as increasing chlorophyll content and photosynthetic activity, accelerating translocation from source to economic parts. HBL increases the enzyme levels, which are responsible for sugars, proteins and nucleic acid. HBL promotes the proline production, which imparts a greater increase in plants' resistance against adverse weather conditions than other BRs (Sridhara et al., 2021). (Edupuganti et al., 2019) already showed improvement in maize crop growth due to exogenously applied HBL. However, extensive studies with respect to different dosages and application methods were not properly documented, which has played a key role in decreasing the cost and quantity of HBL.

These BRs play important roles in development, plant growth, adaptation to environmental stress and fruit quality (Siddiqi & Husen, 2021; Zhang & Yang, 2021; shehata, 2024). By controlling the antioxidant system, the application of exogenous BRs makes plants more resistant to the toxicity of pesticides (Sharma et al., 2018; Zhou et al., 2015). As an example, pretreatment with 24-epibrassinolide, a BR analogue, can reduce the oxidative stress response in cucumbers (Cucumis sativus) and grapes (Vitis vinifera) brought on by the insecticide chlorpyrifos and (mostly) the fungicide chlorothalonil (Wang et al., 2017; Xia et al., 2006, 2009). In mustard (Brassica juncea), castasterone, a BR, can lessen the insecticide imidacloprid's reactive toxicity (Sharma et al., 2019). Brassinosteroid signalling component (OsBZR4) plays a significant role in atrazine and isoproturon detoxification and metabolism in rice (Su et al., 2024). Yang et al., 2021 indicate that the possible risk of boscalid residue could be alleviated by EBR pretreatment through activating detoxification enzymes. This study provided further evidence about the possibility of utilizing 28-Homobrassinolide, a BR analogue, as a spray treatment to improve detoxification of pesticide residues from fresh strawberry fruits under field conditions.

Acknowledgements

I am deeply grateful to Kayan Company for import and export agricultural services for funded this research.

Situational Analysis of Kenyan Slaughterhouses in Relation to Resource Utilization. The Case of Nairobi County

Winstone Asugo
Kenya Industrial Research and Development Institute, Kenya

Abstract

The livestock sector plays a vital role in advancing Kenya's Vision 2030, contributing approximately 40% of agriculture's share to the national GDP. Among the key contributors within this sector are slaughterhouses, which generate economically valuable by-products such as hides and skins. This study sought to assess the current utilization of slaughterhouse resources and waste management practices within Nairobi County, with a focus on identifying challenges and opportunities for improved efficiency and value addition.

A descriptive research design was employed, utilizing mixed methods for data collection. Quantitative data from structured questionnaires were triangulated with qualitative insights from focus group discussions, key informant interviews, direct observation, and literature review. Reviewed documents included the Kenya Livestock Sector Report (USAID, 2023), Mapping of Beef Systems in Nairobi Report (Agrisys, 2023), and the Kenya Livestock Market Assessment Report (USAID, 2023).

Findings revealed that while red and green offal are the most commonly sold by-products—averaging KES 350 and KES 170 respectively—market structures remain poorly organized. Only 18% of slaughterhouses sell by-products to established enterprises, with the majority (82%) relying on informal individual buyers. Furthermore, value addition is minimal, with only 46% of facilities utilizing by-products for biogas or animal feed production. The study also highlighted the reliance on outdated equipment and an expressed need among stakeholders for support in acquiring modern technologies.

Overall, the research underscores the untapped potential of slaughterhouse by-products in contributing to Kenya's economic growth. Strategic investment in technology, formal market linkages, and enhanced waste management practices could significantly boost productivity and sustainability within the livestock sector.

Resource Mapping and Economic Potential Assessment of Turkana County, Kenya

Winstone Asugo

Agribusiness and Economics, Kenya

Abstract

This report summarizes a resource mapping study in Turkana County, Kenya, commissioned by the International Labour Organization (ILO) and conducted by the Kenya Industrial Research and Development Institute (KIRDI) under the PROSPECTS programme. The study aims to support social and economic inclusion for refugees and host communities through job creation. Using a mixed-methods approach—desktop research, interviews, focus group discussions, and surveys with 184 stakeholders—the research focused on sub-counties within the PROSPECTS initiative.

Findings reveal that Turkana is rich in resources, with livestock (45%), fisheries (19%), and minerals (11%) being the most prevalent. Seasonal variations affect resource availability, especially in livestock, agriculture, and fisheries. While 49% of producers reported increased availability due to development support, discovery of new resources, high demand, and price increases, 43% reported declines, mainly due to drought. This highlights the need for climate adaptation strategies.

The most traded resources—livestock, fish, agriculture, and charcoal—indicate strong market demand and economic potential. The county government is actively promoting resource development through initiatives in livestock (e.g., slaughterhouse support, dairy goat farming), fisheries (reviving processing facilities, sustainable fishing), and agriculture (irrigation schemes, despite operational challenges).

Key gaps identified include post-harvest losses in fisheries due to limited cold storage, inefficient irrigation systems, and low value addition in forestry. Promising emerging areas include plastic recycling and climate adaptation.

The study recommends further value chain viability assessments, fostering cross-sector collaboration, and establishing a Common Manufacturing Facility (CMF) to boost value addition, productivity, and job creation. Overall, the report provides a strategic foundation for sustainable economic development in Turkana County, offering valuable insights for policymakers, development partners, and local stakeholders.

Abstract

Rice yield significantly reduced due to drought stress in northwest Bangladesh. Drought-tolerant rice genotypes could play a vital role in increasing rice productivity and sustainability, and improving the livelihood of farmers in drought-prone rainfed ecosystems. Therefore, the study was undertaken to investigate the responses of rice genotypes under drought drought-prone rainfed environment and to select rice genotypes tolerant to drought stress. A total of 30 rice genotypes were evaluated in the drought-prone rainfed high Barind tract at Godagari, Rajshahi, Bangladesh (24.27 N latitude, 88.21 E longitude, 40 masl) over two wet seasons (WS), July to December. Twenty-five-day-old seedlings were transplanted in 25 x 15 cm spacing @ 3 seedlings hill-1 following a randomized complete block design with 3 replications on 16 August of both the WS. Rainfall, temperature, drought severity, groundwater depth, soil moisture content, soil water potential, phenology, leaf rolling and drying, spikelet sterility, dendogram clustering, rooting behaviors, yield, and yield component data were measured to understand drought stress and to evaluate the performance of the genotype. Yield, yield components, leaf rolling, spikelet sterility, and root characteristics varied significantly (p=0.001) among rice cultivars. Grain yield and harvest index of the tested rice genotypes ranged from 1.28 to 4.51 t ha-1 and 0.25 to 0.47, respectively, based on drought severity. Across genotypes, 61% of root biomass was located in the upper 0-10 cm soil layer, and decreased sharply in the layers below (27%, 9%, and 3% in the 10-20, 20-30, and 30-40 cm layers, respectively). Based on overall performance under drought stress, four rice genotypes (IR74371-70-1-1, IR83377-B-B-93-3, IRRI123, and IR83381-B-B-6-1) were selected as drought tolerant, and BR7873-5*(NIL)-51-HR6 was selected as drought escaping. The genotypes IR74371-70-1-1 and BR7873-5*(NIL)-51-HR6 were released as drought-tolerant variety BRRI dhan56 and drought-escaping BRRI dhan57, respectively. Consequently, the genotypic variation in our germplasm selection indicated considerable scope to develop drought-tolerant varieties through breeding to improve rainfed lowland rice.

1. Introduction

Drought stress is a serious threat to sustainable rice production worldwide since water resources are limited and good quality irrigation water resources are scarce. However, drought occurrence and its effects on rice productivity often depend more on the rainfall distribution rather than total seasonal rainfall (Hijmans and Serraj, 2008). Intense drought can cause significant damage to the rice crop, often resulting in profound losses impacting farmers' families and the economy (Pandey et al., 2007). In many regions, drought induced losses in crop yields exceed losses from all other stresses, since both its severity and duration are critical (Farooq et al., 2009). The northwest part (Rajshahi region) of Bangladesh is such a drought prone area with low and erratic rainfalls, and limited irrigation potential (Saleh et al., 2000; Saleh and Bhuiyan, 1995). Erratic rainfall distribution causes drought frequently in this region, and results in yield losses that are generally higher than the damage due to flooding and submergence. The recurrent interval of drought is about 2−3 years, and drought occurs especially during the reproductive phase of wet season rice, which is generally classified as terminal drought (Islam, 2007). Often drought is also occurring at the beginning of the wet season, just prior to transplanting of rice seedlings. But apart from these regular events, any growth stage of rice crop can experience intermittent drought during the season due to uneven rainfall patterns (Kamoshita et al., 2008). These conditions are typical for about 0.16 M ha land of northwest Bangladesh which are rainfed and mainly drought prone (Saleh et al., 2000). The major portion of this region is part of the Barind tract which is a distinctive physiographic unit comprising a series of uplifted blocks of undulating terraces. The Barind has a higher elevation than the adjoining floodplain, with two terrace levels, one at 40 masl and another at 20−23 masl (Riches, 2008). Bangladesh as a whole has an average rainfall of about 2300 mm, ranging from 1000 to 5000 mm, but mean annual rainfall is lowest (1000-1200 mm) in the northwestern region (Karmakar et al., 2012; Saleh et al., 2000). Due to the effect of climate change, the weather of this region is getting extremer over the years. Karmakar et al. (2010) reported that only 800 mm rain occurred in Rajshahi during 2009. Annual average rainfall of the Rajshahi region showed a decreasing trend, declining by 3.1 mm per year since the last 50 years (Ferdous and Baten, 2011). Considering these changes occurring, comprehensive research on field screening of rice genotypes were undertaken in the drought prone rainfed environment of northwest Bangladesh.

The wet season (Aman) rice production in Bangladesh is dependent on monsoon rainfall. Farmers largely rely on rainfall and experience late transplanting of Aman rice when the monsoon is delayed, or yield reduction when drought occurs during the booting stage of rice in October. Delayed onset of the monsoon can create water stress for transplanted rice seedlings resulting to lower yields. Water stress due to extended delay of rainfall may even destroy rice seedlings (Mahmood et al., 2003) which is a recurrent phenomenon and an important constraint to rainfed rice production in Asia. However, rice yield is more affected by drought from panicle initiation to the grain filling stage. These stages occur late in the season when the probability of drought is higher than early in the season. Thus, late-season drought has a larger aggregated production impact than early-season drought (Pandey and Bhandari, 2008). Genotypes with increased drought tolerance are considered to be the first necessary step to improve the productivity of drought-prone rice-based systems. Consequently, research efforts were directed for many years towards the development of early-maturing and drought-tolerant rice varieties.

Another important element in drought tolerance are root systems. Rice root systems vary significantly among genotypes and soil conditions in drought prone rainfed environments (ref???). Root characteristics are strongly associated with drought resistance under rainfed conditions (Sharma et al., 1994). The root system of rice cultivars is strongly determined by genetics, however, it also affected by the soil moisture situation and crop management practices (Mambani et al., 1990; Sharma et al., 1987; Cruz et al., 1986). Reports showed that root length density (RLD) in lowland rice is affected by environmental conditions, genotype, management practices and soil depth (Tuong et al., 2002; Samson et al., 2002).

Recent research at the International Rice Research Institute (IRRI) has shown that direct selection for grain yield under drought stress is effective (Bernier et al., 2007; Venuprasad et al., 2007). IRRI and its National Agricultural Research and Extension System (NARES) partners identified several promising breeding lines that can produce 1.0−1.5 t ha^{-1} higher yield than current mega varieties in drought prone environments (Mackill et al., 1996). However, many of these promising genotypes have not yet been tested in drought prone rainfed environments of Bangladesh. But in order to identify the most promising and adaptable genotypes, screening and fine-tuning are required in the target environment. Therefore, a drought screening trial needed to be pursued in the drought-prone rainfed northwest Bangladesh. The main purposes of this study were to evaluate the performance of rice genotypes in drought-prone rainfed environment, and to select rice genotypes for drought tolerance based on root index and overall performance.

2. Materials and methods

2.1 Experimental site

The experiments were conducted in a farmer's field at Edulpur, Godagari, Rajshahi, Bangladesh (24°27′N latitude, 88°21′ E longitude, 43 masl) during the 2009 and 2010 wet season (WS). A drought prone rainfed topmost field in the *Barind tract* was selected for the experiment. The experimental site belongs to the Agro-ecological Zone (AEZ) 26, having silt loam to silty clay soils with a grey color (BARC, 2018). The topsoil at the experimental site had a soil pH of 5.8, a texture of 17% clay - 68% silt - 15% sand, soil organic carbon of 0.70%, total soil N of 0.078%, a C/N ratio of 9.0, available P_{Olsen} of 10.0 mg kg^{-1}, exchangeable $K_{exch.}$ of 0.21 me/100 g and a cation exchange capacity (CEC) of 6.8 cmol kg^{-1}.

2.2 Background of the tested rice genotypes

Thirty rice genotypes including 4 check varieties were tested for drought tolerance in the drought-prone rainfed conditions (Table 1). The rice genotypes were collected from the International Rice Research Institute (IRRI), the Bangladesh Rice Research Institute (BRRI), the Bangladesh Institute of Nuclear Agriculture (BINA) and farmers. IRRI and NARES partners identified several promising breeding lines that can produce 1.0–1.5 t ha^{-1} higher yield than current mega varieties under drought stress (Mackill et al., 1996). Some of the breeding lines were developed following crosses between two drought-tolerant breeding lines with the aim to accumulate positive alleles for drought tolerance from the two parents. Another set of breeding lines were developed by crossing drought-tolerant breeding lines with high-yielding popular drought-susceptible lines, with the aim to develop drought-tolerant breeding lines with high yield potential and good grain quality. All crosses were advanced through cyclic selection under reproductive stage drought stress from F_2 to F_6 generations based on drought tolerance, high yield, insect and disease tolerance, and good grain quality traits (amylose content, chalkiness etc.). The F_6 generation was transplanted under reproductive stage drought and selection was carried out in the nurseries. High-yielding lines under drought stress were bulked and forwarded to the observational yield trial (OYT). In the OYT, selection for high yield was repeated under reproductive stage drought stress and the best lines were forwarded to the advanced yield trials (AYT). In the AYT, selected lines were again tested with drought imposition at the reproductive stage. Selected drought tolerant genotypes from IRRI Philippines were then brought to Bangladesh for field screening in drought prone rainfed environments. Since there was no existing drought tolerant rice variety, 4 promising rice varieties were used as checks in the screening experiments.

Table 1. Rice genotypes tested in the experiments

SN	Rice genotype	Parentage (Male parent/Female parent)
1	IR83376-B-B-71-1	IR71700-247-1-1-2 (DT)/IR77080-B-34-1-1 (DT)

2.3 Experimental protocol and management practices

Seedlings were raised in a seedbed according to the traditional farm practice. Seeds were soaked in water for 24 h and incubated until the radicle emerged. Sprouted seeds were broadcasted at 80 g m^{-2} on 22 July of the two successive wet seasons 2009 and 2010. Fertilizers containing N, P, K and S at 46, 20, 30 and 18 kg ha^{-1}, respectively, were applied in the seedbed during final land preparation (BRRI, 2019). Urea (N at 46 kg ha^{-1}) was top dressed at 10 days after seeding (DAS). Wet land soil preparation with puddling was done according to the common practice. Initially, the land was ploughed once with a country plow, followed by two power tiller passes and laddering. After 7 days, the land was finally prepared by one pass with a power tiller, followed by laddering to level the land. The levee around the plot was newly made. Fertilizers used were urea, TSP, MOP, gypsum and zinc sulfate, applied at a rate of N, P, K, S and Zn of 82, 15, 38, 10.6 and 2.7 kg ha^{-1}, respectively. The full amount of TSP, MOP, gypsum, zinc sulfate and one-third of the urea were applied basally during the final land preparation. The remaining urea was top-dressed in two equal splits at 20 days after transplanting (DAT) and 40 DAT synchronized with rainfall or wet soil conditions as the experiment was conducted under rainfed conditions. The experiment was laid out following a randomized complete block design with 3 replications. Twenty five-day-old seedlings were transplanted with a 25 x 15 cm spacing (BRRI, 2019) at 3 seedlings $hill^{-1}$ on 16th August in both years. Transplanting of rice seedlings purposely delayed from optimum planting (July) to address terminal drought at reproductive stage. Unit plot size was 2.5 m x 4 m. Based on the drought characteristics of the experimental site, transplanting was purposively delayed compared with the normal transplanting time (July) of Aman rice (wet season) to increase the potential exposure to drought stress (Torres et al., 2012). The levee around the experimental plots was opened at 28 DAT to ensure severe drought stress at reproductive stage of the crop. Uniform and standard management practices were followed to control weed and pest in the plots.

2.4 Sampling and data collection

Recommended procedures were followed to collect data for yield and yield components, agronomic parameters, and drought stress measurements (Gomez, 1972; Gomez and Gomez, 1984; IRRI, 2002; IRRI, 1994). At maturity, tillers and panicles $hill^{-1}$, empty and full spikelets $hill^{-1}$, and 1000-grain weight were counted from 2 x 2 hill

sampling units from three places (12 hills plot^{-1}) sampled on a diagonal in each plot (Gomez, 1972). From the center of each plot, 6-m^2 areas were harvested for determination of grain and straw yields at maturity. After harvest and threshing, grains were sun-dried, and weight and moisture content were measured. Grain yield was adjusted to 14% moisture content, and expressed in t ha^{-1}.

2.5 Climate monitoring and drought stress characterization

Meteorological data (daily rainfall, air temperature, evaporation and sun shine hour) were collected from the mini-weather station at Edulpur, Godagari, Rajshahi, Bangladesh set up by BRRI Rajshahi and very close (25 m) to the experimental plots.

2.6 Rainfall status

The experimental site at Edulpur, Godagari, Rajshahi received the lowest seasonal rainfall (744 mm) since a decade in the year 2009. Of the total, 210 mm occurred in August, which also had 17 rainless days (Fig.1). In September, rainfall was 181 mm but 80% of that occurred in the 1st half of the month and 21 days were rainless. There were 27 rainless days in October and only 15.8 mm rainfall was observed (Fig. 1). Consequently, the crop of 2009WS experienced severe drought stress during the reproductive phase. In contrast, 897 mm rain occurred at the experimental site in the WS 2010 of which 115, 160, 192, 133 and 2.4 mm rain occurred in July, August, September, October and November, respectively (Fig. 2). Rainfall from July to October 2010 was well distributed (Fig. 2). Therefore, especially the short and medium duration genotypes did not face drought stress in the 2010WS. However, the long duration genotypes flowering after the 3rd week of October experienced medium drought stress.

2.7 2Temperature status

Monthly mean temperatures from July to November of 2009 were comparatively higher than in 2010. Temperature fluctuation of both years followed similar trends, but the day-night temperature difference in October to November 2009 was higher than in 2010. Monthly mean maximum and minimum temperatures at the site from July to November were 32.1 and 20.5 °C in 2009, and 29.4 and 25.2 °C in 2010. The mean daily sunshine duration was 6.14 h in the 2009WS and 5.65 h in the 2010WS.

2.8 Drought measuring protocol

Drought stress was assessed indirectly by measuring soil moisture content, soil water potential, drought amount quantification, leaf rolling and drying score, spikelet sterility percentage, phenotypic acceptability and root characteristics. The methods are outlined below.

2.9 Ground water depth measurement

Ground/perched water table was monitored daily with Polyvinyl chloride (PVC) pipe/ piezometers of 1 m length and 0.05 m diameter. The lower 0.8 m end of the pipe, which was below ground, was perforated with 4 mm holes. Three PVC pipes were installed in the experimental plots and the water level was regularly monitored in relation to the upper end of the pipe. Water table depth in the experimental field fell sharply from 13th September onward in the 2009 WS (Fig. 3). It reached 0.8 m below ground on the 25th September and stayed there until the end of the 2009 season. In the 2010 WS, the perched water table started to fall from the 27th September but fell slowly. This confirmed that the 2009 WS experienced a severe drought while the 2010-WS was only a moderately drought for the crop.

2.10 Soil moisture content measurement

The levee surrounding the plots was cut at 28 DAT, so that the soil dried faster during rainless days. Cracks developed in the soil of the plots quickly and became deeper during the season. Three soil samples from 0-0.2 m depth of each replication were taken by auger twice weekly from 30 DAT until the ripening stage. After recording the initial weight, the soil samples were wrapped in aluminum foil and oven dry weight was determined after drying at 70 ˚C temperature for 72 h. Initial and oven dry weight of the soil samples were used to calculate soil moisture content as a measure of soil water status in the field. Soil moisture content was calculated using the following formula:

$$\text{Soil moisture content (\%)} = \frac{\text{W1-W2}}{\text{W1}} \times 1 - W \qquad (1)$$

where W1 is the initial weight of the sample and W2 is the oven dried weight of the sample.

Soil moisture status of the experimental plots during the seasons is shown in Fig.4. In general, soil moisture during the 2009 WS was much lower than in the 2010 WS. It decreased to 8% at the last week of October during 2009 WS while it was still 20% at the end of the 2010 WS.

2.11 Soil water potential measurement using Tensiometer

Soil water potential measured with tensiometers (give specs of the equipment used???) after draining the plots at 28 DAT in both seasons is shown in Fig. 5. The soil water potential declined generally but fluctuated up and down in both early seasons due to alternating periods of drought and rainfall (Fig. 5). Fluctuating soil water potentials continued longer in the 2010 WS. A steady decline started from 7th October 2009 but only the 17th October 2010.

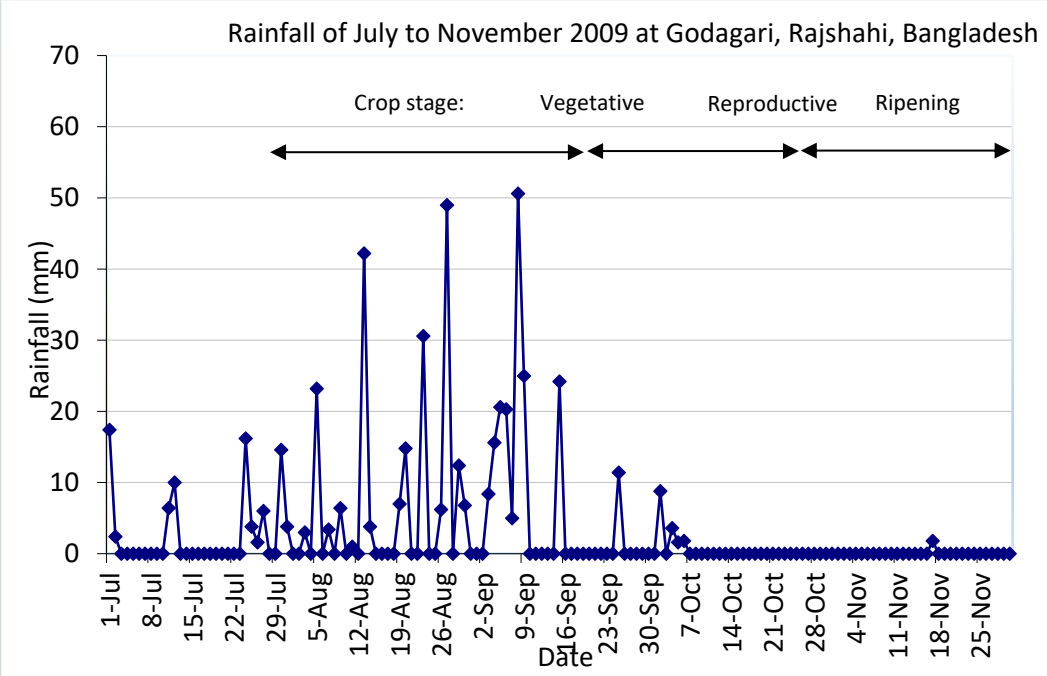

Figure 1. Crop stage and rainfall distribution at the experimental site during July-November 2009 (Source: Mini weather station of BRRI Rajshahi at Godagari, Rajshahi, Bangladesh).

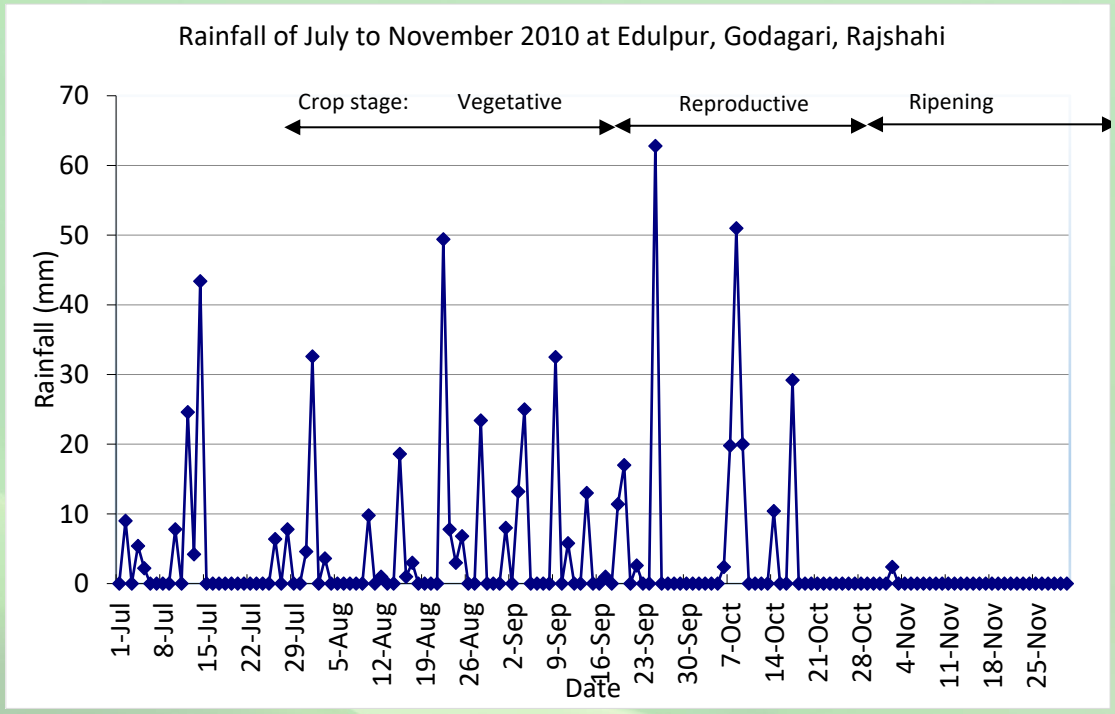

Figure 2. Crop stage and rainfall distribution at the experimental site during July-November 2010 (Source: Mini weather station of BRRI Rajshahi at Godagari, Rajshahi, Bangladesh).

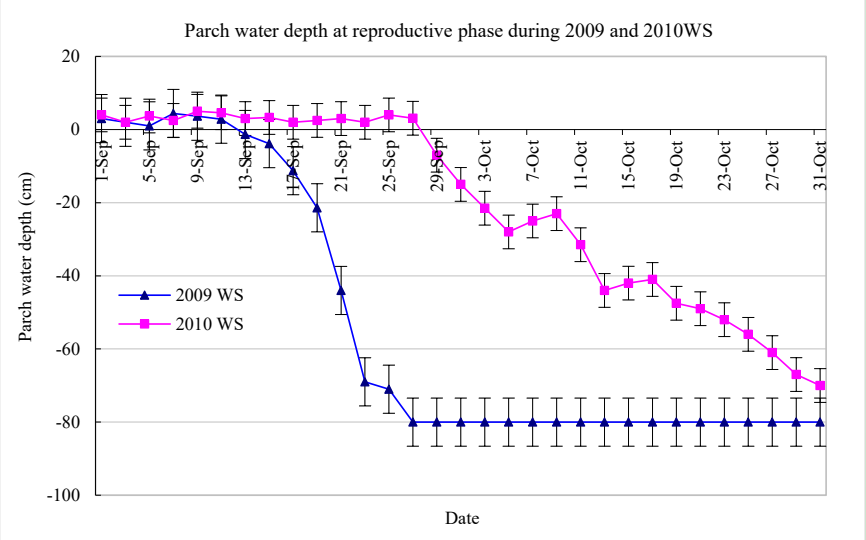

Figure 3. Parch water depth at the experimental field during 2009WS and 2010WS at Godagari, Rajshahi, Bangladesh.

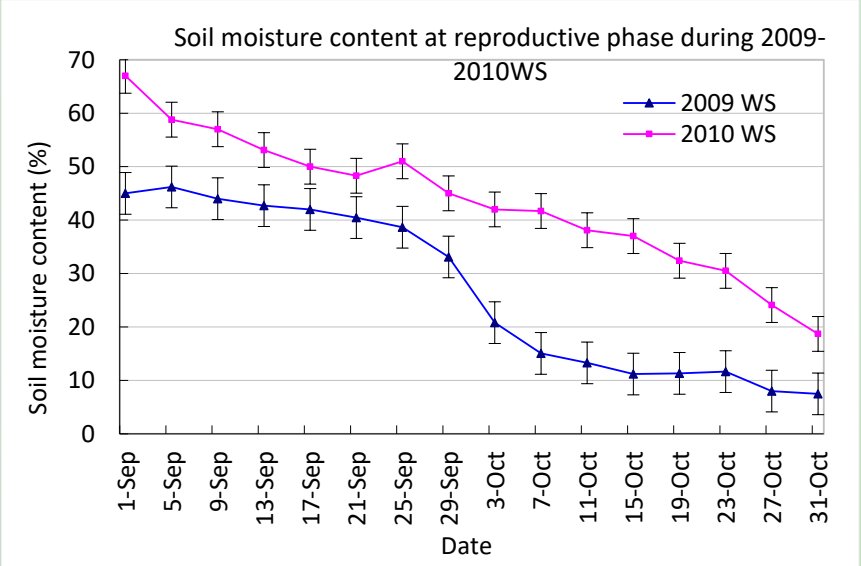

Figure 4. Soil moisture content at the experimental fields during 2009WS and 2010WS at Godagari, Rajshahi.

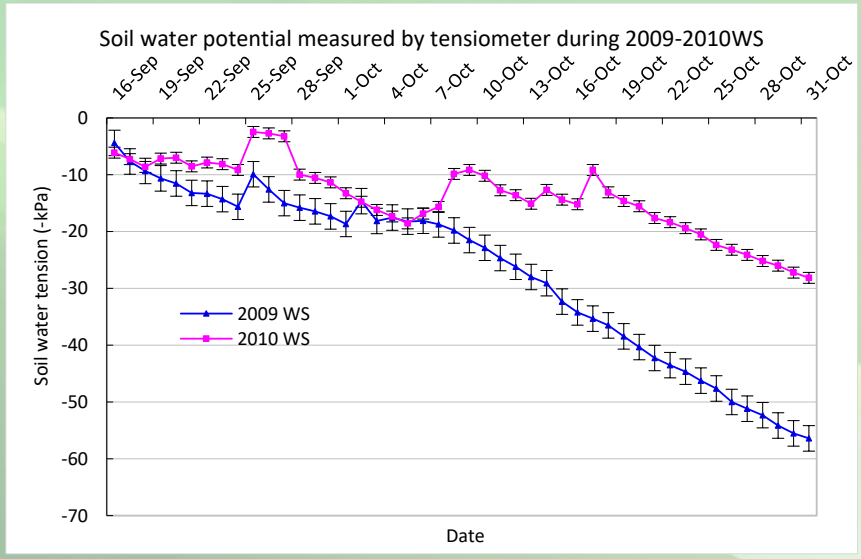

Figure 5. Soil water potential at the experimental fields during 2009WS and 2010WS at Godagari, Rajshahi, Bangladesh.

2.12 Drought Severity quantification

Drought Severity was determined using Drought Simulation Model (Islam et al., 2007) and expressed in water deficit compared to a simulated normal watered crop. Drought severity was considered as the water deficit in the soil being equal to the unfulfilled demand of a simulated normal crop and drought duration was the period of time during which the crop suffered from drought. Drought severity was the cumulative amount of drought for that duration. Based on the seeding and transplanting date of the crop in 2009 and 2010WS, drought amount and duration were quantified in three crop stages like vegetative (08 August to 15 September), reproductive (16 September to 15 October) and ripening stage (16 October to 15 November). The model assumes two storages of water; the first one is called surface water storage (SWS) and the second one is soil moisture storage (SMS). SWS contain standing water in the field above the soil surface and SMS contains soil moisture in the root zone soil. The ET demand of crop is met from the first storage (SWS) if there is water in it on the dry days. When first storage is exhausted then ET demand is met from the second storage (SMS). If the SMS is unable to satisfy ET demand in the continued dry period, and the crop experiences drought stress. The amount of drought is considered to be equal to ET demand that remains unfulfilled due to inadequate moisture in the soil.

2.13 Leaf-rolling and Leaf-drying

Drought sensitivity of the germplasm tested was measured through scoring of leaf rolling and drying during the vegetative and reproductive stage of the crop following the protocol developed by IRRI, using a score between 0 (leaves healthy; no rolling) and 9 (leaves tightly rolled) (IRRI, 2002).

2.14 Spikelet fertility and sterility

Drought stress was also measured indirectly through the level of spikelet sterility, using a score between 1 (less than 20% sterility) and 9 (more than 90%) (IRRI, 2002).

2.15 Root Biomass

Roots from the depth of 0-10, 10-20, 20-30 and 30-40 cm were collected during harvest, by soil core sampler (10 cm diameter auger) from the center of a hill and 5 cm apart from the center of hills with average tiller number (Karmakar et al., 2004). The soil core sampler was placed on the soil surface and hammered in to 40 cm depth (Uddin et al., 2009). Five samples were taken from each plot. After sampling, soil cores were divided into 0-10, 10-20, 20-30 and 30-40 cm layers with a knife. Each layer was kept on an iron net (2 mm mesh) and the roots were separated from soil by applying water. After washing each sample was spread out and root length was measured with a Comair Root Length Scanner (Hawker De Havill and Victoria Ltd., Australia). After root length scanning, root samples were dried in an oven at 70 $^{\circ}$C for 48 hours (Henry et al., 2012; Uddin et al., 2009; Karmakar et al., 2004). A high precision balance (milligram) was used to measure the dry weight of root biomass.

2.16 Statistical analysis

Data recorded in the experiments were statistically analyzed following procedures described by Gomez and Gomez (1984). Analysis of variance (ANOVA) was conducted using statistical software CropStat 7.2, cluster constructed by JMP 7.0.2 based on phenotypic characteristics and diversity analyses were done by GenStat 5.3. Means were compared with the least significant difference (LSD) test.

3. Results and Discussion

3.1 Drought severity and drought duration quantification

The genotype screening experiment was conducted under rainfed conditions and the bund was cut at 28 days after transplanting (DAT). Consequently, the crop was fully depended on rainfall. The crop of the wet season 2009 received rains up to the vegetative stage while the crop of 2010 received rainwater up to reproductive stage. Therefore, drought severity and drought duration were higher in 2009 WS than in the 2010 WS. Drought severity at vegetative, reproductive and ripening stage in 2009 was 2, 93 and 152 mm water deficit, respectively while it was 9, 22 and 76 mm water deficit in 2010 WS (Fig. 6). Accordingly, the total water deficit (247 mm) was remarkably higher during in 2009 WS than 2010 WS (107 mm). For drought duration, the data followed the trend of drought amount. Drought duration at vegetative, reproductive and ripening stage was 1, 22 and 20 days in 2009 but it was 3, 8 and 14 days in 2010 WS. Therefore, the crop of the 2009 WS faced 43 days drought stress whereas the stress duration was only 25 days in 2010 WS. Consequently, the crop of the 2009 WS experienced a severe drought stress while it faced moderate drought stress in the 2010 WS.

3.2 Genotype clustering through dendogram regarding leaf rolling and drying, spikelet sterility; and phenotypic acceptability

A dendogram was constructed using a distance matrix which was calculated from phenotypic acceptability, leaf-rolling, leaf-drying and spikelet fertility values. This dendogram determined the relationship among the tested 30 rice genotypes and grouped them into 3 clusters (Fig. 7). The distribution pattern indicated that cluster I comprised the highest number of tested entries (22), followed by cluster II (2), and cluster III (6) (Table 2). Among the clusters, genotypes in cluster III had the highest score having lowest values of phenotypic acceptability, leaf rolling, leaf drying and spikelet sterility scores, indicating that these genotypes possess more drought tolerance compared to other clusters. In contrast, the mega varieties BRRI dhan49 and Guti Swarna were placed in cluster II which showed more susceptibility to drought stress. Cluster I showed intermediate drought tolerance, having values of the parameters

phenotypic acceptability, leaf-rolling, leaf-drying and spikelet fertility in between cluster II and III. Cluster mean of 30 rice genotypes was the highest (8.167) in phenotypic acceptability at the reproductive stage ranging from 1.267 to 8.167 (Table 3). Differences in cluster means existed for almost all the characters studied. Inter and intra cluster distance varied from cluster to cluster (Table 3). Inter cluster distance was the highest (10.936) in between cluster II and III that was followed by cluster I and III (7.245) and the lowest was in cluster I and II (5.952). Intra cluster distances were calculated from the value of distance matrix of tested 30 rice genotypes. Genotypes in cluster I showed the highest intra cluster distance (0.745), followed by cluster III (0.615) and cluster II (0.382). Relative contribution towards divergence is presented in Table 4. Among characteristics for drought tolerance, the value of phenotypic acceptability at vegetative, leaf-rolling and leaf-drying at vegetative and reproductive stage of the genotypes showed positive divergence in vector I (Table 4). It indicated that these characters contributed more towards divergence among the genotypes. In contrast, the values of phenotypic acceptability at vegetative stage and spikelet sterility were negative in vector I contributed less toward divergence. All the parameters scored at reproductive stage showed positive value in vector-II while it was negative in case of scored recorded at vegetative stage (Table 4). The double positive values generally contributed higher in divergence. In the present study, three characters such as phenotypic acceptability, leaf-rolling and leaf-drying at reproductive stage showed double positive value in both the vectors indicated that those characters contributed most towards divergence. In contrast, single character phenotypic acceptability at vegetative showed double negative value in both the vectors. Spikelet sterility showed positive value in vector-II and negative value in Vector-I indicated that it also contributed remarkably for divergence.

3.3 Genotypic variation on yield, yield attributes and agronomic parameters under drought stress

Significant genotypic difference existed among the rice cultivars for grain yield, yield components and agronomic parameters in both the 2009 and 2010WS (Table 5). Across the genotypes, IR83377-B-B-93-3 attained the highest grain yield (3.65 t ha^{-1}) followed by IRRI 123 (3.53 t ha^{-1}) and IR74371-70-1-1 (3.52 t ha^{-1}) in 2009WS under severe drought stress. Quite the reverse, locally popular mega variety Guti Swarna produced the lowest grain yield (1.30 t ha^{-1}) followed by BRRI dhan49 (1.36 t ha^{-1}). The genotype NERICA4 gave 2.10 and 2.71 t ha^{-1} grain yield during 2009 and 2010WS, respectively. In general, yield of the tested genotypes was lower in 2009WS than 2010 WS as the crop of 2009 WS faced more drought stress at reproductive phase compared to 2010 WS (Fig. 6).

Grain yield ranged from 1.28 to 3.65 t ha^{-1} in 2009WS while it was 2.44 to 4.51 t ha^{-1} in 2010WS. Similarly, percentage of grain yield reduction in 2009 over 2010 ranged from 14 to 57.0% (Table 5). Grain yield reduction was the highest (57.0%) in the Guti Swarna while the lowest (14%) was in IR74371-70-1-1 followed by IR83377-B-B-93-3 (19%) and IRRI 123 (20%) in 2009WS over 2010WS. In general, harvest index was lower than the optimum level of high yielding variety and it was also lower in 2009WS than 2010WS. Across the genotypes and years, most of the genotypes contained lower harvest index with an average of 0.37 ranging from 0.25 to 0.45 in 2009WS while it was 0.41 ranging from 0.33 to 0.47 during 2010WS. Harvest index was the highest (0.45) in IR83377-B-B-93-3 followed by IR74371-70-1-1 (0.44) and IRRI (0.44) in 2009WS. It was the lowest (0.25) in Guti Swarna in 2009WS while it was the lowest (0.27) in BRRI dhan49 in 2010WS. Days required to maturity and plant height remarkably affected by the genotypes (Table 5). Days to maturity ranged from 102 to 134 during 2009WS while it was 105 to 136 days in 2010WS. In general, soil water tension was higher in 2009WS compared to 2010WS (Fig. 5).

*Significant at P≤0.05, **Significant at P≤0.01 and ns=not significant.

Across the experimental years and genotypes, plant height varied from 87 to 111 cm due to water stress. Panicle production m^{-2} ranged from 167 to 252 in 2009 while it was 190 to 267 during 2010WS. Moreover, the mega variety BRRI dhan49 and Guti Swarna produced significantly lower panicles m^{-2} than the highest one. The tested genotypes expressed high significant variability regarding spikelet sterility (Table 5). Sterility percentage was the highest (62%) in Guti Swarna during 2009WS despite the fact that the highest percentage of sterility (42%) was found in BRRI dhan49 and IR83376-B-B-24-2 in 2010WS. In contrast, IR74371-70-1-1 and IR83377-B-B-93-3 performed better with the lowest sterility 26 and 22%, respectively. Strong significant differences in respect of 1000-grain weight of the genotypes found in both the experimental years. Among the cultivars, IR83387-B-B-27-4 produced grain with highest 1000-grain weight (23.8 and 24.3 g in 2009 and 2010, respectively) at the same time as the genotype BR7873-5*(NIL)-51-HR6 gave constantly the lowest 1000-grain weight of 20.7 and 21.0 g in 2009 and 2010, respectively.

3.4 Relationship of grain yield and yield attributes

Correlation between yield and yield parameters was highly significant in both the experimental years (Table 6). Moreover, Fig.8 and 9 showed the relationship among grain yield with panicles m^{-2}, spikelet sterility, 1000-grain weight, plant height, biomass and harvest index during 2009 and 2010WS. The highest R^2 values (0.927 and 0.853 in 2009 and 2010Ws, respectively) found in the relation of yield and biomass followed by harvest index (Fig 7 and 8). Compound interrelationship among various traits was found between yield and yield components determining one depended variable such as grain yield. Grain yield showed positive association with all the parameters except spikelet sterility. Panicles m^{-2}, biomass and harvest index were high positively related with grain yield while plant height and 1000-grain weight low positively related. In contrast, spikelet sterility was high negatively related with grain yield during both the experimental years.

3.5 Root Biomass

Root biomass varied significantly across the genotypes in both experimental years. Most of the roots of all the genotypes existed in 0 to 10 cm soil depth and, thereafter reduced the root biomass into 10 to 40 cm depth. Among the 30 rice genotypes, the highest mean root dry matter (4.21 g/0.015 cm^3) was observed in the genotype IR74371-70-1-1 which was statistically similar to NERICA 4 (4.19 g/0.015 cm^3), IR83377-B-B-93-3 (4.15 g/0.015 cm^3), IRRI 123 (4.13 g/0.015 cm^3) and IR83381-B-B-6-1 (3.80 g/0.015 cm^3) across the two seasons. (Fig. 10). Root biomass ranged from 2.05 to 4.21 g/0.015 cm^3. Thereby, the five IR74371-70-1-1, NERICA, IR83377-B-B-93-3, IRRI 123 and IR83381-B-B-6-1 found drought tolerant.

4. Discussion

4.1 Drought stress quantifying based on rainfall, soil moisture and soil water potential

Different intensities of drought stress occurred in each season of the study, where drought severity was higher in 2009WS compared to 2010WS (Henry et al., 2011). Rainfall received by the crops of the experiments was considerably lower at the northwest region of Bangladesh (Karmakar et al., 2010). Moreover, the rains were very much unevenly distributed (Fig. 1) within the years and seasons (Haefele et al., 2006). Mean annual rainfall of the experimental years (744 and 897 mm in 2009 and 2010, respectively) were much lower than the country average 2300 mm ranged from 1000 to 5000 mm (Saleh et al., 2000; Karmakar et al., 2012).

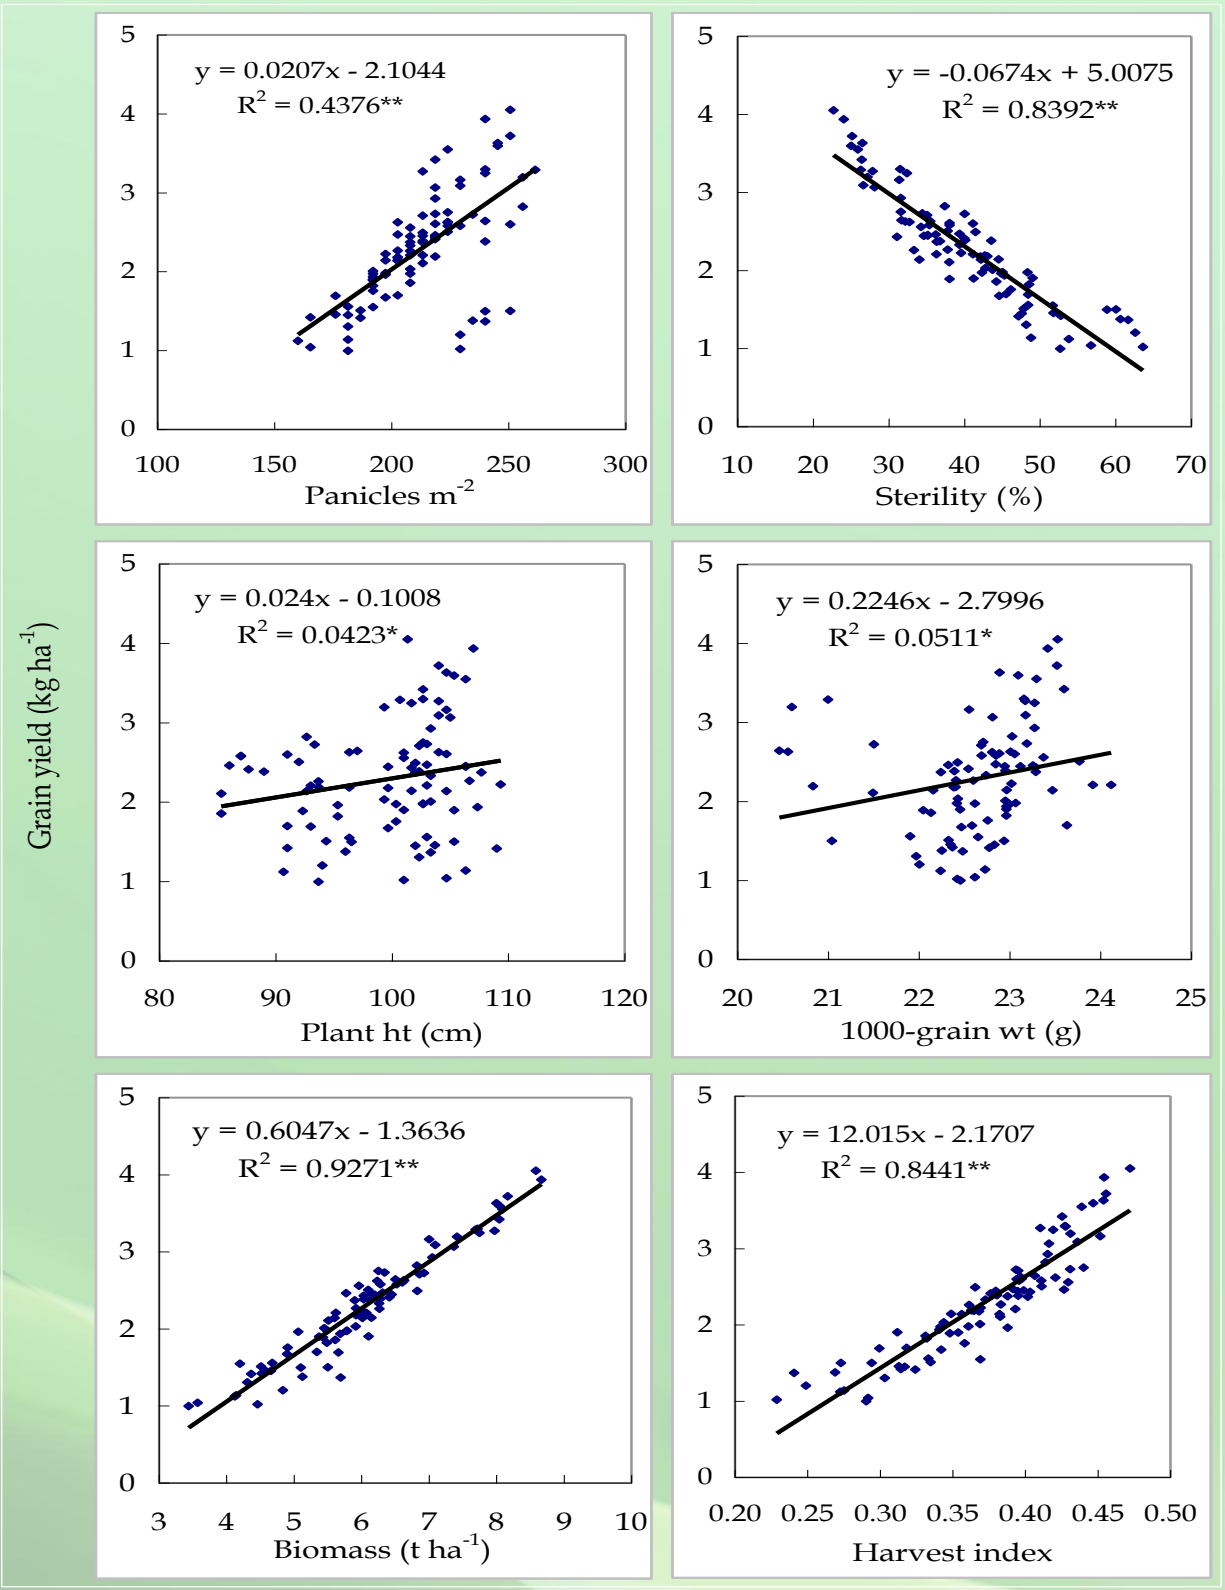

Figure 8. Relationship of grain yield and yield attributes of 30 rice genotypes under drought prone rainfed environment during 2009WS.

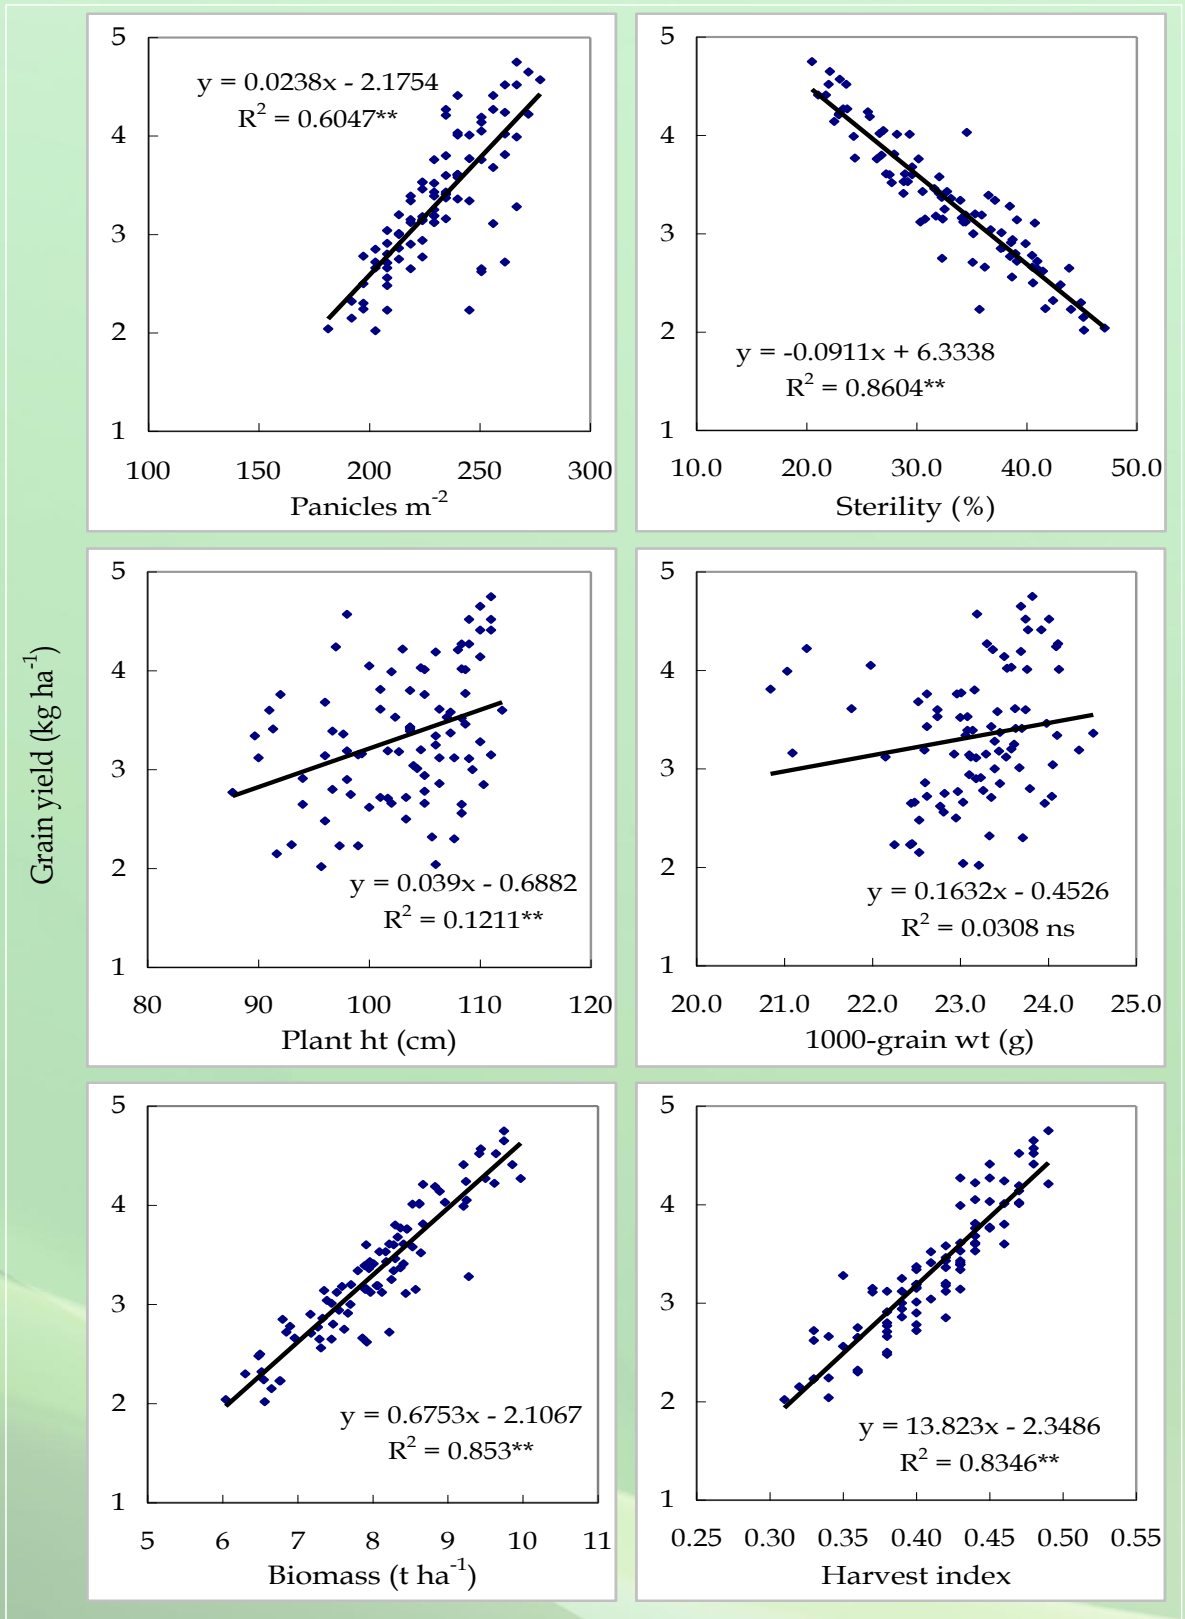

Figure 9. Relationship of grain yield and yield attributes of 30 rice genotypes under drought prone rainfed environment during 2010WS.

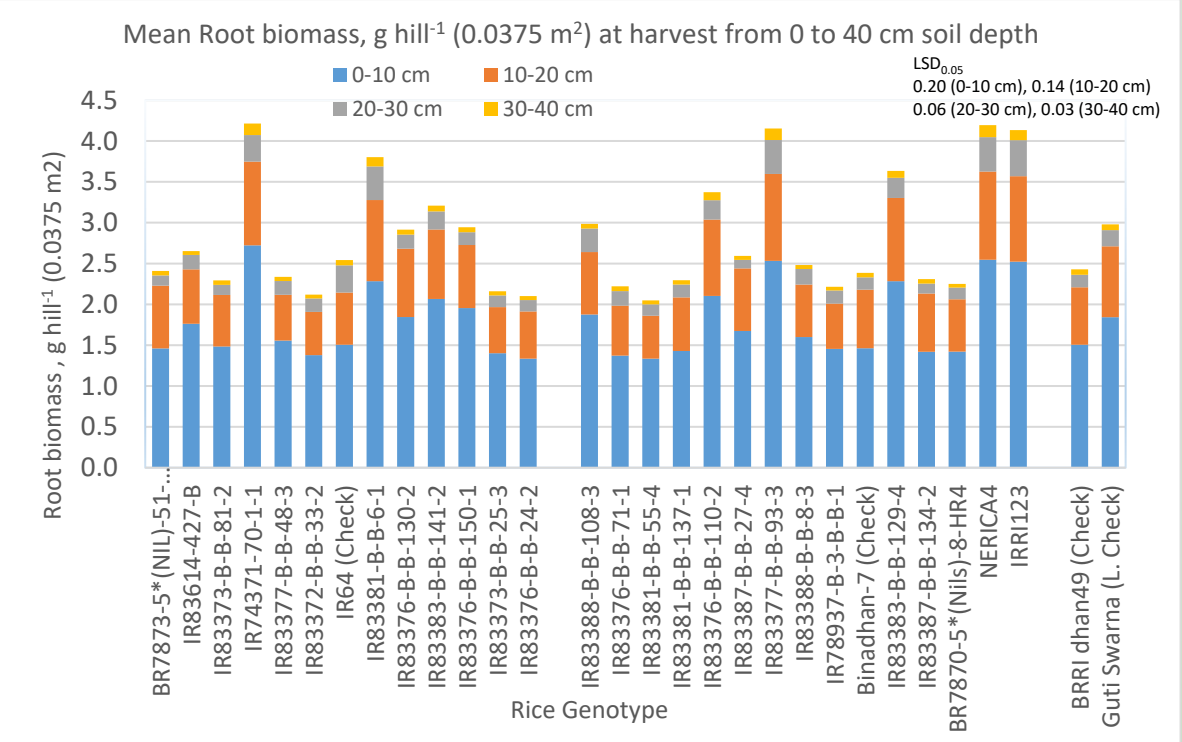

Figure 10. Mean Root biomass, g hill^{-1} (0.0375 m^2) of the rice genotypes in 0 to 40 cm soil depth at harvest under drought prone rainfed environment during 2009 and 2010WS

Meteorological data shows that much less rains occurred in 2009WS while 2010WS was moderately rainy (Fig. 1& 2). Consequently, the crop experienced substantial and intermittent drought stress in 2009 and 2010WS, respectively. Rainfall distribution, groundwater level (Haefele and Bouman, 2008) and soil moisture content and soil water tension (Henry et al., 2011) during reproductive phase of crop indicated a higher water stress for the trials conducted under rainfed environment. Consequently, no doubt that rainfall is an important determinant of the yield of rainfed lowland rice (Wade et al., 1998). Drought amount and duration varied in different crop stage as well as cropping years. Crop at vegetative stage did not face drought stress in both the years. However, severe drought stress existed in reproductive and ripening stage caused higher spikelet sterility (Islam and Islam, 2010) in 2009WS while it was moderate in 2010WS. Drought amount and duration was significantly higher in 2009WS than 2010WS that caused higher grain yield reduction (14 to 57%) in 2009WS over 2010WS. This result corroborates with Islam and Islam (2010) found that yield was reduced by 30 to 55% due to drought stress. Moreover, crop experienced severe drought stress with 43 drought days amounting 247 mm drought in 2009 while it was only 25 days and 107 mm in 2010, respectively. These findings are alignment with Islam et al. (2007) who reported maximum drought of 40 days and minimum drought of 22 days in northwest Bangladesh.

4.2 Genotype clustering through dendogram regarding phenotypic acceptability, leaf-rolling, leaf-drying and spikelet sterility

Dendogram of the rice genotypes showed drought stress severity that drawn based on phenotypic acceptability, leaf-rolling and leaf-drying score, and spikelet fertility. Genotypes belonging to the distant clusters maintained highest genetic variation. Genotypic variability in any crop is requirement for selection of superior genotypes over the existing cultivars (Murthy et al., 2011). The genotypes having lower inter cluster distances values in cluster I and III could be used as parents for the development of drought-resistant varieties. The other cluster (II) had the highest inter cluster mean value indicated that materials of this cluster are highly susceptible to drought. These results indicated, selection of genotype(s) from cluster III have positive impact and selection of genotype from cluster I and II have negative impact for drought resistant. It was preferential to make a decision that intra-cluster diversity was the highest in cluster I indicated more heterogeneous genotypes had in this cluster. Higher inter and intra cluster distances indicate higher genetic variability among genotypes between and within clusters, respectively. Phenotypic acceptability, leaf-rolling and leaf-drying at reproductive stage had positive impact in both the vectors. The characters that showed positive value in both vectors contributed most towards divergence. Spikelet sterility had negative impact in vector I and positive impact in vector II towards divergence. Double negative value of phenotypic acceptability at vegetative stage in vector I and II contributed lowest for divergence in the studied materials. Generally, positive value of the parameters like phenotypic acceptability, leaf rolling, leaf drying and spikelet sterility towards the vectors contributed higher for divergence while the negative value had lower contribution.

4.3 Genotypic variation on yield, yield attributes and agronomic parameters under drought stress

The tested genotypes varied significantly in respect of grain yield, yield attributes and agronomic parameters under drought stress (Murthy et al., 2011). It was might be due to the genotypic variability in response to drought stress of the genotypes (Sakai et al., 2010; Sarvestani et al., 2008). In general grain yield was lower in 2009WS compared to 2010WS as because drought stress was more in 2009WS than 2010WS. Genotypes responded differently under different drought stress conditions and habitually reduced grain yield of rainfed rice (Pantuwan et al., 2002b). Grain yield reduction varied from 14 to 57% due to drought stress across the cropping years and genotypes. Kumar et al., (2007) reported that drought stress at the flowering stage reduced yield by an average of 80% relative to a non-stressed control condition. Sarvestani et al. (2008) reported that grain yield reduced by 21, 50 and 21% due to water deficit at vegetative, flowering and grain filling stages, respectively. Yield of second year was higher than first year due to higher number of panicles m^{-2}, higher grain weight and lower spikelet sterility in 2010 compared to 2009. Genotypes performed differently in terms of yield and yield attributes under drought stress (Sakai et al., 2010). Long duration varieties like Guti Swarna and BRRI dhan49 suffered severely due to late season drought stress so that yield of these mega varieties reduced much more due to less panicle development and panicle exertion. Sarvestani et al. (2008) also found lower yield in the long duration cultivar Nemat due to late season drought. The low yield obtained in the genotypes was generally caused by a large percentage of unfilled grains per panicle due to reproductive phase drought (Wopereis et al., 1996). The main reasons for yield reduction was late season drought that were not suitable for panicle development impaired with reduced grain filling, grain number and weight (Sarvestani *et al.,* 2008; Islam et al., 1994; Bouman and Toung, 2001). Grain yield reduction resulted from greatly reduction of filled grain per panicle (Pantuwan et al., 2002a). Across the genotypes and years, harvest index fluctuated from 0.25 to 0.45 among the genotypes. These findings are in conformity with those of Fageria et al., 2010 and Kiniry et al., 2001. Harvest index varied significantly among cultivars ranging from 0.36 to 0.52 (Fageria et al., 2010) and from 0.35 to 0.62 (Kiniry et al., 2001) indicating the importance of this variable for yield stimulation. Harvest index generally was lower than the optimum level of high yielding variety in 2009 (more drought stress existed) but it was comparatively higher in 2010WS. Extremely low harvest index values related to drought stress resulted higher sterility, lower spikelet fertility, lower grain filling and lower grain weight and thereby grain yield (Haefele et al., 2003). Genotypes produced comparatively higher yield even under drought stress contained higher harvest index. These results are in accordance with Jearakongman et al. (1995) who reported that cultivars suitable for rainfed conditions are those with high yield potential resulting from high harvest index. Spikelet sterility and harvest index are the important parameters to quantify drought stress. Higher value of sterility and lower value of harvest index indicate susceptibility to drought tolerance (IRRI, 2002; Lafitte et al., 2002).

Days to flowering and maturity of almost all the genotypes in generally reduced by 1 to 5 days in 2009WS due to drought stress compared to 2010WS prevailed less drought stress. In general, time required to flowering ranged to a great extent among the genotypes and experimental years (Henry et al., 2012). Drought stress started from panicle initiation to maturity of many cultivars. However, some short duration genotypes escaped some extent this drought stress. Rainfed rice is extremely sensitive to water deficit from about 12 days before 50% flowering to about 7 days after flowering (Fischer et al., 2012). Drought stress at reproductive phase enhanced crop to reach early maturity. It happened might be due to water stress at reproductive stage forced the plant to switch over from flowering to maturity very faster. In contrast, many researchers (Sakai et al., 2008) reported that drought stress prior to flowering delayed flowering and maturity. However, Atlin et al., (2006) reported that days to flowering of high yielding rice varieties was delayed by 15 days while it was 5 days earlier for *japonica* varieties in water stressed drought prone environment than well watered condition. Plant height, panicles m^{-2}, grains $panicle^{-1}$, grain weight, fertility were reduced while sterility increased significantly in the severe drought year compared to less drought year. These findings are in agreement with Pantuwan *et al.,* (2002a) who reported that unfilled grain in the drought stress condition was 48% compared with 20% in well watered condition while 1000-grain weight was 18% smaller in drought stress. It happened might be due to genetically variability of the genotypes and also affected by drought stress (Fageria and Filho, 2007; Peng et al., 2000). Spikelet fertility was judged the most practical character by which to score cultivar performance (Garrity and O'Toole, 1994). It increased in comparatively less drought year 2010 over severe drought year 2009WS.

Grain yield was significantly and positively associated with all the yield attributes like panicles m^{-2}, grains $panicle^{-1}$, grain weight, spikelet fertility under drought stress however; spikelet sterility had negative correlation with yield (Pantuwan et al., 2002a; Murthy et al., 2011; Yadav, 1992). Haider *et al.,* (2012) also found that thousand grain weight (0.476**), grains per panicle (0.733**), spikelet fertility (0.709**) had positive and significant association with grain yield under drought stress; whereas, spikelet sterility had significantly negative correlation with yield. Short-duration genotypes would be preferable for many drought-prone environments because this could reduce the late-season drought risk and open options for post-rice crops in favorable years (Haefele et al., 2006). However, short duration variety has limitation that could produce comparatively lower yield than the mega variety in the

favorable years (Pantuwan et al., 2002a; Fischer et al., 2012). Drought resistant cultivars may be considered to be those produce higher grain yield under drought conditions (Pantuwan et al., 2002b).

4.4 Root biomass

Root biomass of the tested genotypes varied significantly across the genotypes (Fageria, 2010; Uddin et al., 2009). The highest root biomass (61.1%) of the genotypes located in the 0-10 cm soil depth followed by 10-20 cm (27.1%), 20-30 cm (8.8%) and the lowest (3.0%) was in 30-40 cm. These results are in alignment with the findings of Henry et al., 2011; Fageria, 2010; Uddin et al., 2009. That means most of the root system (88.2%) positioned to the top 20 cm of the soil layer. Similar findings also reported by Sharma et al. (1994) who found that 90% of the total root system restricted in the 0-20 cm soil depth. Some genotypes having more roots biomass extracted more water from deeper soil than others and acquired more drought tolerance.

5. Conclusion

Based on overall performances, the genotypes IR74371-70-1-1, NERICA4, IRRI 123, IR83377-B-B-93-3, and IR83381-B-B-6-1 were selected as drought tolerant and BR7873-5*(NIL)-51-HR6 was selected as drought escaping. From these findings, the genotypes IR74371-70-1-1 and BR7873-5*(NIL)-51-HR6 released as drought tolerant rice variety named BRRI dhan56 and BRRI dhan57, respectively through national variety release system. Rice cultivars having extensive deep root systems are proficient to mine moisture from deep soil layer indicated that more efficient in drought prone rainfed environments. Moreover, the selected genotypes could be utilized to improve varieties through classical breeding or using biotechnology linked with innovative agronomic management.

Declarations

Ethical Approval Certificate

The experimental procedures of this study were approved by the authority of Bangladesh Rice Research Institute, 1701, Gazipur, Bangladesh.

A Bibliometric Analysis on Food Waste and Sustainability in Central Asia

Fatih Ramazan İSTANBULLUGİL [1]

1 Kyrgyz-Turkish Manas University, Faculty of Veterinary Medicine, Department of Food Hygiene and Technology, Kyrgyz Republic, Bishkek.

Abstract

Food waste and sustainability have increasingly become the focus of the global agenda in regions facing economic, environmental, and food security problems. Central Asia, consisting of Kazakhstan, Kyrgyzstan, Uzbekistan, Turkmenistan, and Tajikistan, presents a unique context in this field due to its Soviet legacy, transitioning economies, and growing population. Food waste is not only a problem that causes economic losses, but also a global crisis that threatens environmental sustainability by leading to inefficient use of natural resources and an increase in greenhouse gas emissions. This waste, which occurs at all stages from agricultural production to consumption, is of great importance for the sustainability of food systems.

The aim of this study is to analyze scientific publications on food waste and sustainability in Central Asian countries (Kyrgyzstan, Kazakhstan, Uzbekistan, Tajikistan, Turkmenistan) using bibliometric methods, and to reveal regional research trends and academic collaboration structures. For this purpose, literature between 2000 and 2024 was scanned in Scopus and Web of Science databases using keywords such as “food waste,” “food loss,” “sustainability,” “Central Asia,” “Kyrgyzstan,” “Kazakhstan,” “Uzbekistan.” The obtained data were analyzed using the VOSviewer software.

According to the results, the number of publications on food waste and sustainability in Central Asia is limited, but has shown an increasing trend especially in the last five years. Academic collaborations with countries such as Türkiye, China, and Germany stand out. In the keyword analysis, concepts such as “climate change,” “agri-food systems,” “circular economy,” and “food security” came to the forefront. This study is important in terms of showing the research gaps and future academic opportunities for sustainable food systems in the region.

Key Words: *Central Asia, food waste, sustainability, bibliometric analysis, food security*

Orta Asya’da Gıda İsrafı ve Sürdürülebilirlik Üzerine Bibliyometrik Bir Analiz

Özet

Gıda israfı ve sürdürülebilirlik, ekonomik, çevresel ve gıda güvenliği sorunlarıyla karşı karşıya olan bölgelerde giderek artan bir şekilde küresel gündemin merkezine yerleşmiştir. Kazakistan, Kırgızistan, Özbekistan, Türkmenistan ve Tacikistan’dan oluşan Orta Asya, Sovyet geçmişi, geçiş sürecindeki ekonomileri ve artan nüfusu nedeniyle bu alanda benzersiz bir bağlam sunmaktadır. Gıda israfı, yalnızca ekonomik kayıplara yol açan bir sorun değil, aynı zamanda doğal kaynakların verimsiz kullanımına ve sera gazı emisyonlarının artmasına neden olarak çevresel sürdürülebilirliği tehdit eden küresel bir krizdir. Tarımsal üretimden tüketime kadar olan tüm aşamalarda meydana gelen bu israf, gıda sistemlerinin sürdürülebilirliği açısından büyük önem taşımaktadır.

Bu çalışmanın amacı, Orta Asya ülkelerinde (Kırgızistan, Kazakistan, Özbekistan, Tacikistan, Türkmenistan) gıda israfı ve sürdürülebilirlik konularında yapılmış bilimsel yayınları bibliyometrik yöntemle analiz ederek, bölgesel araştırma eğilimlerini ve akademik iş birliği yapılarını ortaya koymaktır. Bu kapsamda, 2000–2024 yılları arasındaki literatür, Scopus ve Web of Science veri tabanlarında “food waste”, “food loss”, “sustainability”, “Central Asia”, “Kyrgyzstan”, “Kazakhstan”, “Uzbekistan” gibi anahtar kelimeler kullanılarak taranmıştır. Elde edilen veriler VOSviewer yazılımı aracılığıyla analiz edilmiştir.

Analiz sonuçlarına göre, Orta Asya’da söz konusu konularda yapılan yayın sayısı sınırlı olmakla birlikte, özellikle son beş yılda artan bir eğilim göstermektedir. Türkiye, Çin ve Almanya gibi ülkelerle gerçekleştirilen akademik iş birlikleri dikkat çekmektedir. Anahtar kelime analizinde ise “climate change”, “agri-food systems”, “circular economy” ve “food security” kavramlarının öne çıktığı görülmüştür. Bu çalışma, bölgedeki sürdürülebilir gıda sistemlerine yönelik araştırma boşluklarını ve gelecekteki akademik fırsatları ortaya koyması açısından önemli bir kaynak niteliğindedir.

Anahtar Kelimeler: *Orta Asya, gıda israfı, sürdürülebilirlik, bibliyometrik analiz, gıda güvenliği*

Abstract
Drought is a significant challenge to wheat productivity in changing climate conditions. Breeding strategies have been successful in producing drought-resistant wheat varieties. This study aimed to assess the morpho-physiological and biochemical responses of durum wheat landraces to drought stress. Twenty landraces and four checks were grown in pots under non-stressed (70%) and stressed (35%) conditions, using a completely randomized design (CRD) with three replicates. Data on yield, yield-related traits, and physiological-biochemical characteristics were collected. ANOVA results indicated significant impacts of genotype and stress on all parameters, with drought having a noticeable influence on morpho-physiological and biochemical traits. Key characteristics for drought tolerance included earlier heading dates, optimal tiller production, and shorter grain filling periods. Maintaining high proline and relative water content (RWC) was crucial for supporting metabolic processes under stress. Phenotypic and genotypic correlations and path coefficient analysis offered insights into the direct and indirect effects of these traits on grain yield. Landraces ETDW/15DZ023, ETDW/15DZ04, 34217, and 31831 consistently produced high yields under non-stressed and stressed conditions, demonstrating superior drought tolerance compared to other tested genotypes. This highlights their potential for inclusion in breeding programs to improve drought resilience in durum wheat.

Key words: *Drought tolerance; Durum wheat; Greenhouse; Physiological trait; Proline content; Stress-adaptative*

Enhancing Cotton Yield through Adoption of Climate Smart Agriculture: A Case of Smallholder Farmers in Bariadi District, Tanzania

Fredrick Alleni Mfinanga [1] Barakael Israel Panga [2] Jacqueline Temba [2]

[1]Department of Development Finance and Management Studies, Mwanza, Tanzania
[2]Department of Rural Development and Regional Development, Mwanza, Tanzania

Abstract

Climate variability threatens cotton farming in Tanzania, highlighting the need for sustainable strategies to boost smallholder productivity and resilience. This study aimed to establish the effects of Climate Smart Agriculture (CSA) practices on cotton yield among smallholder farmers in Bariadi District, Simiyu Region, Tanzania. Specifically, the study sought to determine the effects of CSA practices on cotton yield among cotton smallholder farmers. A cross-sectional research design was employed, and data were collected using structured questionnaires from a sample of 384 smallholder cotton farmers. Descriptive analysis revealed varied levels of CSA adoption, with intercropping, soil and water conservation, and integrated pest management being among the most practiced. The Ordinary Least Squares (OLS) regression analysis was used to estimate the effects of CSA practices and selected socio-economic factors on cotton yield. The results showed that adoption of intercropping, integrated pest management, soil and water conservation techniques, efficient irrigation methods, and access to CSA-related training had statistically significant positive effects on cotton yield. Moreover, farm size and having alternative sources of income particularly government employment and commercial work were also positively associated with increased cotton production. The study concludes that CSA practices significantly contribute to higher cotton yield and potentially enhance household income. Therefore, it is recommended that local government authorities and Ministry of Agriculture strengthen agricultural extension services and prioritize regular on-farm training and demonstration programs to improve farmers' awareness and practical adoption of CSA practices.

Keywords: *Climate Smart Agriculture, cotton yield, smallholder farmer*

Abstract

Climate variability threatens cotton farming in Tanzania, highlighting the need for sustainable strategies to boost smallholder productivity and resilience. This study aimed to establish the effects of Climate Smart Agriculture (CSA) practices on cotton yield among smallholder farmers in Bariadi District, Simiyu Region, Tanzania. A cross-sectional research design was employed, and data were collected using structured questionnaires from a sample of 384 smallholder cotton farmers. Descriptive analysis revealed varied levels of CSA adoption, with diversified crop planting, intercropping, soil and water conservation, and integrated pest management being among the most practiced. The Ordinary Least Squares (OLS) regression analysis was used to estimate the effects of CSA practices and selected socio-economic factors on cotton yield. The results showed that adoption of intercropping, integrated pest management, soil and water conservation techniques, irrigating with motor powered pump, and access to CSA related training had statistically significant positive effects on cotton yield. Moreover, farm size and having alternative sources of income particularly government employment and commercial work were also positively associated with increased cotton production. The study concludes that CSA practices significantly contribute to higher cotton yield and potentially enhance household income. Therefore, it is recommended that local government authorities and Ministry of Agriculture strengthen agricultural extension services and prioritize regular on-farm training and demonstration programs to improve farmers' awareness and practical adoption of CSA practices.

Background information

Agriculture is the backbone of livelihoods across Sub-Saharan Africa (Nyathi et al., 2025; AGRA, 2022) employing nearly two-thirds of the population. In many Sub-Saharan African countries, agriculture contributes approximately 30% to the region's GDP (Hodjo et al., 2023). Smallholder farmers cultivate many crops including cotton for business purpose. However, the sector faces growing threats from climate change, including erratic rainfall patterns, prolonged droughts, soil degradation, and increasing pest infestations (FAO, 2023; Alotaibi et al., 2023; Ruiz & McCue, 2024). These challenges have led to declining agricultural productivity (Ruiz and McCue, 2024; Cunningham et al., 2021) particularly among smallholder farmers who lack access to modern technologies and they have opted for climate change adaptation strategies to secure cotton yield (Fadeyi, et al., 2022).

In Eastern Africa, agriculture is equally vulnerable, with climate change projected to reduce crop yields by up to 30% by 2050 if no adaptive measures are taken (World Bank, 2022). Cotton, an important cash crop in many parts of the region, has been particularly affected due to its sensitivity to water stress, pest , disease infestations and low yield (Malinga & Laing, 2023; Babu et al., 2024; Faisal et al., 2025; Tlatlaa et al., 2023). In countries like Ethiopia, Mali, Kenya, South Africa and Tanzania, cotton farming is largely dominated by smallholder farmers with limited capacity to respond to climate risks (Salisali, 2016; Bwana *et al.,* 2020).

In Tanzania, cotton is the second-largest export crop after tobacco and supports over 500,000 smallholder farmers, primarily in the Western Cotton Growing Area (WCGA), which includes Simiyu Region and Bariadi District in particular (Tanzania Cotton Board, 2023). Despite its economic importance, cotton yields remain low and unstable due to climate-related constraints and poor farming practices and volatile market (Cornelia & Bernhard, 2015). Smallholder farmers in Tanzania including those in Bariadi District continue to rely on rain-fed systems, outdated agronomic techniques, and lack access to extension services or climate-resilient innovations (Abdallah, 2020; Yao, 2023).

To address these challenges, Climate Smart Agriculture (CSA) has been promoted as a sustainable solution to boost crop productivity while enhancing resilience to climate shocks (AkhRegmi & Paudel, 2024; Tilahun et al., 2025; Ma & Rahut, 2024). CSA is an integrated approach that involves the adoption of techniques such as intercropping, conservation agriculture, efficient irrigation, integrated pest management (IPM), and access to weather and agronomic information (Lipper et al., 2014). While numerous studies including (Bongole, 2023; Jones et al., 2023; Yusuph et al., 2024; Msongaleli, 2024;Erick et al., 2025) have shown the benefits of CSA in improving yields for staple crops like maize, leaf vegetables and rice in Tanzania, less is known about its

effectiveness in cotton production. In the Bariadi District, climate variability particularly unreliable rainfall and prolonged dry spells has increasingly threatened cotton productivity. While some farmers have begun adopting CSA practices, the uptake remains uneven and poorly documented. There is a critical knowledge gap regarding which specific CSA practices are most effective in enhancing cotton yield under local conditions, and what socio-economic factors influence their adoption. Therefore, this study was undertaken to examine the effects of CSA practices on cotton yield among smallholder farmers in Bariadi District. By identifying the most impactful practices and associated socio-economic drivers, the study aims to provide evidence-based insights to guide agricultural policy, extension services, and investment in climate-resilient cotton farming systems.

Theoretical underpinnings

This study is anchored in Rogers' (2003) Diffusion of Innovation Theory**,** which explains how new ideas and technologies spread within a social system. According to this framework, the diffusion process is shaped by three core elements: the traits of the individuals adopting the innovation, the attributes of the innovation itself, and the communication pathways through which the innovation is conveyed. In the context of this research, household characteristics such as gender, education level, marital status, age, income sources, farm size, and farming experience correspond to the adopter traits highlighted in the theory. The innovation attributes namely, Climate Smart Agriculture (CSA) practices including diversified cropping, intercropping, soil and water conservation, integrated pest management, and irrigation using motorized pumps align with the theory's emphasis on the perceived features of innovations. Furthermore, the institutional mechanisms that influence dissemination, such as access to agricultural training, credit facilities, and farm inputs, represent the communication channels that facilitate the diffusion process within cotton smallholder farmers in the study area.

Methodology

Study Area

The study was conducted in Bariadi District at Sapiwi and Dutwa wards. The study area was selected because it is characterized by its semi-arid climate, with erratic rainfall patterns and high temperatures posing challenges to agricultural production, particularly cotton (Malamsha & Lughuyu, 2024). In addition, the study areas were selected because the primary economic activity is agriculture, with cotton farming being a key sector (URT, 2017).

Research design, sampling procedure and sample size

The study used a cross-sectional research design, with all cotton smallholder farmers in the study area serving as the sampling frame. The sampling unit was the individual cotton smallholder farmer, and a multistage sampling method was used to select respondents. First, Bariadi District was purposively selected, followed by Sapiwi and Dutwa wards, where cotton farming is the main economic activity. Next, five villages were purposively chosen three from Sapiwi and two from Dutwa. Finally, cotton smallholder farmers were selected through simple random sampling.

The total population of 9,717 cotton smallholder farmers was used to calculate the sample size of 384 farmers, applying Yamane's formula as follows:

$$n = \frac{N}{1+N\,(e)^2} = \frac{9717}{1+9717(0.05)^2} = 384 \quad \text{..... (i)}$$

In this formula, n represents the sample size, N is the total population (9,717 cotton farmers), and e is the margin of error or precision level (set at 5 percent). According to Bariadi Agricultural Marketing Cooperative Society (AMCOS), the village populations were as follows: Igegu (2,850), Sapiwi (1,800), Nyamikoma (1,567) from Sapiwi ward, and Itemelo (1,800) and Ipundula (1,700) from Dutwa ward.

The sample size for each village was then calculated using Salkind's (2010) proportional sampling formula, as shown in equation (ii) and Table 1:

$$n_b = \frac{N_h}{N} \text{ x } n \quad \text{.....(ii)}$$

Here, n_b is the sample for each village, N_h is the population of the village, N is the total population across all five villages, and n is the total sample size of 384 farmers. For example, the sample for Igegu was calculated as follows: $n_b = (2{,}850 / 9{,}717) \times 384 \approx 113$.

Table 1: Sample size composition of the villages in the study area

Ward	Village	Population	Sample size
Sapiwi	Igegu	2850	113
	Sapiwi	1800	71
	Nyamikoma	1567	62
Dutwa	Itemelo	1800	71
	Ipundula	1700	67
	Total	9717	384

Data collection methods

Information was obtained from both primary and secondary sources to enhance the accuracy and depth of the findings. Primary data were gathered through a household survey using semi-structured questionnaires administered to cotton smallholder farmers affiliated with cooperatives (AMCOS) in Sapiwi and Dutwa wards. Secondary data were obtained by reviewing agricultural policies, scholarly literature, books, articles, and other relevant documents to provide background and supporting insights for the study.

Measurement of the study variables

In the study area, cotton smallholder farmers were interviewed to examine how Climate Smart Agriculture (CSA) practices influence cotton yield. Based on their farming experience, farmers reported adopting several CSA practices, including crop diversification, intercropping, soil and water conservation, irrigation using motor-powered pumps, and integrated pest management (Bongole, 2023; Erick et al., 2025; Sekabira et al., 2022). In this study, these CSA practices were treated as independent variables. Additional independent variables, along with the dependent variable cotton yield are outlined in Table 2, which provides descriptions and measurement details for each variable used in the analysis.

Table 3.7.1: List of variables and their measurement scales

Variable	Scale	Measurement
Cotton growers yield	Ratio	Kilograms per hector
Age of a Cotton grower	Ratio	Years
Years of practicing CSA Practices (experience)	Ratio	Years
Farm size	Ratio	Hectors
Education	Ordinal	Informal education, primary education, Secondary education or tertiary education
Marital Status	Nominal	Single, married, widowed and divorced
Other Source of Income besides farming	Nominal	Peasant, Agri-non farm entrepreneur, government employee and other sources of income
CSA practices implemented by a cotton grower	Nominal	Diversified crop planting, Intercropping, Soil and water conservation technique, Integrated pest management and irrigating with motor powered pump
Access to funds for adoption of CSA	Nominal	Yes and No
Access to information and training	Nominal	Yes and No
Access to agricultural inputs	Nominal	Yes and No

Data analysis

The quantitative data were analyzed by using SPSS version 20 and Stata version 16. SPSS was used to analyze descriptive statistics of the socio-economic, technological and institutional factors of the surveyed households. In the case of inferential statistics, the quantitative data were coded and entered in the stata version 20 for analysis. The inferential statistics applied Ordinary Least Squares (OLS) regression to analyze the influence of climate smart agriculture practices on cotton yield among smallholder farmers in the study area.

Estimation of the model

The Ordinary Least Squares (OLS) regression model was employed in this study to assess the effect of Climate Smart Agriculture (CSA) practices on cotton yield among smallholder farmers. OLS is suitable because the dependent variable cotton yield is continuous and measurable in quantitative units (e.g., kilograms per hectare). This method allows for estimating the linear relationship between multiple independent variables (adopted CSA practices and other socioeconomic factors) and the outcome variable cotton yield. Moreover, OLS is widely used in agricultural economics due to its simplicity, interpretability, and ability to provide unbiased and efficient estimates under the assumption of linearity, homoscedasticity, and normally distributed residuals (Mahaboob et al., 2018; Fox, 2016).

The Ordinary Least Squares (OLS) regression model (equation iii) was applied as follows;

$$Y = \beta_0 + \beta_i X_i + \beta_i D_{kj} + \varepsilon_i$$

Where Y is the dependent variable (Yield), β_0 is the intercept of the model, β_i is the coefficients of the explanatory variables to be estimated, X_i corresponds to the i^{th} continuous explanatory variable of the model ($i = 1\ to\ 4$), D_{kj} corresponds to the i^{th} categorical/dummy explanatory variable of the model ($k = 1\ to\ 11$) and ε is the random error with expectation 0 and variance σ^2.

Results

Socio-economic characteristics of the respondents

Table 2 presents the socio-economic characteristics of cotton smallholder farmers in the study area. A total of 384 respondents participated, with 41.4% from Dutwa Ward and 58.6% from Sapiwi Ward. The sample was predominantly male (69.5%), while females accounted for 30.5%.In terms of education, most farmers had attained primary education (56%), followed by secondary education (27.3%), informal education (11.5%), and tertiary education (5.2%). Regarding marital status, the majority were married (63.8%), while 22.7% were single, 13% were widowed, and only 0.5% were divorced. In terms of other sources of income besides farming, the vast majority identified as peasants (78.4%), followed by Agri-non farm entrepreneur s (17.7%), government employees (3.7%), and a small fraction (0.3%) under other categories.

Table 2: Socio-economic characteristics of the respondents

Variable	Frequency	Percent
Ward		
Dutwa ward	159	41.41
Sapiwi ward	225	58.59
Sex		
Male	267	69.53
Female	117	30.47
Education

Government employee	14	3.65
Other	1	0.26

Climate-Smart Agriculture Practices and Socio-Economic Characteristics

Table 3 summarises the climate-smart agriculture (CSA) practices adopted by cotton farmers along with other key socio-economic characteristics. Among the 384 farmers surveyed, nearly half (49.5%) practiced diversified crop planting, while 41.4% used intercropping methods. Soil and water conservation techniques were applied by 7.6% of the farmers, irrigating with motor powered pump (1.0%) and very few adopted integrated pest management (0.5%).

Regarding access to resources, only 10.7% of the farmers reported having access to credits to support CSA adoption, while a striking 89.3% did not (Table 3). Extension services played an important role, with 83.1% of farmers confirming they received support from extension officers promoting CSA practices. Access to information and training was reported by 86.2% of farmers, showing a strong flow of knowledge within the farming community. Finally, 59.6% of cotton farmers had access to agricultural inputs, whereas 40.4% lacked such access (Table 3).

Ordinary Least Squares (OLS) regression results

An Ordinary Least Squares (OLS) regression was conducted to estimate the effects of Climate Smart Agriculture (CSA) practices and socio-economic factors on cotton yield among smallholder cotton farmers in Bariadi District. The model showed a good fit with an **R-squared of 0.2537** and an **adjusted R-squared of 0.2126**, indicating that about 21% of the variation in cotton yield is explained by the predictors in the model.

Significant Factors Affecting Cotton Yield

Farm size

Study findings showed that farm size was positively and significantly related to cotton yield, with a regression coefficient (β) of 64.02 and a p-value below 0.01. This means that as the size of a farmer's land increases, their cotton yield also tends to increase. Specifically, for every additional unit of land (hectare), the cotton yield is expected to rise by approximately 64.02 units, assuming all other factors remain constant. The small p-value ($p < 0.01$) indicates that this relationship is statistically significant, meaning there is strong evidence that farm size is an important factor influencing cotton yield in the study area.

Table 3: Climate smart agriculture practices adopted by farmers and other socio-economic characteristics

CSA practices and socio-economic factors	Frequency	Percentage
Diversified crop planting	190	49.48
Intercropping	159	41.41
Soil and water conservation technique	29	7.55
Integrated pest management	2	0.52

R-squared =0.2537; Adj R-squared=0.2126, significance levels of 1%, 5%, and 10% are indicated by ***, **, and * respectively.

Other sources of income such as government employee

The findings revealed that government employment was strongly and significantly linked to higher cotton yields, with a regression coefficient (β) of 281.44 and a p-value less than 0.01. On average, government employees produced approximately 281.44 more units of cotton compared to farmers in other occupational groups, holding all other variables constant. The low p-value ($p < 0.01$) confirms that this difference is statistically significant, providing strong evidence that government employees consistently achieved higher yields than their counterparts in the study.

Agri-non-farm entrepreneur

The study results indicated that being a Agri-non-farm entrepreneur was significantly associated with higher cotton yields, with a regression coefficient (β) of 114.13 and a p-value below 0.05. This means that, on average, Agri-non-farm entrepreneur s produced about 114.13 units more cotton compared to farmers from other occupational groups, assuming all other factors remain constant. The p-value ($p < 0.05$) indicates that this difference is statistically significant, meaning there is solid evidence that Agri-non-farm entrepreneur s achieved higher yields compared to others in the study.

Intercropping

The results showed that intercropping had a significant positive effect on cotton yields. Specifically, when farmers did not practice intercropping, their yields were about 90.58 kg/ha lower ($\beta = -90.58$, $p < 0.05$), compared to those who did intercrop, assuming all other factors remained constant. The negative coefficient means that the absence of intercropping reduced yields, highlighting the important role of intercropping in boosting cotton productivity. The p-value ($p < 0.05$) confirms that this result is statistically significant, providing strong evidence that intercropping contributes to higher cotton yields.

Soil and water conservation technique

The results indicates that soil and water conservation techniques had a strong positive effect on cotton yields. When farmers did not apply these practices, their yields were reduced by about 130.85 kg/ha ($\beta = -130.85$, $p < 0.01$), compared to farmers who used them, assuming all other factors remained constant. The negative coefficient indicates that the absence of these techniques significantly lowered yields, underlining the important role they play in improving cotton productivity. The p-value ($p < 0.01$) shows that this result is statistically significant, providing strong evidence that adopting soil and water conservation practices leads to better yields.

Integrated pest management (IPM)

The study findings revealed that integrated pest management (IPM) had the most substantial positive impact on cotton yield among the factors examined. Specifically, the yield decreased by 185.46 kg/ha when IPM was not applied ($\beta = -185.46$, $p < 0.01$), showing a highly significant relationship. This means that farmers who implemented IPM practices achieved notably higher cotton yields compared to those who did not. The strong effect can be attributed to IPM's ability to effectively control pest populations, reduce crop damage, and improve overall plant health, ultimately enhancing productivity.

Irrigating with motor powered pump

The results showed that irrigating with motor-powered pump had a significant positive effect on cotton yield. When motor-powered pumps were not used for irrigation, the yield declined by 124.55 kg/ha ($\beta = -124.55$, $p < 0.05$), indicating a meaningful relationship. This suggests that farmers who irrigated with motor-powered pumps achieved notably higher yields compared to those relying on less efficient or traditional methods. The positive impact is likely due to the ability of motor-powered pumps to provide a steady and sufficient water supply, reduce water stress, and improve nutrient uptake, all of which contribute to better crop growth and higher cotton yield.

Access to Climate Smart Agriculture practices related training and information

The analysis revealed that access to CSA-related training and information had a significant positive impact on cotton yield. Farmers who did not have access to such training and information experienced a yield decrease of 203.79 kg/ha ($\beta = -203.79$, $p < 0.01$), indicating a highly significant relationship. This finding suggests that farmers who received training and information on climate-smart practices achieved considerably higher yields compared to those who lacked such support. The positive effect is likely because training equips farmers with knowledge on best practices, efficient resource use, and adaptive strategies, all of which help improve cotton yield and resilience to climate related challenges.

Discussion

The socio-economic profile of cotton farmers in Bariadi District highlights important structural factors shaping agricultural practices and livelihood outcomes. The predominance of male farmers and those with primary-level education aligns with patterns reported in other Tanzanian farming communities, where limited education often constrains technology adoption and farm productivity (Mmbando & Baiyegunhi, 2016). The dominance of married households suggests the importance of family labor in cotton production, consistent with findings by Chami (2018).

In addition, the uptake of climate-smart agriculture (CSA) practices among cotton farmers is shaped by both technical and socio-economic factors. Consistent with Ma and Rahut (2024) and Ewulo et al. (2025) access to extension services and training plays a crucial role in improving farmers' knowledge and willingness to adopt CSA innovations. However, limited access to credit remains a key barrier, as echoed in Agyekum et al. (2024), who emphasized that financial support is essential to scale CSA practices effectively.

The adoption of Climate-Smart Agriculture (CSA) practices has been shown to significantly enhance cotton yields among smallholder farmers in Bariadi District. Our analysis identified several key CSA practices including intercropping, soil and water conservation techniques, integrated pest management (IPM), and irrigating with motor powered pump that positively influence cotton yield.

Intercropping emerged as a highly beneficial practice, with farmers who adopted it achieving significantly higher yields compared to those using monoculture systems. This finding is consistent with recent evidence showing that intercropping optimizes resource use efficiency by improving light interception, nutrient uptake, and soil moisture utilization (Ma & Rahut, 2024). Beyond immediate productivity gains, intercropping also enhances soil fertility through complementary plant interactions, contributing to long-term system sustainability and resilience against environmental stresses.

The adoption of soil and water conservation techniques emerged as a significant factor in enhancing cotton yields, underscoring their role in maintaining soil fertility and optimizing moisture availability. These practices not only reduce soil erosion but also strengthen the soil's capacity to retain water, which is essential for stabilizing yields under increasingly erratic rainfall patterns linked to climate change (Li et al., 2023). Moreover, their integration into farming systems contributes to long-term sustainability by improving soil structure, enhancing nutrient cycling, and reducing vulnerability to land degradation.

Integrated Pest Management (IPM) demonstrated the strongest positive impact on cotton yield, highlighting its critical role in sustainable crop production systems. By combining biological, cultural, and mechanical control methods, IPM not only reduces dependence on chemical pesticides but also fosters ecological balance within the agroecosystem (Zhou et al., 2023). This holistic approach enhances pest suppression, minimizes crop damage, and improves overall plant health, ultimately translating into higher and more stable yields. Moreover, IPM's emphasis on environmental stewardship positions it as a cornerstone strategy for resilient and climate-smart cotton farming.

The use of motor-powered pumps for irrigation emerged as a key driver of cotton productivity, with farmers utilizing this technology attaining significantly higher yields. This underscores the pivotal role of efficient and reliable water management in optimizing cotton production, particularly in regions prone to rainfall variability. Consistent with recent research, motorized irrigation not only improves water use efficiency but also enables timely water delivery during critical growth stages, thereby safeguarding yields under water-limited conditions (Kifle et al., 2022). Furthermore, its adoption reflects the increasing importance of mechanization in enhancing smallholder resilience and productivity.

Furthermore, access to CSA related training and information was positively correlated with higher cotton yields. This highlights the role of agricultural extension services in facilitating the adoption of improved practices. Recent research emphasizes that informed farmers are more likely to implement CSA techniques effectively, leading to better outcomes (Asante et al., 2024).

Conclusion

The study concludes that the adoption of Climate Smart Agriculture practices is not just beneficial it is essential for improving cotton yield and building resilience among smallholder farmers in the face of climate variability. However, for these benefits to be fully realized, farmers must be supported with targeted interventions such as access to training, irrigation technologies, and off-farm income opportunities. The results highlight the importance of practical, context-specific support systems that enable farmers to adopt and sustain CSA practices.

In conclusion, promoting CSA adoption among cotton farmers in Bariadi District is a viable pathway toward sustainable agricultural productivity, improved livelihoods, and long-term climate resilience. Policymakers, extension agents, and development partners should prioritize actions that break down barriers to CSA implementation and ensure that no farmer is left behind in the transition toward climate-smart cotton production.

Recommendations

Based on the findings of this study, several practical and actionable recommendations are proposed to enhance cotton yields among smallholder farmers in Bariadi District through increased adoption of Climate Smart Agriculture (CSA) practices.

Firstly, the Ministry of Agriculture, in collaboration with local government authorities and NGOs, should strengthen access to CSA training and extension services. This can be done by recruiting and deploying more extension officers who are well-trained in CSA practices. These officers should conduct regular on-farm training, set up demonstration plots, and utilize mobile platforms to deliver advisory services in local languages. This

approach ensures that even farmers with limited formal education can understand and implement practices such as intercropping, efficient irrigation, soil conservation, and integrated pest management.

Secondly, the District Agricultural Office should partner with the National Irrigation Commission and agro-tech companies to scale up the availability of efficient irrigation technologies. This can involve providing subsidized drip or sprinkler irrigation kits to farmers, especially those in drought-prone areas. Establishing Water User Associations (WUAs) will help farmers manage shared irrigation infrastructure and ensure sustainability through local oversight and maintenance.

Thirdly, local governments and farmer cooperative unions should facilitate improved access to agricultural inputs by organizing farmers into cooperatives. These cooperatives can engage in bulk purchasing of key inputs such as pest control products, irrigation equipment, and improved cotton seed varieties. Additionally, cooperatives can serve as platforms for technical training and sharing of best practices among members.

Another critical recommendation is to promote off-farm income opportunities to enable farmers to invest in CSA technologies. District Development Officers, in partnership with the Ministry of Labor and Employment, vocational training centers, and private sector actors, should implement rural employment schemes and small business initiatives. Programs could include agro-processing, community infrastructure development, and vocational skills training. These alternative income sources can reduce financial barriers that limit CSA adoption.

Furthermore, village agricultural committees, supported by the Tanzania Agricultural Research Institute (TARI), should lead community-based land management programs that promote intercropping and soil conservation. This could involve distributing starter seed packs for legume intercrops and training lead farmers in techniques like contour farming and mulching, which help preserve soil structure and moisture.

Finally, Ward Agricultural Officers should work with local farmer groups to establish CSA champions at the village level. These are lead farmers who will model best practices, host demonstration activities, and provide peer guidance. To keep them motivated and impactful, they should receive technical support, inputs, and community recognition.

In sum, these recommendations call for coordinated action from government agencies, research institutions, NGOs, and local community structures to drive adoption of CSA practices and enhance cotton productivity in a sustainable, inclusive manner.

*jimmypreye@ndu.edu.ng

Abstract

This study examines the choice of climate change adaptation strategies among fish farmers in Bayelsa State. The specific objectives were to describe the socio-economic characteristics of the fish farmers and to examine the effect of socioeconomic characteristics of the farmers on their choice of climate change adaptation strategies in the study area. The study selected 120 fish farmers using multistage random sampling methods and primary data were collected from the farmers using questionnaire. The study employed frequency, percentages, mean, and multinomial logistic regression model to analyze data. The results indicate that household income, educational status, and access to credit are the most significant determinants of farmers' adaptation choices. Older farmers tend to adopt more adaptation strategies due to their experience, while larger household sizes positively influence labor-intensive adaptation techniques. Educational status strongly impacts information and education strategies, as well-educated farmers are more likely to access and utilize climate-related information. Farm size and extension contact significantly affect economic and diversification strategies, highlighting the importance of resource availability and advisory services in adaptation efforts. The study recommends the implementation of targeted policies to support farmers in building climate resilience. These include enhancing access to credit through financial programs, strengthening agricultural extension services, and promoting education on climate adaptation practices. Furthermore, investing in climate-resilient infrastructure and providing incentives for sustainable farming practices can improve farmers' adaptive capacity. By addressing these socioeconomic barriers, policymakers can enhance climate resilience and ensure food security.

Key words: *fish farmers, adaptation strategies, multinomial logistics, Bayelsa state, climate change*

[4]Department of Forestry
Audu Bako College of Agriculture Dambatta, Kano

Abstract

The concept of farmer-farmer knowledge sharing was introduced to bridge the extension worker-farmer ratio gap in developing countries. However, the idea was poorly accepted, especially in typical agrarian communities. Therefore, the study explores the concept of a farmer-to-farmer knowledge-sharing network to enhance extension service delivery. The study collected data from 80 farmers randomly selected through a series of multiple stages. The Data was analysed using a 5-point Likert scale and descriptive statistics. The Likert scale results revealed that 62.5% of the farmers are satisfied with farmer-to-farmer knowledge-sharing networks. Moreover, descriptive statistics show that lack of capacity building and low level of education are the most significant problems affecting farmer-farmer sharing networks. The major implication of these findings is that the concept of farmer-farmer knowledge-sharing networks can work better for farmers in developing countries as it was perceived by them as a reliable alternative for information sharing. Therefore, the study recommends introducing incentives into the concept of farmer-farmer knowledge-sharing networks and enhancing the capabilities of farmers who are opinion leaders in the farmer-farmer concept of knowledge-sharing to make it more sustainable.

Ameliorative Effects of *Citrus limetta* raw juice on Cyclophosphamide-Induced Organ Toxicity in Rats

Shazia Batool[1], Laaraib Nawaz[2*]

[1]Department of Emerging Allied Health Technology (DEAHT), Faculty of Allied Health Sciences, University of Lahore 54000, Punjab, Pakistan.

Abstract

The administration of cyclophosphamide (CYP) as a chemotherapeutic drug has been associated with organ toxicities by generative oxidative stress through its reactive metabolites. Thus, current study is aimed to explore the ameliorative effect of Citrus limetta (CL) raw juice treatment against CYP-induced nephrotoxicity and hepatotoxicity in rats. Following one week acclimatization, female Albino rats (N=24), were equally and randomly divided into four groups: control negative (CN) provided with normal feed and water intake, positive control group (CYP) was given intra-peritoneal injection of CYP at 20mg/kg/bw, positive control group (CL) was given oral CL treatment at 25ml/kg/bw without toxicity induction by CYP and treatment group (CYP+CL) received CL juice (25mL/Kg BW orally) after injection of CYP (20mg/kg intra-peritoneal). After 7 days of treatment, blood and tissue samples were collected and processed for biochemical markers and histopathology of liver and renal tissue. After statistical analyses, our results showed that CL juice significantly ($p \leq 0.05$) restored hepatic serum markers (ALT, AST, and total proteins), renal profile (creatinine, BUN, and uric acid), and cell injury markers (LDH and CK). Histopathological findings further supported biochemical findings and confirmed that CL juice preserved the architectural integrity and restored functions of the liver and kidney. Based on our findings, it is implied that CL may offer hepatic and renal protection by ameliorating oxidative stress produced by CYP administration.

Key Words: Cyclophosphamide, *Citrus limetta*, Nephrotoxicity, Hepatotoxicity.

1. Introduction:

The limited effectiveness of chemotherapy is mainly due to its inability to distinguish between healthy and abnormal tissues, causing widespread damage. This not only reduces the patient's quality of life but also results in life-threatening consequences (Mayne et al., 2006, Manavi et al., 2024). Among these immunosuppressant and antitumor drugs is cyclophosphamide (CYP), which is used to treat a wide range of neoplastic disorders and autoimmune diseases (Jalali et al., 2012, Sinanoglu et al., 2012, Zheng et al., 2022). Generally, CYP requires metabolic activation to exert its metabolic and toxic effects. It is activated in the liver by the hepatic cytochrome p450 oxidase system, leading to the formation of its active metabolites, especially 4-hydroxycyclophosphamide, which exists in equilibrium with aldophosphamide. These metabolites diffuse into the cells and are eventually converted into phosphoramide mustard, a potent DNA alkylating agent that interferes with DNA replication and transcription, ultimately leading to cell death (Hall and Tilby, 1992, Krüger-Genge et al., 2023). In addition to its cytotoxic action on rapidly dividing cancerous cells, the metabolic breakdown of CYP also generates several other toxic metabolic byproducts like acrolein and phosphoramide mustard (Al-Amarat et al., 2022). These metabolites are highly reactive, particularly acrolein generate free radical species. Excessive accumulation of these species results in oxidative stress, which causes damage to lipids, proteins, and nucleic acid within cells (Cengiz et al., 2022). This oxidative stress plays a critical role in causing hepatic (Senthilkumar et al., 2006, Rezaei et al., 2023, Tureyen et al., 2025), and renal toxicities (Ayhanci et al., 2010, Tureyen et al., 2025), associated with CYP administration. Since cyclophosphamide cause organ toxicity primarily through oxidative stress, it is essential to explore natural therapies with strong antioxidant properties to help mitigate its effect.

In this context, the Citrus family plants have been valued for their medicinal properties since the Middle Ages, largely due to their limonoids and flavonoids, which possess antitumor and anti-inflammatory properties (Perez et al., 2010). Citrus fruits are cultivated in more than 140 countries worldwide, with China, Brazil, India, and the United States being the major producing countries (Rao et al., 2021). These fruits are enriched with numerous antioxidative biomolecules, including phenolic acids, flavonones, flavanols, and their derivatives (Dadwal and Gupta, 2023), known to prevent, inhibit, or delay the process of oxidation (Hussain et al., 2018). Oxidation is a biochemical process that leads to the generation of free radicals that may directly or indirectly damage the cellular components (DNA, proteins, etc.) (Zandalinas et al., 2017). Citrus produce an ample quantity of endogenous antioxidants such as carotenoids, ascorbic acid (vitamin C), flavonoids, and tocopherols (vitamin E) (Racchi, 2013). These antioxidants detoxify or reduce the negative effects of reactive oxygen species (ROS), thus protecting the cellular components from ROS damage (Khalid et al., 2022). Furthermore, the potential antioxidant application of Citrus plants has been proven to be beneficial in various oxidative stress disorders, including obesity (Huang et

al., 2020), inflammatory diseases (Rong et al., 2021), atherosclerosis (Hu et al., 2021), neurodegenerative diseases (Cirmi et al., 2021), and cancer (Kitagawa et al., 2021).

As CYP administration is associated with organ toxicity, the current study aims at exploring the ameliorative effects of *Citrus limetta* raw juice against CYP-induced hepatotoxicity and nephrotoxicity in rats.

2. Material and Methods:

2.1. Procurement of materials:

Citrus limetta fruits were procured from the local market in Lahore and identified at the Botany Department of Government College University, Lahore (GC.Herb BOT.3472). Fresh juice was manually extracted daily and stored in a glass bottle at 4°C until use. Cyclophosphamide, available under the brand name Cyclomide (500 mg/1000 mg), was purchased from Sehat Clinic, Lahore.

2.2. Experimental design and animal grouping:

Twenty-four female wistar albino rats (6–8 weeks old, 230–250 g) were acclimatized for one week in the experimental animal facility at the Department of Physiology, University of Veterinary and Animal Sciences (UVAS). The rats were maintained under standard housing conditions, including a 12-hour light/dark cycle, a temperature of 22°C ± 3°C, and 60–70% humidity. They were provided standard chow feed and water *ad libitum.* The Institutional Ethical Committee of UVAS, Lahore approved all experimental procedures (DR #/1326). The rats were randomly and equally divided into 4 groups (n=6) as (a) control negative (CN) rats received basal diet, (b) CYP positive control group received intraperitoneal injection of CYP at 20mg/kg/bw (Kurdi and Alamri, 2016), (c) CL positive control group received orally CL juice at 25 ml/kg/bw (Ezeigwe et al., 2022), and (d) treatment group that was treated with CL juice at 25ml/kg/bw orally following CP 20mg/kg intra-peritoneal injection. Treatment was administered for seven days after CYP induction.

2.3. Body measurements and blood sample collection:

Body weight (g) was measured at the start and end of the experiment. Daily feed consumption (g/day) was measured throughout the trial by using equation 1 (Laaksonen et al., 2013). Body mass index (g/cm^2) was measured by using equation 2 (Bastías-Pérez et al., 2020).

$$\text{Daily feed intake} = Feed\ intake\ (g) - Feed\ leftover\ (g) \qquad Eq.1$$

$$\text{BMI} = \frac{\text{Body Weight(g)}}{\text{Nasoanal Length (cm2)}} \qquad Eq.2$$

At the end of 7-day, the rats in all the groups were sacrificed by cervical dislocation and blood samples from rats was processed into two different vials i.e. clot activator and anticoagulants. Anticoagulant vials were processed for complete hematology analysis by using Abacus Junior Vet hematology analyzer (Diamond Diagnostics Inc. Holliston, US). Procoagulant vials were processed for serum separation. After centrifugation 2000× g for 10 mins, serum was separated and stored at -20°C.

2.4. Biochemical parameters: Determination of hepatic profile

Serum liver parameters included total proteins (TP; Ref#10570) , albumin (A; Ref#10560), globulin (G), albumin-to-globulin ratio A/G ratio, and serum enzymes including aspartate transaminase (AST; Ref#12017), alanine transaminase (ALT; 12117), alkaline phosphatase (ALP; Ref#12117), and gamma-glutamyl transferase (GGT; Ref#12033) were measured using commercially available kits Human Diagnostics, Wiesbaden, Germany were used to assess all the parameters. The readings of these were taken on the Epoch™ microplate reader (Biotek Instruments Inc. Winooski, US).

Globulin levels were measured by using following formula:

$$Globulin\ \left(\frac{g}{dL}\right) = Total\ protein\ \left(\frac{g}{dl}\right) - Albumin\ \left(\frac{g}{dl}\right) \qquad Eq\ 3$$

2.5. Assessment of renal profile:

Renal profile parameters were determined by using commercially available kits by Human Diagnostics, Germany (Creatinine LOT#10053), blood urea nitrogen (BUN; LOT# 16010), and uric acid levels were determined by using (LOT#16005).

2.6. Assessment of cell injury markers:

Serum lactate dehydrogenase (LDH), and creatine kinase (CK) were evaluated by using Commercial kits from Human Diagnostics, Germany, (LOT#16001 for LDH) (LOT# A170245/6 FOR CK).

2.7. Assessment of Lipid profile:

Lipid profile parameters were measured by using human diagnostics, Germany (Total cholesterol LOT# 16008, Triglycerides LOT#16005, and HDL LOT#16002). LDL was measured by using the formula (Nawaz et al., 2024):

$$LDL_c = Total\ cholesterol - HDL_c - \left(\frac{Triglycerides}{5}\right) \qquad Eq\ 4$$

2.8. Histopathology and histomorphometry:

For histopathology, liver and kidney tissue samples were retrieved from 10% formalin and embedded in paraffin to construct blocks. For analysis, 4-5µm thin sections were mounted on albumin-coated slides and stained with hematoxylin and eosin (H&E). Sections were observed under light microscope at 40x magnification. Histomorphometry was performed by using ImageJ software (1.54d, Java 1.8.0_345).

2.9. Statistical analysis:

Data is expressed as the mean ± standard error of mean (SEM). One-way analysis of variance (ANOVA) followed by Tukey's post hoc multiple comparison test to assess the difference between groups. A value of $p \leq 0.05$ were considered statistically significant.

3. Results:

3.1. Anthropometric measurement and analysis:

Anthropometric parameters revealed (Figure 1A-C) that there was a significant (P≤0.05) reduction in body weight (225±12), feed intake (66±2.3), and body mass index (BMI, 0.45±0.04) in the CYP group as compared to control negative group (body weight: 255±11, feed intake: 79±3.2, and BMI: 0.56±0.04), indicating significant anthropometric effects of cyclophosphamide. Whereas, supplementation with Citrus limetta resulted in significant (P≤0.05) restoration of these levels, exhibited in the CYP+CL group (body weight: 240±13, feed intake: 71±2.3, and BMI: 0.51±0.03) showing its protective and restorative effects, potentially mitigating cyclophosphamide-induced metabolic and nutritional disturbance.

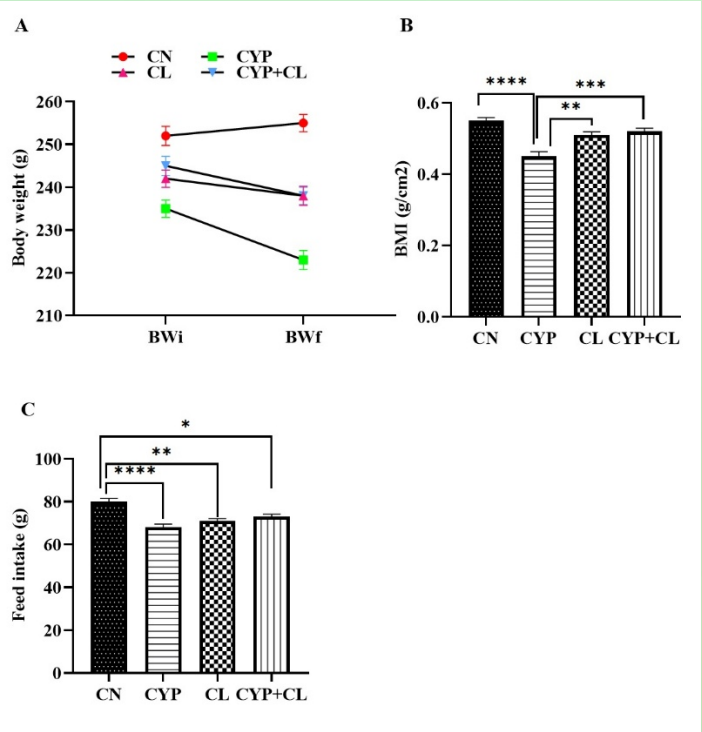

Figure 1. *Citrus limetta* supplementation mitigated cyclophosphamide-induced organ toxicity by improving key anthropometric parameters.

These parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). These parameters include (A) Body weight, (B) Body mass index (BMI), and (C) Feed intake. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

3.2. Hematological analysis and results:

Analyses of hematological parameters revealed significant (P≤0.05) suppression in white blood cells (WBC: 3.2±0.8 10^3/µl), lymphocytes (2.2±0.9 10^3/µl), and platelets (350±21 10^3/µl) in CYP group as compared to the control negative group (WBC: 7.2±2.8, lymphocytes 2.2±0.9, and platelets: 980±23), indicating cyclophosphamide-induced hematotoxicity (Fig 2A-C). However, *Citrus limetta* supplementation significantly (P≤0.05) restored these levels showing its immunomodulatory and hematoprotective properties and mitigating the myelosuppressive effects of cyclophosphamide. Moreover, no significant difference was observed in hematocrit levels (HCT), RBCs, and hemoglobin (Hb) among all groups (Fig 2 D-F).

3.3. Biochemical assessment of liver function:

Liver enzymes and protein levels were analyzed to assess liver function (Fig 3A-F). Cyclophosphamide administration significantly (P≤0.05) elevated ALT (175±13.2), and GGT (1.25±0.34) levels, along with the increase in total proteins levels (7.2±1.01) and decreased albumin to globulin ratio (A/G; 0.67±0.07) as compared to control negative (ALT: 118±12.4, GGT: 0.45±0.21, total proteins: 5.3±1.05, and A/G ratio:1.52±0.03), indicating hepatic toxicity and dysfunction. However, *Citrus limetta* supplementation significantly (P≤0.05) restored these biomarkers showing its potent hepatoprotective potential against cyclophosphamide-induced hepatotoxicity.

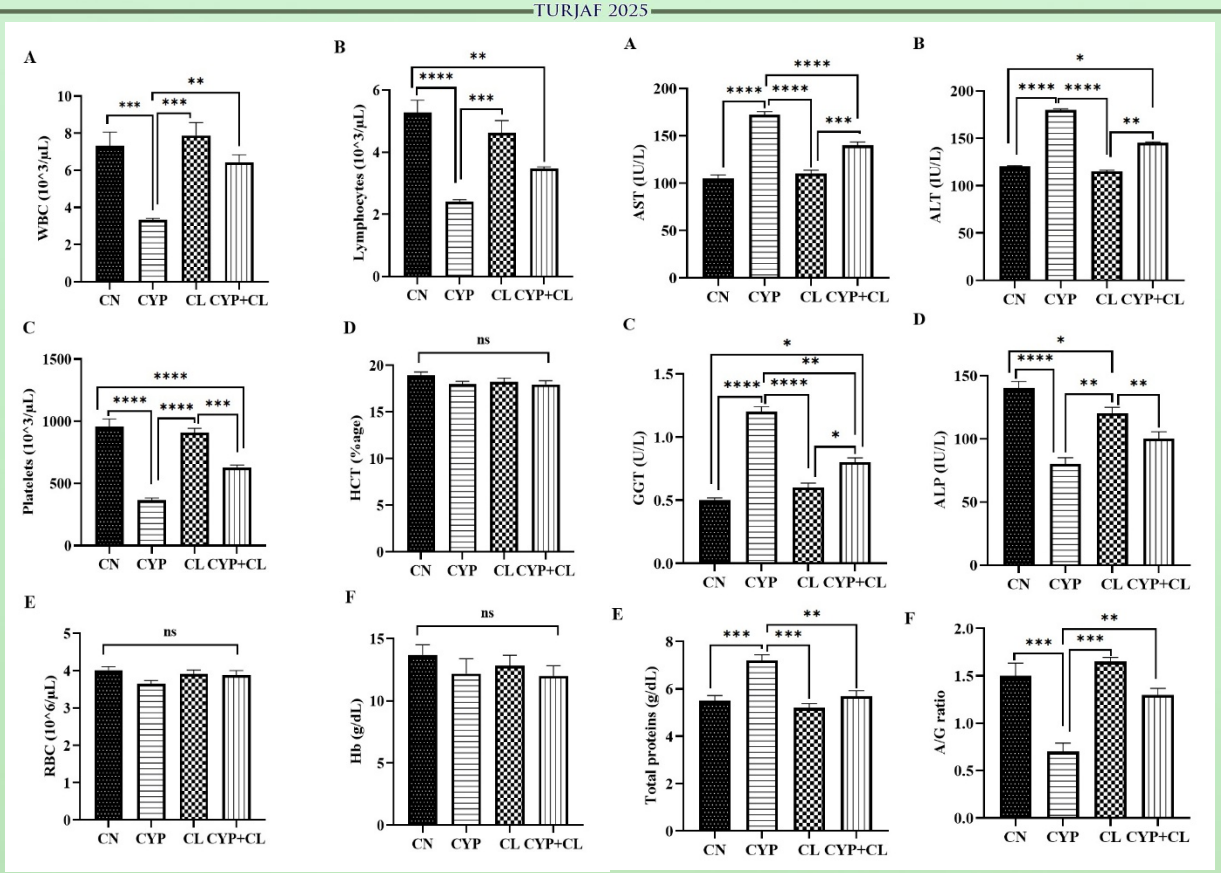

Figure 2. *Citrus limetta* supplementation facilitated hematological restoration against cyclophosphamide-induced organ toxicity.

The following parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). These parameters include (A) White blood cells (WBC), (B) Lymphocytes, (C) Platelets, (D) Hematocrit (HCT), (E) Red blood cells (RBCs), and (F) Hemoglobin (Hb). Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05. ns=non-significant.

Figure 3. *Citrus limetta* supplementation alleviated cyclophosphamide-induced hepatotoxicity by improving liver enzyme profiles and protein homeostasis.

The following parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). These parameters include (A) AST, (B) ALT, (C) GGT, (D) ALP), (E) Total proteins, and (F) A/G ratio. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

3.4. Biochemical assessment of renal function:

Renal function markers including creatinine, blood urea nitrogen (BUN), and uric acid levels were monitored to evaluate renal health (Fig 4A-C). This study revealed a significant (P≤0.05) increase in the levels of creatinine (1.39±0.23), BUN (23.5±3.2), and uric acid (8.5±2.7) in the CYP group as compared to control negative (creatinine: 0.68±0.11, BUN: 13.5±2.3, and uric acid: 5.2±1.9), indicating renal damage. However, *Citrus limetta* effectively mitigated these elevations, reducing creatinine (0.81±0.13), BUN (17.5±2.4), and uric acid (6.1±1.9), indicating its nephroprotective potential against cyclophosphamide-induced nephrotoxicity.

3.5. Biochemical assessment of cell injury markers:

Citrus limetta raw juice consumption alongside cyclophosphamide administration indicated a significant effect (P≤0.05) on lactate dehydrogenase (LDH), and creatine kinase (CK), key markers of cell injury (Fig 5A-B). This study revealed a substantial elevation in LDH (810±18) and CK (126±15) levels in the CYP group compared to normal control (LDH: 570±17, CK: 72±12), indicating increased cellular damage. However, *Citrus limetta* supplementation significantly (P≤0.05) reduced these levels (LDH: 650±12, CK: 83±17), highlighting its cytoprotective potential against cyclophosphamide-induced toxicity.

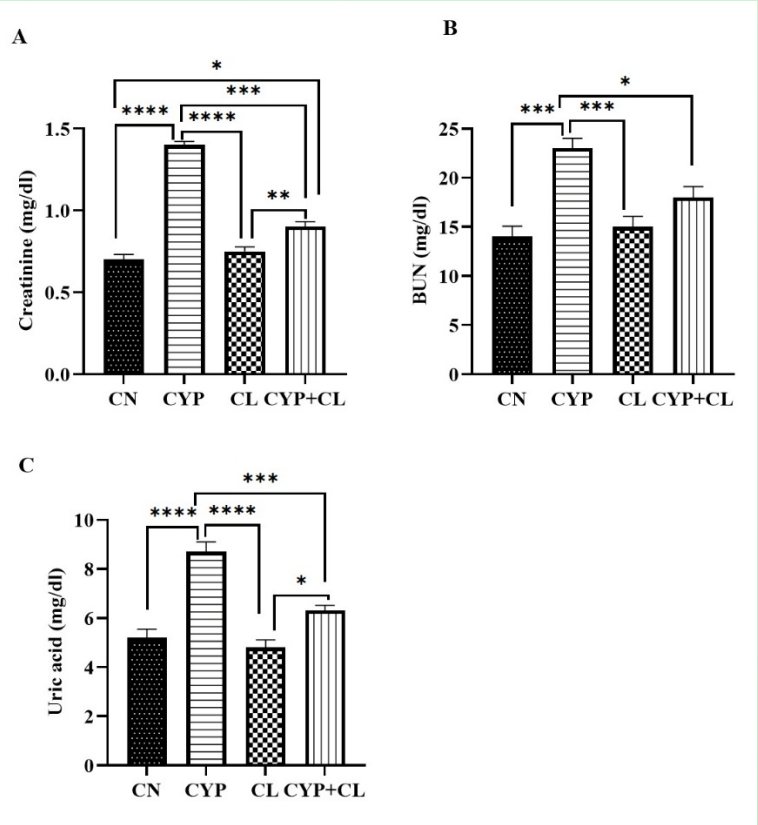

Figure 4. *Citrus limetta* supplementation mitigated cyclophosphamide-induced nephrotoxicity by restoring creatinine, BUN, and uric acid concentrations.

The following parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), Citrus limetta control (CL), and the treatment group receiving Citrus limetta following cyclophosphamide administration (CYP+CL). These parameters include (A) Creatinine, (B) BUN, and (C) Uric acid. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

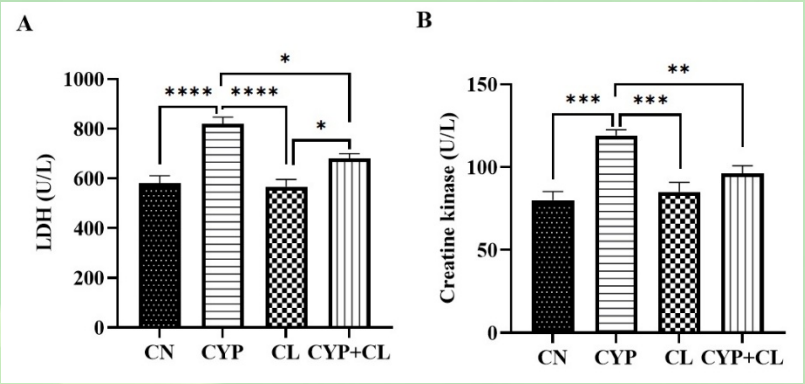

Figure 5. *Citrus limetta* supplementation attenuated cyclophosphamide-induced organ toxicity by reducing cell injury markers.

The following parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). These parameters include (A) LDH, and (B) Creatine kinase. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

3.6. Biochemical assessment of lipid profile:

Lipid profile analyses revealed significant (P≤0.05) dyslipidemia as evidenced by elevation in total cholesterol (149±5.4), and triglycerides (175±4.5) accompanied by a marked reduction in HDL-c (14±1.3) levels in the CYP group (Fig 6A-D), as compared to the control negative group (total cholesterol: 78±4.3, triglycerides: 123±5.7, and HDL-c 25±2.1) showing potential disruption of lipid homeostasis associated with cyclophosphamide. However, supplementation with *Citrus limetta* resulted in the restoration of lipid levels, exhibited in the CYP+CL group, indicative of vital role in mitigating cyclophosphamide-induced dyslipidemia and contributing to lipid profile normalization.

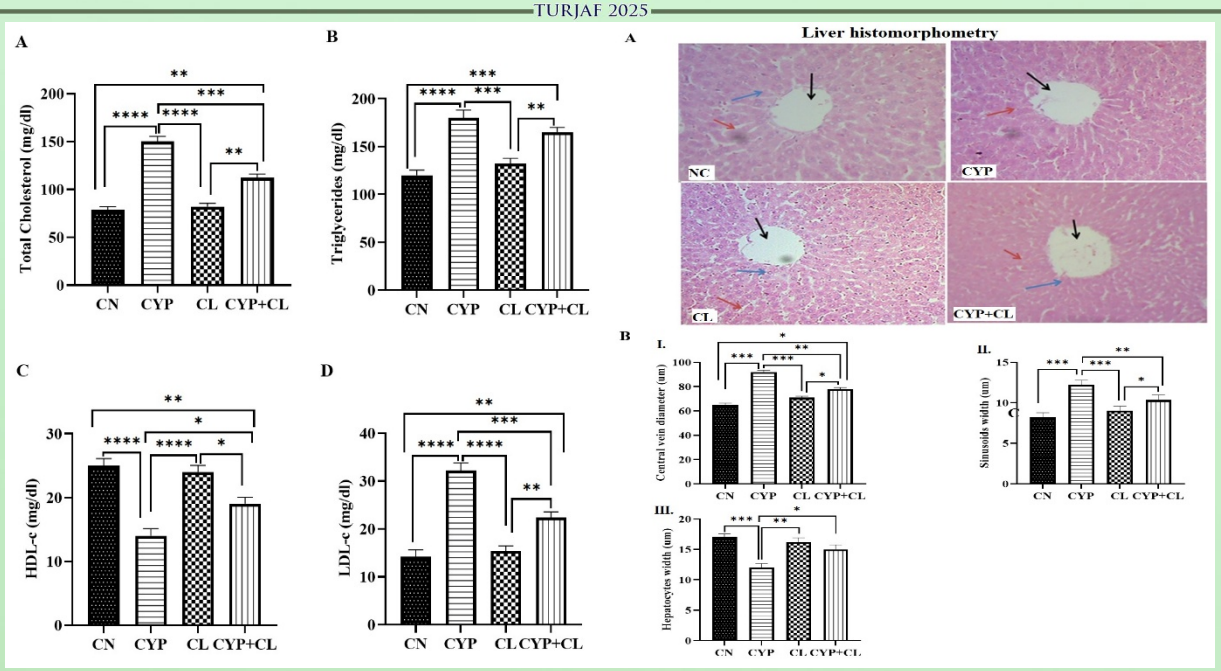

Figure 6. *Citrus limetta* supplementation mitigated cyclophosphamide-induced dyslipidemia by optimizing lipid profile parameters.

The following parameters were evaluated across four groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). These parameters include (A) Total cholesterol, (B) Triglycerides, (C) HDL-c, and (D) LDL-c. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

Figure 7. *Citrus limetta* supplementation mitigated cyclophosphamide-induced hepatic damage, preserving liver structure.

(A) Representative photomicrographs of liver sections stained with Hematoxylin and Eosin (H&E) at 40× magnification, illustrating histological variations in different experimental groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). Cyclophosphamide administration led to significant hepatic alterations, including an increased central vein diameter and sinusoidal width, and reduction in hepatocyte size. These structural disruptions were effectively normalized in the Citrus limetta-treated group. Histological analysis (H&E, 40x) highlights central vein dilation (black arrow), sinusoidal congestion (red arrow), and restored hepatocyte morphology (blue arrow) following Citrus limetta supplementation. (B) Quantitative histomorphometric data depicting (I) Central vein diameter, (II) Sinusoid width, and (C) Hepatocyte width. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

3.7. Liver histomorphometry:

Liver histopathological analyses (Fig 7A-B) revealed that cyclophosphamide administration induced significant (P≤0.05) hepatic alterations as evidenced by an increased central vein diameter (91±4.2) and sinusoidal width (13.2±0.78), and with a notable reduction in hepatocyte size 12.5±1.07) in CYP group as compared to control negative group (central vein diameter: 63±3.2, sinusoidal width: 7.5±0.89, and hepatocyte diameter: 16.5±1.03). These alterations indicate extensive hepatocellular damage and vascular remodeling, suggesting hepatotoxicity. However, these structural disruptions were effectively normalized in the *Citrus limetta* supplemented group, depicted by CYP+CL, affirming its hepatoprotective potential in maintaining structural integrity of liver against cyclophosphamide-induced hepatotoxicity.

3.8. Renal histopathology:

Histopathological analyses of renal tissue (Fig 8) revealed that cyclophosphamide administration induced structural disruptions as evidenced by increased capsule and glomerular thickness, along with significant dilation of PCT and DCT diameter in the CYP group as compared to the control negative group. Furthermore, CL supplementation resulted in the restoration of glomerular and tubular structural integrity by mitigating cyclophosphamide-induced nephrotoxicity, thereby promoting renal health and functional recovery.

3.9. Renal histomorphometry:

Quantitative histomorphometric analyses of renal tissue revealed significantly (P≤0.05) increased renal corpuscle thickness, increased PCT and DCT diameter, increased PCT wall-to-lumen (W/L) ratio, and significantly decreased DCT W/L ratio in the CYP group (capsule: 85±2.3, PCT W/L: 0.52±0.04, and DCT W/L 0.14±0.03), indicative of nephrotoxicity, as compared to control negative (capsule: 79±1.9, PCT W/L: 0.41±0.03, and DCT W/L 0.19±0.02), and *Citrus limetta* supplemented group (CYP+CL; capsule: 80±1.8, PCT W/L: 0.45±0.05, and DCT W/L 0.21±0.04). These findings imply that *Citrus limetta* possesses strong nephroprotective properties by mitigating cyclophosphamide-induced structural alterations.

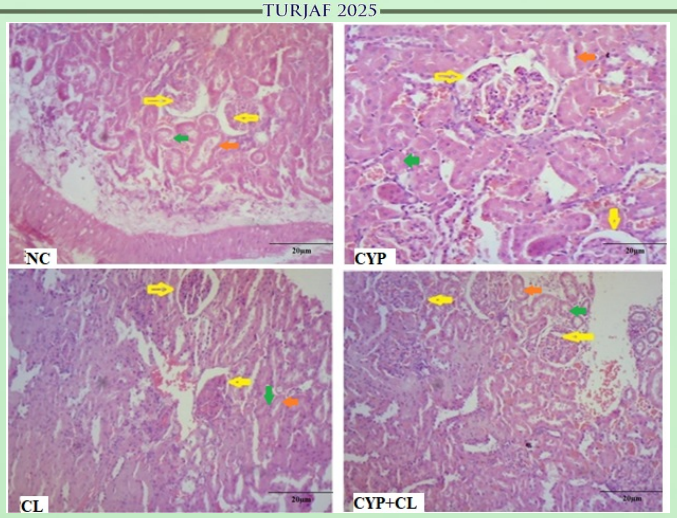

Figure 8. *Citrus limetta* supplementation safeguarded renal tissue integrity by counteracting cyclophosphamide-induced nephrotoxicity.

Representative photomicrographs of renal sections stained with Hematoxylin and Eosin (H&E) at 40× magnification, illustrating histological variations in different experimental groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). Cyclophosphamide exposure resulted in pronounced renal structure disruption including increased capsule and glomerulus thickness, dilation of both proximal (PCT) and distal convoluted tubules (DCT). These pathological alterations were effectively mitigated by *Citrus limetta* supplementation which helped restore renal architecture. Histological features are indicated as follows: renal corpuscle (yellow arrows), proximal convoluted tubules (PCT, orange arrows), and distal convoluted tubules (DCT, green arrows. Scale bar = 20 µm.

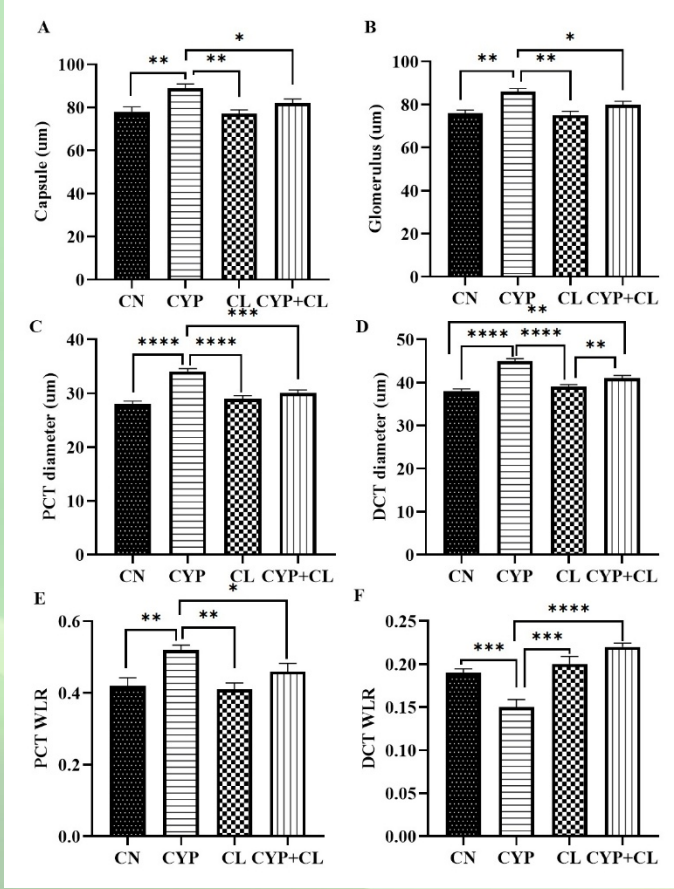

Figure 9. *Citrus limetta* effectively preserved the structural integrity of renal tissues, mitigating cyclophosphamide-induced nephrotoxicity and preventing structural alterations.

Quantitative histomorphometric analysis of renal structural parameters across different experimental groups: the control negative (CN), cyclophosphamide-induced positive control (CYP), *Citrus limetta* control (CL), and the treatment group receiving *Citrus limetta* following cyclophosphamide administration (CYP+CL). Quantitative histomorphometric data depicting: (A) capsule thickness (µm), (B) glomerulus diameter (µm), (C) proximal convoluted tubule (PCT) diameter (µm), (D) distal convoluted tubule (DCT) diameter (µm), (E) PCT wall-to-lumen ratio, and (F) DCT wall-to-lumen ratio. Mean±SEM values are displayed on bars, N=6. ****P<0.0001, ***P<0.001, **P<0.01, *P<0.05.

4. Discussion:

Currently, there is significant research interest in medicinal plants, which confer therapeutic effects, both in modern medicine and allopathy, due to their pronounced antioxidant and antihyperglycemic properties, reduced side effects, and low cost (Nawaz et al., 2024). Among these, the *Citrus* species stands out due to its potent antioxidant and anti-inflammatory properties, which effectively reduce oxidative stress and inflammation __ key contributors to cellular injury and organ damage. Cyclophosphamide, a widely used chemotherapeutic agent induces organ toxicity primarily through oxidative stress. Thus current study is aimed at exploring the protective and restorative effects of *Citrus limetta* raw juice against cyclophosphamide-induced organ toxicity.

Anthropometric data indicated a reduction in body weight, feed intake, and BMI in the CYP group, likely due to the ability of CYP to impair the integrity of the intestinal mucosa, disrupt the morphology of the intestinal villi, increase the permeability of the intestinal mucosal barrier, and resultant nutrient malabsorption leading to weight loss (Zhao et al., 2024). Whereas, supplementation with *Citrus limetta* restored these parameters (**Fig 1A-C**) which could be attributed to its rich flavonoid content. *Citrus* flavonoids, such as naringenin and hesperidin, have been demonstrated to upregulate the expression of tight junction proteins, thereby strengthening the intestinal barrier function and reducing permeability (Stevens et al., 2019, Noda et al., 2013). Thus it is implied that *Citrus limetta* may exert protective and restorative effects on gut health by mitigating CYP-induced intestinal disturbances.

Hematological analysis revealed that CYP remarkably reduced WBC, lymphocytes, and platelets levels in the CYP group likely due to its myelosuppressive effects. CYP disrupts the bone marrow niche by disrupting the interactions between hematopoietic stem cells and their supportive microenvironment, leading to impaired hematopoiesis (Lévesque et al., 2003). Whereas these alterations were restored by *Citrus limetta* (**Fig 2A-F**)which could be due to its strong flavonoid content. As flavonoids have been shown to positively modulate gut microbiota enhancing the production of short-chain fatty acids (SCFAs), which play a crucial role in immune modulation and hematopoiesis (Zhao et al., 2023). Furthermore, no significant effects were seen on hematocrit, hemoglobin, and RBC levels due to selective toxicity of CYP towards rapidly dividing cells. As an alkylating agent, CYP targets rapidly dividing cells by interfering with DNA replication, leading to cell death and immunosuppression (De Jonge et al., 2005). On contrary, mature RBC are non-dividing cells and lack nuclei, rendering them less susceptible to the direct cytotoxic effects of CYP (Sheng et al., 2020). Additionally, RBCs have a longer lifespan, and the study's short duration was insufficient to impact their levels unless severe hemolysis occurred. These findings suggest *Citrus limetta* may exert immunomodulatory effects due to its flavonoid-rich composition.

Liver enzymes profile was monitored to evaluate liver function, as liver is the primary site of drig metabolism, primarily mediated by cytochrome p450 system (Allameh et al., 2023). During CYP metabolism by the liver, acrolein- a highly reactive byproduct, induces excessive free radicals production, overwhelming the liver's antioxidant defenses. These free radicals initiate lipid peroxidation by attacking polyunsaturated fatty acids in cell membranes (May-Zhang et al., 2021), compromise membrane integrity, increasing permeability and ultimately induce hepatocyte injury. Consequently, intracellular enzymes like ALT and GGT leak into the bloodstream, serving as biomarkers of liver dysfunction (Afzal et al., 2023). It was consistent with our findings as AST, ALT, ALP, and GGT levels were significantly raised in CP group along with increased total proteins levels. Whereas these perturbations were restored in CL treated group, as shown in **Fig 3A-F**, which could be attributed to its strong antioxidant activity exerted by flavonoids. Flavonoids are reported to neutralize ROS and inhibit lipid peroxidation, reducing membrane damage and preventing enzyme leakage (restoring **ALT** and **GGT** levels) (Shirani et al., 2020). These restorative activities of CL were further confirmed by histopathology revealing structural preservation, restored central vein diameter, sinusoids width, and hepatocytes diameter as shown in **Fig 7 A-B**. These findings suggest that Citrus species, including *Citrus limetta*, may enhance the liver's antioxidant defenses, thereby aiding in hepatic regeneration and functional recovery.

Serum creatinine, BUN, and uric acid are kidney-specific biomarkers used to monitor renal health. Our findings indicated a significant elevation of these biomarkers after CYP administration (**Fig 4A-C**). Although CYP is an effective chemotherapeutic drug, it has certain toxic effects on different organs like kidneys. Acrolein, a highly toxic metabolite, is filtered by the kidneys and accumulates in the bladder and renal tubules (Hałka et al., 2022). This accumulation directly damages renal tubular cells and causes apoptosis and necrosis (Mohamed et al., 2023). These toxic effects were further confirmed by renal histopathology (**Figure 8-9**)which exhibited glomerular congestion, increased PCT and DCT diameter, and significant tubular damage. These functional and structural alterations were however, ameliorated by *Citrus limetta* juice supplementation which could be attributed to its strong antioxidant defense system, and its citrus-derived compounds known to stabilize podocyte functions (Gong et al., 2023), and ultimately maintain filtration barrier integrity. Thus, *Citrus limetta* protects against CYP-induced nephrotoxicity by enhancing antioxidant defenses and preserving renal structure and function.

Cell injury markers CK and LDH were significantly increased in CYP administered group which indicates widespread tissue injury (**Fig 5A-B**). As explained earlier, CYP metabolism leads to hepatic injury which causes the release of intracellular enzyme LDH leakage into the plasma (Bale et al., 2014). However, an increase in CK levels indicates the myotoxic effects of CYP as seen in some cases of rhabdomyolysis (Shima et al., 2002).

Whereas *Citrus limetta* showed cytoprotective effects due to the presence of vitamin C which enhances levels of glutathione, a key cellular antioxidant in the cellular membrane (Heaney et al., 2008, Metwaly et al., 2022).
The metabolism and physiology of lipids and lipoproteins is a dynamic integrated process with the liver playing a central role in lipid homeostasis. Given the hepatotoxic effects of CYP, the current study revealed that the CYP-administered group showed elevated total cholesterol and triglycerides levels (**Fig 6A-D**) which could be due to the acrolein-lysine adducts known to cause hypertriglyceridemia and hypercholesterolemia by increasing cellular cholesterol accumulation, and by reducing cholesterol efflux by generation of free radicals and inhibition of lipoprotein-lipase (Yahya et al., 2022). *Citrus limetta* exhibited significant hypolipidemic effects, primarily due to its rich flavonoid content. Flavonoids function as cellular signaling molecules, modulating sterol signal transduction pathways, which enhance lipoprotein reuptake and thereby lower circulating LDL levels (Oboh et al., 2014). Thus it is implied that *Citrus limetta* mitigates CYP-induced dyslipidemia by enhancing lipid metabolism and reducing circulating LDL levels through its flavonoid-mediated regulatory effects.

5. Conclusion:

Bases on our findings it is concluded that *Citrus limetta* demonstrated significant protective and restorative effects against cyclophosphamide-induced organ toxicity. Its rich flavonoid content contributed to antioxidant defense, immunomodulation, and lipid metabolism regulation. The juice effectively mitigated CYP-induced hepatotoxicity, nephrotoxicity, dyslipidemia, and myelosuppression by reducing oxidative stress, stabilizing cellular structures, and enhancing metabolic pathways. These findings suggest that *Citrus limetta* holds therapeutic potential in counteracting chemotherapy-induced toxicity, supporting its role as a natural cytoprotective agent.

6. Strengths, limitations and future prospective

This study provides valuable insights into the protective effects of *Citrus limetta* against cyclophosphamide-induced organ toxicity, demonstrating its antioxidant, immunomodulatory, and hypolipidemic potential. The integration of biochemical, hematological, and histopathological analyses strengthens the reliability of the findings. Despite its promising findings, the study has some limitations. The sample size was limited, and the study duration may not have been sufficient to observe long-term protective effects. Additionally, molecular mechanisms underlying the observed protective effects were not extensively explored, warranting further investigation into specific signaling pathways and gene expressions involved.

Abstract

Soil erosion is a major environmental challenge that necessitates meticulous investigation and the implementation of sustainable management practices. The objective of this study is to provide a thorough assessment of soil erosion in the Bay region from 2020 to 2023, utilizing the Revised Universal Soil Loss Equation (RUSLE) and advanced geospatial technologies, particularly Google Earth Engine, to guide sustainable land management strategies. The study integrates multiple datasets, including CHIRPS for rainfall measurement, MODIS for land use analysis, and a digital elevation model for slope calculation, to offer a comprehensive understanding of the factors contributing to soil erosion. The rainfall erosivity (R) factor is calculated using CHIRPS data, while the soil erodibility (K-factor) is derived from the soil dataset. The topographic (LS-factor) is computed using the digital elevation model, and the cover-management (C) and support practice (P) factors are determined from the NDVI and land use data, respectively. The findings reveal considerable spatial variation in soil erosion across the Hirshabelle regions. The results are categorized into five levels based on the severity of soil loss: Slight (<10), Moderate (10-20), High (20-30), very high (30-40), and Severe (>40). While areas classified under “Slight” soil loss are dominant, indicating relatively stable soils, regions under “Severe” soil loss signal potential land degradation and the need for immediate intervention. Furthermore, the study revealed the intricate interplay of slope, vegetation, and land use in influencing soil erosion. Areas with steeper slopes and less vegetation were more susceptible to soil loss, emphasizing the need for targeted soil conservation measures in these regions. The land use factor played a crucial role, with certain land uses contributing more to soil erosion than others.

Abstract

The study was conducted in the laboratory of animal sciences Bayero University, Kano to investigate the best value among 7 minerals to improve roughages value feed to cattle. a laboratory trial laid in a 7 x 3 factorial arrangement of a completely randomized design with 7 treatments (Rice straw treated with Sesame salt (T1), Rice straw treated with Doum fruit salt (T2), Rice straw treated with urea (T3), Rice straw treated with potassium (T4), Rice straw treated with poultry waste manure (T5), Rice straw treated with Doum fruit salt+urea (T6) and rice straw alone (T7) as control) and three incubations periods (14, 21 and 28 days) was applied to detect the best mineral and period to improve the nutritional value of rice straw. The source of mineral treatments significantly ($P<0.05$) affected the nutritive value of roughages and 28 days incubation period yielded the highest value for crude protein. The best was obtain from T5, T3, and T2 respectively in term of CP and Nitrogen value.

Abstract

The study evaluated the quality characteristics of the marmalade produced from oranges and honey. In the production of the marmalade, combination of orange and honey were used at different ratios. The ratio of orange to honey were OHM0(100:0) OHM1(80:20), OHM2(70:30), OHM3(60:40) and OHM4(50:50). The marmalade were analyzed for chemical composition, physiochemical, microbiological and sensory properties. Statistical analysis was carried out using one way analysis of variance (ANOVA) and mean was separated using Duncan new multiple range test. The moisture, protein, fat, fibre, ash and carbohydrate ranged from 10.69 - 43.62%, 1.27 - 1.87%, 1.07 - 1.69%, 0.20 - 0.45%, 1.08 - 1.92% and 50.46 - 85.71%, respectively. Sample OHM1 had the highest moisture content. The composition for vitamin A, B3, B1, B2 and C ranged from 0 - 0.45mg/100g, 0.12 - 0.17 mg/100g, 0.47 - 0.71mg/100g, 0.34 - 0.54mg/100g and 16.04 - 24.09mg/100g, respectively. The magnesium, iron and calcium ranged from 34.29 - 39.83mg/100g, 0.58 - 1.02mg/100g and 43.04 - 50.10mg/100g, respectively. The results of the physicochemical parameters for pH and total titrable acid ranged from 2.60 - 3.30, 0.95 - 1.28. Total viable count and the mould count were not detected in the samples. Sensory scores indicated that the marmalade with 80% orange, 20% Honey was most accepted by consumers amongst other formulations, resulting in improved taste and texture. Overall, the use of honey in the production of marmalade is a promising approach for producing nutritious and acceptable fruit beverage.

Key words: *Production, evaluation, marmalade, orange, honey*

Impact of Storage Conditions on the Stability and Bioactivity of Date Vinegar: A Comprehensive Study on Its Efficacy in Managing Metabolic Diseases

Zeshan Ali[1*], Zinanone Rosaire Brottier[1]

[1]College of Food Science and Technology, Bohai University; National & Local Joint Engineering Research Center of Storage, Processing and Safety Control Technology for Fresh Agricultural and Aquatic Products, Jinzhou, Liaoning, 121013, China

Abstract

Date vinegar, a functional beverage derived from dates (*Phoenix dactylifera*), has garnered attention for its potential health benefits, including antidiabetic and cardiovascular effects. This study investigates the efficacy of date vinegar in managing type 2 diabetes mellitus (T2DM) and cardiovascular diseases while also examining how different storage conditions influence the stability and bioactivity of the beverage. In the first phase, a 10-week randomized controlled trial was conducted to assess the clinical effects of date vinegar on glycemic control and lipid profiles in adults with T2DM and dyslipidemia. Significant improvements were observed in HbA1c, LDL cholesterol, and fasting blood sugar levels ($p < 0.05$). Complementary computational docking and molecular dynamics simulations identified binding interactions between key bioactive compounds in date vinegar and therapeutic protein targets, such as ACE, β1AR, and DPP-IV. In the second phase, the stability of date vinegar was tested under different storage conditions. A beverage was prepared by blending date vinegar and goji berry juice, then stored at three different temperatures (room temperature, 40°C, and 50°C) for one and two months. Changes in physicochemical and phytochemical parameters were monitored, including total sugar content, antioxidant activity, and phenolic content. After two months, an electronic nose analysis was performed to evaluate sensory changes under different storage conditions. The results indicated that higher temperatures (40°C and 50°C) negatively affected the integrity of bioactive compounds, whereas storage at room temperature better preserved the beverage's quality. When stored appropriately, this integrated study demonstrates that date vinegar provides a dual-target therapeutic strategy for managing T2DM and cardiovascular diseases. The clinical findings confirm its efficacy, while the storage conditions emphasize the importance of proper storage to maintain its bioactive properties for optimal therapeutic benefits.

Key Words: *Date vinegar, Storage conditions, Bioactive compounds, Type 2 diabetes, Cardiovascular diseases, Stability, Molecular dynamics simulations, Glycemic control.*

Nutritional, Medicinal, and Industrial Applications of Tokma (*Hyptis suaveolens*), Isabgol (*Plantago ovata*), and Chia (*Salvia hispanica*): A Comprehensive Review

Md. Solayman Ope, Sumaia Sultana, Samir Shakir and M. Ashrafuzzaman
Laboratory of Medicinal Plant Resources, Department of Crop Botany, Bangladesh Agricultural University, Mymensingh 2202, Bangladesh.
Corresponding author: ashrafcbot@bau.edu.bd

Abstract

Herbal plants offer three significant benefits: nutritional support, disease treatment, and industrial utility. For centuries, they have been valued for their beneficial properties. Among them, Tokma (*Hyptis suaveolens*), Isabgol (*Plantago ovata*), and Chia (*Salvia hispanica*) are well known and widely used for multiple health benefits and diverse applications. This review aims to provide a comprehensive overview of the nutritional, medicinal, and industrial use of *Hyptis suaveolens*, *Plantago ovata*, and *Salvia hispanica*, thereby facilitating further research and understanding. A systematic review of peer-reviewed articles was conducted, supplemented by self-exploration. The study highlights that *Plantago ovata* is notable for its high fiber content and positive impact on gut health, making it widely used in dietary supplements and animal feed. It can also be researched for its application in green food packaging and emulsion-based drug delivery systems. *Salvia hispanica* is rich in omega-3 fatty acids and essential minerals and is especially valued for its cardiovascular and metabolic health benefits. It is used largely in bakery products, beverages, and cosmetics. Although *Hyptis suaveolens* is less researched globally, it shows significant medicinal potential, including anti-inflammatory, antiviral, antimicrobial, and blood purifying properties. Its oil has potential insecticidal properties and may be used in agriculture as a natural herbicide or grain preservative. In conclusion, *Salvia hispanica* is more nutritionally balanced and has more diversified use compared to the other two. Nevertheless, *Hyptis suaveolens* and *Plantago ovata,* also offer diverse health benefits and applications. Further studies are essential to fully explore their potential and uses.

Abstract

In this study, setae morphology on the prosoma, opisthosoma and legs of male and female individuals of *Oxyopes ramosus* (Martini & Goeze, 1778) from the spider family Oxyopidae was determined by Scanning Electron Microscopy (SEM). It was seen that a scaly type setae, which is specific to the genus, was also present in this species, but this setae type showed slight differences in male and female individuals of this species. This is also the first study to compare the setae morphology in both sexes of *Oxyopes ramosus* (Martini & Goeze, 1778).

Key Words: *Oxyopes*, Setae morphology, Spider, Türkiye.

Introduction

Spiders are one of the most successful organisms in the arachnids (Arachnida) class of the arthropods (Arthropoda), adapted to terrestrial ecosystems. Most of the spiders, which are mostly adapted to terrestrial habitats, live on the ground, on or in the soil surface, in stony areas, rocky areas and on herbaceous or woody plants. Very few of them live on the edges and near the surface of fresh water. They are carnivorous creatures and with this feature, they show dominant feature in the ecosystem (Foelix, 2011). They usually feed on insects, but they can also eat each other. Since insects constitute the majority of their diet, they are used as biological control agents in agricultural ecosystems (Bayram and Allahverdi, 1999).

The outer part of the body of spiders consists of a hard layer of chitin and scleroprotiene, called the cuticle. The cuticle is covered with hair-like structures called setae, which fulfil various tasks. Setae are usually concentrated on the abdomen, but are also found on the prosoma, legs, palps and ducklings. The linear setae are usually associated with a receptor cell and act as sensory organs or mechanoreceptors, whereas the scale-like ones are not associated with any receptor cell and act only as a covering (Zakharov and Ovtsharenko, 2015).

Among all spider families, 13 families (Anyphaenidae, Araneidae, Corinnidae, Gnaphosidae, Heteropodidae, Liocranidae, Lycosidae, Oxyopidae, Philodromidae, Pisauridae, Salticidae, Thomisidae and Uloboridae) had at least one type of seta. Studies on the seta morphology of ground spiders revealed the presence of 10 different cover setae and it was stated that the diversity of these seta morphologies can be used in the classification of spiders at the genus and species level (Lehtinen, 1975).

The first aim of this study was to determine the seta morphology of *Oxyopes ramosus* belonging to the family Oxyopidae. The second aim of the study was to make a comparison of the morphological structures of the setae in male and female individuals of this species.

Materials and Methods

Materials

The male and female individuals of *Oxyopes ramosus* belonging to the family Oxyopidae used in this study were obtained from Niğde Ömer Halisdemir University Arachnological Museum (NOHUAM) (Figure 1).

Methods

The Electron Microscope in the Central Research Laboratory of Niğde Ömer Halisdemir University was used to determine the seta morphology of male and female individuals of Oxyopes ramosus. The prosoma, opisthosoma and legs of each individual were placed on staps and the surface of the specimens were coated with gold using a Sputter Coater (Cressingto Auto 108). Photographs were taken using EVO LS 10 ZEISS brand device (Figure 2).

Results and Discussion

The morphology of the setae on the prosoma, opisthosoma and segments of both sexes of *O. ramosus* (Martini & Goeze, 1778) belonging to the *Oxyopes* species of the Oxyopidae family was determined by SEM. The SEM photographs obtained are given below (Figures 3,4).

Figure 1. General Habitus of *Oxyopes ramosus* species

Figure 2. EVO LS 10 ZEISS brand SEM device

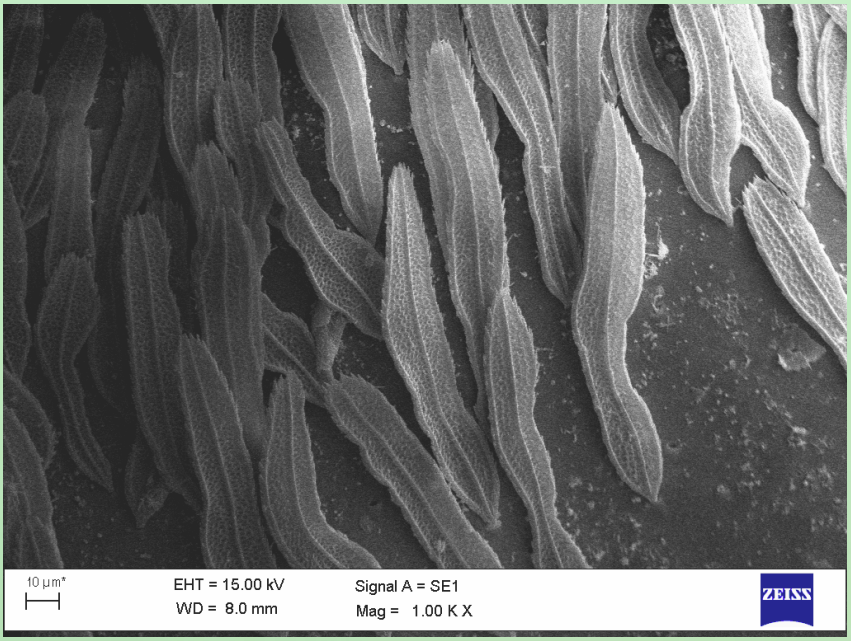

Figure 2. Setae of the female specimen of *Oxyopes ramosus* (Martini & Goeze, 1778)

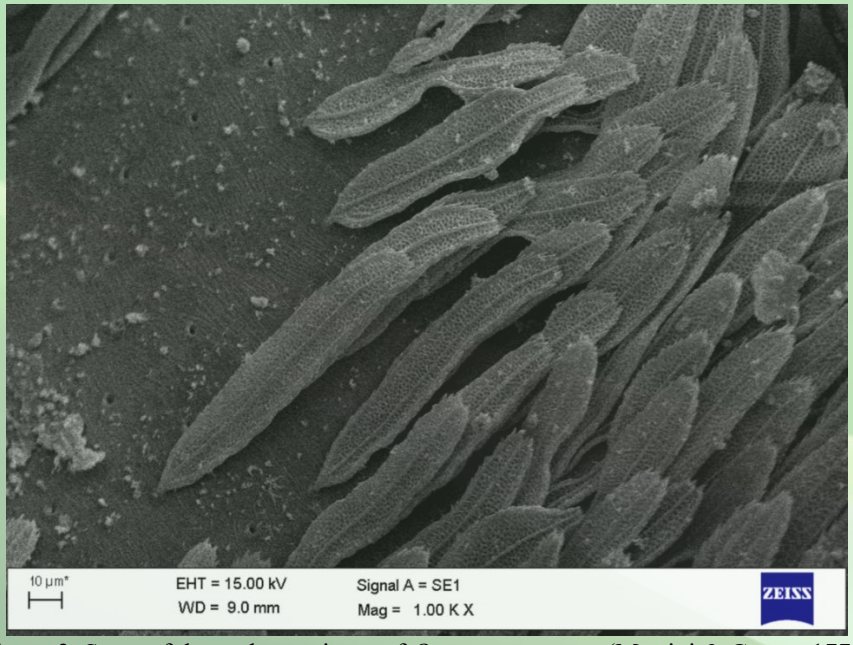

Figure 3. Setae of the male specimen of *Oxyopes ramosus* (Martini & Goeze, 1778)

The bodies of most lynx spiders are covered with cuticular structures called setae. These setae are more densely located on the dorsal and lateral parts of the prosoma and abdomen. It is thought that these setae covering the body have defense, heat regulation and communication functions. In lynx spiders, studies have been conducted on the seta morphologies of the *Oxyopes* and *Peucetia* genera so far (Townsend Jr and Felgenhauer, 2001). In the studies conducted, setae with a scaly morphology were observed in *Oxyopes aglossus* and *O. salticus*. Another genus belonging to the Oxyopidae family, the *P. viridans* species belonging to the *Peucetia* genus, had a hairy type seta morphology (Townsend Jr and Felgenhauer, 2001).

In Türkiye, the family Oxyopidae is represented by 2 genera and 7 species. One of these two genera, *Oxyopes*, is represented by subspecies, these are *Oxyopes globifer* Simon, 1876, O. heterophthalmus (Latreille, 1804), *O. lineatus* Latreille, 1806, *O. nigripalpis* Kulczyński, 1891, *O. pigmentatus* Simon, 1890 and *O. ramosus* (Martini & Goeze, 1778) (Danışman et al., 2023). Among these species, in this study, SEM photographs were made on both male and female individuals of *O. ramosus* (Martini & Goeze, 1778).

According to the literature, the seta morphology of six *Oxyopes* species has been studied so far and all of them have the same morphological type of scaly setae. This *Oxyopes* genus-specific scaly seta type shows marginal and apical spines with a single shaft and abundant plicae Townsend and Felgenhauer, 2001). In this study, SEM photographs of both male and female individuals of *O. ramosus* (Martini & Goeze, 1778) showed that although the seta morphology of the male and female were largely similar, there were differences in the apical spines of the seta (Figure 4).

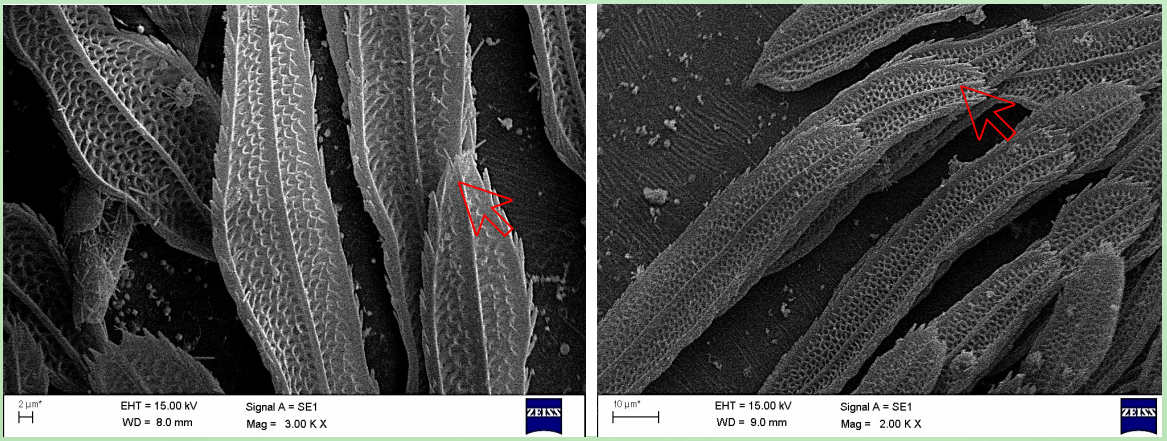

Figure 4. Differences in seta morphology in males and females of *O. ramosus*

Food Waste Prevention Training: Content Determination

Emre Hastaoğlu[1]

[1]Department of Gastronomy and Clunary Arts, Faculty of Tourism, Sivas Cumhuriyet University, Sivas, Türkiye

Abstract

Food waste is one of the most important issues facing the food and beverage industry today. Food waste means that about one-third of the food produced worldwide is lost before it reaches the consumer. In Turkey, millions of tons of food are wasted every year, and a significant portion of this occurs in the food and beverage sector. Food and beverage businesses play a critical role in preventing waste at every step from the supply chain to the service stage. Raising the awareness of sector employees is one of the most important steps to be taken to solve this problem. A training content should be developed on this subject and awareness of food waste in society and individuals should be increased and ways to contribute to minimizing waste should be presented. The content should emphasize the causes of food waste, its consequences and strategies to reduce it. At the beginning, food waste should be defined and its dimensions should be detailed. The current state of food waste both in the world and in Turkey, supported by current statistics, should be presented to the participants. In this way, participants can reach a better level of awareness to grasp the seriousness of this important problem. One of the other main topics that should be covered within the framework of the training is the root causes of waste. Themes such as consumer behavior, deficiencies or malpractices in production and distribution processes, storage and handling errors should be emphasized. Each cause should be examined in detail and clarified with concrete examples of common mistakes. Strategies to prevent food waste constitute the most vital part of the training. Participants should be given practical advice on proper buying habits, storage techniques and how to utilize leftovers. At the same time, information should be provided on policies and concert projects that can be implemented on a larger scale. Finally, trainings should be interactive and planned to provide opportunities for active participation. Group activities, debates and case studies can be used to engage participants and make the training effective. The ultimate goal of this program is to bring about lasting behavioral changes in individual lives in relation to food waste.

Key Words: *Food waste, Education, Food waste prevention*

Gıda İsrafını Önleme Eğitimi: İçerik Belirleme

Özet

Gıda israfı, günümüzde yiyecek içecek sektörünün karşı karşıya kaldığı en önemli sorunlardan biridir. Gıda israfı, dünya genelinde üretilen gıdaların yaklaşık üçte birinin tüketiciye ulaşmadan kaybedilmesi anlamına gelmektedir. Türkiye'de her yıl milyonlarca ton gıda çöpe gitmekte ve bunun önemli bir kısmı yiyecek içecek sektöründe gerçekleşmektedir. Yiyecek içecek işletmeleri, tedarik zincirinden servis aşamasına kadar her adımda israfın önlenmesinde kritik rol oynamaktadır. Sektör çalışanlarının bilinçlendirilmesi, bu sorunun çözümü için atılacak en önemli adımlardan biridir. Bu konuda bir eğitim içeriği geliştirilmeli ve toplumda ve bireylerde gıda israfı konusundaki farkındalığı artırılmalı ve israfın en aza indirgenmesine katkı sağlayacak yollar sunulmalıdır. İçerik olarak, gıda israfının nedenleri, oluşturtuğu sonuçlar ve azaltılması için geliştirilen stratejilere vurgu yapılmalıdır. Başlangıçta gıda israfının tanımı yapılmalı ve boyutları detaylandırılmalıdır. Hem dünyada hem de Türkiye'de gıda israfının mevcut hali, güncel istatistiklerle desteklenip katılımcılara sunulmalıdır. Böylece katılımcılar, bu önemli sorunun ciddiyetini kavrama noktasında daha iyi bir bilinç düzeyine ulaşabilirler. Eğitimin çerçevesinde işlenmesi gereken diğer ana konulardan biri, israfın kökeninde yatan nedenlerdir. Tüketici davranışları, üretim ve dağıtım süreçlerindeki eksiklikler veya yanlış uygulamalar, saklama ve depolama hataları gibi temalar üzerinde durulmalıdır. Her bir neden ayrıntılı incelenmeli ve yanlara sık karşılaşılan hatalar üzerinden somut örneklerle açıklığa kavuşturulmalıdır. Gıda israfını engellemek adına geliştirilen stratejiler ise eğitimin en hayati bölümünü oluşturur. Katılımcılara doğru alım alışkanlıkları, saklama teknikleri ve yemeklerin artıkları nasıl değerlendirilebilir gibi konular hakkında pratik öneriler verilmelidir. Aynı zamanda, daha geniş ölçekte uygulanabilecek politikalar ve konser projeler hakkında bilgi aktarılmalıdır. Son olarak, eğitimler interaktif bir yapıya sahip olmalı ve katılımcılara aktif katılım imkanları sunacak şekilde planlanmalıdır. Grup aktiviteleri, münazara ortamları ve vaka çalışmaları gibi yöntemlerle katılımcıların ilgisini çekmek ve eğitimi etkili hale getirmek arzulanan düzeyde mümkündür. Bu programın nihai hedefi, bireysel hayatlarda gıda israfı ile ilgili kalıcı davranış değişimlerini sağlamaktır.

Anahtar Kelimeler: *Gıda israfı, Eğitim, Gıda israfı önleme*

Giriş

Gıda israfı, günümüzde yiyecek içecek sektörünün karşı karşıya kaldığı en önemli sorunlardan biridir. Bu eğitim, işletme çalışanlarının israfı önleme konusunda bilinçlenmesini ve pratik becerileri kazanmasını hedeflemektedir.

Gıda israfı, dünya genelinde üretilen gıdaların yaklaşık üçte birinin tüketiciye ulaşmadan kaybedilmesi anlamına gelmektedir. Türkiye'de her yıl milyonlarca ton gıda çöpe gitmekte ve bunun önemli bir kısmı yiyecek içecek sektöründe gerçekleşmektedir.

Yiyecek içecek işletmeleri, tedarik zincirinden servis aşamasına kadar her adımda israfın önlenmesinde kritik rol oynamaktadır. Sektör çalışanlarının bilinçlendirilmesi, bu sorunun çözümü için atılacak en önemli adımlardan biridir.

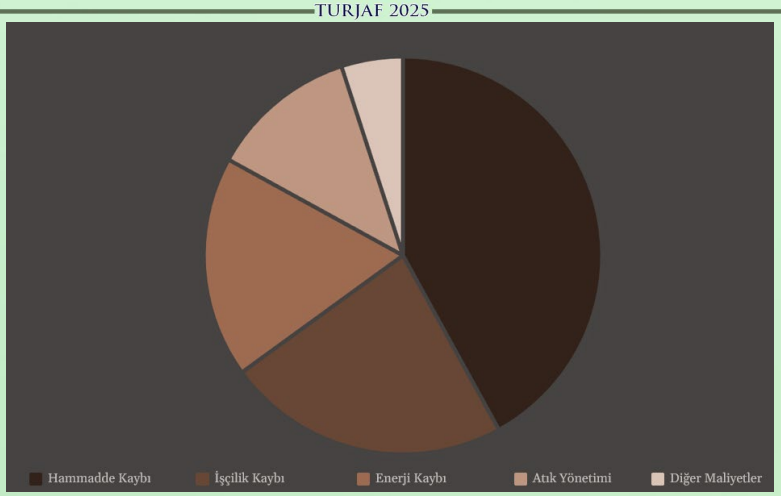
Bu çalışmanın amacı gıda israfının en yaygın görülen yiyecek ve içecek işletmelerinde, işletme çalışanlarına verilebilece gıda israfını eğitiminin içeriğini belirlemektedir.

Gıda İsrafını Önleme Eğitimin Amacı ve Hedefleri

Bu eğitim programı, yiyecek içecek işletmelerinde çalışan tüm personelin gıda israfını önleme konusunda aktif rol almasını sağlamayı amaçlamaktadır. Eğitim sonunda, çalışanların kendi pozisyonlarında israfı nasıl azaltabileceklerine dair somut adımlar atabilmeleri hedeflenmektedir.

a. Farkındalık Oluşturma: Çalışanların gıda israfının boyutları, nedenleri ve etkileri konusunda bilinçlendirilmesi ve sorumluluk duygusunun geliştirilmesi
b. Bilgi ve Beceri Kazandırma: İsrafı azaltmaya yönelik temel prensiplerin, tekniklerin ve uygulamaların öğretilmesi
c. Davranış Değişikliği Sağlama: Edinilen bilgilerin günlük iş akışına entegre edilmesi ve sürdürülebilir alışkanlıklar oluşturulması

Gıda İsrafının Tanımı ve Türleri



Gıda israfı, insan tüketimine uygun olan yiyeceklerin çeşitli sebeplerle tüketilmeden atılması olarak tanımlanmaktadır. Yiyecek içecek işletmelerinde israf, tedarik zincirinin her aşamasında meydana gelebilmektedir.

Türkiye'deki işletmelerde en çok görülen israf türü, porsiyon kontrolündeki yetersizliklerden kaynaklanmaktadır. Bunu hazırlık aşamasındaki kayıplar ve uygun olmayan depolama koşulları takip etmektedir. İsraf türlerinin doğru tanımlanması, etkili önleme stratejilerinin geliştirilmesi için kritik öneme sahiptir.

Gıda İsrafının Ekonomik Etkileri

Gıda israfı, yiyecek içecek işletmelerini doğrudan ve dolaylı ekonomik maliyetlerle karşı karşıya bırakmaktadır. Ortalama bir restoranda, toplam maliyetlerin %2-10'u israf edilen gıdalardan kaynaklanmaktadır. Bu durum, işletmelerin kâr marjlarını önemli ölçüde etkilemektedir.

İsrafın azaltılması, işletme maliyetlerini düşürmenin yanı sıra, sektörel rekabet gücünü artırmakta ve ulusal ekonomiye katkı sağlamaktadır. Uluslararası araştırmalar, gıda israfını %20 oranında azaltan işletmelerin yıllık kârlarını ortalama %30 artırabildiklerini göstermektedir.

Şekil 1. Gıda İsrafının Ekonomik Etkileri

Gıda İsrafının Çevresel Etkileri

Gıda israfının çevresel etkileri, genellikle gözle görülmediği için göz ardı edilebilmektedir. Ancak, israf edilen her gıda maddesi, üretiminden atık haline gelene kadar çevre üzerinde ciddi bir yük oluşturmaktadır.

- Karbon Ayak İzi: Atılan her kilogram gıda, üretiminden atık haline gelene kadar yaklaşık 4.5 kg karbondioksit salınımına neden olmaktadır. Türkiye'deki yiyecek içecek sektörünün israftan kaynaklanan karbon ayak izi yıllık 2.3 milyon ton CO2 eşdeğeridir.
- Su Ayak İzi: İsraf edilen her kilogram gıda için üretim sürecinde ortalama 1500 litre su kullanılmaktadır. Sektördeki israf, yılda milyarlarca litre suyun boşa harcanması anlamına gelmektedir.
- Biyoçeşitlilik Kaybı: Gıda üretimi için yapılan tarım faaliyetleri habitat kayıplarına yol açmakta, israf ise bu etkiyi gereksiz yere artırmaktadır. Türkiye'deki endemik türlerin %15'i tarım alanlarının genişlemesinden olumsuz etkilenmektedir.

Gıda Güvenliği ve İsraf İlişkisi

Gıda güvenliği ve israf arasında doğrudan bir ilişki bulunmaktadır. Güvenli olmayan gıdaların tüketilememesi ve imha edilmesi gerektiği açıktır, ancak uygun saklama ve işleme koşullarıyla pek çok gıdanın güvenli kalma süresi uzatılabilir.

- Uygun Olmayan Saklama Koşulları: Sıcaklık kontrolü yapılmayan depolarda ürünlerin hızla bozulması ve atık haline gelmesi. Soğuk zincirin kırılması sonucu et ve süt ürünlerinde oluşan mikrobiyolojik riskler.
- Son Kullanma Tarihi Yönetimi: TETT (Tavsiye Edilen Tüketim Tarihi) ve SKT (Son Kullanma Tarihi) arasındaki farkın bilinmemesi nedeniyle güvenli gıdaların israf edilmesi. Etiketleme hatalarından kaynaklanan gereksiz imhalar.
- Çapraz Kontaminasyon: Çiğ ve pişmiş gıdaların aynı alanlarda muhafaza edilmesi sonucu oluşan bulaşmalar. Kontamine olmuş gıdaların zorunlu olarak atılması ve ekonomik kayıp.

Satın Alma, Tedarik Zinciri ve Stok Yönetimi

Etkili bir satın alma ve tedarik zinciri yönetimi, gıda israfını kaynağında önlemenin en etkili yollarından biridir. Doğru miktarda ve kalitede ürün temin edilmesi, işletme içindeki diğer israf önleme çabalarının da temelini oluşturmaktadır. Türkiye'deki başarılı işletmeler, mevsimsel ürünleri menülerine dahil ederek hem tazelik ve lezzet avantajı elde etmekte hem de israfı azaltmaktadır. Tedarikçilerle kurulan güçlü iş birlikleri sayesinde, standart dışı ancak tüketilebilir ürünler değerlendirilebilmekte ve ekonomik kazanç sağlanmaktadır.

- Bu süreçte satın alma ve tedarik zincirinin daha sağlıklı yürütülebilmesi için ihtiyaç analizi, sipariş yönetimi, tedarikçi seçimi ve teslimat kontrolü aşamaları iyi takip edilmelidir.
- Gerçek ihtiyaçların belirlenmesi ve satış tahminlerinin doğru yapılması. Geçmiş verilerden yararlanarak mevsimsel değişimlerin öngörülmesi ve sipariş miktarlarının optimize edilmesi
- Minimum sipariş miktarlarının optimizasyonu ve sık aralıklarla küçük siparişler verilmesi. Özel anlaşmalarla iade ve değişim koşullarının iyileştirilmesi.
- Sürdürülebilir üretim yapan, kaliteli ve standart ürünler sunan tedarikçilerin tercih edilmesi. Yerel üreticilerle çalışarak tazelik ve teslimat sürelerinin iyileştirilmesi.
- Gelen ürünlerin kalite ve miktar kontrollerinin titizlikle yapılması. Tedarikçilerle sürekli iletişim halinde olunması ve geri bildirimlerin paylaşılması.

Stok yönetimi yiyecek içecek işletmelerinde gıda israfının azaltılmasında önemlidir. Türkiye'deki işletmelerde yapılan araştırmalar, FIFO (ilk giren ilk çıkar) prensibinin doğru uygulanması durumunda depolama kaynaklı israfın %60'a varan oranlarda azaltılabildiğini göstermektedir. Dijital stok takip sistemlerinin kullanılması, insan hatalarını azaltarak verimlilik artışı sağlamaktadır.

Menü Planlaması, Porsiyon Kontrolü ve Servis Teknikleri

Doğru menü planlaması ve porsiyon kontrolü, işletmelerin hem maliyetleri düşürmesine hem de müşteri memnuniyetini artırmasına olanak sağlar. İyi tasarlanmış bir menü, minimum atıkla maksimum verim elde etmeyi mümkün kılar. Türkiye'deki önde gelen restoran zincirleri, esnek menü yapıları sayesinde stok fazlası ürünleri değerlendirerek israfı önlemekte ve kârlılıklarını artırmaktadır. Porsiyon kontrolü yapan işletmelerde, tabak artıklarının %30'a varan oranlarda azaldığı gözlemlenmiştir.

Servis aşaması, gıda israfının en görünür şekilde ortaya çıktığı noktadır. Tabak artıkları, müşteri tarafından yenmeyen ve doğrudan çöpe giden gıdaların başında gelmektedir. Etkili servis teknikleri, müşteri memnuniyetini korurken israfı minimize etmeyi amaçlar. Açık büfelerde küçük servis kaplarının kullanılması ve sık aralıklarla yenilenmesi, hem tazeliği artırmakta hem de büfenin her zaman dolu görünmesini sağlarken daha az gıdanın israf edilmesine olanak tanımaktadır. Ayrıca, müşterilere paket servis opsiyonu sunmak, yenmeyen yemeklerin değerlendirilmesini sağlamaktadır. Tabak tasarımında daha az garnitür kullanılması ve yenilebilir süslemelerin tercih edilmesi, görsel estetiği korurken israfı azaltmaktadır. Türk mutfağının geleneksel sunumları, genellikle sade ve fonksiyoneldir, bu yaklaşım modern işletmelerde de benimsenmelidir.

Çalışan Eğitimi ve Motivasyonu

Çalışanların eğitimi ve motivasyonu, israf önleme stratejilerinin başarısında belirleyici rol oynar. İsrafı önleme bilincine sahip ve bu konuda motive olmuş bir ekip, işletmenin her aşamasında fark yaratabilir. Türk yiyecek içecek sektöründe yapılan araştırmalar, düzenli eğitim alan ve ödüllendirme sistemleriyle desteklenen personelin, israfı %50'ye varan oranlarda azaltabildiğini göstermektedir. Çalışanların sürece dahil edilmesi ve fikirlerinin değerlendirilmesi, aidiyet duygusunu güçlendirerek motivasyonu artırmaktadır. Çalışanlara düzenli olarak departmana özel eğitim programları, yeni başlayanlar için oryantasyon programları ve üst yönetim için farkındalık ve liderlik eğitimleri düzenlemek gıda israfının orta vadeli adımları arasında yer almalıdır. Ayrıca işletme içi açık iletişim kanallarının oluşturulması, çalışanlardan gelen iyileştirme önerilerinin değerlendirilmesi, düzenli toplantılarla israf verilerinin paylaşılması ve başarı hikayelerinin tüm ekiple paylaşılması bu eğitimlerin parçası olmalıdır. Bunun yanı sıra personel içinde gıda israfını azaltma hedeflerine ulaşan ya da konu ile ilgili inovatif çözümler sunan personelin ya da ekiplerin takdir edilmesi motivasyonu artıracak ve israf konusunda bilinç kültürünü oluşturacaktır.

Sonuç

Gıda israfının önlenmesi, karmaşık ve çok boyutlu bir sorun olmasına rağmen, sistematik bir yaklaşımla önemli ölçüde azaltılabilir. Bu eğitim içeriğinde ele alınan stratejiler ve teknikler, işletmenin israfla mücadelesinde etkili araçlar sunmaktadır. İsrafın önlenmesi sadece ekonomik bir kazanç değil, aynı zamanda çevresel ve sosyal bir sorumluluktur. Kısa vadeli adımlar, hem işletmenin sürdürülebilirliğine katkı sağlayacak hem de gelecek nesillere daha yaşanabilir bir dünya bırakmanıza yardımcı olacaktır.

Turkey's Map of Aromatic Plants and Spices

Emre Hastaoğlu[1]

[1]Department of Gastronomy and Clunary Arts, Faculty of Tourism, Sivas Cumhuriyet University, Sivas, Türkiye

Abstract

Turkey has a rich potential of aromatic herbs and spices thanks to its geographical location and climate diversity. Under the influence of Mediterranean, Aegean and Black Sea climates, the country is home to diverse ecosystems that allow different plant species to grow. Aromatic plants have an important place in both traditional culinary culture and the modern food industry. Among Turkey's aromatic plants, thyme, mint, sage, chili peppers and basil stand out. The Southeastern Anatolia region in particular stands out with its rich variety of spices. Spices such as pistachio, sumac and isot are the gastronomic identity of this region. The Aegean region is known for herbs and spices used in olive oil dishes, while the humid climate of the Black Sea region allows for the growth of various green herbs. The cultivation of aromatic plants contributes to local economies and supports rural development. However, the sustainable use of these plants is of great importance for maintaining ecosystem balance. Turkey's aromatic herbs and spices map is considered as a critical resource for both the conservation of biodiversity and the preservation of cultural heritage. In this context, supporting local producers and marketing their products play an important role in increasing the economic value of aromatic plants. In conclusion, Turkey's rich diversity of aromatic plants and spices offers gastronomic and economic opportunities at both national and international levels. Utilizing this potential is vital for both agricultural sustainability and the protection of cultural heritage.

Key Words: *Spice, Gastronomy, Aromatic plants*

Türkiye'nin Aromatik Bitki ve Baharat Haritası

Özet

Türkiye, coğrafi konumu ve iklim çeşitliliği sayesinde zengin bir aromatik bitki ve baharat potansiyeline sahiptir. Ülke, Akdeniz, Ege ve Karadeniz iklimlerinin etkisi altında, farklı bitki türlerinin yetişmesine olanak tanıyan çeşitli ekosistemlere ev sahipliği yapmaktadır. Aromatik bitkiler, hem geleneksel mutfak kültüründe hem de modern gıda endüstrisinde önemli bir yere sahiptir. Türkiye'nin aromatik bitkeleri arasında kekik, nane, adaçayı, pul biber ve reyhan gibi türler öne çıkmaktadır. Özellikle Güneydoğu Anadolu Bölgesi, zengin baharat çeşitliliği ile dikkat çekmektedir. Antep fıstığı, sumak ve isot gibi baharatlar, bu bölgenin gastronomik kimliğini oluşturmaktadır. Ege Bölgesi ise zeytinyağlı yemeklerde kullanılan otlar ve baharatlarla tanınırken, Karadeniz Bölgesi'nin nemli iklimi, çeşitli yeşil otların yetişmesine olanak sağlamaktadır. Aromatik bitkilerin tarımı, yerel ekonomilere katkı sağlamakta ve kırsal kalkınmayı desteklemektedir. Bununla birlikte, bu bitkilerin sürdürülebilir bir şekilde kullanımı, ekosistem dengesinin korunması açısından büyük önem taşımaktadır. Türkiye'nin aromatik bitki ve baharat haritası, hem biyolojik çeşitliliğin korunması hem de kültürel mirasın yaşatılması açısından kritik bir kaynak olarak değerlendirilmektedir. Bu bağlamda, yerel üreticilerin desteklenmesi ve ürünlerin pazarlanması, aromatik bitkilerin ekonomik değerinin artırılmasında önemli bir rol oynamaktadır. Sonuç olarak, Türkiye'nin zengin aromatik bitki ve baharat çeşitliliği, hem ulusal hem de uluslararası düzeyde gastronomik ve ekonomik fırsatlar sunmaktadır. Bu potansiyelin değerlendirilmesi, hem tarımsal sürdürülebilirlik hem de kültürel mirasın korunması açısından hayati öneme sahiptir.

Anahtar Kelimeler: *Baharat, Gastronomi, Aromatik bitki*

Giriş

Türkiye, zengin biyoçeşitliliği ve coğrafi konumu sayesinde aromatik bitki ve baharatlar açısından büyük bir potansiyele sahiptir. Bu sunum, Türkiye'nin dört bir yanındaki aromatik bitki ve baharatların haritasını çıkarmayı amaçlamaktadır. Aromatik bitkiler ve baharatlar, hem ekonomik hem de kültürel açıdan büyük öneme sahiptir. Türk mutfağının vazgeçilmez unsurları olmalarının yanı sıra, geleneksel tıpta, kozmetik sektöründe ve aromaterapide de yaygın olarak kullanılmaktadırlar.

Türkiye'nin Coğrafi Avantajları

Türkiye'de birbirinden değerli ve farklı çeşitlerde baharat ve aromatik bitki üretiliyor olmasının başında ülkenin coğrafi avantajları yer almaktadır. İklim çeşitliliği, konumu ve endemik türleri ülkenin coğrafi avantajları arasında yer almaktadır.

Türkiye'nin farklı iklim bölgelerine sahip olması, zengin bir bitki örtüsünün oluşmasını sağlamıştır. Bu çeşitlilik, farklı aromatik bitki ve baharat türlerinin yetişmesine olanak tanır. Karadeniz'in nemli ikliminden Akdeniz'in sıcak iklimine kadar farklı koşullar, çeşitli bitki türlerinin yetişmesi için uygun ortamlar sunar.

Anadolu, tarih boyunca farklı kültürlerin kesişim noktası olmuştur. Baharat Yolu üzerinde bulunması, Türkiye'nin baharat ticaretinde önemli bir rol oynamasına katkıda bulunmuştur. Bu tarihi bağlantılar, Türk mutfağının ve kültürünün zenginleşmesine de büyük ölçüde katkı sağlamıştır.

Türkiye, birçok endemik bitki türüne ev sahipliği yapmaktadır. Bu türler, yalnızca Türkiye'ye özgü olup, ülkenin biyoçeşitliliğinin önemli bir parçasını oluşturur. Yerel çeşitlilik de Türkiye'nin aromatik bitki ve baharat potansiyelini artırmaktadır.

Bölgeler Düzeyinde Aromatik Bitki ve Baharatlar

- Akdeniz Bölgesi

Defne: Türkiye'deki defne üretiminin %80'i Akdeniz Bölgesi'nde gerçekleştirilmektedir. Defne, hem mutfakta hem de geleneksel tıpta yaygın olarak kullanılan bir bitkidir. Özellikle Akdeniz mutfağının vazgeçilmezlerinden biridir.

Mersin: Mersin bitkisinin doğal yetişme alanları bu bölgede bulunmaktadır. Mersin, hem yaprakları hem de meyveleriyle çeşitli kullanım alanlarına sahiptir. Özellikle parfüm ve kozmetik sanayisinde tercih edilen bir bitkidir.

Kekik: Akdeniz Bölgesi, farklı kekik türlerine ev sahipliği yapmaktadır. Dağ kekiği, İzmir kekiği gibi çeşitler, bölgenin zengin bitki örtüsünün bir parçasıdır. Kekik, hem baharat olarak hem de şifalı bitki olarak kullanılmaktadır.

- Ege Bölgesi

Adaçayı: Ege Bölgesi, adaçayı üretimiyle öne çıkar. Adaçayı, şifalı özellikleri nedeniyle hem içecek olarak tüketilir hem de çeşitli sağlık sorunlarına karşı kullanılır. Ayrıca, ihracat potansiyeli yüksek olan bir bitkidir.

Zeytinyağı: Ege Bölgesi'nin zeytinyağları, aromatik bitkilerle zenginleştirilerek farklı lezzetler elde edilir. Zeytinyağı, hem sağlıklı bir yağ kaynağıdır hem de yemeklere eşsiz bir aroma katar.

Rezene: Rezene bitkisinin hem tohumları hem de yaprakları çeşitli kullanım alanlarına sahiptir. Ege Bölgesi'nde rezene, özellikle çay olarak tüketilir ve sindirim sorunlarına iyi geldiğine inanılır.

- Karadeniz Bölgesi

Isırgan Otu: Karadeniz Bölgesi'nde ısırgan otu, hem besin değeri yüksek bir bitki olarak tüketilir hem de geleneksel tıpta çeşitli amaçlarla kullanılır. Özellikle çorba ve börek yapımında tercih edilir.

Mısır Unu: Mısır unu, aromatik bitkilerle birlikte Karadeniz'e özgü mısır ekmeği çeşitlerinin yapımında kullanılır. Bu ekmekler, bölgenin kendine has lezzetlerini yansıtır.

Fındık Yaprağı: Fındık yaprağı, Karadeniz Bölgesi'nde çay olarak tüketilir ve çeşitli faydaları olduğuna inanılır. Fındık yaprağı çayı, özellikle soğuk algınlığına karşı kullanılır.

- Marmara Bölgesi

Lavanta: Marmara Bölgesi'nde lavanta, özellikle kozmetik ve aromaterapi sektöründe yaygın olarak kullanılmaktadır. Lavanta yağı, rahatlatıcı ve sakinleştirici özellikleriyle bilinir.

Nane: Nane, ferahlatıcı özelliği sayesinde Marmara Bölgesi'nde çeşitli kullanım alanlarına sahiptir. Özellikle çaylarda, salatalarda ve tatlılarda tercih edilir.

Biberiye: Biberiye, hem tıbbi hem de mutfak alanında faydaları olan bir bitkidir. Marmara Bölgesi'nde biberiye, özellikle et yemeklerinde ve çaylarda kullanılır.

- İç Anadolu Bölgesi

Kimyon: İç Anadolu Bölgesi'nde kimyon, yemeklerde ve geleneksel tıpta yaygın olarak kullanılan bir baharattır. Özellikle et yemeklerine ve çorbalara lezzet katar.

Anason: Anason, özellikle rakı yapımında kullanılan önemli bir bitkidir. İç Anadolu Bölgesi'nde anason, ayrıca çeşitli tatlılarda ve hamur işlerinde de kullanılır.

Çörek Otu: Çörek otu, şifalı özellikleri nedeniyle İç Anadolu Bölgesi'nde yaygın olarak kullanılan bir bitkidir. Özellikle ekmeklerde, böreklerde ve salatalarda tercih edilir.

- Güney Doğu Anadolu Bölgesi

Pul Biber: Güneydoğu Anadolu Bölgesi, baharatlar konusunda oldukça zengindir. Pul biber, farklı acılık derecelerine sahip çeşitleriyle bölgenin en önemli baharatlarından biridir.

Sumak: Sumak, ekşi tadıyla yemeklere farklı bir lezzet katar.

Mahlep: Mahlep ise tatlılarda ve pastalarda yaygın olarak kullanılır ve kendine özgü bir aroma verir. Bölgenin mutfak kültürü, bu baharatlarla zenginleşmiştir.

- Doğu Anadolu Bölgesi: Doğu Anadolu Bölgesi'nin sert iklimi, bazı özel aromatik bitki türlerinin yetişmesine olanak sağlar. Dağ reyhanı, yüksek rakımlı bölgelerde yetişen ve kendine özgü aroması olan bir bitkidir. Yabani nane, bölgede hem yemeklerde hem de çaylarda yaygın olarak kullanılır. Keven otu ise geleneksel tıpta çeşitli amaçlarla kullanılan bir bitkidir. Bu bitkiler, bölgenin doğal zenginliklerini yansıtır.

Dağ Reyhanı: Yüksek rakımlı bölgelerde yetişen özel bir tür.

Yabani Nane: Yemeklerde ve çaylarda kullanımı.

Keven Otu: Geleneksel tıpta kullanımı.

Türkiye, tarih boyunca Baharat Yolu üzerinde önemli bir роль oynamıştır. Farklı kültürlerin etkileşimi, Türk mutfağının zenginleşmesine katkı sağlamıştır. Baharatlar, geçmişten günümüze Türk mutfağının vazgeçilmez unsurları olmuştur. Baharatların kullanımı, yemeklere farklı lezzetler ve aromalar katarken, aynı zamanda kültürel bir mirasın da yaşatılmasını sağlar.

Türkiye, aromatik bitki ve baharat ihracatında önemli bir potansiyele sahiptir. İhracat yapılan başlıca ülkeler arasında Avrupa Birliği ülkeleri, Amerika Birleşik Devletleri ve Orta Doğu ülkeleri yer almaktadır. İhracatı artırmak için kalite standartlarının yükseltilmesi, yeni pazarlara giriş yapılması ve etkili pazarlama stratejileri geliştirilmesi gerekmektedir.

Türk mutfağında aromatik bitki ve baharatların kullanımı oldukça yaygındır. Her bölgenin kendine özgü yemeklerinde öne çıkan baharatlar bulunmaktadır. Örneğin, Güneydoğu Anadolu mutfağında pul biber ve isot, Ege mutfağında ise kekik ve defne sıklıkla kullanılır.

Baharatlar, yemeklere sadece lezzet değil, aynı zamanda aroma da katarlar. Doğru baharat kullanımı, yemeklerin tadını zenginleştirir ve unutulmaz bir lezzet deneyimi sunar. Türk mutfağının zenginliği, baharatların doğru ve etkili kullanımıyla sağlanır.

Sonuç

Baharatlar, yemeklere sadece lezzet değil, aynı zamanda aroma da katarlar. Doğru baharat kullanımı, yemeklerin tadını zenginleştirir ve unutulmaz bir lezzet deneyimi sunar. Türk mutfağının zenginliği, baharatların doğru ve etkili kullanımıyla sağlanır. Dünyadaki yeni mutfak trendleri (moleküler gastronomi, füzyon mutfağı vs.) arttıkça, Türkiye'nin aromatik bitki ve baharat zenginliğinin önemi de artmaktadır. Sürdürülebilir tarım uygulamaları, iyi tarım uygulamaları ve planlı üretim ile gelecek nesillere aktarılması gereken bu değerli mirasın korunması gerekmektedir.

Abstract

Poultry especially broiler constitutes a large part of protein production in Iran. Nonetheless, farmers use antibiotics for prevention, treatment, and growth enhancement. The objective of this investigation was to determine antibiotic resistance patterns of *S. aureus* isolated from commercial poultry carcasses in Ardabil province, northwest of Iran. Samples were taken from heart blood and liver's visceral surface of 125 carcasses obtained from 30 flocks (including 27 broiler flocks, 1 laying flocks and 2 breeder flocks) located in different parts of Ardabil province. The isolates of *S. aureus* were determined based on microbiological standard methods. The antibiotic susceptibility test was performed using the Kirby-Bauer disk diffusion method. 98 bacteria isolates were identified from 125 carcasses while no bacteria were found in 34 carcasses. Out of 98 isolates, 8 (8.16%) isolates were detected as Staphylococcus aureus. The S. aureus isolates showed resistance to Doxycycline (100 %), Ampicillin (87.5%), followed by Methicillin (75.0%), Sulfamethoxazole-trimethoprim (62.5%), Ciprofloxacin (62.5%), Erythromycin (50.0%), Chloramphenicol (37. 5%), Gentamicin (37.5%), Vancomycin (25.0%) and Cefoxitin (12.5%). Our data indicated that antimicrobial resistance of *S. aureus* was in poultry flocks of Ardabil province, northwest of Iran, and that antibiotics, especially tetracycline and ampicillin, to treat in poultry should be used with caution.

Key Words: *Antibiotic resistance, Poultry carcasses, S. aureus, Ardabil province*

Introduction

Staphylococcus aureus is one of the most prevalent opportunistic pathogens and causes invasive and indubitably life-threatening infections (Amoako et al., 2020). In humans, it is the 3rd most common cause of food poisoning (Amoako et al., 2020). Infections caused by *S. aureus* have been reported in different type of meat like raw chicken, turkey, veal, beef, pork, lamb, and rabbit all over the world. *S. aureus* was found to be most prevalent in turkey followed by chicken, veal, pork, and beef 35.3%, 16.0%, 15.2%, 10.7% and 10.6% ,respectively in Netherland (De Boer et al., 2009). While in Germany, its prevalence was reported in 37.2% of samples of poultry food products (Feßler et al., 2011). In the USA, it was detected in 42.1% of poultry samples (Abdalrahman et al., 2015). From Asia, only a few reports are available, and mainly these reports are of livestock-associated *S. aureus* infections (Chuang et al., 2015). S. aureus is the prominent cause of many infections in the chicken like synovitis, osteomyelitis, and cellulitis (Amoako et al., 2020). It is renowned for its ability to develop resistance to antibiotics. In addition to this, antimicrobial resistance is causing financial loss to the poultry industry because poultry birds have developed resistance to antibiotics. Ample use of antibiotics in animal farming is the prime cause of the prevalence of drug resistance among foodborne pathogens mainly in *Salmonella*, *Staphylococcus spp*. and *E. coli* (Amoako et al., 2020; Ali et al., 2017; Vickers, 2017). It is a widely accepted notion that antibiotics provided in the diet generate selective pressure on the microbial flora that in return facilitates the persistence transfer of antimicrobial resistance determinants among bacterial species which leads to the emergence of multi-drug resistant bacteria (Amoako et al., 2020; De Boer et al., 2009; Suleiman et al., 2013).
Many researchers have isolated (MRSA) from poultry because of the excessive use of antibiotics in the poultry sector. Despite the fundamental consequences of AMR in poultry, our knowledge about antibiotic resistance in *S. aureus* in commercial poultry of Iran is rudimentary, ergo comprehensive research is needed. The present study is aimed to determine the prevalence and antibiotic resistance of *S. aureus* isolated from isolated from commercial poultry carcasses in Ardabil province, northwest of Iran.

Materials and Methods

Sample collection

The study was carried out on 125 carcasses obtained from 30 commercial poultry flocks (including 27 broiler flocks, 1 laying flocks and 2 breeder flocks) in different parts of Ardabil province. So that, five carcasses were

randomly selected from each flock and after necropsy, the heart blood and liver's visceral surface were sampled next to the flame. Collected samples were transported to the laboratory for *S. aureus* isolation.

Identification of *S. aureus*

For processing, enrichment of each sample was carried out in buffer peptone water (BPW) and incubated at 37 ° C for 24 h. Mannitol Salt Agar (MSA) was used as a selective and differential medium for the identification of *S. aureus*. For its purification purpose, distinct yellow colonies from MSA were streaked again onto MSA and stored in glycerol stocks. Initial identification was done based on colony morphology. Afterwards, Gram staining and biochemical characterization were carried out for complete identification which included catalase and coagulase tests.

Antibiotic Susceptibility Test

To determine the antibiotic resistance of the isolates against 10 drugs commonly in the veterinary and medical fields was used qualitative disc diffusion method by Kirby Bauer procedure on Mueller-Hinton agar (Merck, Germany) in according with instructions of Clinical Laboratory Standards Institute Guidelines (CLSI) 2018. On this criterion, the organisms were classified as Resistant (R), Intermediate (I) or Susceptible (S).

Antibiotic disks, procured from Padtan Teb Company of Iran, were amoxicillin (10), doxycycline (30), Vancomycin (30), Sulfamethoxazole-trimethoprim (30), gentamicin (10), ciprofloxacin (5), Erythromycin (10 µg), chloramphenicol (30), Cefoxitin (30) and Methicillin (10 µg).

Result

In this study, 98 bacteria isolates were obtained from 125 carcasses while no bacteria were found in 34 carcasses. Out of 98 isolates, 8 (8.16%) isolates were detected as *S. aureus*. The frequency of resistance of *S. aureus* isolates to ten antimicrobial agents is is as follows:

All isolates were resistant to to doxycycline (100 %) and the resistance to the 9 other antibiotics ranged from 87.5 to 12.5 %. In 9 antibiotics, the highest resistance was found against Ampicillin (87.5%), followed by Methicillin (75.0%),Sulfamethoxazole-trimethoprim (62.5%), Ciprofloxacin (62.5%), Erythromycin (50.0%) and the lowest resistance was found in Chloramphenicol (37. 5%), Gentamicin (37.5%), Vancomycin (25.0%) and Cefoxitin (12.5%).

Discussion

Staphylococcosis caused by S. aureus have varying degrees of morbidity and mortality. It has been reported as a leading pathogen in the poultry industry with a 38.5 % average disease prevalence in 21 European countries (Vickers, 2017). Prevalence of *S. aureus* (8.2%) was observed in the current work While Suleiman et al., (2013) and Ali et al., (2017) reported a higher prevalence (52% and 28%, respectively) [6, 8].

In this study, among all the samples of *S. aureus*, 100 %, 62.5 % and 50 % of isolates showed resistance against doxycycline, Sulfamethoxazole-trimethoprim and Erythromycin, respectively and a similar trend was shown by Yin et al., (2010); Agyare et al., (2018). These three antibiotics are most commonly used in poultry husbandry for prophylactic, metaphylactic and therapeutic purposes. Among all of these isolates 75% were resistant to methicillin and a similar trend was shown by Ali et al., (2017). The reason behind the more prevalence of MRSA might be due to the more common use of methicillin and oxacillin for treatment and growth purposes. In this study less resistance by these isolates to Chloramphenicol; Gentamicin, Vancomycin, and Cefoxitin was observed as 37.5%, 37.5% , 25% and 12.5%. The reason behind less resistance of four antibiotics is not being used or very little of common use in the poultry industry of Iran

Conclusion

In this study, from a total of 98 isolates, 8 isolates were identified as *S. aureus*. High resistance was observed against Doxycycline, Ampicillin, Methicillin, Sulfamethoxazole-trimethoprim, Ciprofloxacin and Erythromycin with 100 %, 87.5%, 75.0%, 62.5%%,62.5% and 50.0% respectively. Isolates were the most susceptible to Cefoxitin, Vancomycin , Gentamicin and Chloramphenicol. Among isolates, only 75 % of isolates were found to be MRSA. The development of drug resistance by *S. aureus* is a matter of concern for food safety because this resistance is transferred from animals to humans. Surveillance of an antibiogram of *S. aureus* is essential for one health concept.

Geospatial Analysis And Quantification Of Bioaccumulated Pollutants In Fresh Milk

Irfana Parveen[a]; Kousar Parveen[a*]; Saira Mansab[a]

Department of Environmental Sciences, The Women University Multan, Multan Pakistan
*Corresponding Author: kousar.parveen@wum.edu.pk

Abstract

Heavy metals are recognized as non-biodegradable and persistent pollutants released into the water bodies from industries, mining, and agricultural runoff. It not only deteriorates the water quality but also pollutes the soil which further affects plant, animal, and human health. Once it enters the environment it is very difficult to remove. It is common practice in developing countries to use untreated wastewater for irrigation purposes due to a limited water resource. Heavy metals present in untreated industrial wastewater intercalate into the soil where they bio-accumulate in the different parts of plants, that are used as a source of food and fodder. Keeping in this view, the present study is designed to quantify the concentration of heavy metals in fresh milk collected from peri-urban areas of Multan, Pakistan. A total of 80 samples including water, soil, plant, and fresh milk were collected from the five different locations in Multan. The three sites were from urban areas (New Multan, Vehari Chowkh, and Samejabad), and the two sites were from peri-urban areas (Tatty pur and Khandar Wala). The collected samples were prepared using the wet digestion method. Atomic absorption spectroscopy was used for the determination of the concentration of lead, chromium, and cadmium in water, soil, Plant, and fresh milk. The result showed that a high concentration of cadmium in milk at New Multan Milk Site 3 (0.11mg/L) and water at Samejabad site 1 (0.118mg/L) which is above the WHO permissible limit for milk (0.0026µg/g) and water (0.005mg/L). The concentration of chromium in milk is at Samejabad Milk site 2 (0.182mg/L), and water at New Multan Water Site 2 (0.235mg/L) is also above the permissible limit of chromium for milk (0.05mg/L) and water (0.1mg/L). The concentration of lead in milk at Samejabad Milk Site 3 (1.982mg/L) and lead in water at Vehari chowk water site 4 (0.38mg/L) is higher than the permissible limit of lead for milk (0.02 mg/kg) and water (0. 05mg/L). Furthermore, the concentration of cadmium and lead is high in plants used as fodder while the concentration of lead in soil is also above the WHO permissible limit. The geospatial analysis i.e., kriging and Inverse Distance weighted were applied to interpolate lead, cadmium, and chromium in water, soil, plant, and fresh milk. The interpolation of data using kriging and Inverse distance weighted showed that water, soil containing lead, plants containing cadmium and lead, milk containing heavy metals were prevalent sources of metal. It might be possible that water is consumed by animals and fodder grown using canal water is the main source of metal bioaccumulation in milk.

Abstract

This study explores farmers' role in the conservation of the Western Wildlife Corridor and associated Community Resource Management Areas in Ghana. Through focus group discussions and key informant interviews, it was found that local communities possess a deep understanding of the corridor's ecological, economic, and cultural values. Farmers identified a wide range of ecosystem services, including provisioning (e.g., firewood, fruits, construction materials), regulating (e.g., climate regulation, water purification), cultural (e.g., traditional knowledge, spiritual value), and supporting services (e.g., soil fertility, pollination). This knowledge has positively influenced the widespread acceptance of community-based natural resource management programmes as conservation tools. Despite facing land-use pressures from commercial farming, grazing, logging, and mining, communities demonstrate a strong commitment to conserving the wildlife corridor, motivated by intrinsic, cultural, and heritage values of biodiversity. Farmers' tolerance of wildlife—despite crop raiding and livestock depredation—is underpinned by cultural beliefs, especially in communities where wildlife are totemic animals. However, delayed or absent compensation for wildlife-related losses remains a critical concern that threatens long-term community support for conservation efforts. Conservation initiatives such as the Modified Taungya System (MTS), green firebelts, and capacity-building under national projects have reinforced local participation. The study highlights that the success of community-based conservation projects stems from collaborative governance structures involving local farmers, forestry and wildlife authorities, and NGOs. However, sustaining these gains requires continued investment in conservation-compatible livelihoods and prompt compensation mechanisms. The findings suggest that integrated landscape management, when informed by local knowledge and supported by inclusive conservation policies, can harmonize agricultural production with biodiversity conservation. Future research is recommended to explore land tenure dynamics in the WWC, particularly regarding commercial land acquisition, to inform sustainable land use planning.

Introduction

As land-based activities, agriculture and wildlife conservation are increasingly becoming conflicting land use enterprises as human population surges (Shackelford et al. 2015; Fischer et al. 2017; Egli et al. 2018). This kind of conflict is not only detrimental to biodiversity conservation worldwide but inimical to economic development, food security and sustainable resource use (Watson et al. 2019). The relationship between agriculture and wildlife conservation is complex and multifaceted, particularly in the context of land use. As agriculture expands to meet the growing global demand for food, fiber, and fuel, natural habitats are increasingly converted into farmland, leading to significant shrinkage of wildlife habitats and populations (Ullah & Shabir, 2023; Ortiz et al., 2021). Agricultural activities influence land use patterns, affecting habitat availability, connectivity, and ecosystem health. However, agriculture also has the potential to support wildlife conservation through sustainable and integrated land management practices (Rehman et al., 2022; Williams et al., 2021; Kremsa, 2021).

Recent studies indicate that the main driver of land use and land cover change in Africa is change in agricultural practices through reduction in fallow duration and expansion of commercial agriculture to meet the ever-increasing food demand (Assede et al., 2023; Mala et al., 2020; Gondwe et al., 2019). The consequences of these changes include the loss of vegetation cover, soil erosion, and reduction of agricultural yields in some areas in the continent (Assede et al., 2023). According to Ortiz et al. (2021), shifts in forest cover in Africa could be linked to poverty levels of the population and the need for cultivated land, particularly with the introduction of marked-oriented agriculture systems.

Denudation of Ghana's forest cover has been massive in the last three decades with protected forest reserves suffering average annual deforestation rates of 0.7%, 0.5%, 0.4%, and 0.6% for the periods 1990–2000, 2000–

2005, 2005–2010 and 2010–2015, respectively (FOA, 2015). This process diminishes biodiversity and disrupts ecosystems, making it challenging for both wildlife and cultivated crops to thrive. Forest resources contribute more than one-third (38%) of the income of Ghana's forest-dependent rural population and about 6% of annual Gross Domestic Product of the country (Acheampong et al., 2019; Adjei et al., 2014). With the support of government policies, commercial agriculture is thriving steadily in Ghana and more land is being converted into farms. This makes it difficult to make new cases for the creation of protected areas in the country. The decline of the resource will impact on the livelihoods of those who depend directly on the forest and the economy of the country. If the current rate of deforestation persists, Ghana's forests could completely disappear in two and a half decades time (Boafo, 2013).

To restore degraded forest reserves (protected areas), farmers are allowed to cultivate food crops in affected reserves. This is done under an arrangement known as modified taungya system (MTS). The MTS is an agroforestry system in which during the initial three years of cultivation, farmers are allowed to grow food crops in the allies of planted tree seedlings. The farmers tend both the trees and food crops until the trees form a closed canopy and then they stop growing food crops. However, the farmers continue to tend the trees until they mature. This makes arable land available to landless farmers, but it reduces biodiversity by clearing indigenous species and planting only single economic species in the space (Acheampong et al., 2016).

Another means to curb deforestation is to find an effective way to balance agriculture and biodiversity conservation to achieve conservation goals and agricultural outcomes. This will involve identifying and reforming farming methods that involve total vegetation clearance in favour of single crop cultivation and excessive use of agrochemicals (Dudley et al., 2017; Baudron & Giller, 2014).

Although most rural households keep some sort of livestock, livestock farming is adjunct to crop farming in Ghana. In the Savannah zones, cattle, Sheep, goats and poultry are kept by many households as social security and only sold during household emergencies (Aketemah, 2018). Livestock farming, particularly cattle, has become commercial and widespread in recent times in the savanna agroecological zone. Apart from cattle owned by local farmers, nomads come into northern Ghana from the Sahelian countries such as Niger and Mali to look for better grazing areas, water sources or to sell some animals at international markets (Boesen & Marfaing, 2014; Azarya, 2001). The increasing number of animals creates a new wave of environmental degradation through overgrazing and pollution of water sources for human consumption. Herder-farmer conflicts are also becoming a major security threat as livestock numbers increase. In places where there are forest reserves or wildlife corridors, the herdsmen concentrate grazing (or even settle) in those protected areas to avoid trouble with farmers (Agana et al., 2018). This practice degrades the protected areas and causes biodiversity loss.

The Western Wildlife Corridor (WWC) is part of the greater Mole Landscape linking the Mole National Park in Ghana and the Nazinga Game Ranch in Burkina Faso. The corridor is part of the northern Ghana elephant range, which has the eastern corridor to the east at the border with Togo, and the Nandom range at the extreme north-west of Ghana (Wildlife Division 2000; Blanc et al. 2003). The corridor since its creation has been extended westward to include areas between the Mole National Park and the Gbele Resource Reserve (Majam et al., 2017). It encompasses the sub-watersheds of the main tributaries of the Sissili and Kulpawn Rivers that flow into northern Ghana from Burkina Faso. The corridor contains several forest reserves including Sissili North, Chiana Hills, Sissili Central, Bepona, Gia, Fumbisi, Ghira, Tumu, Mawbia, Ambalara, Kulpawn Headwaters, and Kulpawn Tributaries Forest Reserves. Wildlife protected areas in the corridor are Gbele Resource Reserve and Mole National Park. The Corridor also encloses several hill ranges - the Minjali, Pudo and Chiana hills as well as sacred groves of religious significance that are protected by cultural and traditional norms (Majam et al., 2017). The WWC covers an area of about 3,713km^2 and the distance along the length from Mole National Park to Nazinga Game Ranch is about 143 km. The corridor engulfs over one hundred communities which are mainly farming villages (Majam et al., 2017). The farmers cultivate mainly annual crops including millet (*Pennisetum glaucum*), sorghum (*Sorghum bicolor*), white beans (*Phaseolus vulgaris*), sesame (*Sesamum indicum*), maize (*Zea mays*), yam (*Dioscorea spp*), cassava (*Manihot esculenta*) and groundnuts (*Arachis hypogaea*). The area is therefore important for both agriculture and biodiversity conservation.

This study was conducted to understand farmers' perception about having to combine agriculture and conservation efforts amidst increasing land hunger and commercial agriculture. The specific objectives include: i) to assess farmers' knowledge of the ecological importance of the wildlife corridor; ii) to assess farmers' acceptance of wildlife as an integral part of their farm space and human-wildlife conflicts; iv) to find out if farmers are still ready to accommodate the wildlife corridor, and v) identify any efforts that may be going on currently to improve the ecological integrity of the wildlife corridor.

Materials and Methods

The study area

The study was conducted in communities within the WWC in northern Ghana (Figure 1). The corridor passes through nine administrative districts in the Upper East, Upper West and North East Regions of Ghana. The human population within the nine districts is 627,180 and the majority of them are farmers. The catchment area of the WWC comprises of wildlife-protected areas, forest reserves and community resource management areas (CREMAs) (Box 1). The reserves and protected areas serve as critical wildlife habitats and provide essential ecosystem goods and services (Majam et al., 2017). The ecosystem services include pollinating agricultural crops, protecting water bodies and creating conducive microclimates for agriculture productivity. The heterogeneous collections of trees meet domestic requirements for firewood and charcoal, construction materials for houses, cattle kraals and fencing of gardens. Dominant tree species in the corridor at naturally vegetated areas include *Terminalia avicennioides, Combretum sp., Anogeissus leiocarpus*, *Vitellaria paradoxa, Daniellia oliveri, Grewia mollis, Gardenia sp., Piliostigma thonningii and Acacia sp.* Economic trees such as *Vitellaria paradoxa, Parkia biglobosa* and *Adansonia digitata* (baobab) are common in cultivated fields (Majam et al., 2017). The shorter shrubs and grasses provide fodder for livestock, which have resulted in high influx of alien Fulani herdsmen into the Corridor (Majam et al., 2017). Some of the most densely vegetated parts of the Corridor are along the channels of Kulpawn and Sissili rivers. However, this riverine vegetation that provides critical habitats for wildlife are under threat (Majam et al., 2017).

Some mammals found in the corridor include Waterbucks (*Kobus ellipsiprymnus defassa*), Bohor reedbuck (*Redunca redunca*), Bushbuck (*Tragelaphus scriptus*), African giant rat (*Cricetomys emini),* stripped Ground Squirrel (*Xerus erythropus*), Nile crocodile (*Crocodylus niloticus*), the monitor lizard (*Varanus sp.),* Oribi (*Ourebia ourebi*), Patas Monkey (*Erythrocebus patas*), Giant Rat (*Cricetomys gambianus*), Togo Hare (*Lepus microtis*), common Genet Cat (*Genetta genetta*), Civet Cat (*Civettictis civetta*), and Grasscutter (*Thryonomys swinderianus*) (Majam et al., 2017). Common bird species within the Corridor include Senegal Parrot (*Poicephalus senegalus*), Cattle Egret (*Bubulcus ibis*), African Green Pigeon (*Treron calvus*), African Grey Hornbill (*Tockus nasutus*), Senegal Coucal (*Centropus senegalensis*), Yellow-Fronted Canary (*Serinus mozambicus*), African Golden Oriole(*Oriolus auratus*), Spotted Fly Catcher (*Muscicapa striata*), Grey-Backed Camaroptera (*Camaroptera brevicaudata*), Yellow-Fronted Tinker Bird (*Pogoniulus chrysoconus* and Grasshopper Buzzard (*Butastur rufipennis)* (Majam et al., 2017).The CREMAs areas and reserves also have socio-economic and cultural functions for the communities (Pienaah et al., 2024).

The WWC falls within the West African semi-arid Guinea savannah belt, which has two main climatic seasons – the rainy season and dry season. The Sissili and Kulpawn Rivers with their many streams and tributaries drain WWC into the White Volta. The geology of the area is that of Middle Voltaic rocks. It consists mainly of Birimian, granite, igneous and metamorphic rock formations some of which are noted for deposits of gold and have consequently attracted illegal mining activities in communities such as Nangurima (Mamprugu Moagduri District), Bassisan and Pido (Sissala East Municipal), Duu, Joanfian and Danyokura (Wa East District) (Majam et al., 2017).

Box 1. **The Community Resource Management Areas (CREMAs) concept**
A CREMA is a geographically defined area that includes one or more communities that have agreed to manage natural resources in a sustainable manner. The CREMA serves as a community-based organization built on existing community decision-making structures including an executive body and a constitution that guides the activities and regulations of the CREMA. A District Assembly bylaw gives legal recognition and backing to the constitution. The community benefits as the CREMA provides a structure which enables collective decision-making for these shared resources while also enabling the community to make collective rules and establish a means by which to enforce these rules. The CREMA also provides a forum whereby external entities are able to access communities.

Data collection methods

Qualitative data collection approaches were used to achieve the study objectives. These include desk study, key informant interviews and focused group discussions.

Desk study: desk study was used to review literature to gather and analyze existing research and publications related to elephant populations, distribution, and movement in Africa and Ghana in particular. We used the African Elephant Database (AED) and Google Scholar web search engine to access scholarly literature, including articles, books, thesis and other relevant sources of literature. Some key phrases used in searches include ‘‘Agriculture and land use’’, ‘‘wildlife habitats’’, ‘‘Agriculture and conservation’’, ‘‘wildlife corridors’’, ‘‘wildlife corridors in Ghana’’, ‘‘human-wildlife conflicts’’, ‘‘conservation in Ghana’’ and ‘‘the CREMA Concept’’

Key informant interviews: key informant interview method was used to gather in-depth information (Taylor & Blake, 2015) and insights from local farmers who possess deep knowledge on wildlife movements and human-wildlife conflicts in the study area. Eight persons, including, two experienced hunters, three local farmers and three

old women were identified in five different communities. All eight persons were older than 60 years. Only people over 50 years were selected because it is believed they might have had the opportunity of witnessing the effective co-existence between humans and wildlife or human-wildlife conflicts in the past. Two senior officials (Assistant Park Manager, MNP and Park Manager, Gbele Resource Reserve) at the Wildlife Division of the Forestry Commission were also interviewed as key informants. Three Forest Guards in charge of forest reserves in the WWC and four Range officers at the Mole National Park and Gbele Game Resource Reserve were interviewed as well.

Sanyiga Kasena Gavara Kara (SKGK)	Nakong	8	8	10.819513	-1.416515
Sanyiga Kasena Gavara Kara (SKGK)	Kayoro	8	12	10.983318	-1.416515
Chakali Sungmaaluu (CS)	Kulpong	9	11	9.859343	-2.249154
Moagduri Wuntanluri Kuwomsaasi (MWK)	Yizisi	12	9	10.262915	-1.451160

Focused group discussions (FGDs): The FGDs were conducted in six CREMA communities (Figure 1). These communities were purposively (Taylor & Blake, 2015) selected across the length of the WWC to cover its entirety. Participants in the groups comprised of local farmers who also double as community resource management committee (CRMC) members. We deliberately constituted groups with mixed age categories that include elderly people of 50 years or older. The age composition was a measure to ensure that some of the participants have lived long enough to have firsthand information on human-wildlife interaction in the past. Anecdotal statements indicated that wildlife presence in the WWC has been limited in recent years. Table 1 presents the communities and number of participants that took part in the focused group discussions.

Results and Discussion

Farmers' knowledge of the ecosystem services from the WWC and CREMAs

Communities within and around the WWC have demonstrated knowledge of the ecological and socio-economic importance of the WWC. Key informants and focus group discussants listed several ecosystem services including habitat for wildlife, food for human beings, water for all living organisms, fuelwood, wood for construction, cultural identity, indigenous knowledge systems, pollination of flowers, seeds dispersal, climate regulation and soil fertility support and improvement. These services can be categorized into the four main ecosystem services: provisioning, cultural, regulating and supporting services. Table 2 has details of responses from the focus group discussants.

Table 2. farmers' knowledge of ecosystem services

Benefits from WWC and CREMAs	Examples	Category of ecosystem service
Firewood, fruits, grass and rafters for roofing, medicine, fodder	❖ Our wives collect firewood from the CREMAs and the WWC. ❖ We collect edible fruits from shea (*Vitellaria paradoxa*), dawadawa (*Parkia biglobosa*), baobab (*Adansonia digitata*), *Gardenia erubescens* and *Diospyros mespiliformis*. ❖ We harvest thatching grass (*Cymbopogon giganteus*, *Pennisetum purpureum, Pennisetum pedicellatum* Trin) and cut poles (Anogeissus leiocarpus, Pterocarpus erinaceus) for constructing our housing structures.	provision service
The WWC and the CREMAs help to bring rain	❖ The presence of the vegetation in the WWC and the CREMAs provides us with purified water in our area. ❖ The trees in the CREMAs and WWC reduce wind speed to protect our crops from lodging. ❖ The air we breathe here is cleaner than the air at places where there are no trees. ❖ Some insects from trees make our crops produce fruits and seeds. ❖ The weather here is always cooler than the weather in the cities because of the trees we have	Regulating services
For cultural activities	❖ We learn a lot of traditional knowledge on the trees and grasses. ❖ When you walk through the forest your mind becomes relaxed. ❖ Some of the trees and animals represent our items of worship. ❖ We go on communal hunting in the forest.	Cultural services
Brings rain and fertile soil	❖ The plants make our soil fertile for cultivating our crops. ❖ The trees make the rain fall frequently in our area.	Supporting service

This knowledge of ecosystem services may have influenced the acceptance of CREMA establishment in most communities within and around the WWC. This finding is in line with the report of Lamarque et al. (2014) who indicated that farmers in the Central French Alps make environmental/conservation decisions mostly based on their knowledge of ecosystem services. The link between biodiversity loss and food insecurity is a key reminder of farmers about the importance of ecosystem services for effective agricultural productivity (Kpienbaareh et al., 2020). In this study, farmers have also recognized the intrinsic value of wildlife and consider the wild animals as a heritage that must be passed on from one generation to another. A female focus group discussant summarized this: '*The presence of the wild animals in our village lands is important for our community because our forebearers bequeathed them to us and we must also bequeath them to posterity'*. Intrinsic and heritage values of biodiversity

are significant determinants of positive attitudes towards conservation of nature across different classes of society (Abukari & Mwalyosi, 2018; Synman, 2014) and thus contribute to people's acceptance of conservation actions (Roszczynska-Kurasinska et al., 2021; Vucetich et al., 2015). Conservation incentives such as the provision of beehives for apiculture and the provision of cashew seedlings for the cultivation of perennial tree crops in some CREMA communities are very much recognized and appreciated in the studied communities. Success stories from the first beneficiary communities are being used to motivate new and prospective CREMA communities to establish their own CREMAs. However, the communities appealed to wildlife authorities and non-governmental conservation organizations to consider incentives that can benefit both humans and wildlife. For example, the construction of dugouts and dams for irrigation to enable dry season farming. This they indicated can boost their livelihoods through the cultivation of vegetables in the dry season and also serve as watering points for animals, including wildlife.

Farmers' acceptance and tolerance of wildlife albeit problems

In all visited communities, farmers through focused group discussions demonstrated high levels of wildlife tolerance, albeit the challenges they face including crop raiding, wildlife depredation and threat to human life. Figure 2 shows reported incidence of wildlife destruction in the previous five years. The incidence of wildlife destructions is common in communities adjacent to the two main protected areas linked by the WWC – the Mole National Park and the Nazinga Game Reserve. The most affected communities are Kayoro, the closest to the Nazinga Game Reserve and Kulpong, the closest to the Mole National Park. Though farmers are hesitant to retaliate the loss of their crops and livestock to wildlife, they strongly demand conservation authorities to pay them compensation for their loss. The non-payment or inadequacy of compensation for wildlife destruction is the main challenge identified by the communities as emphasized by a FGD participant *'we understand the animals to be animals, as such we can forgive their wrong doing, …but when our fellow human beings in charge of the animals refuse to help us when the animals destroy our crops or kill our livestock, it is frustrating and making it look like the sacrifices we make to protect the wild animals and their habitats are not appreciated'* (FGD; Kayoro; October 2024). None or delay payment of compensation for wildlife destruction is one of the key factors triggering aversion and negative attitudes towards wildlife conservation globally (Gross et al., 2025).

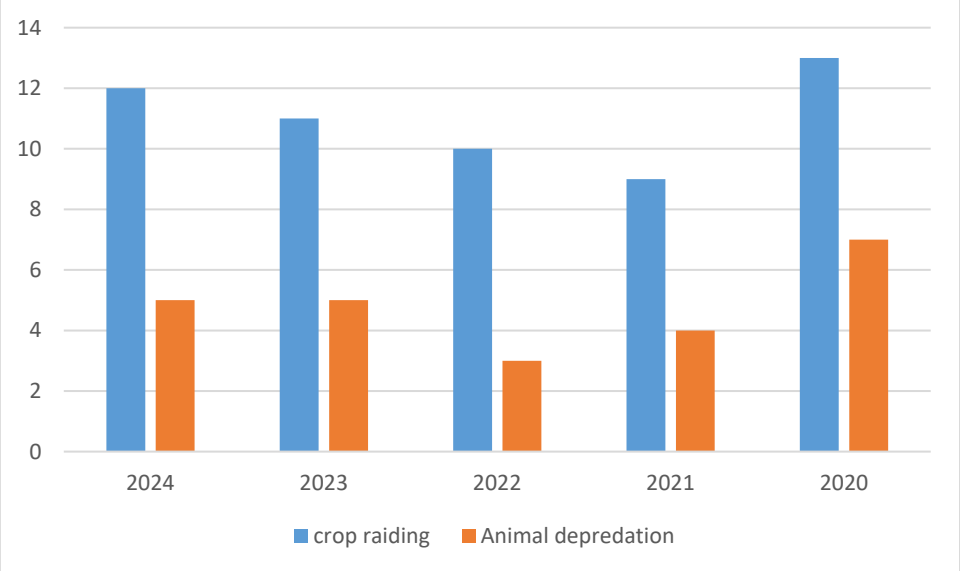

Figure 2. Reported wildlife destruction incidences From 2020 - 2024

Proulx (2024) notes that the cost of wildlife conservation should be borne by all beneficiaries of conservation benefits and not only communities adjacent to protected areas. Compensation for wildlife destruction is therefore one way to distribute the cost of conservation to lessen the burden of victims and present cost-sharing opportunities to other citizens. Crop raiding and livestock depredation are the two main wildlife destructions reported in the in the study area. Crop raiding cases are always more than depredation cases because there are always more herbivorous than carnivorous animals.

Though costly to victims, wildlife destruction does not escalate human-wildlife conflicts in the study area. All key informants and FGD discussants indicated that human-wildlife conflicts have never been a serious concern in the corridor. Though elephants (key crop raiding species) and other wild animals have always been destroying crops on farms, the people have always been tolerant of them and only find ways of driving them away from the farms. These tolerance and positive attitude towards elephants are attributed to the use of the elephant as a totem in many communities in the WWC. Human behavior towards wildlife is often judged on the bases of rational calculus of cost and benefits, ignoring the emotional and cultural aspects of the interaction (Suwannarong et al., 2024; Slagle

& Bruskotter, 2019) that influence behaviour. In this study, the cultural reasons are the key ones engendering positive attitudes and tolerance of wildlife in communities within the WWC. Key informants indicated that there has never been retaliatory killing of elephants for crop raiding. Poachers for the purpose of ivory extraction mostly carried out elephant killings that happened in the corridor. An old hunter however revealed that, even poaching for ivory is no longer lucrative because the current population of elephants in the area carry small tusks, which have low demand. However, it is instructive to note that hunting is a cultural heritage for some clans and individuals in the area. Such hunters will go hunting at all costs just to keep the cultural values alive. This category of hunters also targets the elephant to increase their fame and prestige. According to the traditional hunters' hierarchical arrangement, the highest ranked hunters are the ones that have ever killed an elephant. For this reason, traditional hunters always aspire to kill an elephant to get the highest rank. Farmers who also double as members of CREMA committees are always on the lookout for hunting activities in their vicinities. The CREMA committee members work collaboratively with wildlife authorities and non-governmental conservation organizations to expose wildlife crimes and other illegal activities in the WWC. When they observe illegal activities, CREMA members report to the wildlife authorities or conservation organizations to act.

Should the WWC be maintained?

We posed the question to find out if farmers were comfortable with the WWC's continuous existence because it may appear to be a competing land use activity for them. All participants in the focus group discussions agreed that the WWC should be maintained. They indicated that sustainability and rewilding of the WWC are hinged on the CREMAs in and around the corridor. A key informant at Nakong who was part of the establishment of one of the first CREMAs (SKGK) had this to say: '*at the beginning, we were informed that the main objective of creating the CREMAs in our communities is to help maintain the WWC, and so all the communities that accepted the CREMAs had in deed, agreed to protect the WWC'* (Interview #6; Kong; 2023). However, many key informants and focus group discussants expressed fear about the survival of the WWC and some CREMAs because of current developments. According to discussants and informants, the major threats to the survival of the WWC and CREMAs are expansion of commercial farmlands, expansion of build-up areas, grazing, logging, and mining for minerals such as gold. These activities are creating land hunger in the communities and destroying wildlife habitats. The communities have identified population growth and commercial farming as key underlying factors that drive encroachment into the WWC and some CREMAs. Globally, wildlife habitats are being threatened by the same human activities identified in this study (Padhiary & Kumar, 2024; Taylor-Brown et al., 2019; Scanes, 2018; Wantzen & Mol, 2013). However, the efforts of farmers in the current study to reverse wildlife habitat degradation is similar to those of their counterparts in Naibung'a in northern Kenya, where conservancies are managed through land zoning to improve security of wildlife and livelihoods in same space for farming, grazing and conservation activities (Mureithi et al., 2019). Such community-based initiatives seem to be effective for biodiversity conservation because all stakeholders are involved, and the motivation is based on multiple factors including economic and noneconomic.

Industry players and experts confirmed that the WWC is still relevant as it serves the purpose for which it was created. Forestry and wildlife officers indicated that the WWC is active, but a lot more must be done to provide alternative livelihood activities to communities in and around the corridor. Such livelihood activities must be conservation-compatible and more rewarding than existing livelihoods. Common livelihood activities in the corridor are farming, fuelwood extraction and charcoal production. These land-based livelihood activities put pressure on the resources within the WWC and reduce the quality of wildlife habitats. Farmers in the study area are active in participating in the integrated landscape management to sustain both farming and wildlife corridors and habitats.

Measures taken to safeguard the WWC include proper management of the forest reserves and the creation and maintenance of CREMAs in community lands in and around the corridor. To this end, a WWC management plan was designed mainly to help establish and maintain CREMAs in and around the WWC from 2017 to 2021. The goal was to get the CREMAs to become self-sustaining after their establishment. The Wildlife Division of the FC was largely the technical advisory agency for the implementation of the management plan. The goal of the management plan is largely achieved because six CREMAs are fully established and running. Eight more CREMAs have been inaugurated and are developing at various stages in and around the WWC under the auspices of the Upper West Regional office of the Forestry Commission. At the southern end of the corridor, the Mole National Park is also spearheading the establishment of five new CREMAs to secure a buffer zone around the park and enhance the integrity of the WWC.

Approaches to improve the agri-conservation landscape status of the WWC

Conservation interventions that aim to protect wildlife and their habitats in the corridor and enhance agriculture are often embedded in broader projects being implemented in northern Ghana. On-going projects at the time of this report included the Ghana Landscape Restoration and Small-Scale Mining Project (GLRSSMP) and the Ghana Shea Landscape Emission Reductions project (GSLERP). Under the GLRSSMP, the Forestry Commission (FC) through its Forest Services Division (FSD) undertook green firebreak establishment around forest reserves to prevent or minimize wildfires in the reserves and farms. Local farmers are key participants in this project where

they are taught to plant trees to create green fire belts to protect forest reserves and their farmlands from wildfire. Farmers in Ghana are already conscious about the dangers of wildfires and have over the years adopted indigenous wildfire management regimes for different agroecological zones (Appiah et al., 2010). The green firebelt initiative was therefore an improvement in their capacity to manage wildfire. The findings are also in line with Pinzón et al. (2025) who acknowledged the pivotal role farmers play in the prevention and control of wildfires in California. To ensure sustainability in the management of wildfires among farmers, the FSD also carried out wildfire prevention education, targeting the farmers in communities within the corridor. All these activities aimed at improving wildlife habitats and crop farms in forest reserves and off-reserve areas, respectively. Under the GSLERP, the FSD supported farmers to reforest degraded forest reserves through the modified taungya system (MTS). Taungya is an agroforestry system that combines a stand of woody species and agricultural crops during the early years of plantation development to improve food production and reforestation of degraded areas (Acheampong et al., 2016). The MTS is an improvement of the taungya system to ensure that farmers and other local stakeholders benefit from the proceeds made from harvested timber trees by the state institution in charge of forest resources – the FC (Acheampong et al., 2016). The Wildlife Division (WD) of the FC also received support from the GLRSSMP to strengthen existing CREMAs and create new ones. Through this support, eleven new CREMAs were being established in addition to the existing eight CREMAs at the time this report was made. It is widely recognized that community-based natural resources management approaches like the CREMA in Ghana are designed to empower local communities and make them conscious of their ownership rights of the resources in their vicinity (Heffernan, 2022; Fabricius, 2013; Gruber, 2010; Fabricius & Collins, 2007)

Conservation efforts in maintaining the WWC have largely been successful in both forest reserves and off-reserve areas due to the buy-in of local farmers. According to FSD officials, the forest reserves are in good shape and more farming communities continue to accept the CREMA concept and create CREMAs in their lands. However, a major challenge is the expansion of commercial farmlands in and around the corridor. Grazing, charcoal production and logging are other important activities threatening the ecological integrity of the WWC.

Conclusion

The study has examined the participation of local farmers in an integrated landscape management approach to enhance agriculture and wildlife conservation in same spaces. The results suggest that with the right approach and strategies, seemingly conflicting land use activities such as crop farming and conservation can be married effectively. Underlying cultural values and knowledge of ecosystem services are significant factors that can engender positive attitudes and exude behaviours from farmers that favour conservation. It will therefore be useful to precede community-based conservation interventions with some community education and awarenesss campaigns on all the ecosystem services. This may draw the target audience's attention to the noneconomic services such as supporting, cultural and regulating services, and may secure their buy-in into proposed interventions. Collaboration between various stakeholders in different institutions at the national and local levels is essential to secure genuine participation of local communities. The effective collaboration between the various divisions of the Forestry Commission and the local farmers ensures the successful creation and management of CREMAs in many communities. The local farmers who also double as CREMA executives agreed to participate in protecting the WWC due to the trust established between them and the wildlife authorities. However, it is important to note that financing of various direct and indirect conservation projects in the WWC must be continued since this supports the creation and maintenance of the CREMAs established at different places. It will also be useful to consider the prompt payment of compensation to farmers when they fall victim to wildlife depredation and crop raiding. This will strengthen the support of farmers for the conservation of the WWC and CREMAs. Further studies are needed in the WWC to establish land tenure systems and land transactions to understand how commercial farmers and other investors are able to get large parcels of land for their business activities.

Acknowledgements

The information used in this paper is part of research work that was funded with support from the Biodiversity Division of the United States Agency for International Development (USAID), through the Centre for International Forestry Research – World Agroforesty (CIFOR-ICRAF). The authors greatly acknowledge the time of all actors in the WWC of Ghana who contributed interviews and discussions to this study.

[2]Department of Agricultural Biotechnology, Faculty of Agriculture, Kırşehir Ahi Evran University, Kırşehir, Türkiye
[3]Department of Field Crops, , Faculty of Agriculture, Kırşehir Ahi Evran University, Kırşehir, Türkiye

Abstract

This study was conducted to determine the effects of adding five different commercial inoculants to Sorghum BicolorXSorghum Sudanese silage on silage quality, microbial development, and aerobic stability. The study consisted of a control group (C) and five inoculant groups (SSSILD, SSSILAP, SSLAC, SSSILAL, SSMIC), prepared in 2 kg vacuum-sealed packages with eight replicates. The prepared silage samples were subjected to fermentation under laboratory conditions, and physical, chemical, microbiological, and aerobic stability analyses were performed after 90 days. Chemical analyses revealed that inoculant addition significantly reduced the pH levels of the silages (P<0.01), with the lowest pH value (4.55±0.00) observed in SSSILAP. The highest crude protein content (10.20±0.00%) was found in SSMIC, while the highest water-soluble carbohydrate (WSC) value (16.15°Brix) was recorded in Control group. Although no statistical differences were observed in color parameters among the groups, inoculant applications positively influenced color stability in terms of ΔE* and hue (h) values (P>0.05). Microbiological analyses showed the highest lactic acid bacteria population (11.00 log5 cfu/g) in SSMIC, with the lowest yeast and mold development. This supports the positive effect of inoculants on aerobic stability. Regarding nutritional value parameters, SSSILAL exhibited the highest digestible dry matter (60.16%), SSMIC had the highest total digestible nutrients (59.02%), Control, SSSILAP and SSMIC showed the highest metabolic energy (2.13 Mcal/kg), and SSSILAP and SSMIC had the highest net energy for lactation (NEL: 1.41 Mcal/kg). In conclusion, inoculant applications significantly improved silage quality, enhanced fermentation efficiency by lowering pH levels, suppressed yeast and mold formation, and improved aerobic stability. SSSILAL and SSMIC outperformed the others, particularly in terms of chemical composition, energy value, and microbiological quality.

Key Words: *Sorghum Bicolor X Sorghum Sudanese Plant, Silage Quality, Microbial Inoculant, Fermentation, Aerobic Stability, Lactic Acid Bacteria, Color Stability, Energy Value, Feed Quality*

Introduction

Silage is an effective preservation method that allows forage crops to be stored for extended periods through fermentation under anaerobic conditions and is used as a fundamental feed source in animal husbandry. High-quality silage production increases agricultural efficiency by reducing animal feeding costs and contributes to environmental sustainability (McDonald et al., 1991). Sorghum bicolor X Sorghum sudanese hybrids are increasingly utilized for silage due to their high biomass yield, drought tolerance, and adaptability to diverse climates (Bean et al., 2013). These hybrids are particularly valued for their ability to produce substantial dry matter yields under water-limited conditions, making them a viable alternative to traditional silage crops like maize in arid and semi-arid regions (Getachew et al., 2016). Studies have shown that Sorghum bicolor X Sorghum sudanese hybrids exhibit favorable nutritional profiles for silage, with moderate crude protein content and high digestible dry matter, enhancing their suitability for ruminant diets (Sánchez-Duarte et al., 2019). For instance, research by Marsalis et al. (2010) demonstrated that these hybrids, when harvested at the soft dough stage, achieve optimal fermentable carbohydrate levels, improving silage quality and aerobic stability. However, their high fiber content and variable carbohydrate levels can complicate fermentation, necessitating the use of microbial inoculants to enhance silage quality (Kung et al., 2003). Lactic acid bacteria (LAB) produce lactic acid by utilizing easily fermentable carbohydrates in plant material, lowering the silage pH, reducing nutrient losses, and inhibiting the growth of undesirable microorganisms (e.g., molds and yeasts) (Kung et al., 2003). Homofermentative bacteria (e.g., Lactobacillus plantarum, Pediococcus acidilactici) enhance aerobic stability through rapid acid production, while heterofermentative bacteria (e.g., *Lactobacillus buchneri*) are effective in preventing aerobic spoilage (Filya, 2004; Muck, 2010). Enzyme-containing inoculants (e.g., cellulase, xylanase) break down plant cell walls, providing more fermentable substrates for LAB and increasing silage digestibility (Özduven et al., 2017). Inoculants combining LAB and enzymes have been reported to reduce NDF and ADF contents and improve organic matter digestibility (Özduven et al., 2017). Similarly, Özduven et al. (2009) reported that LAB inoculants improved fermentation parameters and aerobic stability in corn silage. This study aims to investigate the effects

of different microbial inoculants (SSSILD, SSSILAP, SSLAC, SSSILAL, SSMIC) on the physical, chemical, microbiological, and aerobic stability properties of Sorghum bicolor x Sorghum sudanese silage, optimizing silage quality and nutritional value. The study seeks to contribute to the more effective use of alternative crops like Sorghum bicolor X Sorghum sudanese in sustainable livestock systems.

Materials and Methods

In this study, Sorghum-Sudan Grass Hybrid (Sorghum Bicolor X Sorghum Sudanese) harvested from the research field of Kırşehir Ahi Evran University's Department of Field Crops (Latitude: 39.1286°N, Longitude: 34.1078°E) was used as the primary silage material. The Sorghum Bicolor X Sorghum Sudanese was harvested at the dough stage, chopped to approximately 2.0 cm using a silage machine, and 1000 g of plant material was placed into 2 kg plastic bags. Control group (Control-SS) and five inoculant groups Sorghum Bicolor X Sorghum Sudanese+*Lactobacillus plantarum*, *Enterococcus faecium* bacteria and cellulase, pentosanase, amylase enzymes (SILAID, Global Nutritech Biotechnology LLC, USA), Sorghum Bicolor x Sorghum Sudanese+*L.plantarum, Pediococcus acidilactici, P. pentosaceus, Propionibacteria acidipropionici* and xylanase, β-glucanase enzymes (SILAP Timac Agro, USA), Sorghum Bicolor X Sorghum Sudanese+*Lactobacillus plantarum* only (LAC, Centro Sperimentale Del Latte, Italy), Sorghum Bicolor X Sorghum Sudanese+*L. plantarum, P. acidilactici, P. pentosaceus, P. acidipropionici* and xylanase, β-glucanase, cellulase, amylase enzymes (SILAL, Alltech, UK), Sorghum Bicolor X Sorghum Sudanese+*Lactobacillus brevis, Enterococcus faecium, Bacillus subtilis, Pediococcus acidilactici* and alpha–amylase (*A. oryzae*), cellulase, hemicellulase (*A. niger*) enzymes (MIC, Cuprem®, USA) were treated with inoculants at a concentration of 1×10^5 cfu/g, sprayed homogeneously onto the fresh material After inoculation, the air inside the bags was vacuumed using a vacuum device (Packtech PT-VKM-CPRO). Following vacuum sealing, a total of 30 silage samples (eight replicates per group) were incubated in laboratory conditions at 18.5±2°C in a dark environment for 90 days. At the end of the fermentation process, eight parallel samples from each group were taken, and physical, chemical, microbiological, and statistical analyses were conducted. Dry matter (DM), crude protein (CP), and ash contents of silage samples were analyzed according to AOAC (1998) methods. Organic matter (OM) content was calculated using the formula [%OM = 100 - %ash]. Acid detergent fiber (ADF) and neutral detergent fiber (NDF) analyses were performed following the methods described by Van Soest et al. (1991), using amylase and sodium sulfite, with results expressed including residual ash. Additionally, NDF and ADF contents were corrected for residual ash and reported as NDFom and ADFom, respectively. Hemicellulose content was calculated as [Hemicellulose = NDF - ADF] as defined by Van Soest et al. (1991). Ether extract (EE) content was determined using the ANKOM XT15 Extraction System based on AOCS (2005) protocols. The pH values of silages were measured following Chen et al. (1994), and total soluble solids (TSM) contents were measured according to Singh et al. (2020). Total digestible nutrients (TDN), digestible crude protein (DCP), and metabolizable energy values were calculated using formulas reported by Filik (2020). Color measurements of silages were conducted using a Konica-Minolta CR-410 colorimeter after opening the silage packages, recording L*, a*, and b* values from three different regions of each sample. Chroma (C*, saturation index) and hue angle (h°) were calculated from a* and b* values following AMSA (2012) methods. Lactic acid bacteria, yeast, and mold counts in silage samples were determined using the method described by Seale et al. (1990). Carbon dioxide (CO_2) and pH values on the fifth day after opening the silage packages were measured according to the procedure reported by Ashbell et al. (1991). Relative feed value (RFV) and relative forage quality (RFQ) of silages were calculated using formulas reported by Kılıç and Abdiwali (2016) and Filik (2020). These analyses were conducted at the Animal Biotechnology Laboratory and the Enzyme and Microbial Biotechnology Laboratory of Kırşehir Ahi Evran University's Faculty of Agriculture, Department of Agricultural Biotechnology. Statistical analyses were performed using the SAS (2001) statistical package program. The General Linear Model (PROC GLM) procedure was applied based on a randomized complete block design, and linear relationships between experimental groups were evaluated using orthogonal polynomial contrast analysis. Differences between groups were determined using Duncan's Multiple Comparison Test (Genç & Soysal, 2018).

Results and Discussion

SSSILD had the highest DM content (941.00 g/kg), while SSMIC showed the lowest value (937.15 g/kg). The differences were significant ($p=0.0060$). No significant difference was found in OM and ash ratios ($p=0.1404$), indicating that the mineral content of the silages was similar. SSMIC had the highest CP (10.20%), while SSSILD showed the lowest value (8.87%). There were significant differences in terms of protein content ($p=0.0002$). SSMIC had the highest EE (4.95%), while SSSILAL showed the lowest value (3.86%) ($p<0.0001$). SSSILD has the highest CF (28.91%), ADF (38.74%) and NDF (65.82%) values, indicating higher fiber content. SSSILAL has the lowest ADF (36.90%) and ADFom (29.55%) values, indicating lower lignification and better digestibility. Square and cubic effects for CP, EE, ADF and NDF are significant ($p<0.05$), indicating that the effects of additives on nutrient content are not linear (Table 1). Fiber content (ADF, NDF) in the document aligns with Öten et al. (2024), where ADF ranged from 30.74–35% and NDF from 57.86–62%. The document's SSSILD (ADF: 38.74%, NDF: 65.82%) is higher, indicating lower digestibility, while SSSILAL's lower values (ADF: 36.90%, NDF:63.30%) match BMR cultivars' improved digestibility.

1 g/kg natural material, 2 (%) of dry matter, 3 ADFom=ADF ash, NDFom=NDF ash; 4 DM: In Air Dry Matter (g/kg); OM: Organic Matter (%); Ash (%); CP: Crude Protein (%); EE: Ether Extract (%); CF: Crude Fibre (%); ADF: Acid Detergent Fibre (%) and NDF: Neutral Detergent Fibre (%). a,b,c,d .Means within the same column with no common superscript differ. significantly (P<0.01). ¥ L: linear; Q: quadratic; C: cubic effects. SED: Standard error of the difference between 2 means.

SSSILAL had the highest NFE value (51.56%), while SSMIC showed the lowest value (48.87%) (p<0.0001). SSSILAL had the highest NFC (16.23%), while SSSILD showed the lowest value (13.83%). However, this difference was not statistically significant (p=0.2149). SSSILD had the highest TC (79.65%), while SSMIC showed the lowest value (77.30%) (p=0.0001). Control, SSSILAP and SSMIC had the highest energy values (DE: 2.60 Mcal/kg, ME: 2.13 Mcal/kg), while SSSILD showed the lowest energy values (DE: 2.54 Mcal/kg, ME: 2.08 Mcal/kg). NEL, NEM and NEG values also followed a similar trend. The square and cubic effects on energy values are significant (p<0.05), indicating that the effects of additives on energy content are complex (Table 2). Öten et al. (2024) reported digestible energy (DE) and metabolizable energy (ME) improvements with molasses, with DE values around 2.5–2.7 Mcal/kg, closely matching the document's range (2.54–2.60 Mcal/kg). The document's high-energy silages (Control, SSSILAP, SSMIC) align with these findings.

[1](%) of dry matter;[2] Data represent the mean of four applications of each treatment; [3] NFE: nitrogen-free extract (g/kg); NFC: non-fibre carbohydrates (g/kg) and TC: total carbohydrates (g/kg), DE: digestible energy (Mcal/kg); ME: Metabolizable energy (ME Mcal/kg), NEL : net energylactation (Mcal/kg), NEM: net energy-maintenance (Mcal/kg), NEG : net energy-gain (Mcal/kg). a,b,c Means within the same column without common superscript are significantly different (P<0.01). ¥ L: linear; Q: quadratic; C: cubic effects. SED: Standard error of the difference between 2 means.

SSSILAL had the highest DDM (60.16%), while SSSILD had the lowest value (58.72%) (p=0.0006). SSMIC had the highest DMI (1.93%), while SSSILD had the lowest value (1.83%) (p=0.0444). SSMIC had the highest TDN (59.02%), while SSSILD had the lowest value (57.61%) (p=0.0003). SSMIC had the highest RFV (89.43) and RFQ (92.81) values, while SSSILD showed the lowest values (RFV: 83.00, RFQ: 85.40). Square and cubic effects were significant for DDM, TDN, RFV and RFQ (p<0.05) (Table 3). Öten et al. (2024) reported RFV values of 63.78–81.53 for Sorghum x Sudan grass hybrids, lower than the document's range (83.00–89.43). The document's SSMIC (RFV: 89.43) exceeds these values, likely due to lower ADF/NDF and higher CP. DDM and DMI values in the document are comparable to high-quality silages reported by Aguiar et al. (2006), where Sudan grass silage matched ruminant nutritional standards.

The control group had the highest temperature (20.28°C), while SSSILD showed the lowest temperature (16.18°C). The temperature differences are statistically significant (p<0.0001). Lower temperature may indicate better preservation of silage. SSSILAP had the lowest pH value (4.55), while the control group showed the highest

pH (4.68). Lower pH means better lactic acid fermentation and silage stability. SSLAC had the highest WSC value (17.40), indicating more fermentable carbohydrates. SSSILAL had the lowest WSC (15.23). SSSILAL has the highest L* (56.33, lighter color) and ΔE (59.77, total color difference) values, which may indicate that the color change is more pronounced. SSSILD has the highest a* (4.08, redness), while b* (yellowishness) and C* (chroma) values are generally similar. Although there are some significant differences in color parameters (e.g. p=0.0341 for h), no major differences are observed overall. Linear (L), quadratic (Q) and cubic (C) effects for temperature and pH are significant (p<0.0001). However, these effects are less pronounced in color parameters (Table 4). A study by Salman and Budak (2015) evaluated Sorghum x Sudan grass hybrids (e.g., Nutri Honey, Aneto) and reported pH values for silages ranging from 4.2 to 4.8, aligning with the document's range (4.55–4.68). The lower pH in SSSILAP (4.55) is consistent with high-quality silage, as pH below 4.6 is optimal for lactic acid fermentation.

DM (After Aerobic Stability), SSLAC had the highest DM (55.54%), while SSMIC showed the lowest value (48.91%) (p<0.0001). SSLAC had the lowest pH (4.36), while SSSILD showed the highest value (4.54) (p<0.0001). Low pH is advantageous in terms of aerobic stability. There is no significant difference in CO_2 production (p=0.9669), which may indicate that aerobic degradation was similar in all silages. SSMIC had the highest LAB count (11.00 $Log10^5$ cfu/g) before aerobic stability, while LAB counts were low in other silages (1.00-2.50 $Log10^5$ cfu/g). However, this difference is only marginally significant (p=0.0527). Linear, quadratic and cubic effects for DM and pH are significant (p<0.05). Öten et al. (2024) reported pH values of 3.99–4.5 post-aerobic exposure, aligning with the document's range (4.36–4.54). SSLAC's low pH (4.36) matches high-stability silages enhanced by molasses.

The low pH in SSLAC (4.36) indicates effective preservation, Likely due to high organic acid content (e.g., acetic acid), which inhibits spoilage organisms. This aligns with findings by Kung et al. (2003), who reported that rapid pH decline in silages treated with homofermentative LAB enhances preservation by limiting the growth of yeasts and molds. Similarly, Contreras-Govea et al. (2013) observed that sorghum silages with pH below 4.4, driven by increased lactic and acetic acid production, exhibited superior fermentation quality. The higher pH in SSSILD

(4.54) suggests reduced stability, possibly due to lower acid production or consumption by aerobic microbes, consistent with Muck (2010), who noted that inadequate acid accumulation can lead to secondary fermentation and reduced aerobic stability. The lack of significant CO_2 differences implies that all silages experienced comparable aerobic microbial activity post-exposure, despite differences in pH and DM. This could indicate that CO_2 production is less sensitive to additive effects in this study, as supported by Ashbell et al. (1991), who found that CO_2 levels in silages may not always correlate with microbial inoculant efficacy due to variable aerobic deterioration rates. Weinberg and Muck (1996) further suggest that CO_2 production is influenced by residual fermentable substrates, which may be similar across treatments in this case. LAB Count: SSMIC's high LAB count (11.00 Log10 cfu/g) reflects strong fermentation, likely driven by homofermentative or heterofermentative LAB inoculants. Filya (2004) reported that high LAB populations in inoculated silages enhance lactic acid production, improving fermentation efficiency. However, the low DM (48.91%) in SSMIC suggests that LAB activity may have consumed DM during aerobic exposure, reducing stability, as noted by McAllister et al. (2018), who found that excessive LAB activity in sorghum silages can lead to DM losses under aerobic conditions. Other treatments (e.g., SSLAC) with lower LAB counts maintained higher DM, indicating better aerobic stability, consistent with Contreras-Govea et al. (2013), who emphasized that balanced LAB populations optimize both fermentation and aerobic stability in sorghum silages.

Conclusion

The quality of Sorghum bicolor X Sorghum Sudanese silages varies significantly depending on the LAB inoculant applied. Especially SSLAC and SSMIC (homofermantative) groups showed superior performance compared to other groups in terms of silage quality, nutritional values and microbiology. Both high energy content and good feed quality parameters in these groups support the preference of these inoculants in practice. In conclusion, this study shows that different LAB inoculants can significantly improve the properties of Sorghum bicolor X Sorghum Sudanese Silage silages. This can provide important contributions to farmers in terms of reducing feed costs and increasing animal health and performance. Future research should focus on optimizing inoculant combinations, different plant species, and regional climate conditions. Additionally, more comprehensive studies on the long-term effects and economic feasibility of inoculants could support the widespread adoption of this technology at a commercial scale. Such studies will contribute to developing innovative and environmentally friendly solutions in global feed production.

Abstract

Potential copolymers as industrial precursors were developed from *Carica papaya* seeds oil. *Carica papaya* fruits were collected in Ibadan, Nigeria. Seed oils of this fruit were extracted using n-hexane and concentrated. Phenolated *carica- papaya* biopolymer(PCPB) was prepared by polymerizing the oil with phenol through cationic polymerization method. Polyacrylamide(PAA) and Polyacrylonitrile(PAN) were prepared through free radical polymerization technique. The copolymers were prepared by polymerizing PCPB, PAA and PAN to produce PCPB-PAA and PCPB-PAN. They were characterized using FTIR for functional groups modifications, ^{1}H-NMR for changes in chemical environments and Viscometry techniques for mean molecular weight determination.

The oil yield is 32.22%. Iodine value(gI_2/100g) is 99.55±0.38 and 61.98±0.06 for oil and PCPB respectively. FTIR band shifts at 1552.75cm^{-1} confirm C=C stretch of aromatics in PCPB. PAA formation was confirmed with C=O stretch at 1680.00cm^{-1}. Peak at 2250cm^{-1} confirm C≡N of PAN. Peak at 3474.24cm^{-1} confirm N-H stretching vibration of amides that suggest polyester-amide copolymer. C-N bond occurred at 2034.28cm^{-1} to establishe PCPB-PAN copolymer. The ^{1}H-NMR spectra showed peaks at δppm, δ8.11ppm(s, 2H) to confirm aromatics in PCPB. δppm at 7.18 confirmed peptide protons in PAA. δ 7.18(s, 1H) and 6.86(s, 3H) suggest that PAA was grafted to PCPB backbone. δ4.89ppm(q, J = 8.8 Hz, 1H) suggests the presence of substituted nitrile in PCPB-PAN. Both FTIR and ^{1}H-NMR results confirmed formation of new copolymers. The mean molecular weight(g/mol) for PCPB, PCPB-PAA and PCPB-PAN are 7.482x10^9, 1.062x10^{12} and 1.135x 10^{12} respectively to affirm the grafting processes.

The results suggest that ecologically friendly industrial precursors are feasible from Agricultural wastes.

Keywords: *Copolymers, Industrial, Agricultural wastes, polymerization, Carica Papaya*

Introduction

Agricultural activities all over the world generate wastes that are underutilised or not in use at all. In most countries in Africa, these wastes are consistently discarded as there are less available proven technologies to find purposes for them (Nikesh and Prakash 2015; Srikanth et al., 2022). Some of the wastes includes seeds of fruits, peels, rice bran, fruits shells, nuts of fruits like cashew, palm fruit and coconuts and the list is endless. Many of them are allowed to decompose and germinate and others litter the environments(Montero et al., 2011). Among these endless waste seed is *Carica papaya* seeds. Carica papaya fruit is widely produced and consumed on the African continent. This is because most of the countries in Africa operate agro-based economies. Nigeria in particular, Agriculture has been a stable component of the life of people in the various savannahs. *Carica papaya* is an annual crop which means its available every year. It will also be available all through the year round if it is well preserved (Malacridai et al., 2011). The seeds from this fruits are often discarded after the flesh has been consumed since they have limited use. Researchers have however shown that the seed is rich in viable functional groups like esters, vinyl group, carbonyl group, fatty acid group, fatty alcohol and ether groups. These seeds can then be modified under suitable chemical/unit process to obtain viable chemical precursors.

The feedstock used in the various industries like the petrochemicals, pharmauticals, textile, polymer industries and a host of others have gotten their starting materials majorly from petroleum sources(Askarian et al., 2018). These petroleum sources have been found to be finite and hence at a certain time and counts, it may not be available to man anymore. Besides, relying heavily on petroleum has resulted into some environmental nuisances. Plastics from ethane and propene monomers are not biodegradable. They can occupy the land fill sites for years and then lead to alteration in the food chain which can contribute to food scarcity and astronomical prices. One of the problems facing the earth today is the end use of the plastics that have been produced(Gupta and Kashani 2021). Several propositions have been made such as recycling, incineration and sustainable processes with each creating new set of problems. Incineration releases toxic chemicals to the environment like CO and SO_2 (Poudyal and Adhikari, 2021). Recycling releases harmful chemicals such as HCl and H_2S and the sustainable process implies postponing the evil day for a foreseeable future. Relying on petrol for fuel has contributed heavily to the release of excess CO_2 into the environment which had led to sporadic increase in the temperature of the earth(Nair and Vishnudas, 2024). Excess heat can also lead to the denaturation of proteins in the body that can lead to various

degree of sicknesses and major life damages such as infertility, undue death, weakness of the flora and fauna antibodies and blue blood syndrome. Oil spillage, water pollution and poisoning are other problems associated with regions where oil rigs exist. Aquatic species are facing difficulty in breathing ,migration and extinction and quality of water available to homo-sapiens in these regions are low and uneconomical. Wrong government policies and allied by the oil industries contribute further issues around these parts of the countries. Nations in Africa always experiences militancy, bunker, pipe line vanderlization (Thomas 2018).

These problems and similar factors had prepared the chemical industries to think of alternatives to crude oil for feed stock production (Jittin et al., 2021; Afolabi et al., 2020). Among the array of other things such as coal, ammoniacal liquols, bitumen, biomass and others considered, the biomass wastes offers viable alternative. Biomass are all from agricultural sources. To avoid creating problems of sporadic increase in food prices, the non –edible underutilised biomass have been the most viable agricultural wastes that can moderately satisfy the requirement of man in his technological growth and desires without affecting the ecosystem. Among these non-edible underutilised biomass is *carica papaya* seed oil.

Carica papaya L. is grown all over the world and is available to the tone of 100 million metric tons, all over the world annually. Its central cavity contains large quantities of seeds that comprise averagely 15% of the wet weight. *Carica papaya* L. seeds have been used for decades in parts of Asia and South America as a vermifugal agent, folk medicine due to its abortive properties, to enhance good menstrual flow in women and to adulterate black pepper. The availability of the seeds shows that it can be depended upon. The oil yield from literatures shows the oil to be in the range of 30-45% depending on the region to suggest commercial viability. The oil has also been confirmed to be rich in oleic acid up to 70%. This makes the oil to be a viable candidate for addition polymerization reaction (Elahi et al., 2020).

Despite the plethora of literature works on this *carica papaya L.* seed oil. There are sparse literary submissions on its viability as source for producing feedstock for chemical industries. This research therefore probe into the possible use of *Carica papaya* seed oils for production of suitable industrial precursors for chemical industries with the focus on mitigating the problems associated with those from petroleum sources (Blesson et al., 2023; Omotoso and Akinsanoye, 2017). The precursors and materials form them are expected to be biodegradable and photodegradable. The research will also contribute immensely to the available agricultural starting materials for producing environmental friendly industrial chemicals' precursors.

Methodology

Materials

The materials employed for this research work include Pawpaw seeds (*Carica papaya),* phenol, acrylamide, acrylonitrile, toluene, perchloric acid, distilled water, hydroquinone, Fenton's reagent (Hydrogen peroxide+ Ferric ammonium sulphate in 1:1), ethanol.

Methods

Sample collection and sampling methods

Pawpaw seed sample preparation

Pawpaw seeds were obtained largely from Ibadan in Oyo state, Nigeria. The seeds were obtained from the fruits by mechanical means. The seed samples were dried and the moisture contents were determined. The seeds (dark brown) were grounded with a blender and were prepared for extraction.

Extraction and phenolation of oil

The oil was extracted from the seeds using hot extraction technique and concentrated. Physicochemical parameters were determined. The extracted oil was phenolated with phenol through grafting technique. This was done by mixing melted phenol and the triglyceride in ratio 1:3 using a batch reactor in the presence of nitrogen gas to provide inert environment. The mixture was thoroughly homogenised for few minutes. The reaction mixture (1% of the combination) was combined with perchloric acid ($HClO_4$) as catalyst. They were allowed to proceed for six hours at 90^0C in an inert atmosphere created by utilizing nitrogen gas. After the reaction materials were polymerized for six hours, they became dark-brown. The reaction products were observed to have grown very viscous after four hours of polymerization. The final product was a dark-brown viscous liquid. The process was stopped after six hours. They were allowed for 20 minutes to cool. To ensure that the unreacted phenol, unreacted triglycerides, and acid catalysts were eliminated, powdered $Ca(OH)_2$ was added to the reaction mass. To get rid of any remaining impurities, ethanol was used to wash the finished product. The resultant phenolated product was dried for 48 hours on sodium sulfate. The product obtained were stored in tightly fitting containers until Analysis. ^{1}H-NMR, FTIR and iodine value were used in the analysis. The products were used as starting materials for the copolymers.

Percentage Oil yield determination
The oil yield was determined from the relationship.

$$\text{Percentage oil yield} = A\text{-}B \times \frac{100}{W}$$

Where:
A = weight of flask + oil
B = weight of flask only
W = weight of sample
Determination of Physiochemical parameters:
The iodine value, free fatty acid, saponification value and peroxide value were determined using standard techniques.
Iodine value measurement.
0.1g of the sample was weighed into 200ml flask. Solution is effected by adding 5ml of carbon tetrachloride, dried over calcium chloride, 10ml of the Wij's solution was added from a dry pipette, the flask is closed with a stopper and allowed to stand for few minutes. 5ml of 10% KI solution and 50 ml of water was added to the content. Titration was conducted with 0.1N sodium thiosulphate solution using 10 drops of 1% starch solution as indicator. A blank test, omitting the sample was simultaneously performed. Similar test was carried out for the PCPB. The iodine value was calculated using the formula:

$$\text{Iodine value} = \frac{(x\text{-}y) \times 1.269}{w}$$

where x = ml of thiosulphate solution required by the blank, y = ml of thiosulphate solution required in the test. w = weight of sample. The factor 1.269 is for an accurate 0.1N solution of sodium thiosulphate (AOAC, 1984).
Saponification value measurement
The saponification value was determined by taking 1.0 g of the oil sample in a conical flask to which was added 15 mL 1 N KOH and 10 mL of distilled water and heated under a reserved condenser for 40 min to ensure that the sample was fully dissolved. After this sample was cooled, phenolphthalein was added and titrated with 0.5 M of HCl until a pink endpoint was reached. A blank was determined with the same time conditions (Zahir et al., 2014).
Peroxide value measurement
1.0g of oil sample was dissolved in acetic acid then chloroform and saturated KI mixture were added. The iodine liberated from KI by the oxidative action of peroxides present in the oil was determined by titration with standard sodium thiosulphate using starch solution as the indicator. Titration was also performed for blanks (AOAC, 1984, Zahir et al., 2014).

$$PV\ (meq/kg\ oil) = (S\text{-}B) \times W \times N.$$

Where B is the volume of sodium thiosulphate used for blank, W is the weight of sample, S is the volume of sodium thiosulphate consumed by the sample oil and N is the normality of standard sodium thiosulphate.
Free fatty acids determination
The acid value was determined using the method described by Ronald (1991). Equal volumes of diethyl ether and ethanol were mixed together and 1ml of 1% phenolphthalein indicator solution was added and then neutralized with 0.1M potassium hydroxide solution. The oil was dissolved in the neutralized solvent mixture and titrated with 0.1M potassium hydroxide solution with constant shaking until a pink colour which persists for 15seconds is obtained.

$$\text{Acid value} = \frac{\text{Titre value (ml)} \times 5.61}{\text{Weight of sample used (g)}}$$

Preparation of copolymers from phenolated vegetable oils.
Homopolymerization of acrylamide and acrylonitrile.
Preparation of polyacrylamide(PAA)
1.5 litres of 30% wt./vol. acrylamide in water was transferred into a three necked batch reactor, 30ml of 0.05M $NaNO_3$ solution was added. The mixture was thoroughly stirred for few minutes under nitrogen gas. Fe^{2+}-H_2O_2 (Fenton's reagent) was added as initiator and this was stirred for 5 minutes. Nitrogen gas was bubbled through for sometimes. The reaction continued for the next four hours. After the desired reaction time, the reaction was terminated by adding 0.2 g hydroquinone powder and the contents were stirred for another some minutes before being stopped. The homopolymer was cleaned with ethanol to remove unreacted acrylamide, remnants of $NaNO_3$ solution and the catalyst. The product was allowed to dry for half a day over sodium sulphate to ensure the total

removal of the moisture content. It was kept in a cool dry place until the period of further application and analysis. The product was analysed with FTIR and ^{1}H-NMR.

Homopolymerization of acrylonitrile

100g of acrylonitrile was added to 200mL of distilled water in a 3-necked batch reactor equipped with a mechanical stirrer and gas inlet. Then 1.5g of Fenton's reagent (H_2O_2-Fe^{2+}) was added to the acrylonitrile solution. The mixture reacted at 90^0C for 3 h. Then, the precipitates were collected by filtration, washed with acetone, and dried under vacuum at room temperature, yielding Polyacrylacrylonitrile.

Copolymerization reactions.

The copolymerization reaction of PCPB with polyacrylamide and Polyacrylonitrile was performed using the same method in a 1 L isothermal three-necked batch reactor, equipped with an overhead stirrer and a temperature regulator to allow the control of the reaction temperature. The catalysts employed are Fenton's reagents (Hydrogen peroxide + Ferric ammonium sulphate in 1:1). The copolymerization reactions were carried out using a hybrid of the methods described by Witono in 2012 and Nur Azmyra et al., 2014.

PCPB was loaded into the reactor and mixed with a known volume of distilled water. The mixture was thoroughly stirred for some minutes under nitrogen gas environment. This was followed by the addition of predetermined amount of homopolymerized polyacrylamide to give specific ratios. The mixture was stirred for 5 minutes and was heated under nitrogen gas atmosphere at 70^0C for 25 minutes. The temperature was reduced to 60^0C for the first two and increase to 80^0C for the last 4. Each of the reaction continued for 5 or 6 hours. The reaction was ceased by adding 2 ml of 0.1 M hydroquinone and the contents were stirred for another 10 minutes before opening the reactor to collect the samples. The copolymerized phenol and vegetable oils and the various homopolymers were separated from the unreacted homopolymer by washing a representative sample of 30 g from the reaction contents with 40ml of acetone for several times until homopolymer could not be detected in the supernatant. The product obtained was dried and then transferred into separate labelled containers for analysis and applications.

Analytical techniques

The oil, PCPB and the synthesized copolymer precursors were analysed using a ^{1}H-NMR techniques. The NMR analysis were carried out using Agilent - 400 MHz, temperature of 31^0C and $CDCl_3$ as solvent, FTIR was used to monitor the change in functional groups. This was done by using Perkin Elmer FTIR system spectrum BX. Viscometry was used to monitor the change in molecular weights. Details of results are in the next chapter.

Results and Discussion

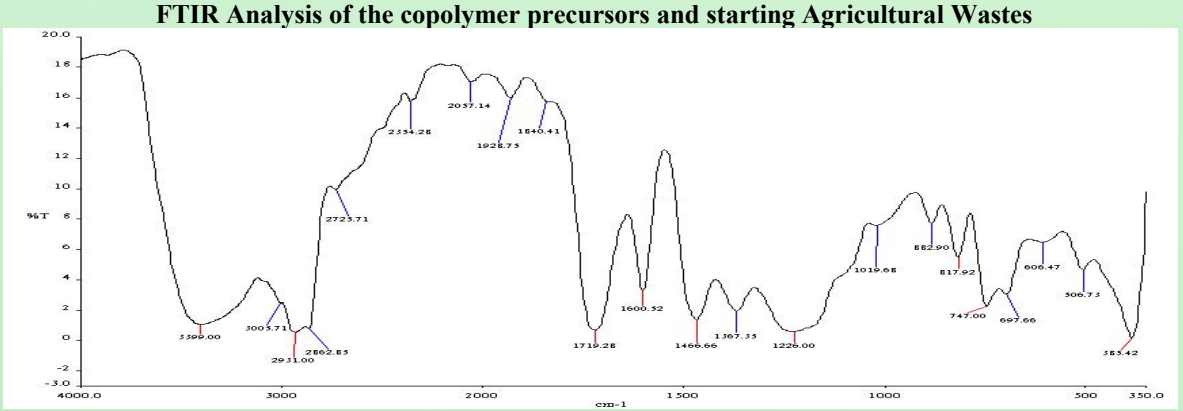

Table 1: Physicochemical analysis of oil

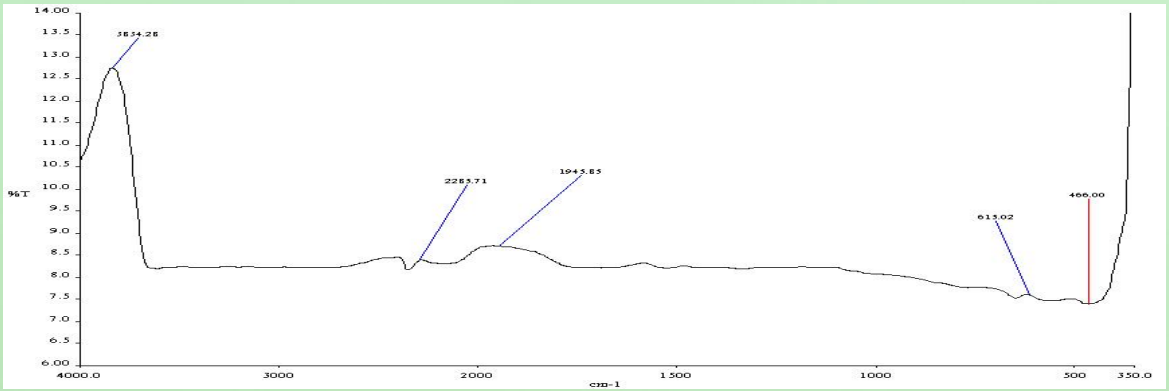
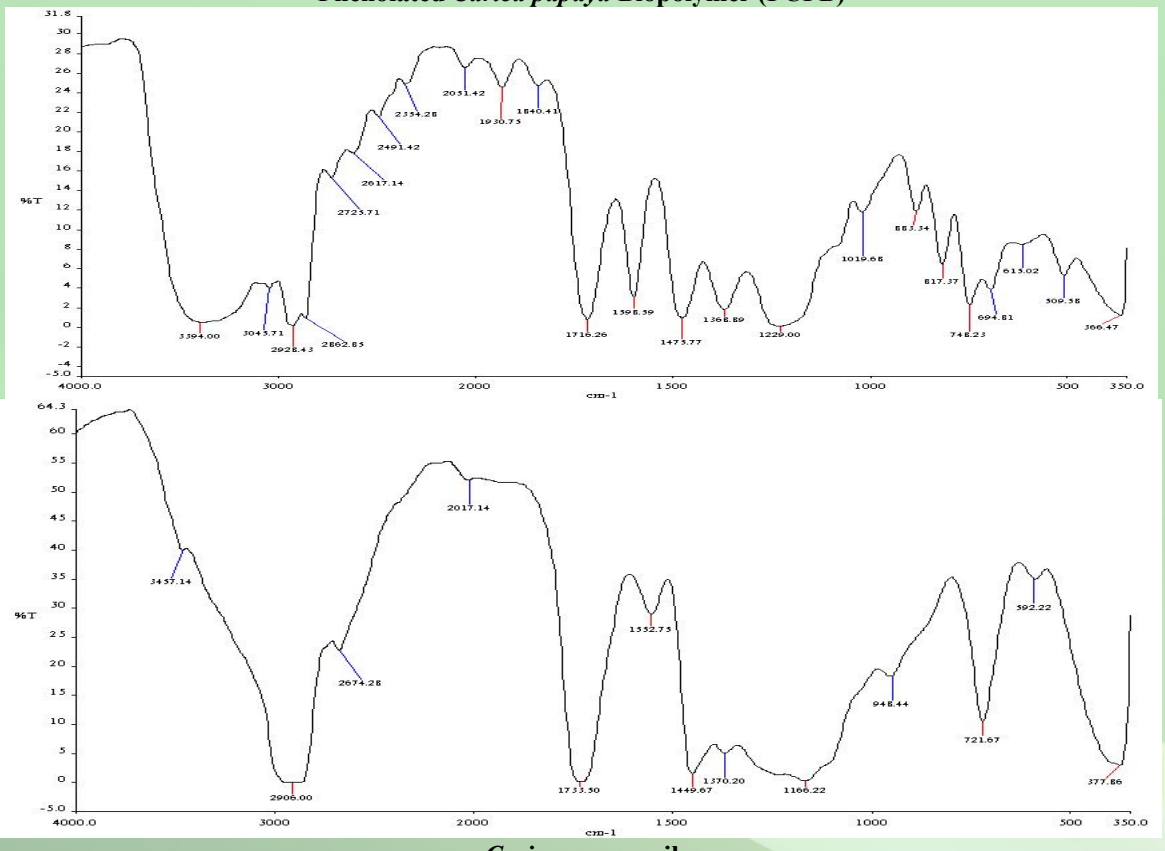
Samples	Oil yield (%)	Iodine value of oils (gI_2/100g)	Iodine value of PCPB(gI_2/100g)	Peroxide value (meq/kg)	Saponification value (mgKOH/g)	Free fatty acids (%)
Carica papaya oil	32.22	99.55±0.38	61.98±0.06	10.56±0.51	186.39±0.42	7.56±0.07



Mean value ±standard deviation (n=3).

The oil yield for this sample is 32.22%. This suggests that the oil quantity is of commercial viability for the production of oleo chemicals. It is also in the range of values reported for most oil employed for polymerization processes such as Neem seed oil, soya bean oil, rape seed oil and lots more. The oil showed an iodine value of 99.55±0.38(gI_2/100g) to suggest it's a semi drying oil. This feature shows that the oil is rich in unsaturation. Literature works on the oil confirmed it to be rich in oleic acid. This level of unsaturation suggests that the oil has potential features of been deployed into chain growth polymerization techniques, be it cationic, anionic or free radical. The PCPB showed a lesser iodine value(Table 1) to suggest that grafting of phenol to the oil(triglyceride) backbone occurred at the vinyl groups present in the oil moiety. This led to a reduction in the number of vinyl groups within the *Carica papaya* oil sample (Oladiji et al., 2010). Peroxide value is an indicator of oil's rancidity. Values lower than 10 ml/kg does not show rancidity but values around 30 to 40 ml/kg suggest that the oil may be rancid. PCPB showed a value of 10.56±0.51 meq/kg to suggest that it is extremely low in rancidity or less oxidized. A non-rancid oil gives information about its stability, the high stability of this seed oil shows that it has the potential to be modified into suitable product(s) of interest. Saponification value of the oil (Table 1) is the range coated in literatures for seed oil. The saponification value of the oil suggests that oil is rich in unsaturated fatty acids. This also complement the iodine value result and affirm the suitability of the oil for chain growth polymerization processes. The free fatty acid gives information about oil quality, a low value of free fatty acid suggests better oil and complement the peroxide value result for the sample. The oil's free fatty 7.56±0.07% to show that its of good quality and stability. The physicochemical analysis outcome suggests that the seed oil sample which is an Agricultural wastes has viable features that can convert it to useful starting material in the chemical industries. This will inevitably create a market for this agricultural waste and similar others with minimal impairment to the environment.

FTIR Analysis of the copolymer precursors and starting Agricultural Wastes



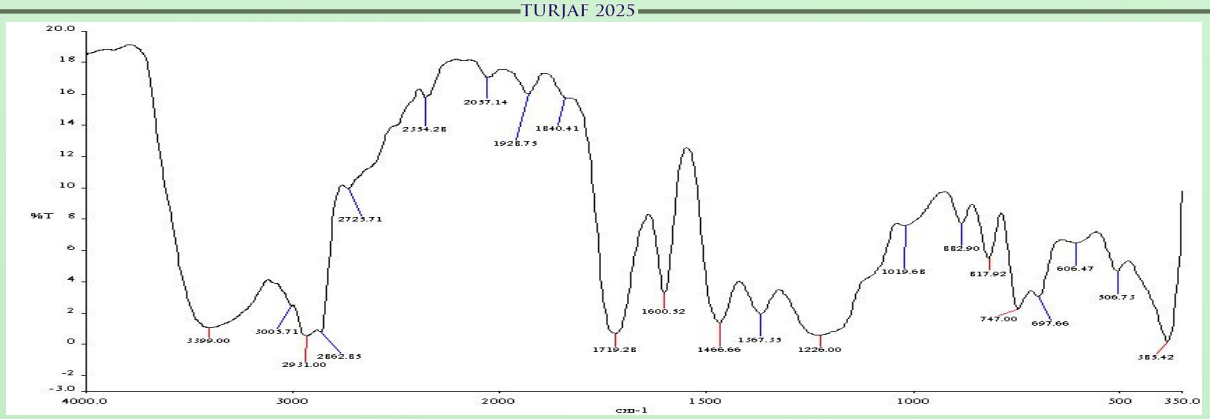
PCPB-PAA

Polyacrylamide (PAA)

Phenolated *Carica papaya* Biopolymer (PCPB)

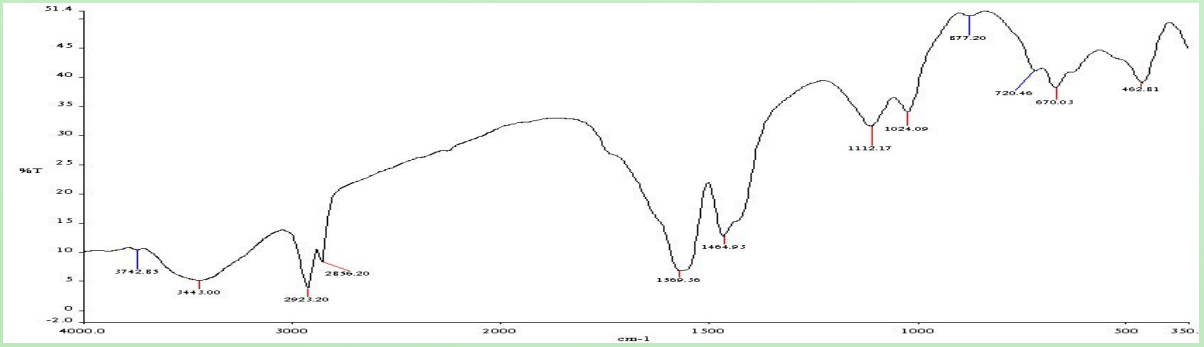
***Carica papaya* oil**

Figure 1: **FTIR spectra of the copolymer precursors and starting Agricultural Wastes**



The spectrum of *carica papaya* oil (Figure 1) showed a carbonyl group of an ester at 1733.50 cm^{-1}, C-O band at 1166.22 cm^{-1} and a C-H band at 2906.00 cm^{-1}. This bands confirmed this oil to be a fatty esters. This establishes the literature reports that triglycerides are majorly esters. The peaks at 1449.67 cm^{-1}, 948.44 cm^{-1} and 721.62 cm^{-1} confirm C-C stress and C-H bend of aromatics and vinyl groups in the triglyceride moiety. This shows that the crude sample contain some phenolic. The peak at 1552.75 cm^{-1} serves as evidence that the oil is rich in substituted alkene. This complements the result of the physiochemical parameters for the sample. This peak affirms that the oil can undergo addition polymerisation processes. The presence of ester and vinyl functional groups in this agricultural waste carica papaya seed oil show that it can be a viable feedstock in producing useful industrial chemicals precursors (Takahashi et al., 2008). The carbonyl group in the fatty ester is an evidence that the products from this feedstock will be biodegradable and photodegradable.

Polymerising phenol and the *Carica papaya* oil produced Phenol *Carica papaya* biopolymer (PCPB). The spectrum is presented in Figure 1. Strong C=O stretch of ester was found at 1716.26cm^{-1}, C-O stretch was confirmed at 1229.00cm^{-1} and 1019.68cm-1. These peaks confirmed the existence of the triglyceride in the new material. This shows that grafting did not occur at the ester/triglyceride group since there is no hydrolysis. C-C stretch band of aromatics was confirmed at 1475.77cm^{-1} and C=C. Stretching vibrations of arene occurred at 1552.75cm^{-1} to show that the new material contains phenolic. The starting material also show the presence of phenolics but the number of C-H bending vibration in PCPB outweighs those in the oil to confirm grafting (Figure 1). The oil shows two C-H bending vibrations at 948.44cm^{-1} and 721.62cm^{-1} while the PCPB showed 4 distinct C-H bending vibrations of aromatic at 883.34cm^{-1}, 817.37cm^{-1}, 748.23cm^{-1} and 694.81cm^{-1} to affirm the grafting process. O-H stretch of phenolic was similarly affirmed at 3394.00cm^{-1}. The grafted oil showed additional reactive groups through the phenolic/arene on its backbone and hence may be deployed as biodegradable alternatives alkenes in the production of materials such as bio-plastics, bio-polyvinyl chlorides and other bio-polymeric materials.



In this research, it was deployed to the production of copolymer by grafting PAA unto its backbone. The spectrum of the polyacrylamide that was synthesized showed C=O vibrational stretch at 1680.00cm^{-1}. C-N stretch band peak occurred at 2285.71cm^{-1}. C-H bend of alkenes was found around 615.02cm^{-1} to show that the PAA homopolymer is unsaturated. PCPB-PAA is the grafted copolymer material from the agricultural waste. The spectrum showed the presence of C=O stretch of esters at 1711.21cm^{-1} , C-O stretch occurred at 1025.38cm^{-1} and C-H stretch appearing as a doublet occurred at 2927.57cm^{-1} and 2862.85cm^{-1} . These peaks similarly establishes that the ester and triglyceride moiety is still present in the new copolymer material. The spectrum also showed invaluable bands at 2354.28cm-1 and 3472.24cm-1 to suggest that C-N stretch and N-H stretch are present in the new material. These bands are commonly found in amides and are absent in the starting material. They are evidences that the polyacrylamide was grafted to the PCPB backbone. The bands occurring at 1600.46cm-1, 1465.18cm-1 are due to C=C stretch of aromatics and C-C stretch of aromatics. They confirm that the phenolic group is still present in the new copolymer. C-H bend of aromatics were also found within the finger print region at 948.44cm^{-1}, 885.75cm^{-1}, 819.30cm^{-1} and 697.36cm^{-1} to affirm this observation. The multiple reactive groups in the copolymer makes it a good starting precursor for various industrial chemical synthesis. This material can therefore be a substitute to styrene, propene, but-1, 3 diene and lots more in industrial processes as a precursor (Srikanth et al., 2022). Exploring the *Carica papaya* oil also yielded another copolymer with the IR details presented in Figure 2.

The *carica papaya* and phenol *carica papaya* biopolymer (PCPB) have been earlier discussed in Figure 1. Polyacrylonitrile was employed as the second grafting parameter to the PCPB. The spectrum is presented in Figure 2. The spectrum confirms PAN bands at 1569.36cm^{-1} and 1464.93cm^{-1} stretching vibration. This occurred due to high crosslinking and ladder-like structure within the PAN homopolymer moiety. Methylene group vibration occurred at 2923.20cm^{-1} and 2856.20cm^{-1}. They are attributed to the loss of hydrogen atoms as part of the hydrogenation process. Copolymerizing the PCPB and PAN produces PCPB-PAA. The spectrum is presented in Figure 2. The spectrum showed similar features as found in the triglyceride with C=O stretch occurring at 1719.28cm^{-1} and C-O band vibration found at 1226.00cm^{-1} and 1019.68cm^{-1}. C=C stretch of alkenes/arene occurred at 1600.52cm^{-1} to affirm unsaturation within the newly synthesized PCPB-PAA material. It shows that the grafting process occurred within the vinyl moiety. The C=C bending vibrations were found at 882.92cm^{-1}, 817.92cm^{-1}, 747.00cm^{-1}, 697.66cm^{-1}, 606.47cm^{-1} and 506.73cm^{-1} as additional factors suggesting the vinyl and aromatic groups in the new copolymer. The evidence of the cross-linked polyacrylonitrile in the new material was found at 1466.66cm^{-1} and 1387.35cm^{-1} . This affirm that the Polyacrylonitrile was grafted to the PCPB backbone. ^{1}H-NMR was further used to confirm this.

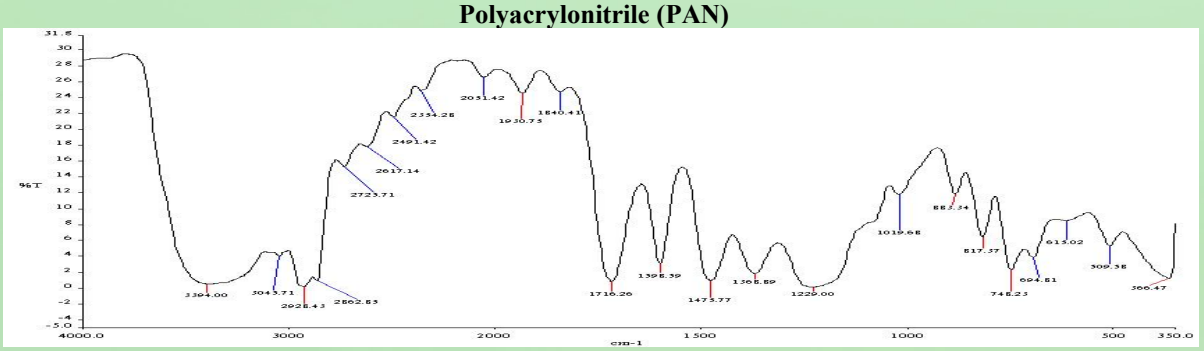


Figure 3 shows the various chemical environments in the carica papaya oil and the industrial precursors from it. The spectrum of carica papaya oil showed five different chemical environments ^{1}H NMR (400 *Carica Papaya* oil (MHz, $cdcl_3$) δ 5.47 (s, 0H), 2.44 (s, 1H), 2.14 (s, 1H), 1.41 (s, 7H), 1.01 (s, 1H). The peak at δ 5.47ppm is for vinyl protons within the oil sample. It is similarly confirmed by the FTIR result for the sample. Substituted carbonyl peaks were found at δ 2.44ppm and δ 2.14ppm as evidences for ester functional group within the oil moiety. Substituted saturated protons common to triglycerides occurred at δ1.41ppm and δ 1.01ppm as singlet. The presence of vinyl protons in the oil affirm its ability to undergo addition polymerization.

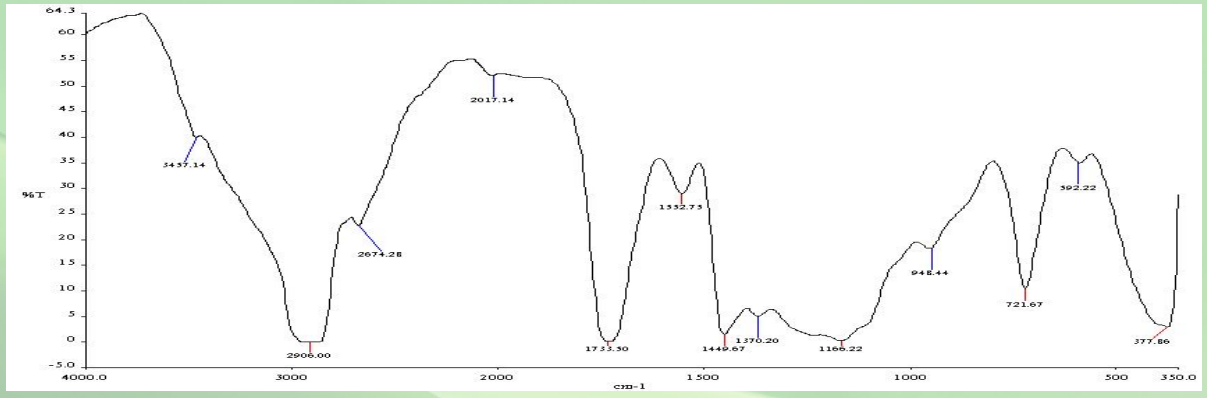

PCPB-PAN

Polyacrylonitrile (PAN)

PCPB

***Carica papaya* waste seed oil**

[1]H NMR spectra of *Carica Papaya* oil and some possible precursors

Figure 3: [1]H NMR spectra of *Carica papaya* oil and some possible precursors

Copolymerizing phenol and the carica papaya oil produced the PCPB. The spectrum is also presented in Figure 3. It shows that the new chemical environments different from those in the oil has been introduced which resulted from the introduction of the phenolic group to the oil's backbone. The chemical environments from the spectrum are highlighted as [1]H NMR of Phenol *Carica Papaya* Biopolymer (PCPB) (400 MHz, cdcl$_3$) δ 8.11 (s, 2H), 7.80 (s, 1H), 7.72 (s, 1H), 6.23 (s, 0H), 3.20 (s, 1H), 2.89 (s, 1H), 2.49 (s, 1H), 2.15 (s, 7H). The peaks at δ, 8.11ppm, δ, 7.80ppm, δ, 7.72ppm and are evidences of substituted protons in the new material. These peaks were absent in the CPO. They therefore affirm that the grafting process occurred. This result was confirmed by the FTIR details for the sample. δ,6.23ppm is also an evidence that the new product is still unsaturated. The higher downfield absorption confirms the effect of the phenolic group on the unsaturated component of the oil. Integrating Polyacrylamide to the PCPB backbone produces PCPB-PAA. The spectrum also is presented in Figure 3 and labelled. It shows several distinct chemical environments form the starting materials. [1]H NMR PCPB-PAA (400 MHz, cdcl$_3$) δ 7.18 (s, 1H), 6.86 (s, 3H), 5.52 (s, 1H), 5.36 (s, 1H), 4.15 (s, 1H), 2.36 (s, 2H), 2.28 (s, 1H), 2.02 (s, 2H), 1.94 (s, 1H), 1.27 (s, 23H), 0.89 (s, 2H), 0.82 (s, 1H). Peaks at δ 7.18ppm, δ 5.52ppm and δ , 5.36ppm

occurred due to the formation of substituted amide and occur as singlet in the spectrum. Peak at δ, 6.86ppm are evidences of highly substituted phenolic group in the new polymeric material. It affirms the presence of PCPB in the new material. The peak at δ, 4.15ppm is an evidence of phenolic protons. It further confirms the grafting process. Carbonyl peaks showing the presence of the ester and triglyceride group moiety in the new polymeric material were affirmed with peaks at δ2.36ppm, δ 2.28ppm and δ2.02ppm. Substituted allylic protons occurred at δ , 1.94ppm. They serve as new reactive centre in the new material. Several authors have confirmed that allylic centres are reactive points in vinyl compounds. Substituted saturated protons were found at δ, 1.27ppm. The large values of the singlet emanates from the hydrogenation occurring at vinyl groups and aromatic groups during the cationic polymerization processes. Other saturated protons in the spectrum are δ, 0.82ppm and δ,0.89ppm. They are further evidences for the further hydrogenation processes. Another copolymer from the PCPB was termed PCPB-PAN. It was formed by copolymerizing with PCPB and Polyacrylonitrile (PAN). The spectrum is also presented in Figure 3. The various chemical environments from the spectrum is ^{1}H NMR for PCPB-PAN (400 MHz, cdcl$_3$) δ 4.89 (q, J = 8.8 Hz, 1H), 1.94 – 1.81 (m, 3H), 1.54 (q, J = 6.5 Hz, 1H), 1.19 (s, 6H), 1.15 (q, J = 7.4 Hz, 1H), 0.96 (s, 2H), 0.90 – 0.83 (m, 4H), 0.86 – 0.76 (m, 6H), 0.41 (t, J = 6.6 Hz, 1H).

The peak at δ 4.89ppm is an evidence for the nitrile formation in the new copolymer. There are no aromatic protons in the spectrum to suggest that the phenolic group in the starting material and vinyl moiety1256that reacted with the polyacrylonitrile have been hydrogenated during the free radical reaction process. This may have resulted from the ability of the Fenton's reagent (catalyst) deployed in the reaction to form categories of intermediates and resonances which had initialized series of reaction while the polymerization was been carried out and had led to the final product observed. Peaks at δ 1.94 – 1.81 (m, 3H) range confirm allylic protons in the new material. The high level of saturation occurring at δ ppm 1.19ppm, δ1.15ppm, 0.96ppm, δ 0.90 – 0.83ppm (m, 4H), δ ,0.86 – 0.76 (m, 6H), 0.41 (t, J = 6.6 Hz, 1H) affirm that phenolic group and vinyl group had been heavily hydrogenated. The result from copolymerizing PAN and PCPB differ greatly from that observed in PAA and PCPB. The drastic observations may have resulted from the triple bonds associated with nitriles and its ease of hydrolysis with acids. The two copolymers spectra analysis affirm that polymerizing carica papaya can be depended upon in producing useful industrial precursors. The new materials shows promising functional groups like amide, arenes, vinyl groups, nitrile, esters and alcohols that can be exploited as precursors for petrochemical companies in polymer production, oil and gas industries in producing oil field chemicals (Falah et al., 2020). The viability of these precursors is in the renewability and availability. They can therefore become long term alternative to fossil fuel in keeping the chemical industries on track with minimal environmental and ecological derails.

Mean molecular weight determination

Table 2:Viscometry analysis results of synthesised Carica papaya oil biomaterials

Biomaterial	Mean Molecular weights (g/mol.)	Copolymers	Average Molecular weights(g/mol.)
PCPB	7.482 x10^{9}	PCPB-PAA	1.062 x 10^{12}
		PCPB-PAN	1.558 x 10^{12}

Keys:
Phenol *Carica papaya* biopolymer (PCPB)
Phenol *Carica papaya* biopolymer-polyacrylamide (PCPB-PAA)
Phenol *Carica papaya* biopolymer-polyacrylonitrile (PCPP-PAN),

The above molecular wrights were determined from Mark-Hauwink Sakurada techniques through the calculations of the flow rates and various viscosities like specific viscosities, intrinsic viscosities', reduced viscosity and inherent viscosity. The results of the viscometry technique are in tandem with the FTIR and ^{1}H-NMR for all the biomaterials considered. The mean molecular weight of the copolymers are greater than the starting PCPB to show that the grafting between PCPB and PAA occurred (Table 2). This was confirmed for the PCPB-PAN. The results affirmed that through various polymerization techniques, seed oils which are agricultural wastes can be used to generate using materials similar to those from petroleum industries and as alternative biodegradable feedstock source. The results showed that there is no part of the Agricultural material that is a waste. The copolymers and phenolated material from the seed oil have the potential to become viable industrial precursors through the right unit operations and unit processes.

Conclusion

The feasibility of producing industrial precursors from seed oils was examined using carica papaya seed as sampled study. The first phase of the research after sample collection and preparation was to extract oil from the carica papaya seeds. The next phase was the determination of the physicochemical properties of the oil extracted oil. The oil contains high iodine value to make it semi drying oil. Saponification value was similarly high and in the expected trend. Free fatty acid value of the oil is in the standard range to affirm no rancidity or oxidation. The third phase was to polymerized the oil with phenol to yield the phenolated intermediate which was identified as

Phenolated *Carica papaya* biopolymer(PCPB. Homopolymers of acrylamide and acrylonitrile were prepared and characterized using FTIR.

The PCPB and polyacrylamide were copolymerized using free radical polymerization method to obtain the corresponding copolymer termed PCPB-PAA. Similarly PCPB and the synthesized PAN were copolymerized to yield the copolymer termed PCPB-PAN. They were all characterized using FTIR to determine the functional groups. ^{1}H-NMR was used to determine the various chemical environments. Viscometry technique was used to measure the flow rates while Mark-Hauwink Sakurada relation was used to estimate the average molecular weights. The new copolymers showed characteristics features of ester, amide, nitrile, alcohols, arenes and vinyl to establish that they possess enough active sites that can make them viable industrial precursors and compete favourably with their counterparts form finite sources like crude oil, coal and shale oil. This research therefore creates environmentally friendly ways of converting agricultural wastes into useful starting materials for the chemical industries. This will increase the economic value of these wastes and ensures that they have improved value chain to the farmers, regions and countries where they are found in large amount such as Nigeria. They will therefore improve the nation's GDP. They are also environmentally friend and photodegradable. Hence they will contribute in mitigating the unpleasant effects of green house gases. This serves as a major route to the sustainability of the green chemistry policies and sustainable development goals (SDGs).

Acknowledgment: The Authors acknowledged the contributions of Mr. Abiodun Usman, Industrial Lab, University of Ibadan for his efforts during this research. We are also grateful to Mr. Silas for contribution to the ^{1}H-NMR analysis in Central Lab, Ahmadu Bello University, Zaria, Nigeria.

Authors' individual contribution:

Dr. Olakunle Alex Akinsanoye was involved in the experimental design, carrying out the experiment, analysis of results, financing and manuscript design.

Professor Olugbenga A. Falode was involved in the composition, result analysis, financing and proof reading of the manuscript.

Professor Mopelola Abeke Omotoso was involved in the conception of the work, financing and guide throughout the research.

Conflict of interests: The authors declare no known financial or personal conflict of interests that influence the work reported in this manuscript.

Data and Code available: Not Applicable

Supplementary information: The flow sheet and viscosity calculations are presented as supplementary information.

Ethical Approval: Not Applicable in this research.

Investigation of Factors Influencing Solubility of Whey Protein Hydrolysate-Skim Milk Powder Mixtures

Vincent Ngetich

Kenya Industrial Research and Development Institute, Kenya

Abstract

Whey protein hydrolysate (WPH) and skim milk powder (SMP) offer nutritional and functional properties of milk proteins. Physicochemical changes during rehydration alter solubility, which is an important techno-functional property of milk powders that may limit their regular usage in food products such as ready-to-drink beverages. This study explored how mixing WPH with SMP and chelating salt affects its solubility in a protein mix. SMP34 and WPH80 were mixed in various ratios, with trisodium citrate added at concentrations from 0 to 2.5% and rehydrated in ultrapure water. The effects of SMP and trisodium citrate on the solubility of WPH, particle size distribution, zeta potential, buffering capacity, pH and colour were investigated. The resulting data were analyzed using Minitab version 14. At 10% and 20% SMP-WPH total solids content (w/v) blend, solubility increased significantly ($P< 0.05$) from 68.9 to 63.5%. There was no significant ($P>0.05$) effect observed on zeta potential with increasing trisodium citrate concentration in the mixtures. However, the protein mixtures demonstrated colloidal stability. The study demonstrated an increase in the solubility of milk protein powder blends with the addition of trisodium citrate, potentially increasing the value of dairy ingredients and their application in new categories of ready-to-drink protein beverages.

Assessing The Physicochemical Composition And Wide Diversity Of Pollen In Honey Samples Procured From Some Markets In Umudim Local Government Area Of Anambra State

Nchedochukwu C. Ikegbunam[1*], Okwong J. Walter[2], Emeka E. Osayi[3], Chiedozie A, Anukwuorji[1]

[1]Department of Botany, Nnamdi Azikiwe University, Along Enugu-Onitsha Expressway, Ifite Road, 420110
[2]Centre for Biodiversity Conservation and Ecosystem Management, University of Lagos Akoka Yaba Lagos
[3]Department of Plant Science and Biotechnology Laboratory, University of Nigeria Nsukka, 410001 Nsukka, Nigeria.

Abstract

A range of honey varieties can be found in Nigerian markets. In the present study, a comprehensive analysis of four honey samples collected from various locations (Eke Osu, Afor Eziama, Eke Amichi and Nkwo-Igbo) in Umudim Local Government Area of Anambra State was carried out with the aim of evaluating the wide diversity of pollen and physicochemical composition of the honey samples using standard methods. A total of forty six (46) distinct pollen types in 22 plant families were recorded. Inclusively, the varying percentage counts of the entire samples were: 650 (22.26%) in Eke osu, 825 (28.25%) in Afor Eziama, 755 (25.86%) in Eke Amichi and 690 (23.63%) in Nkwo Igbo. The frequency class highlighted the presence of pollen types such as *Allophylus africanus*, *Lannea acida*, *Piliostigma* sp. and *Elaeis guinensis*, which were classified as secondary types. The results of the physicochemical composition showed that the samples had pH values ranging from 4.00 - 5.00, moisture (7.60% - 8.21%), ash (0.09% - 1.20%), protein (1.36% - 1.98%), fat (1.05% - 1.43%), polyphenol (60.73% - 84.48%); free acidity (46.00 - 59.00 meq kg-1) and HMF (46.60 – 54.40 mg/kg). Sugar composition analysis showed that the recorded values of fructose and glucose were: Eke osu (57.00±1.73 Mg/100g), Afor Eziama (50.00±0.58 Mg/100g), Eke Amichi (49.00±0.11 Mg/100g) and Nkwo Igbo (53.00±0.33 Mg/100g) for fructose; Eke Osu (43.00±1.15 Mg/100g), Afor Eziama (44.00±0.58 Mg/100g), Eke Amichi (39.00±0.81 Mg/100g) and Nkwo Igbo (49.00±0.42 Mg/100g) for glucose. Higher values were recorded for sucrose. The results demonstrated that most of the parameters aligned with recommended standard of quality honey. Hence, they are good for human consumption.

Morphological Characteristics of Apple Genotypes in Mudurnu (Bolu)

Tuba Bak[1*], Levent Kırca[1]

[1]Department of Horticulture, Faculty of Agriculture, Pamukkale University, Çivril, Denizli, Türkiye
[*]Sorumlu yazar: tubabak81@gmail.com

Abstract

This research was carried out in the Mudurnu district of Bolu province to determine the morphological and chemical properties of 17 apple genotypes. Fruit and seed properties and soluble solids content, pH, titratable acidity, and fruit color (L*, a*, b*, chroma*, and hue°) were examined. Descriptive statistical analysis, principal component analysis, and hierarchical clustering analyses were used to determine the morphological and chemical properties of the genotypes. Fruit weights were determined as 29.06-126.30 g, fruit width as 30.55-74.00 mm, fruit flesh firmness as 2.40-7.00 kg/cm^2, soluble solids content as 12.00-18.21%, and pH as 2.93-5.30 in the examined genotypes. It was determined that G3 and G13 genotypes differed from the other genotypes regarding the examined properties. The genetic diversity identified in this study provides a valuable foundation for breeding programs aimed at developing new apple cultivars that are adapted to regional conditions and meet market demands. Particularly, the distinct genotypes such as G3 and G13 are significant due to their potential use as parents in future selection studies or hybridization programs.

Key Words: *Apple, Genotypes, Selection, PCA, Pomological characteristics*

Introduction

Anatolia, thanks to the ecological opportunities offered by various climate zones and soil structures, allows the growth of many fruit species. Among these fruit species, the apple belongs to the *Malus* genus of the *Rosales* order, *Rosaceae* family, and *Pomoideae* subfamily (Kaşka, 1977). Its origin is the South Caucasus region, including Anatolia (Özbek, 1978). Apple, open to foreign pollination, produces many genotypes with the germination of heterozygous seeds. Today, many local and cultural apple varieties have emerged with selection studies conducted with genotypes (Karadeniz et al., 2013). There are 6,500 local apple varieties worldwide, and approximately 500 in Türkiye, suitable for different ecologies (Özmen and Çekiç, 2021).

The emergence of superior genotypes through targeted selection with selection breeding is an important step. Genotypes grown from natural seeds are valuable sources for increasing the quantity and quality of essential traits such as adaptation to ecological conditions, fruit characteristics, resistance to abiotic and biotic stresses, and nutritional quality due to environmental factors. The emergence of genotypes showing these superior traits is possible with selection breeding studies. Many researchers have used morphological and biochemical markers to reveal genetic diversity (Kaya and Balta, 2009; Bostan and Yılmaz, 2015; Vurgun and Aslantaş, 2016; Kara, 2022; Dumanoglu et al., 2018; Korkmaz and Okatan, 2021; Alan et. al., 2024), molecular (Vurgun, 2012; Güneş, 2017; Daler et al., 2017; Doğru Çokran et al., 2019; Koçyiğit, 2022; Bakır et al., 2022). Although these parameters are affected by genetic structure and environmental conditions, they provide valuable information about the differences and similarities between genotypes (Ebrahimi and Alipour, 2020). It is essential to maintain apple genetic diversity. The basic step in variety development and improvement is to collect and evaluate local germplasm. Multivariate analysis effectively interprets the relationships between genotypes for germplasm characterization (Al-Halabi, Muzher, 2015). This research aimed to determine the fruit traits of apple genotypes in Mudurnu/Bolu province and to reveal their diversity using multivariate analysis methods.

Material and Methods

This research was conducted on 17 apple genotypes grown from seeds found in nature in the Mudurnu district of Bolu province, where no cultural practices were applied. Ten fruit samples were selected to represent each genotype for evaluation. Fruit weight (g) and seed weight (g) were measured with a precision scale, and fruit length (mm), fruit width (mm), seed width (mm), and seed length (mm) were measured with a digital scale. Seed number was obtained by counting the seeds in the carpel of each genotype. Fruit flesh firmness (kg/cm^2) was determined with a hand penetrometer. Soluble solids content (SSC) (%) were determined with a hand refractometer. pH was determined using a pH meter and the titratable acidity (TA) titration method as a percentage. Fruit taste was determined by five panelists giving a score between 1-5. Fruit color (L*, a*, b*, Chroma*, and Hue°) was determined with a colorimeter.

Statistical Analysis

Descriptive statistical analysis was performed for fruit traits of genotypes. Principal Component Analysis (PCA) and Hierarchical Cluster Analysis were conducted to determine the relationships between the examined fruit traits and genotypes. JMP software was used in statistical analyses.

Results and Discussion

Descriptive statistical data of the characteristics examined in apple genotypes are given in Table 1. The analyzed genotypes showed wide variation. The coefficients of variation of the traits studied in genotypes varied between 8.92% (Seed length) and 69.68% (TA). It was determined that fruit and seed weight, seed number, TA, a*, b*, and Hue^o values had high variation (% CV ≥ 35.00). This variability shows that some traits showed more variance than others. A high CV value can clearly distinguish the genotypes regarding these traits and indicate diversity and variability. It was determined that a lower % CV ≤35.00) was found in other pomological characteristics examined. This situation shows that apple genotypes are more consistent regarding these traits.

Fruit weight ranged between 29.06 and 126.30 g, and the coefficient of variation was 36.78% (Table 1). Fruit weight was determined as 26.59-273.75 g by Özmen and Çekiç, (2021), 65.40-205.30 g, Balta et al. (2015), 71.41-245.99 g, Kırkaya et al. (2014) 76.24-247.23g, Uzun et al. (2016) 75.52-191.95 g, Macit and Aydın (2021) 59.3-220.8 g, Özrenk et al. (2011), 20.90-139.30 g, Macit et al. (2021) reported it as 27.56-269.32 g. In our research, fruit length and width varied between 32.38-60.35 mm and 30.55-74.00 mm, respectively. The coefficients of variation are 12.44% and 15.10%, respectively. Fruit length and width were reported as 53.17-81.77 mm and 62.97-91.87 mm by Yarılgaç et al. (2009), 50.3-73.06 mm and 51.65 mm - 75.34 mm by Çöçen et al. (2019), 50.96-78.95 mm and 61.01-95.59 mm by Karadeniz et al. (2013) reported it as 53.14-62.07 mm and 63.46-73.79 mm, Bostan and Acar (2009) as 43.85-74.61 mm and 53.40-86.60 mm, Kırkaya et al. (2014) as 69.03-89.03 mm and 60.96-73.98 mm, Uzun et al. (2016) as 46.81-65.57 mm and 60.61-78.60 mm, Macit and Aydın (2021) as 48.3-67.3 mm and 50.4-85.0 m, Özrenk et al. (2011) as 32.8-54.3 mm and 35.4-60.3 mm. Findings from other researchers show a wide range of these properties. These findings show similar results to previous studies, but some differences may be due to genotypic and ecological conditions, especially genetic structure. Indeed, fruits are characterized by different shapes and sizes. Still, each fruit originates from the development of a single growing meristematic point, and the final size depends on the number of cell divisions and cell expansion during the development of the ovary and fruit. Individual fruit shape and size are determined by the fruit's genetics, phytohormones, and environment (De Mori and Cipriani, 2023) and can vary significantly among different genetic materials (Kumar et al., 2012).

In the genotypes, SSC varied between 12-18.21%, pH between 2.93-5.30, and TA between 0.17-1.88%. TA gave the highest coefficient of variation among the examined traits, at 69.68% (Table 1). Similarly, other researchers reported the SSC, pH and TEA values as 9.2-19.7%, 4.0-5.2%, 0.21-1.40% (Özmen and Çekiç, 2021), 8.40-14.25%, 3.03-4.10, and 0.16-1.08% % (Karakaya et al., 2016), 10.62-13.85%, 3.60-4.82% and 0.699-0.929% (Yarılgaç et al., 2009), 10.07-14.10%, 2.20-3.65% and 0.66-1.12% (Çöçen et al., 2019), 9.40-13.60%, 2.83-4.11% and 0.22-2.01% (Balta et al., 2015). In addition, Osmanoğlu and Balta (2021) reported the SSC values as 9.00-15.00%, Şenyurt et al. (2015) as 11.50-15.25%, and TA as 0.20-1.24%. Findings give slightly higher results than the findings of other researchers. However, SSC is one of the essential quality criteria in fruits, and SSC increases as fruit maturity progresses and reaches the maximum level on the harvest date. It is essential to evaluate SSC and other parameters such as TA and fruit flesh firmness, especially in determining maturity (Yer and Erdoğan, 2022).

In the genotypes examined, seed weight was determined as 0.12-0.55 g, seed length as 6.07-9.38 mm, seed width as 2.71-5.41 mm, and seed number as 1-10 (Table 1). They reported seed weight, seed length, seed width and seed number as 0.20-0.55 g, 7.46-10.59 mm, 3.84-5.58 mm and 3.5-10 pieces (Yarılgaç et al., 2009), 0.02-0.08 g, 7.23-9.11 mm, 3.45-5.28 mm and 3.50-7.25 pieces (Bostan and Acar, 2009), 0.20-0.55 g, 7.46-10.59 mm, 3.84-5.58 mm and 3.5-10 pieces (Karadeniz et al., 2013), respectively. Findings are parallel to those of other researchers.

Fruit flesh firmness values varied between 2.40-7.00 kg/cm^2, while fruit taste took values between 2-5 (Table 1). Fruit flesh firmness has been reported as 9.46-10.33 kg/cm^2 (Karadeniz et al., 2013), 6.45-10.90 kg/cm^2 (Uzun et al., 2016), 6.27-9.39 kg/cm^2 (Şenyurt et al., 2015), 5.04-9.40 kg/cm^2 (Çöçen et al., 2019), 4.33-7.11 kg/cm^2 (Karataş, 2021). Fruit ripening is a complex process that includes flavor, color, cell wall changes and softening, starch degradation, and aroma development, and contributes significantly to distinctive fruit qualities (De Mori and Cipriani, 2023). Fruit firmness is one of the most important quality characteristics in consumer preferences, and fruit firmness may vary depending on variety, location, and environmental factors (Kumar et al., 2018). This research findings are similar to the results of other researchers regarding fruit flesh firmness.

Fruit color values of the genotypes were measured as L*, a*, b*, Chroma*, and hue° values between 29.08-74.70, 7.09-38.50, 7.51-44.19, 13.60-45.83, respectively. The coefficients of variation of the fruit color values generally gave high values for the examined traits and these values were determined as L* 22.99%, a* 35.47%, b* 46.41, Chroma* 25.69% and hue° 49.39% (Table 1). . Özmen and Çekiç (2021) reported L* 42.31-79.96, a* 21.91-27.47, and b* values between 20.79-45.22. In addition to genetic and transcriptional regulation, environmental factors such as light, temperature, water, sugars, plant hormones, and anthocyanin biosynthesis may also be effective in the formation of color in apples (Chen et al., 2021).

The results of the heatmap hierarchical clustering analysis showing how apple genotypes are grouped according to their similarities are given in Figure 2. The heatmap shows the similarities and differences between the samples and the examined traits with a color scale. Red tones represent high values, and blue tones represent low values. The figure shows that 17 apple genotypes are clearly divided into different clusters. G3 and G13 genotypes (marked in green) form a separate cluster from the other genotypes, showing high values especially in fruit weight, fruit length, and color parameters (L*, b*, Hue°, Chroma). Regarding SSC, the G3 genotype differs from all genotypes, especially from the G9 genotype. Indeed, (Mir et al., 2017) reported a similar situation. Within the main cluster, G1, G12, G16, G7, G14, G8 and G2 genotypes form a subcluster; The genotypes G4, G6, G9, G10, G11, G5, G17 and G15 form another sub-cluster. It is observed that the genotypes show significant differences, especially in the seed number, TA, and a* parameters. The clustering between the traits in the lower part of the dendrogram shows that the fruit traits (weight, length, width) and color parameters (L*, b*, Hue°, Chroma) are closely related.

PCA analysis provides essential information about which traits can be evaluated together in breeding programs while determining the selection criteria of genotypes within populations. Principal Component Analysis (PCA) results effectively reveal the variation in pomological and biochemical traits of the examined apple genotypes. The first five principal components (PC) explain 80.09% of the total variation (Table 2). PC1 is the most effective component with 26.61% variation and has positive loadings, especially on color parameters (L*, b*, Chroma*, and Hue°) and fruit sizes (weight, length, and width). PC2 represents 19.92% variation and shows positive loadings on fruit weight, fruit width, and taste parameters, as well as negative loadings on the flesh firmness parameter. When the relationships between genotypes and traits distributed on PC1 and PC2 axes are examined in the biplot graph, G3 and G13 genotypes stand out with positive values on the PC1 axis. In contrast, G6, G10, and G4 genotypes differ on the PC2 axis (Figure 2). The close positioning of fruit width, weight, and length vectors shows that these traits are strongly correlated. While color parameters (L*, b*, Hue°) are positively grouped on the PC1 axis, fruit flesh firmness is negatively prominent on the PC2 axis. Similarly, Mir et al. (2017) reported that the first component is related to fruit color, while SSC values are related to the fourth component.

Table 1. Descriptive statistics of apple genotypes in terms of examined traits.

Traits	Min.	Max.	Mean	±Std Dev	CV%
Fruit weight (g)	29.06	126.30	58.21	21.41	36.78

Conclusion

This research investigated the pomological and biochemical properties of 17 apple genotypes collected from the Mudurnu/Bolu region. The research results revealed significant variation among the examined apple genotypes. A wide variation was observed in fruit weight (29.06-126.30 g), fruit length (32.38-60.35 mm), fruit width (30.55-74.00 mm), SSC (12.00-18.21%), pH (2.93-5.30), TA (0.17-1.88%) and fruit flesh firmness (2.40-7.00 kg/cm²) values. TA (69.68%) and color parameters (Hue° 49.39%, b* 46.41%) especially attracted attention due to their high coefficients of variation. According to PCA results, the first five components explained 80.09% of the total variation, PC1 (26.61%) was found to be effective especially on color parameters and fruit sizes, and PC2 (19.92%) was found to be effective on fruit weight, width, and taste. Hierarchical cluster analysis revealed that G3 and G13 genotypes were separated from other genotypes and showed superior characteristics, especially in fruit weight, length, and color parameters. Strong relationships were determined between fruit characteristics and color parameters. This research has made significant contributions to the characterization of apple genetic resources in the Mudurnu region, and the superior genotypes (especially G3 and G13) can be considered as parents in future breeding studies. In addition, the trait groups determined as a result of PCA and cluster analysis provide essential information on which traits can be evaluated together while establishing selection criteria in apple breeding programs. As a result, this study has provided valuable data for protecting, evaluating, and using regional apple genetic resources in breeding programs.

Conflict of interest statement

The authors declare that there is no conflict of interestregarding the publication of this paper.

Biological Characterization of Tomato brown rugose fruit virus-Antalya Isolates

Derya DEMİRALAN, Eminur ELÇİ

Plant Production and Technologies Department, Agricultural Sciences and Technologies Faculty, Niğde Ömer Halisdemir University, Niğde, Türkiye
Correspondence: eminur@gmail.com

Abstract

Tomato brown rugose fruit virus (ToBRFV, genus *Tobamovirus*) is a major pathogen of *Solanaceous* crops in the world. ToBRFV presents a significant and destructive threat to tomato and pepper plants. Türkiye, an important player in the global tomato supply chain, contributes approximately 13 million metric tons annually, ranking it third worldwide in production volume, following China and India. The majority of the production takes place under greenhouse conditions in the Mediterranean Region of Türkiye. Noteworthy, Antalya, Bursa, and Manisa provinces emerged as the foremost tomato-producing regions in 2023. Therefore, the virus inoculum sources used in this study were obtained from Antalya province. The main objective of this study was to investigate ToBRFV symptom characterization in host plants. For this purpose, in 2024, tomato and pepper varieties were mechanically inoculated with ToBRFV, and disease severity was assessed using a standardized disease severity index. In order to establish a control group, mock inoculated plants were used for each variety. The results revealed that some varieties exhibited severe symptoms, while others showed moderate symptoms, and one variety exhibited only mild symptoms. Based on these symptoms, some varieties are considered to be highly susceptible, others are susceptible and one shows tolerance. A key strategy for management of viral diseases is the development and deployment of resistant cultivars, for which disease epidemiology is crucial.

Key Words: *Tobamovirus fructirugosum, tomato, pepper, mechanical inoculation, disease severity index*

Introduction

The cultivated tomato, *Solanum lycopersicum* belongs to the *Solanaceae* family, a taxon of considerable global economic and agricultural significance. Tomatoes represent a substantial dietary source of essential micronutrients, notably vitamins C and E, the carotenoid lycopene (constituting approximately 80% of total carotenoids), folate, and various flavonoids (Willcox et al., 2003). The substantial nutritional value of tomatoes, attributed to their rich vitamin content and inherent antioxidant properties, underscores their status as a globally significant horticultural crop (Viuda-Martos et al., 2014). Specifically, lycopene, a red carotenoid pigment prevalent in tomatoes and processed products like ketchup, has been quantified in the range of 9.9–13.44 mg per 100 g (Story et al., 2013). This carotenoid contributes significantly to the antioxidant capacity and potential health benefits associated with tomato consumption. According to data released by the Food and Agriculture Organization of the United Nations (FAO) in 2023, the annual global tomato production reached approximately 186 million metric tons. Türkiye, a key player in the global tomato supply chain, contributes approximately 13 million metric tons annually, ranking it third worldwide in production volume, following China and India (TÜİK, 2023).

Tomatoes are cultivated in either small or large quantities across numerous regions of Türkiye. The majority of the production takes place under greenhouse conditions in the Mediterranean Region, particularly in Antalya. The other significant tomato-producing regions within Türkiye include the Aegean and Marmara regions. Noteworthy, in 2023, Antalya, Bursa, and Manisa provinces emerged as the foremost tomato-producing regions. Mersin, Çanakkale, Muğla, Tokat, and Çanakkale are significant provinces where tomato production is focused on table tomatoes. A substantial portion of the production in Izmir, Manisa, Balıkesir, and Şanlıurfa is evaluated in the production of tomato sauce.

Tomato cultivation is persistently challenged by a variety of pests and pathogens, among which viruses represent a significant threat to production. Prominent viral pathogens affecting tomatoes include cucumoviruses, tospoviruses, begomoviruses, potyviruses, and tobamoviruses. Among these, the Tobamovirus genus holds particular significance, as it encompasses several highly destructive pathogens such as tomato mosaic virus (ToMV), cucumber green mottle mosaic virus (CGMMV), tobacco mosaic virus (TMV), pepper mild mottle virus (PMMoV), and tomato mild mottle virus (ToMMV). Recently, tomato brown rugose fruit virus= Tobamovirus fructirugosum (ToBRFV) has emerged as a rapidly spreading RNA virus, primarily targeting peppers and tomatoes, with tomatoes being its primary host.

In tomatoes, ToBRFV infection is characterized by mosaic patterns, dark green blistering, yellow mottling, and leaf deformation, and narrowing of the leaves. Affected fruits exhibit yellow blotches, necrotic spotted, and brown rugose or wrinkled patches often resulting in loss of fruit yield (Salem et al., 2023). While tomato and pepper are

recognized as primary natural hosts, ToBRFV exhibits a broader host range. Experimental inoculation has demonstrated symptomatic infection in *N. glutinosa*, *N. tabacum*, *N. benthamiana*, and *N. sylvestris*. Furthermore, the observation of ToBRFV symptoms in weed species, such as *Solanum nigrum* and *Chenopodiastrum murale*, suggests their potential role as viral reservoirs, facilitating the persistence and spread of ToBRFV (EPPO, 2020).
ToBRFV is noted as a seed-borne virus, with contaminated seeds serving as the primary vector for long-distance dissemination. While mechanical contact facilitates short-distance spread, long-distance transmission occurs predominantly through infected seeds and fruits. The agricultural workers' hands, tools, shoes, and clothes can mechanically spread the virus, as well as plant-to-plant contact between infected and healthy plants (Salem et al., 2016). ToBRFV-infected plants exhibited 100% contamination from the seeds of tomatoes harvested. But just externally on the seed coat of tomato, ToBRFV was determined. Transmission appeared at a low rate from seed to seedling from the contaminated seeds. However, no evidence currently supports transmission by arthropod vectors. The Bombus terrestris (bumblebee) beneficial pollinator can carry away the primary inoculum of ToBRFV, thereby promoting the spread of ToBRFV in tomato crops cultivated in glasshouses or net houses (Dombrovsky et al., 2017; Levitzky et al., 2019).
ToBRFV has been listed in quarantine status in the European Union (EU) countries. Since there is no chemical control in viral diseases, the disease has gained even more importance. ToBRFV management is prevention of infection, hygiene, phytosanitary measures, host resistance, disinfection, biocontrol, and gene editing (Salem et al., 2023). Moreover, ToBRFV is one of the most new major virus diseases in tomato plants in our country. Therefore, the main purpose of this study is characterization of symptoms on tomato varieties and pepper.

Materials and Methods

Materials

This study evaluated the performance of five tomato (*Solanum lycopersicum*) varieties, one pepper (*Capsicum annuum*) variety and one wild-type tomato accession *Solanum pimpinellifolium* (LA1651-used as a control). Commercially available tomato varieties included Rio Grande, H2274, and Pintek. The local tomato and pepper cultivars were “Sazlıca tomato” and “Bor pepper”. Pintek and *S. pimpinellifolium* (LA1651) were specifically included due to their reported resistance or tolerance levels to ToBRFV. ToBRFV-infected tomato plant material, used as the inoculum source, was obtained from the T.R. Ministry of Agriculture and Forestry Plant Health Department, Batı Akdeniz Agricultural Research Institute (BATEM). The experiments were conducted within the controlled greenhouse environment and virology laboratory of the Department of Plant Production and Technologies, Niğde, Türkiye.

Methods

Experimental design

Given the highly contagious and deleterious nature of ToBRFV, this research was conducted in the controlled environment of a greenhouse at the Department of Plant Production and Technologies, Niğde Ömer Halisdemir University, Niğde, Türkiye, during the summer of 2024. The recorded highest average temperature was 35°C, while the lowest was 25°C throughout the summer season. The entire process was conducted between May and August. During this period, the average night temperature was 18°C, and the average daytime temperature reached 27°C in the Niğde province.

Seed Germination

In 2024, the tomato and pepper seeds were sown in the seed viols and subsequently, they were allowed to germinate within the same viols. The each viols includes thirty two holes, and a total of seven seed viols were used for each variety. A total of two hundred ten tomato seeds were sown and each variety included thirty seeds and the pots were utilized for transplanting and a total thirty pots were used for each variety.

Seedling Transplanting

Tomato seedlings were transplanted into pots after the germination of seeds. The seed viols were filled with a mixture of perlite and peat in a ratio of 3:1 while 210 plastic pots were filled with soil and a mixture of peat and perlite (3:1), respectively. For each variety, 30 pots were used and pots contained a total of 150 tomato seedlings and 30 Bor pepper seedlings. Also, the were used total of 30 plants as a control. The tomato and pepper seedlings were irrigated before transplantation and the following day, they were transplanted into the pots. The pots were regulated and labelled according to their properties in order to facilitate identification and the tomatoes were irrigated daily.

Mechanical inoculations of tomato and pepper plants

Following the confirmation of ToBRFV infections on tomato and tobacco plants by symptomatic and molecular analyses, fresh tomato leaves were utilized as an inoculum source for mechanical inoculations on both tomatoes and pepper plants. The leaf samples were manually ground with an inoculation buffer (pH: 7.4) consisting of 1.14 g/l Na_2HPO_4, 0.199 g/l KH_2PO_4, 1% PVP-40, and 0.1% Na_2SO_3. The inoculation was conducted on June 2024. Reinoculations were done after 10-14 days. In order to established a control group mock inoculated plants were used for each variety. The symptoms exhibited by tomato and pepper plants were observed 10 days after the mechanical inoculation and symptoms were monitored for 4 weeks for disease severity index evaluation.

Disease Severity Index (DSI) Evaluation

Following a 30-day period after mechanical inoculation, the severity of ToBRFV symptoms was evaluated using a modified disease severity index (DSI). The evaluation of plant symptoms was conducted in accordance with the 0 to 3 scale reported by Zinger et al. (2021). The DSI employed a 0-3 scale to visually assess symptom development in the inoculated plants. Alongside the DSI assessment, the percentage of ToBRFV-infected plants was also determined. DSI values were then calculated using the formulas (Figure 1) (Kabas et al., 2021; Chiang et al., 2017).

$$DSI(\%) = \frac{\text{Class frequency x score of rating class}}{\text{(Total number of observations) x(Maximal disease index)}} \times 100$$

Figure 1 . Disease severity index formulas

Results and Discussion

Virus Symptom Observations on Inoculated Plants

The study includes a total plant of 150 tomatoes and 30 pepper plants inoculated with ToBRFV on May under greenhouse conditions. All inoculated plants showed ToBRFV symptoms and were mostly observed on the leaves of the plant. The onset of symptoms was observed between 10 and 15 days following inoculation and the most common symptoms included mosaic of dark and light green, chlorotic, blistering, narrowing, leaf curling, and mottling observed on tomato and pepper plants.

H2274 and Pintek tomato varieties showed the same symptoms like malformation and deformation of leaves, narrowing, blistering, and very severe mosaic and mottling symptoms on leaves. Sazlıca and Rio Grande tomato varieties showed similar symptoms such as severe mosaic and yellow or green spotting, blistering, and upward curling edges of leaves. Moreover, Bor pepper variety showed symptoms such as mild mosaic and narrowing symptoms of leaves. In addition, the wild type of tomato (*S. pimpinellifolium*) showed symptoms very mild mosaic and mottling symptoms (Figure 2).

ToBRFV -Disease Severity Indices of tested plants

To demonstrate the impact of ToBRFV on tomato and pepper plants, a scale was constituted by ranking the plants from mild to severe (0 to 3). When creating the disease severity scale, the plant exhibiting the least symptoms was assigned a value of 1, while the plant exhibiting the most symptoms was assigned a value of 3. The plant disease value 1 was selected from infected plants with slight chlorosis, and mosaic form on leaves. Plant disease value 2 was selected from infected plants with severe mosaic form and blistering on leaves. Plant disease value 3 was selected from infected plants with very severe leaf narrowing, blistering on the leaf and wilt. This score rate is intraspecific and interspecific of varieties.

Moreover, to evaluated and determined H2274, Pintek, Sazlıca and Rio Grande tomato varieities symptom score value was 3 and Pintek, Sazlıca, Rio Grande, Bor pepper and *S. pimpinellifolium* tomato vaieities symptom score value was 2 also just bor pepper and *S.pimpinellifolium* varieties symptom score value was 1 after the thirty days of inoculation (Figure 3).

Furthermore, the highest infection value was observed in H2274 tomatoes, with a 100% rate, followed by Pintek varieties at 93.3%. In contrast, the wild type of tomato variety (*S.pimpinellifolium*) development the lowest infection rate of with 70% (Table 1).

The objective of this study was to characterize symptoms of ToBRFV on tomato and pepper varieties. Characteristic symptoms were included leaf deformation, mosaic patterns, green or yellow mottling, and leaf narrowing. Symptom onset occurred between 5 to 10 and 15 days post-inoculation. These findings are consistent with those reported by Salem et al. (2023), who observed similar symptoms of leaf mottling, mosaic, and narrowing in tomato plants infected with ToBRFV. Further, in the H2274 and Pintek tomato varieties, we observed symptoms such as leaf malformation, deformation, narrowing, leaf deformation, and severe mosaic and mottling. In the Sazlıca and Rio Grande varieties, severe mosaic, yellow or green spotting, leaf deformation, and upward leaf curling were prominent. Interestingly, milder symptoms, including mild mosaic and leaf narrowing, were observed in the wild-type tomato (*S. pimpinellifolium*) and Bor pepper varieties. Furthermore, Jewehan et al. (2021) reported that they observed very mild mosaic symptoms in *S. pimpinellifolium* tomatoes or no symptoms similar to those in this study.

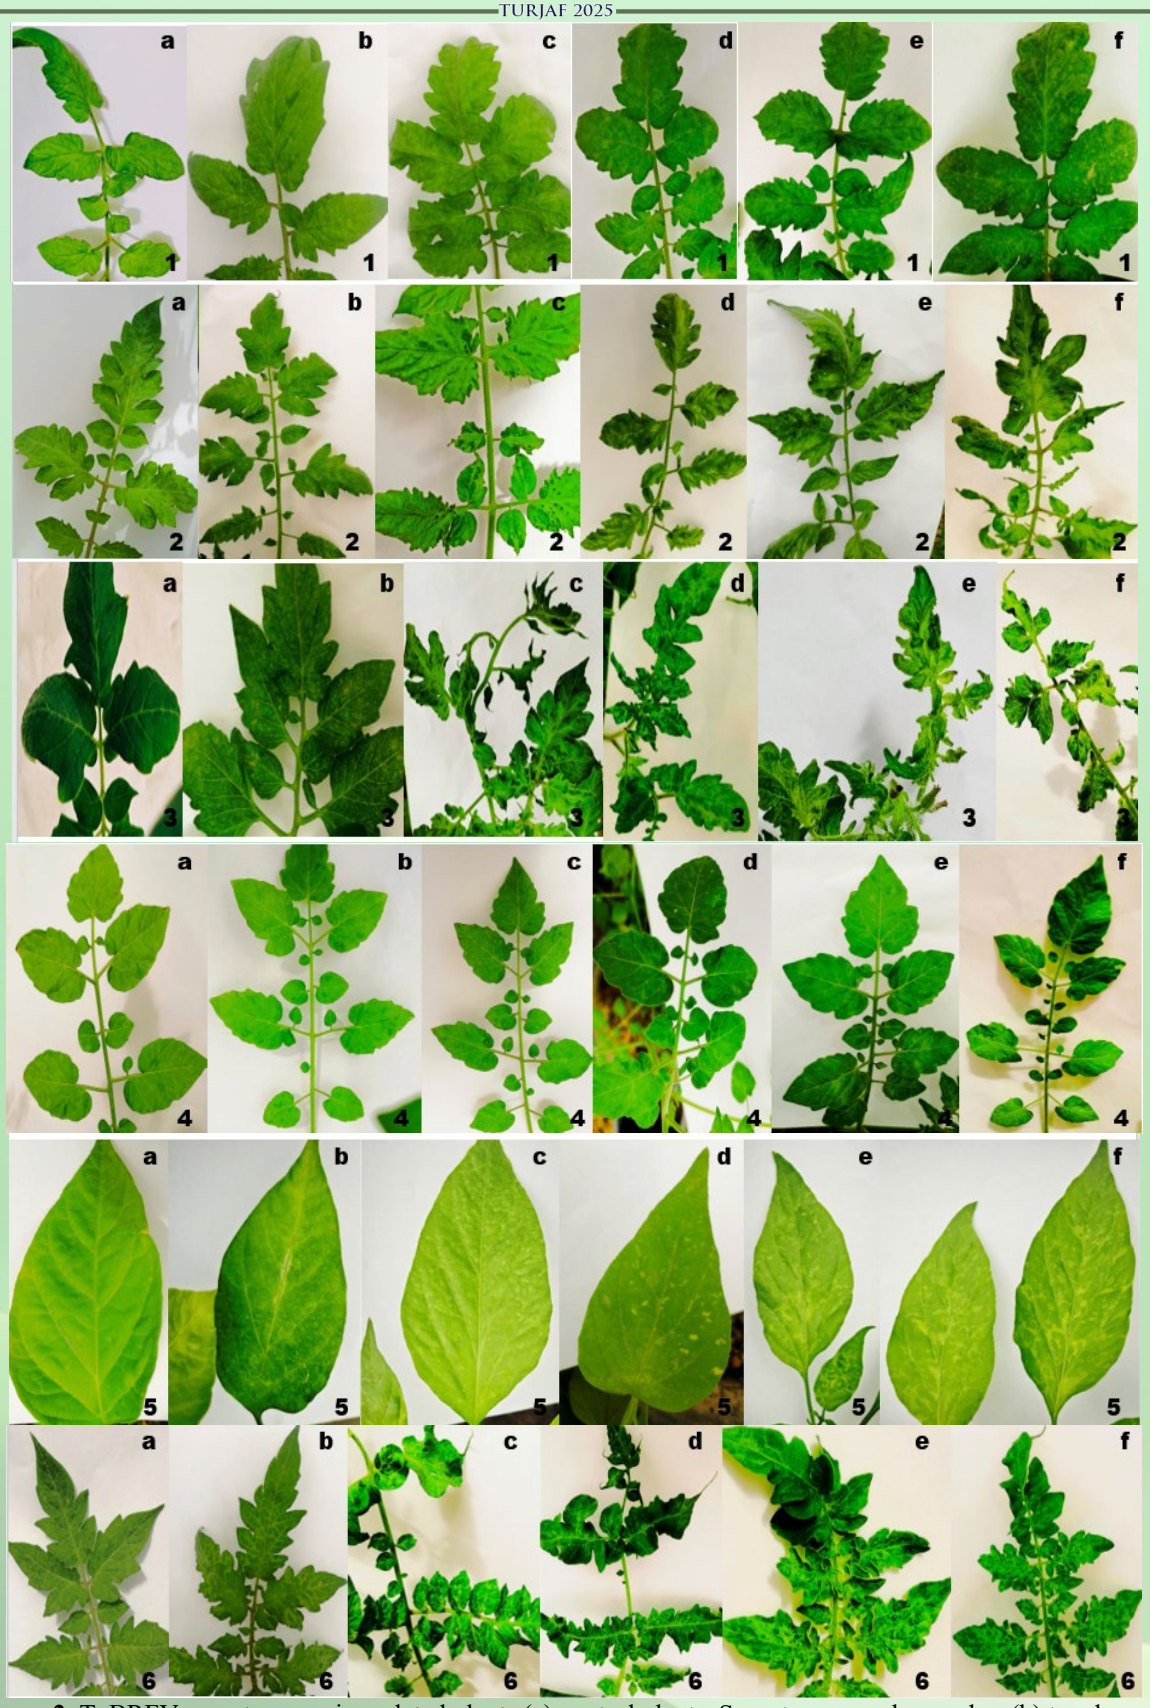

Figure 2. ToBRFV symptoms on inoculated plants (a) control plants, Symptoms are observed as (b) ten days, (c) fifteen days, (d) twenty days, (e) twenty five days and (f) thirty days after the mechanical inoculation. The plant numbers 1 was Rio Grande variety, 2 was Pintek variety, 3 was H2274 variety, 4 was wild type of tomato *S.pimpinellifolium*, 5 was Bor pepper variety and 6 was Sazlıca tomato variety.

Figure 3. Disease severity scales of tested varieties (a) all H2274 tomato score rate is 3, (b) Rio Grande varieties of right pot score rate is 3 and left pot score rate is 2, (c) Pintek varieties of right pot score rate is 3 and left pot score rate is 2, (d) Sazlıca varieties of right pot score rate is 3 and left pot score rate is 2, (e)Bor pepper varieties of right pot score rate is 2 and left pot score rate is 1, (f) wild type of tomato (*S. pimpinellifolium*) varieties of right pot score rate is 2 and left pot score rate is 1.

Additionally, the study focused on disease severity index of ToBRFV infected tomato and pepper plants, including disease infection rate of the plants. To assess the impact of ToBRFV on tomato and pepper plants, disease symptoms were monitored at 10, 15, 20, 25, and 30 days post-mechanical inoculation. A disease severity index was developed to quantify the severity of infection. A scale from 0 to 3 was employed, where 0 represented no

symptoms and 3 indicated the most severe symptoms. Disease severity was assessed at 30 days post-inoculation and the highest infection rate (100%) was observed in H2274 tomatoes, followed by Pintek (93.3%), Bor pepper (85%), and Sazlıca (83%). Rio Grande exhibited a 73% infection rate. In contrast, the wild-type tomato variety *S. pimpinellifolium* (LA1651) displayed the lowest infection rate (70%). These findings align with previous research by Kabas et al. (2022), who reported infection rates ranging from 38% to 60% in two *S. pimpinellifolium* accessions (LA1579 and LA0442).

A comprehensive ToBRFV management plan integrates multiple approaches such as prevention of initial infection, rigorous hygiene practices, utilizing host plant resistance where available, regular disinfection, exploring potential biocontrol agents, and investigating advanced techniques like gene editing for enhanced resistance.

Table 1. Disease severity classes of inoculated plants

Plant	Score number 3 (Highly Susceptible)	Score number 2 (Susceptible)	Score number 1 (Tolerant)	Score number 0 (Resistant)	Disease severity (%)
H2274	30	-	-	-	100
Pintek	24	6	-	-	93.3
Bor pepper	-	21	9	-	85
Sazlıca tomato	15	15	-	-	83.3
Rio Grande	6	24	-	-	73.3
S. pimpinellifolium	-	12	18	-	70

Abstract

Tomato brown rugose fruit virus (ToBRFV; genus Tobamovirus) poses a significant threat to plants belonging to the Solanaceae family, especially tomato and pepper. ToBRFV is rapidly spreading worldwide and threatens global tomato production. This virus is transmitted mechanically or via seeds during agricultural activities. Therefore, effective methods and resistance genes are needed to control ToBRFV and other tobamoviruses. The aim of this study is to characterize the movement protein, which is an important gene region in the transmission, spread and resistance of the virus, by molecular methods. For this purpose, in this study, tomato seedlings showing disease symptoms were collected from tomato greenhouses in Isparta province in the summer of 2023 upon the complaints of the producers and 5 seedling samples from 14 different greenhouses (70 seedlings in total) were tested for the presence of the virus. Mechanical inoculations were done to susceptible tomato varieties using the provided plant leaves and disease symptoms were observed. Nucleic acid isolations were made from plant leaves and cDNA was synthesized. PCR analyses were performed using primer sequences of the virus-specific movement protein and the obtained PCR bands were subjected to DNA sequence analysis. The obtained nucleotide sequences were analyzed in the NCBI database and BLASTn analyses proved the existence of the virus. In addition, alignment of the obtained nucleotide sequences was performed with CLUSTAL W and the neighbor-joining method was used to create a phylogenetic tree with the MEGA11 program. It is thought that the findings will guide the fight against the disease.

Key Words: *tomato, ToBRFV, Mp protein, PCR, phylogenetic.*

Domates Kahverengi Buruşuk Meyve Virüsü- Isparta izolatlarının Hareket Proteininin Moleküler Karakterizasyonu

Özet

Domates kahverengi buruşuk meyve virüsü (ToBRFV) özellikle domates ve biber olmak üzere Solanaceae familyasına ait bitkilerde önemli bir sorun oluşturmaktadır. ToBRFV dünya çapında hızla yayılmakta ve küresel çapta domates üretimini tehdit etmektedir. Bu virüs, tarımsal faaliyetler sırasında mekanik olarak veya tohumlar yoluyla bulaşmaktadır. Bu nedenle, ToBRFV ve diğer tobamovirüsleri kontrol etmek için etkili yöntemlere ve dayanıklılık genlerine ihtiyaç duyulmaktadır. Bu çalışmanın amacı, virüsün bulaşması, yayılması ve dayanıklılığında önemli bir gen bölgesi olan hareket proteininin (movement protein) moleküler yöntemler aracılığıyla karakterize edilmesidir. Bu amaçla, bu çalışmada 2023 yılının yaz aylarında Isparta ili domates seralarından üreticilerin şikâyeti üzerine hastalık belirtileri gösteren domates fideleri toplanmış ve 14 farklı seradan alınan 5'er fide örneği (toplam 70 fide) virüs varlığı açısından test edilmiştir. Temin edilen bitki yaprakları kullanılarak hassas domates çeşidine mekanik inokulasyonlar yapılmış ve hastalık simptomları gözlenmiştir. Bitki yapraklarından nükleik asit izolasyonları yapılmış ve cDNA sentez edilmiştir. Virüse özgü hareket proteine ait primer dizileri kullanılarak PCR analizleri yapılmış ve elde edilen PCR bantları DNA dizi analizine tabii tutulmuştur. Temin edilen nükleotid dizileri NCBI veritabanında analiz edilmiş ve BLASTn analizleri virüsün varlığını kanıtlamıştır. Ayrıca elde edilen nükleotid dizilerinin hizalanması CLUSTAL W ile gerçekleştirilmiş ve MEGA11 programı ile filogenetik ağaç oluşturmak için neighbor-joining yöntemi kullanılmıştır. Bulguların, hastalık ile mücadelede yol gösterici olacağı düşünülmektedir.

Anahtar Kelimeler: *Domates, ToBRFV, Mp proteini, PCR, filogenetik*

Giriş

Domates kahverengi buruşuk meyve virüsü (Tomato brown rugose fruit virus: ToBRFV) özellikle domates başta olmak üzere Solanaceae (patlıcangiller) familyasına ait bitkilerde önemli bir tehdit oluşturan virüstür. ToBRFV, 2014'ün sonlarında İsrail'de keşfedilmiştir. 2015 yılında İsrail'in domates yetiştirilen Melilot, Beit Ezra ve Achituv

alanlarına yayılmıştır. İlk olarak 2016 yılında Ürdün'de rapor edilmiştir (Salem ve diğerleri, 2016). Virüs İsrail'de bir yıl içerisinde neredeyse ülke çapında domates seralarına yayılmıştır. ToBRFV dünya çapında hızla yayılmakta ve küresel domates üretimini tehdit etmektedir. Bu virüs, tarımsal faaliyetler sırasında mekanik olarak veya tohum yoluyla bulaşmaktadırlar (Dombrovsky ve diğerleri, 2017). Bu nedenle, ToBRFV ve diğer tobamovirüsleri kontrol etmek için etkili ve dayanıklılık genlerine ihtiyaç duyulmaktadır.

Virüs enfeksiyon oluşturduğu domates bitkilerinde şiddetli simptomlara neden olur. Hastalık domates yapraklarında mozaikleşme, klorozis, benek şeklinde lekelenme ile ileri dönemlerde nekrotik dokular ve cüceliğe ve sonunda da bitki ölümüne neden olmaktadır. Meyvelerde ise kahverengi lekeler ve buruşuk meyve oluşumu en temel simptomları arasında yer almaktadır (Salem ve diğerleri, 2016).

ToBRFV, uzun ve simetrik çubuksu yapıda virion yapısına sahiptir ve diğer Tobamovirüslerle benzerlik göstermektedir. ToBRFV genomu da diğer tobamovirüslerinkine çok benzerdir. Bu virüslerin genomu, dört açık okuma çerçevesi (ORF) içeren yaklaşık 6.400 nükleotid uzunluğunda tek zincirli pozitif anlamlı bir RNA molekülünden oluşmaktadır. Genomik RNA, CAA tekrarları açısından zengin kısa bir 5' çevrilmemiş bölge (UTR) ve psödoknotlara katlanabilen bir 3' UTR ile kapatılır ve bunu transfer RNA benzeri, amino asit olan bir yapı izlemektedir. İki 5' -terminal ORF doğrudan genomik RNA'dan çevrilir. ORF1, metiltransferaz ve helikaz alanları içeren 126 kDa'lık bir proteine (p126) çevrilir. ORF1 ve ORF2 arasındaki UAG durdurma kodonunun okunması, C-terminal ucunda RNA'ya bağımlı bir RNA polimeraz alanı içeren 183 kDa'lık bir proteinin (p183) ekspresyonuyla sonuçlanabilir. Her iki protein de replikasyon için gereklidir ve p126 ayrıca diğer tobamovirüslerde gösterildiği gibi bir susturma baskılayıcısı olarak işlev görmektedir. ORF3 ve ORF4, 3'- koterminal olan ve sırasıyla 30 kDa'lık bir hareket proteini (MP) ve 17,5 kDa'lık bir kılıf proteini (CP) kodlayan 5'- subgenomik RNA 1 ve 2' den çevrilir (Salem N. ve diğerleri, 2022).

Tobamovirüslerin enfeksiyon döngüsünde en önemli proteinlerden biri hareket proteinidir. Bu protein virüsün bitki içerisinde hareket etmesini sağlar. Virüs, enfekte ettiği hücre içerisinde çoğaldıktan sonra komşu hücrelere yayılmak zorundadır. Hareket proteinleri, virüs genomlarının hücreler arası kanallardan (plasmodesmata) geçerek komşu hücrelere taşınmasını kolaylaştırır. Ayrıca bitki hücresinin mikrotübüller ve aktin filamentleri ile etkileşime girerek virüsün hücre içindeki hareketini yönlendirir ve hızlandırır. Bazı hareket proteinleri, hücre duvarının geçirgenliğini artırarak virüsün hücreler arası geçişini kolaylaştırır. Hareket proteinleri, bitkinin savunma mekanizmalarını baskılayarak virüsün çoğalmasını ve yayılmasını sağlar. Hareket proteini sayesinde tobamovirüsler, enfekte ettikleri bitkinin tüm kısımlarına yayılarak sistemik bir enfeksiyona neden olurlar. Hareket proteininin etkinliği, hastalığın şiddeti ile doğrudan ilişkilidir. Daha etkin hareket proteinlerine sahip virüsler, daha hızlı ve daha geniş alanlara yayılarak bitkiye daha fazla zarar verir. Bununla birlikte, virüsün evrimi için önemli bir faktördür. Mutasyonlar sonucu oluşan yeni hareket proteinleri, virüse yeni konukçularına adapte olma ve daha etkili bir şekilde yayılma avantajı sağlamaktadır.

Bu çalışmanın amacı, Tobamovirus cinsinin hızla yayılmakta olan bu ToBRFV virüsünün bulaşması, yayılması ve dayanıklılığında önemli bir gen bölgesi olan hareket proteininin (movement protein) moleküler yöntemler aracılığıyla karakterize edilmesidir. Bu amaçla, hastalıklı bitki temin edilerek sağlıklı fideler inokule edilmiştir. Bitkilerden nükleik asit izole edilerek virüsün hareket proteini nükleotid düzeyinde moleküler olarak karakterize edilmiştir.

Materyal ve Yöntem

Virüs Kaynağı

Domates kahverengi rugose meyve virüsü (ToBRFV) kaynağı Isparta İlinde bulunan 14 farklı seralardan temin edilmiştir. Her bir seradan beşer adet bitki olmak üzere toplam olarak 70 bitki örneği temin edilmiş olup bu bitkiler şiddetli hastlık belirtisi içeren ve üreticilerin şikâyetleri üzerine toplanmıştır.

Mekanik İnokulasyonlar

Virus kaynağını çoğaltmak için mekanik inokulasyonlar yapılmıştır. Her bir serayı temsilen 14 adet hassas olduğu bilinen H2274 domates tohumları kullanılmış olup tohum ekimi, fide yetiştirme ve belirtileri gözlemleme işlemleri Niğde Ömer Halisdemir Üniversitesi Tarım Bilimleri ve Teknolojileri Fakültesi'ndeki Bitki Virolojisi bitki yetiştirme odasında gerçekleştirilmiştir. Domateslerin 4-5 yapraklı olduğu zaman mekanik inokulasyonu yapılmıştır. Mekanik inokülasyonlar için, 0.199 g/l KH_2PO_4, 1.14 g/l Na_2HPO_4 ve %0,1 Na_2SO_3 ve 1% PVP-40 içeren inokülasyon tampon çözeltisi (pH: 7.4) kullanılmıştır. Mekanik inokulasyon için fosfat solüsyonu içinde homojenize edilen virüs kaynağı yapraklara karborandum serpilmesi ile aşındırma sonucu yaprak yüzeyine sürülmüştür ve yarım saat sonra musluk suyu ile durulanmıştır. İnokülasyonu yapılan domates bitkileri, inokülasyondan bir ay sonra virüs enfeksiyonunu doğrulamak için PCR analizleri yapılmıştır.

Moleküler Analizler

Toplam NA Ekstraksiyonu

İnokulum kaynaklarındaki enfeksiyondan emin olabilmek için, toplam NA, üreticinin talimatlarını izleyerek domates yaprağı dokularından çıkarılmış ve saflaştırılmıştır. İnokule bitkiler ile inokulum kaynağını oluşturan bitkilerin (her bir seradan temin edilen beşer bitki karıştırılarak) yaprak dokularından NA ekstraksiyonu için hızlı ve etkili bir yöntem olan hızlı CTAB yöntemi (Gambino ve diğerleri, 2008) kullanılmıştır. Toplam NA'ların verimi ve kalitesi, bir BioSpec spektrofotometre (Shimatzu, ABD) kullanılarak ölçülmüştür.

cDNA Sentezi ve PCR Analizi

İki aşamalı bir RT-PCR protokolü kullanılmıştır. Birinci iplikçik cDNA, cDNA Sentez Kiti talimatları için rastgele heksamer primerleri ve Superscript Choice Sistemi kullanılarak toplam RNA'ların Ters transkripsiyonuyla sentezlenmiştir. PCR, 2 µl cDNA, 0,5 µl 10mM dNTP, 1 µl 25 mM $MgCl_2$, 2,5 µl 5X PCR tampon çözeltisi ve virüse spesifik primerlerden 0,5 µl 10 µM ve 0.25 µl 5 birim /µl Taq DNA polimerazı ile yapılmıştır. PCR, aşağıdaki koşullar altında gerçekleştirilmiştir: 94 °C'de 5 dakika denatürasyon, 30 saniye boyunca 94 °C'de, 45 saniye boyunca 55 °C'de ve 1 dakika boyunca 72 °C'de 40 döngü ve 72 °C'de 10 dakika boyunca son bir uzama. PCR ürünleri, %1,5 agarose jele yüklenip elektroforezde koşturulmuş ve bir UV-transillüminatör altında ethidium bromide ile uygulandıktan sonra UV ışığı altında incelenmiştir. ToBRFV MP geni için F- 5'-GATGGCTCTTGTTAAGGGTAAA-3' and R- 5'-CCCATGCTGATGACAAAAAC-3'-858 bp primer çifti kullanılmıştır (Güller A ve diğerleri., 2023).

Nükleotid Dizi Analizleri

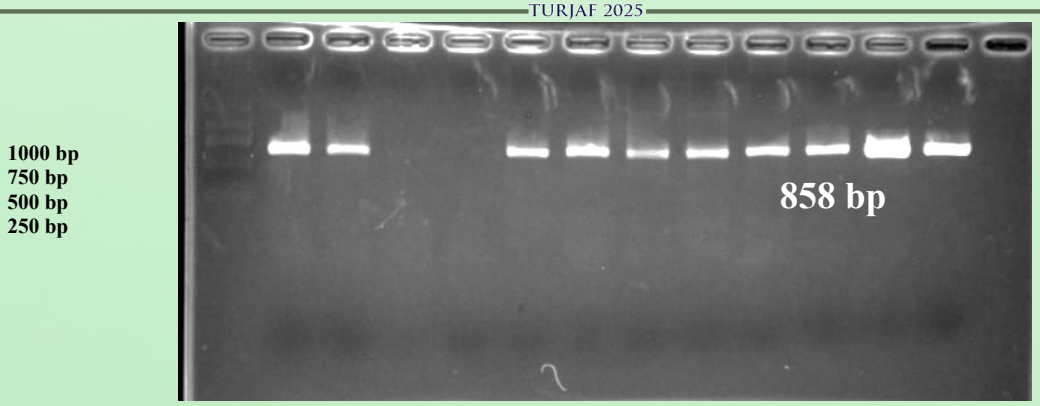
PCR ürünlerinin nükleotid dizi analizleri, BMLabosis Firması (Ankara, Türkiye) ABI 3730 Automated Genetic Analyzer cihazı ile doğrudan dizilenmiştir. Nükleotidleri belirlemek için BLASTn ve BLASTx modülleri kullanılmıştır.

Filogenetik Analizler

GenBank'ta (NCBI) depolanan farklı izolatların dizileri hem nükletid hem de aminosit düzeyinde filogenetik analize alınmıştır. Nükleotid dizilerinin çoklu hizalaması CLUSTAL W ile gerçekleştirilmiş ve Molecular Evolutionary Genetics Analysis MEGA11 programı ile filogenetik ağaç oluşturmak için neighbor-joining yöntemi kullanılamıştır (Tamura ve diğerleri, 2011). Filogenetik ağaçların her bir düğümünün sağlamlığı, 1000 bootstrap kopyasından değerlendirilmiştir.

Bulgular ve Tartışma

Mekanik İnokulasyon Sonuçları



Yapılan inokulasyonlar sonrasında virüs simptomlarının çok hızlı görülmeye başlandığı gözlenmiştir. İnokulasyondan 5-7 gün sonra ilk belirtiler oluşmuştur. Belirtiler arasında en yaygın olanlar mozaikleşmeler olup yaprak kıvırcıklığı ve sarı benekler de yaygın olarak gözlenmiştir. Simptom gelişimleri bir ay boyunca gözlenmiştir. Virus simptomları yedinci gün, onuncu gün belirti vermiştir ve on beş, yirmi, yirmi beş ve otuz günün simptom gelişimleri incelenmiştir ve şiddetli virüs simptomları kaydedilmiştir. Yapraklarda şiddetli belirtiler örneğin yapraklarda mozaikleşme ve sarı renkte benek oluşumları ve kıvırcıklanmalar yaygındır.

Total NA İzolasyonu Sonuçları

CTAB yöntemine göre yapılan izolasyonlar sonucunda elde edilen nükleik asitlerin kalite değerleri nanodrop spektrofotometre cihazı aracılığıyla ölçülmüş olup 230/260 optik okuma değerleri elde edilmiştir. Bu değerlerin 1.5 ila 2-2 ng/ul arası olduğu tespit edilmiş olup bu değerlerin PCR analizleri için uygun kalitede olduğu görülmüştür. Optimum RNA saflığı 260/280 oranının yaklaşık 2,0 ve 260/230 oranının 2,0 ile 2,2 arasında olmasıyla gösterilir. pH bu oranları etkileyebilirken, yukarıdaki değerler 1.8 genellikle kabul edilebilir olarak değerlendirilmektedir.

RT-PCR Analiz sonuçları

Yapraklardan izole edilen virüs RNA'larının iki aşamalı cDNA sentezi yapılıp MP genine özgü primer çiftlerinin kullanılması ile ToBRFV'nin kısmi nükleotid dizileri çoğaltılmıştır. Testlenen tüm izolatlar beklenildiği gibi 858 bp'lik bant göstemiştir (Şekil 1).

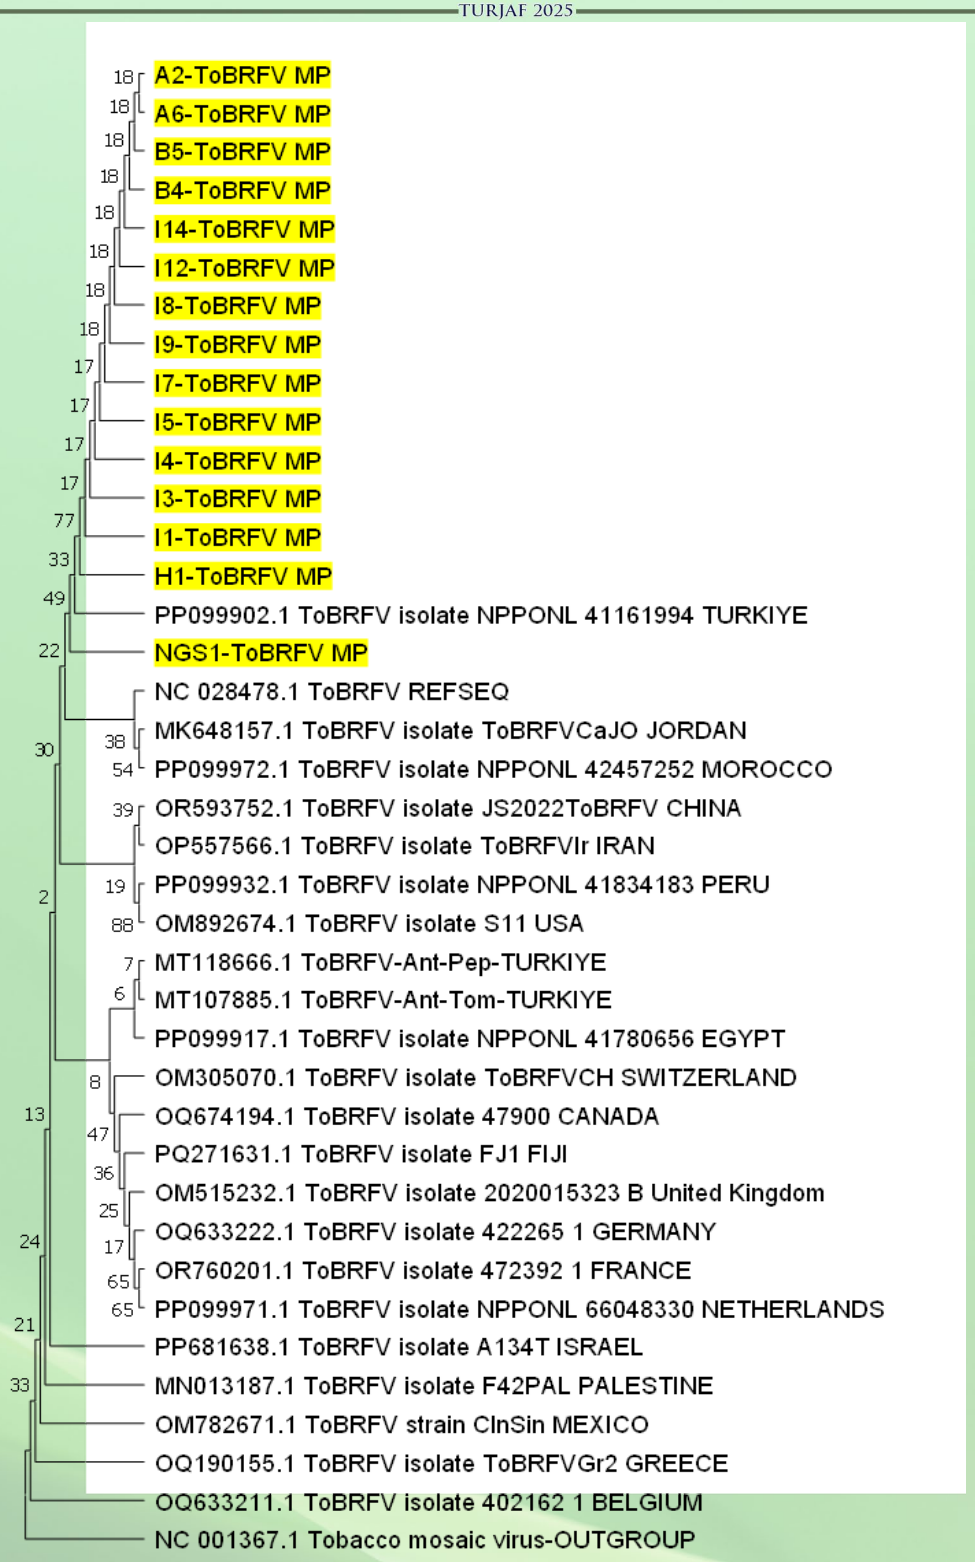
Şekil 1: RT- PCR analizi sonucu agaroz jel görüntüsü, M: Thermo scientific 1 kb plus DNA Ladder

DNA Dizi Analizi Sonuçları

Elde edilen PCR ürünleri DNA dizi analizine alınmış olup 858 bp büyüklüğünde nükleotid dizileri elde edilmiştir. Bu dizilerin BLASTn analizleri yapılmış olup örneklerimizin Gen Bankasına kayıtlı örneklerle kıyaslandığında yakşalık olarak %98 ila 99,5 oranında benzerlik gösterdiği tespit edilmiştir.

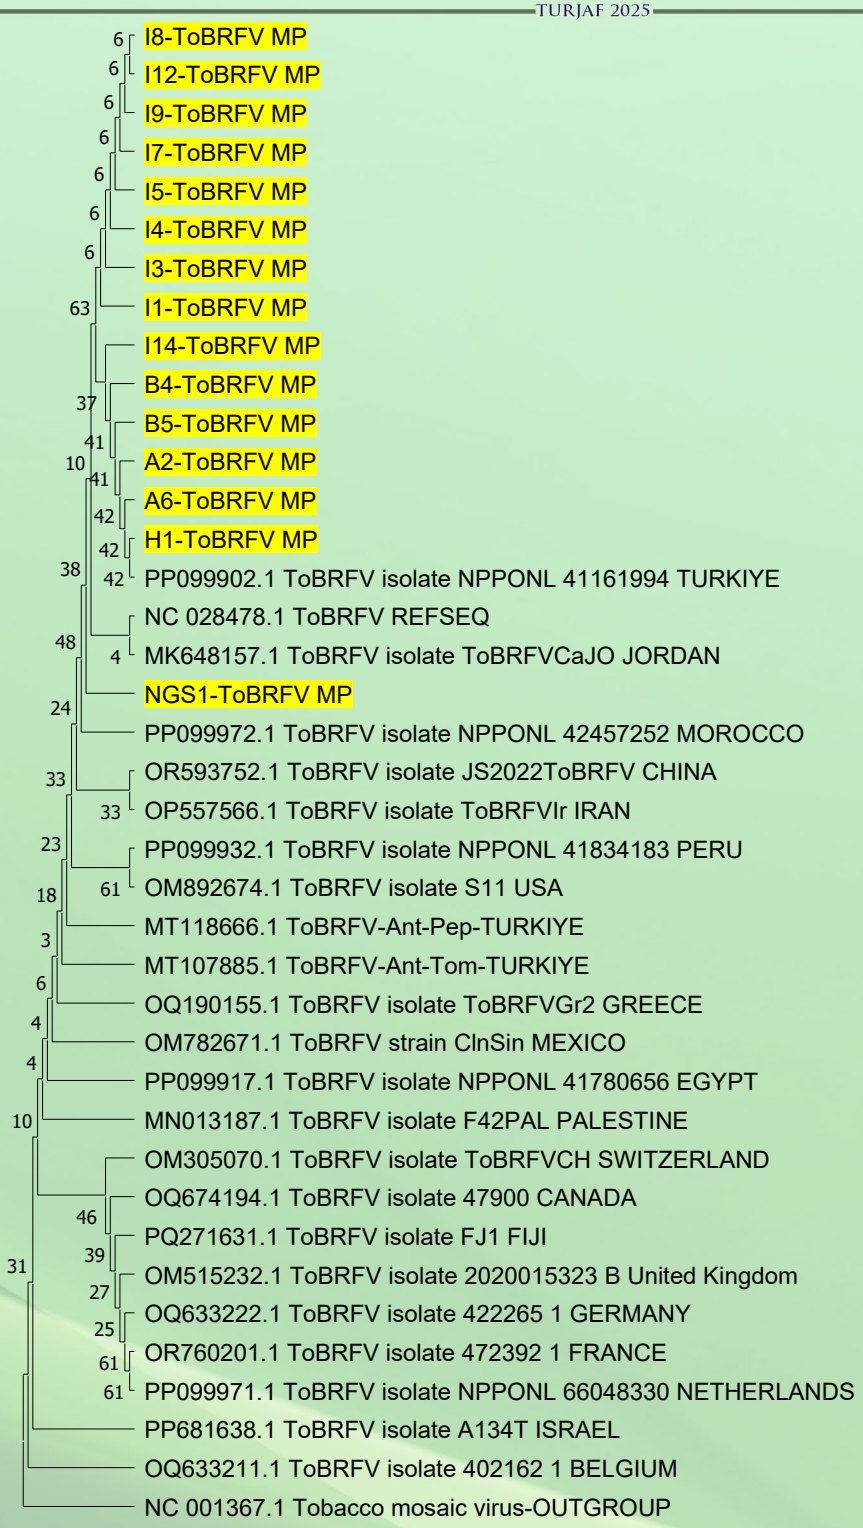
Filogenetik Analiz Sonuçları

Nükleotid ve amino asit dizilerinin tanımlanması ve hizalanması, virüslerin genetik çeşitliliğini analiz etmek için yaygın olarak kullanılmaktadır (Nyalugwe ve diğerleri, 2015; Farzadfar ve Pourrahim, 2017). Isparta ToBRFV izolatının MP gen bölgesinin nükleotid ve amino asit dizileri, maksimum olabilirlik analizi kullanılarak NCBI veri tabanında halihazırda bulunan diğer gen dizileri ile filogenetik ilişkileri açısından karşılaştırılmış ve değerlendirilmiştir. Isparta ToBRFV izolatlarının genetik yapısı mevcut literatürle örtüşmekte, ancak aynı zamanda yeni bilgiler de ortaya koymaktadır.



Kullandığımız Komşu Birleştirme Yönteminde kümelenme temelli algoritmada olduğu gibi taksonların kökten eşit uzaklıkta olduğu varsayılamaz. Yöntemimiz oldukça verimlidir ve geniş çapta verileri ve veri topluluklarını analiz etmeye yardımcı olur. Dış grup takson olarak incelenen organizma grubu TMV ise, evrimsel ilişkileri belirlerken daha uzaktan ilişkili olan ve referans grubu olarak kullanılan organizmalardır ve dış grup, iç grup için bir karşılaştırma noktası olarak kullanılır ve özel olarak da filogeninin kökünün olmasını sağlar.

Nükleotid dizileri ile oluşturulan MP gen bölgesi ağacında, Isparta izolatlarının birbiri ile çok benzer olduğu ve bu izolatların GenBankasına kayıtlı olan PP099902.1 numaralı NPPLONL41161994 nolu Türkiye izolatı ile yüksek oranda homoloji gösterdiği tespit edilmiştir (Şekil 2). Ayrıca Türkiye'den izole edilen Antalya örneklerinin de bizim izolatlarımız ile yakın bir dalda kümelendeği tespit edilmiştir (MT107885.1 ToBRFV-Ant-Tom-TURKIYE ile biberden izole edilen MT118666.1 ToBRFV-Ant-Pep-TURKIYE izolatı). Kontrol grubu olarak kullanılan Tütün mozaik virüsü ise beklendiği gibi en uzak dalda yer almaktadır.



Virüsün nükleotid dizilerinin aminoasite çevrilmesi ile oluşturulan ağaç nükleotid ağacı ile benzer sonuçlar vermis olup farklı olarak MK648157.1 ToBRFV isolate ToBRFVCaJO JORDAN kodlu Ürdün izolatı da bizim örneklerimizle aynı grupta kümelenmiştir (Şekil 3). Tobamovirüslerin stabil yapısı dikkate alındığında bu sonuçların beklenildiği gibi olduğu düşünülmektedir.

Tüm elde edilen verilere dayanılarak; domates buruşuk meyve virüsünün hareket proteini moleküler karekterizasyonu yapılmış olup virüsün bu genindeki varyasyon moleküler olarak belirlenmiştir. Isparta ToBRFV izolatlarının genetik yapısı analiz edilmiş olup GenBankasındaki mevcut dizilerle yüksek oranda homoloji gösterdiği tespit edilmiştirr. Tobamovirüs enfeksiyon döngüsü için çok önemli olan bu hareket proteininin komşu hücrelere geçişi kolaylaştırdığı gibi bitkinin savunma mekanizmasını da baskılayarak virüsün yayılımını ve çoğalımını sağladığı bilinmektedir. Bu nedenle, elde edilen verilerle MP genininin çok fazla varyasyon içermediği ve taşınma kaynaklı mücadele yöntemlerine yardımcı olacağı düşünülmektedir.

ToBRFV tarımsal faaliyetler sırasında mekanik veya tohum yoluyla bulaşmaktadır. Bundan dolayı ToBRFV ve diğer tobamovirüsleri kontrol etmek için etkili ve dayanıklılık genlere ihtiyaç olduğu saptanmıştır. Bu dayanıklılık genlerin ve bitkilerin CRISPR\Cas9 en kısa en doğru genom düzenleme aracı ile üretilebileceği düşünülmekte olup bu yöntem ile ToBRFV dayanıklı domates yetiştiriciliği kolaylaşacağı düşünülmektedir.

Şekil 2: ToBRFV izolatlarının MP (movement protein) nükleotid dizilerinden MEGA11'de Komşu-Birleştirme yöntemi ile çıkarılan filogenetik ağacı. Bu çalışmadan elde edilen izolatlar sarı ile vurgulanmıştır. NGS1 izolatı iç kontrol izolatımızdır. İç düğümlerdeki sayılar, 1.000 tekrarlamaya dayalı bootstrap yüzdelerini göstermektedir. TMV izolatı dizileri dış grup taksonu olarak kullanılmıştır.

Şekil 3: ToBRFV izolatlarının MP (movement protein) aminoasit dizilerinden MEGA11'de Komşu-Birleştirme yöntemi ile çıkarılan filogenetik ağacı. Bu çalışmadan elde edilen izolatlar sarı ile vurgulanmıştır. NGS1 izolatı iç kontrol izolatımızdır. İç düğümlerdeki sayılar, 1.000 tekrarlamaya dayalı bootstrap yüzdelerini göstermektedir. TMV izolatının aa dizileri dış grup taksonu olarak kullanılmıştır.

Abstract

Climate change is accelerating threats to global food and nutritional security, placing unprecedented strain on livelihoods of farming community. Intensifying biotic and abiotic stress are undermining crop productivity, while the soaring costs of cultivation compound the vulnerability of small and marginal farmers—the backbone of the agricultural workforce. Despite widespread recognition of these challenges, scalable, ecosystem-aligned technological interventions that are socially acceptable and economically viable remain elusive. Agri-Net Zero is a top climate action strategy that transforms agricultural landscapes into dynamic carbon sinks while directly reducing greenhouse gas emissions. By integrating regenerative practices with economic and social benefits, it not only drives net zero compliance but also enhances ecosystem resilience and rural livelihoods.

In response, the IBM-IORF Sustainability Accelerator initiative has piloted a climate-resilient Agri-Net Zero model across two agro-ecosystems in India by integrating Inhana Rational Farming (IRF)—a nature-based, regenerative farming framework. IRF eliminates chemical pesticide use, minimizes N fertilizer inputs, restores soil health and enhances plant resilience through targeted physiological interventions .

The outcomes of regenerative, coconut-based integrated farming systems are transformative: a 30% increase in crop yield, 20% improvement in nutrient use efficiency, up to a 60% transition to renewable energy use, 40% boost in farm income, 17% growth in rural employment, and carbon mitigation potential of up to 250 metric tons of CO_2e per hectare. These results, independently verified through third-party audit, led to India's first Agri-Net Zero certification by iNoCarbon, UK. Crucially, innovations such as coir pith recycling and nitrogen input optimization simultaneously advance soil carbon sequestration and reduce greenhouse gas emissions. This model presents a compelling case forcorporate Net Zero ambitions with the sustainability of farming communities, delivering measurable social and environmental co-benefits while directly addressing seven crucial UN Sustainable Development Goals (SDGs). Strategic investment in such regenerative transitions can empower farmers as pivotal actors in the global response to climate change.

Key Words : GHG mitigation, Soil health management, ACFA (version 2.0)

Introduction

Climate change is intensifying biotic and abiotic stresses on agriculture, directly threatening global food and nutritional security (Benitez-Alfonso et al., 2023). These escalating stresses reduce crop productivity and inflate cultivation costs, making climate-resilient, regenerative agricultural practices not only urgent but essential for future food systems (WEF, 2024). These practices—centered on soil and plant health—are key to adapting to climate shocks and mitigating their long-term impacts (Bera et al., 2025). However, small and marginal farmers—who constitute a majority of the global farming population—remain most vulnerable, lacking access to adaptive resources and technical capacity (Mazik et al., 2025).Simultaneously, the corporate sector faces increasing pressure to embed sustainability into operations to meet Net Zero targets and drive ESG commitments. Globally, nearly 9,000 companies have pledged emission reductions, with ~3,500 targeting net-zero. Europe leads with 2,998 companies; Asia follows with 1,846. The UK tops the list (702 firms), while China—despite being the largest global emitter—lags in corporate adoption. India ranks sixth with 127 companies committed to net-zero (ET Energy World, 2024). Bridging this corporate-agriculture divide is vital for achieving scalable, systemic climate action.

Agri-Net Zero emerges as a leading climate action strategy that transforms agricultural landscapes into dynamic carbon sinks, directly reducing greenhouse gas emissions. This innovative approach leverages regenerative practices to improve soil health and enhance biodiversity, positioning agriculture as a key player in net zero compliance. By integrating these sustainable farming methods, Agri-Net Zero not only mitigates emissions but also unlocks significant economic and social benefits for rural communities. Its comprehensive framework strengthens ecosystem resilience while bolstering rural livelihoods, reinforcing the critical role of agriculture in

the broader fight against climate change. Consequently, Agri-Net Zero stands as a transformative strategy, charting a pathway toward a more sustainable and climate-resilient future.

The Regenerative Agri–Net Zero Model offers a transformative pathway, enabling corporations to enhance ESG performance through measurable carbon mitigation alongside social and ecological co-benefits. Yet two persistent gaps hinder progress: the absence of a roadmap for sustainable agriculture, and the challenge of quantifying carbon mitigation, due to the lack of standardized tools tailored to farming (Guan et al., 2023).

For wide-scale success, this model must be climate-resilient, ecosystem-aligned, easily adoptable, financially viable, and scalable. Particularly in India, where over 80% of farmers are smallholders, risk-averse models are crucial. The model must avoid productivity losses while restoring soil–plant–ecosystem balance from the outset. This is achieved through two pillars: (1) a robust bioconversion technology to convert waste into compost—a scalable, low-cost solution for sustainable soil health; and (2) plant health management strategies that ensure smooth transitions from synthetic nitrogen to compost-based systems. Given that abrupt nitrogen reduction often leads to yield loss, targeted plant health practices can safeguard productivity and support nutrient sustainability.

This study documents the development and deployment of the Climate-Smart Agri–Net Zero model, highlighting its dual impact: empowering farmer resilience and accelerating corporate climate goals. It further incorporates ACFA (v2.0)—India's first carbon accounting standard for sustainable agriculture—to address the persistent challenge of carbon measurement (Gomage, 2024). Together, these innovations pave the way for regenerative agricultural transitions that align climate, community, and corporate goals—delivering a viable blueprint for a sustainable, net-zero food future.

Materials and method

Study Area : The study was initiated under IBM-IORF Sustainability Project during 2022-23 at Mandya District, Karnataka, India. The area belongs to hot, moist semiarid agro-ecological sub region 8.2 with medium to deep red loamy soils, low available water holding capacity (AWC) and length of Growing Period 120 – 150 days.

Coir Pith: A Persistent Landfill Hazard, Not Just Agro-Waste

Coir pith—a residue generated from coconut processing—deserves recognition as landfill waste rather than agro-waste due to its inherent recalcitrance and environmental risks. Its high lignin content and markedly imbalanced carbon-to-nitrogen ratio hinder microbial metabolism, resulting in exceedingly slow biodegradation. This persistent nature leads to prolonged accumulation in landfill sites, where coir pith becomes a significant source of methane emissions, a potent greenhouse gas (Rajalakshmi et al., 2018; Brebu & Vasile, 2010). Moreover, coir pith leachates are rich in bioactive compounds such as phenolics and tannins, which can disrupt soil microbial dynamics and nutrient cycling if inadvertently released into the environment (Singh & Patel, 2020; Khan et al., 2011). In light of these complexities and its limited capacity for rapid natural decomposition, coir pith should be reclassified as landfill waste. Such a reclassification would underscore the need for stringent waste management practices and innovative recycling strategies to mitigate its contribution to environmental pollution and methane emissions, aligning regulatory efforts with its true impact on ecological and human health (Kirchherr, Reike, & Hekkert, 2017; FAO, 2018). This new perspective calls for targeted regulatory interventions, as already suggested by agencies in India, including the Central Pollution Control Board and the Tamil Nadu Pollution Control Board, which recognize the severe challenges posed by improperly managed coir pith in landfill settings (CPCB, 2016; TNPCB, 2020; Devanathan, 2021).

Clean Food Net Zero Program: Coconut-Based Circular Economy Model

Under the IBM-IORF Sustainability Project (2021–22 to 2023–24), a comprehensive coconut-based intercropping model was developed to enhance crop diversity and improve farm productivity on marginal soils by integrating Inhana Rational Farming Technology, a nature harnessed complete organic package of practice. This approach repurposes coir pith—traditionally a waste product that contributes to soil and water pollution as well as methane emissions—by subjecting it to Novcom Composting Technology, a process that bio-converts the residue into a safe, stable, and mature compost within 30 days; the resulting product is enriched with native microflora essential for rapid soil microbial regeneration. The Novcom coir pith compost was applied at 40 ton/ha to rehabilitate soils deemed unsuitable for vegetable and other agricultural crops. Post-transplanting, Inhana Plant Health Management solutions were periodically administered according to the recommended schedule, effectively promoting balanced crop growth, enhancing plant immunity, and fortifying defense mechanisms against pests and diseases, thereby reducing pesticide dependency; any minor pest issues that arose were controlled using on-farm neem-based concoctions. Furthermore, the formulation of the Clean Food Net Zero (CFNZ) program was guided by five key criteria: (i) alignment with ecosystem services; (ii) governance by a sustainable agro-technology framework that equally emphasizes soil and plant health management to achieve the program's objectives; (iii) economic viability;

(iv) ease of adoption and social acceptability; and (v) replicability across large landscapes, irrespective of agro-ecological variability and crop choice.

Program undertaken at Mandya, India : Coconut Based Integrated Crop Cultivation towards development of Regenerative Agri-Net Zero Model

Under the IBM-IORF Sustainability Project, an innovative program was undertaken at Mandya to develop coconut-based Regenerative Agri-Net Zero Model by integrating scientific interventions and regenerative farming practices. Three distinct intercrop models were implemented within coconut plantations on marginal red gravelly soils characterized by low fertility and diminished microbial activity—soils traditionally considered unsuitable for nutrient-sensitive, short-duration vegetable crops. Through the elimination of chemical pesticides and nitrogen fertilizers, these lands were transformed into productive fields, thereby illustrating a sustainable, chemical-free approach to modern agriculture. The program was initiated with a comprehensive field and socio-economic survey, followed by grid-wise soil sampling and soil resource mapping, followed by demonstrations of Novcom coir pith composting to valorize coir waste into nutrient-rich compost. Farmers were engaged through meetings designed to develop awareness and impart technical know-how regarding regenerative farming principles, leading to the adoption of Inhana Rational Farming (IRF) Technology. Additionally, a plant health management regime was introduced under the Inhana Plant Health Management (IPHM) program, complemented by integrated pest management strategies utilizing alternate and on-farm concoctions. The circular economy models were rigorously analyzed for their impacts on crop yield, nutrient utilization, soil health, energy consumption, greenhouse gas emissions, and overall cost–benefit ratios—parameters deemed critical for improving the livelihoods of resource-poor farmers. By emphasizing resource efficiency, waste minimization, and the systematic recycling, reusing, and regeneration of resources, this program not only optimized productivity but also reduced environmental impacts, thereby enhancing both the economic prospects and well-being of the farming communities involved.

Inhana Rational Farming Technology

Inhana Rational Farming (IRF) Technology, developed by Dr. Phalguni Das Biswas: pioneer in nature harnessed organic farming technology in India with over 25 years of research experience—provides a nature-receptive pathway for sustainable crop production by harmonizing the interrelated components of the ecosystem. This innovative approach enhances both ecological health and economic sustainability by focusing on two principal objectives: the energization of the soil system to promote its role as an effective growth medium and the energization of the plant system to facilitate optimal nutrient extraction, utilization, and assimilation, as well as to stimulate intrinsic biochemical and structural defenses (Bera et al., 2014). Central to IRF Technology is the use of specially formulated In-House solutions for soil and plant energization. These solutions incorporate technology-specific plants that store the energetic properties of the five basic elements—earth, water, fire, air, and space—as well as the five basic life forces, also known as Prana Shaktis. Selection of these plants is governed by parameters such as sunrise, sunset, seasonal changes, and other critical environmental factors. Their botanical extracts are subsequently potentized and energized following the Element Energy Activation (E.E.A.)® principle, a method that underscores the significance of “Chaitanya Shakti” or the basic life force, which is fundamentally manifested as solar energy.

According to the E.E.A. principle, all living organisms can be likened to complex machines driven by this life force, where two major processes operate continuously: self-nourishment and self-protection. Self-nourishment is supported by the Panchamahabhutas, with earth contributing to nutritional content and structure formation, water facilitating nutrient transport, fire driving metabolism and photosynthesis, air enabling respiration, and space providing the necessary environment for biochemical reactions and plant growth. In contrast, the self-protection mechanism is activated when any imbalance occurs in these vital functions; here, the Prana Shaktis—Apana (governing root function and nutrient extraction), Samana (regulating transpiration), Udana (influencing photosynthesis and enzyme secretion), Prana (controlling respiration), and Vyana (ensuring spatial adequacy for metabolic activities)—collectively work to restore equilibrium. By stimulating these internal life forces rather than relying on external chemical interventions, IRF Technology effectively overcomes plant diseases and pest infestations, ensuring balanced nutrient uptake and improved resilience. This integrative approach, based on precise “Energy Management,” tailors solutions to specific crop and agro-climatic conditions, thereby laying the groundwork for sustainable, chemical-free agriculture.

Coir Pith Composting with Novcom Composting Technology

Novcom Composting Technology harnesses the Element Energy Activation (EEA) Principle to create an optimal environment that accelerates microbial self-generation and expedites the biodegradation of coir pith, a byproduct of coconut processing, into high-quality organic compost. This method employs controlled aeration, precise temperature regulation, and effective moisture management to yield a consistent, microbe-rich product that not only improves soil fertility and water retention but also supports sustainable agriculture by reducing waste and

curtailing the reliance on chemical fertilizers. In a designated upland, flat area, the process begins with constructing a 10 ft. × 8 ft. × 6 ft. support structure made of bamboo strips and coconut leaves, designed to accommodate an approximate 8–9-ton heap of coir pith compost. The preparation involves applying a basal layer of cow dung slurry on the floor and inner walls of the support structure to establish an initial microbially active base. Coir pith is then mixed with cow dung slurry at an 80:20 weight ratio and layered in increments of approximately 0.5 ft. until the structure is filled, with each layer receiving about 60 ml of Novcom solution—this solution is prepared by diluting 25 ml in 5 liters of water—to facilitate microbial activation. Due to the inevitable compression of the material as it is layered, a total of 16 layers (amounting to about 2000 ml of Novcom solution) is required to reach the final 6-ft. height. After assembly, the compost heap is covered with coconut leaves and left undisturbed for the initial 9 days to promote in situ microbial activity. On the 10th day, one side of the heap is opened and the material is thoroughly mixed using a JCB, and the restructured heap is again treated with 2000 ml of the Novcom solution. This mixing process is repeated on the 20th day to ensure uniform microbial distribution and further acceleration of the composting process. Ultimately, by the 30th day, the composite material transforms into a matured, nutrient-rich compost that reflects the efficacy of the EEA Principle in converting a challenging organic residue into a sustainable agricultural resource, aligning with environmentally conscious waste management practices and the principles of circular economy in agriculture (Bera et al., 2023).

Compost, Soil, Crop Productivity, and Energetics Analysis

In this study, fifty composite samples from distinct Novcom coir pith compost heaps were systematically collected and analyzed for various quality parameters in accordance with the standard methodology described by Seal et al. (2012), with the subsequent calculation of a Compost Quality Index following the protocol of Bera et al. (2013). Soil quality was concurrently assessed by procuring samples from the 0–30 cm depth prior to the initiation of the experiment and again one year later; these samples were subjected to rigorous evaluations of physicochemical properties and fertility parameters based on established methods (Jackson, 1973). Additionally, microbial biomass carbon was quantified using the dichromate oxidation method (Vance et al., 1987), while soil respiration was determined through chemical titration of trapped CO_2, and soil FDAH was measured as per the standard procedures outlined by Haney et al. (2008). Crop productivity was assessed following recognized guidelines (Patrick, 1999) and later converted to coconut equivalent yield, ultimately facilitating the computation of total system productivity using methodologies described by Ghosh et al. (2021) and Naveen Kumar et al. (2017). The energy dynamics of the system were evaluated by calculating metrics such as energy use efficiency, energy productivity, specific energy, energy intensiveness, and net energy, all derived according to the standardized procedures reported by Banaeian et al. (2011). Finally, the overall environmental impact was quantified by determining the system's carbon footprint using ACFA (version 2.0), a carbon computing standard specifically developed for Indian agriculture by the Inhana Organization Research Foundation (IORF) in collaboration with ICAR-ATARI, Kolkata (Zone-V) and i-NoCarbon Limited (i-NC), UK, based on relevant IPCC guidelines and substantiated by empirical research (IORF, 2024). Together, these comprehensive analyses provide critical insights into the quality of the compost and soil, the efficiency of nutrient and energy use, and the sustainability of crop production systems, thereby supporting the development of best practices for sustainable agricultural management and reducing the environmental impact of farming operations.

Result and discussion

The result and discussion section comprehensively addresses a range of key issues. It begins with an evaluation of Novcom coir pith compost quality and progresses to assess crop performance, nutrient use efficiency, pesticide load, energy transition, farm income, and employment generation. In addition, it examines the impact of the Regenerative Agri-Net Zero Model on soil quality and quantifies greenhouse gas mitigation achieved through the CFNZ program across various crops. The analysis further encompasses the development of the Regenerative Agri-Net Zero Models, presents a multifaceted impact assessment of these models, and critically evaluates the economic viability of sustainable agricultural initiatives.

Analysis of Novcom Coir Pith Compost Quality

A comprehensive investigation into the efficacy of Novcom Composting Technology was conducted through batchwise 30th day samples of Novcom coir pith compost to evaluate its quality as per National and International Standards. Central to this assessment was the measurement of the carbon-to-nitrogen (C:N) ratio, which declined markedly from an initial approximate value of 100:1 in raw coir pith to less than 30:1 by day 30, signifying rapid organic matter degradation. Concomitant with this decline, total nitrogen content increased by approximately 98%, while lignin content experienced an estimated 60% reduction within the same period, confirming substantial biochemical transformation. Correspondingly, organic carbon content reduced from about 51.78% in the untreated material to approximately 27.50% in the mature compost, aligning with the typical range observed in stable compost (16–38%). These chemical transformations were correlated by very high microbial load, with bacterial, fungal, and actinomycete populations reaching the order of 10^{16} c.f.u. per gram of moist compost, which attests to

the very intense microbial activity essential for accelerated biodegradation. The breakdown of complex organic compounds through microbial enzymatic processes, under optimal conditions, underscores the efficiency of the technology. Additionally, phytotoxicity bioassay tests confirmed the absence of deleterious compounds in the final compost product and revealed that the amendment actively promotes seed germination and root growth, thereby enhancing its agronomic value. Collectively, these results not only demonstrate significant improvements in physicochemical and biological compost parameters but also illustrate the environmental benefits of the technology, positioning Novcom composting as a robust and sustainable strategy for managing coconut processing residues and enhancing soil fertility while mitigating greenhouse gas emissions.

Table 1 : Physicochemical, nutritional, biological quality parameters and lignin content of Novcom coir pith compost.

Test Parameters	Raw Coir pith	Novcom Coir pith Compost
Physicochemical & Nutritional Quality		
Moisture (%)	65.2 – 78.5	69-2 – 74.1
pH (H_2O)	5.30- 5.21	6.24 – 6.78
EC (dSm^{-1})	3.01 – 3.51	2.13 – 2.68
Organic Carbon (%)	49.6 - 52.4	25.1 – 29.7
Total N (%)	0.43 – 0.61	0.89 – 1.28
Total P_2O_5 (%)	0.06 – 0.17	0.15 – 0.21
Total K_2O (%)	1.31 – 1.78	2.69 – 3.78
C:N	94:1 – 108:1	25:1 – 30.4
Biological Quality		
Bacteria (c.f.u. per gm moist compost)	-	$(31 - 78) \times 10^{16}$
Fungi (c.f.u. per gm moist compost)	-	$(17 – 34) \times 10^{16}$
Actinomycetes (c.f.u. per gm moist compost)	-	$(7 – 16) \times 10^{16}$
Stability, Maturity & Phytotoxicity Parameters		
CO_2 Evolution Rate ($mgCO_2$–C/g OC/day)	-	1.13 – 1.89
Germination Index (Phytotoxicity Bioassay)	-	0.91 – 1.11
Lignin Degradation Study		
Total lignin %	39.8 - 43.7	21.2 – 24.7

Crop performance, Nutrient Use efficiency, Pesticide Load, Energy Transition, Farm Income, Employment generation under Regenerative Agri-Net Zero Model

Crop productivity of coconut based intercropping under Regenerative Agri-Net Zero Model adopted in Mandya, Karnataka was compared with conventional coconut based intercropping practice. Under IBM-IORF Sustainability project, 3 major coconut based intercropping viz (i) CBCE 1 : Coconut -Millet – Vegetable, (ii) CBCE 2: Coconut - Maize – Vegetable and CBCE 3: Coconut – Ginger was taken under study and comparative assessment was done under Conventional Farmers Practice (CFP) and Clean Food Net Zero (CFNZ) program.

Table 2 : Comparative study of crop performance, nutrient use efficiency, pesticide load, energy productivity, income generation under CFP and CFNZ management

Sl No	Parameters	Coconut-based Integrated Farming Systems					
		CBCE 1		CBCE 2		CBCE 3	
		CFP	CFNZ	CFP	CFNZ	CFP	CFNZ
1	Coconut Equivalent yield	9473	10666	11044	12574	23025	28535
2	System Productivity	14555	16387	16991	19345	35424	43900
3	Nutrient Use Efficiency	35.96	50.94	35.43	53.07	29.61	32.58
4	Nutrient Use Efficiency (based on availability in org. manure)	35.96	84.90	35.43	88.45	29.61	54.30
5	Pesticide Load	0.091	0.00	0.091	0.00	1.371	0.00
6	Crop Pesticide Pollution Index (CPPI)	0.006	0.00	0.006	0.00	0.084	0.00
7	Energy Productivity	0.28	0.94	0.29	0.99	0.24	0.69
8	Farm Income (gross)	562452	634150	568392	642784	328272	347656
9	Employment Generation Potential	125	245	131	251	230	350

Comparative analyses were conducted across three distinct coconut-based integrated crop production systems under two management regimes: Conventional Farmer Practice (CFP) and the Clean Food Net Zero (CFNZ) program. The results revealed that the CFNZ model consistently outperformed the CFP system, with average crop yield increases ranging from 12.6% to 23.9% across various cropping sequences. In addition, when total nutrient inputs (NPK) were provided through organic manure, nutrient use efficiency (NUE) was 33.8% higher under the CFNZ program. Notably, despite the inherent limitation that only about 30% of nitrogen, 60–70% of phosphorus, and 70% of potassium from organic manure are available to the first crop cycle, the overall nutrient uptake was significantly improved in the CFNZ system compared to CFP. This enhancement is largely attributable to the integrated Inhana Plant Health Management approach incorporated in the CFNZ program, which bolsters plant physiological functions, supports growth in low-input environments, and enhances resistance against both biotic and abiotic stresses. Furthermore, improvements in internal plant immunity and enhanced soil–plant–environment interactions were evidenced by a reduction in crop pesticide load, with the pesticide pollution index dropping to zero under CFNZ—a critical indicator for safe food production. Energy productivity also increased dramatically, exhibiting gains between 187% and 247%, which underscores the effectiveness of the nature-harnessed pathways employed in the CFNZ system. Economically, while overall farm income under CFNZ increased by about 10% relative to CFP, a shift to monoculture coconut cultivation has the potential to boost gross income by more than 50%.

Impact of Regenerative Agri-Net Zero Model on Soil Quality

A comparative assessment of soil health under Conventional Farming Practices (CFP) and the Clean Food Net Zero (CFNZ) management revealed significant differences in soil quality improvements. The CFNZ approach, emphasizing regenerative techniques, demonstrated notable enhancements in both physico-chemical and biological soil properties, surpassing the outcomes observed under CFP.

One of the most striking findings was a 25% increase in soil organic carbon (SOC) in CFNZ-managed fields post-intervention, while CFP fields exhibited negligible changes. This elevation in SOC is critical as it enhances soil structure, water retention, and nutrient availability, contributing to overall soil fertility. In terms of nutrient dynamics, both management systems showed improvements in available nitrogen (N), phosphorus (P_2O_5), and potassium (K_2O) levels. However, CFNZ fields demonstrated a more balanced nutrient profile, indicative of sustainable nutrient cycling facilitated by regenerative practices.

Table 3 : Comparative study of soil quality parameters

Soil Physico-chemical parameters	pH	EC (1:5) dSm^{-1}	Org. C%	Av NO_3 (ppm)	Av-N	Av P_2O_5	Av. K_2O	Av- SO_4
					< ---------- Kg/ha ---------->			
Before experimentation								
CFP	6.14	0.053	0.50	29.19	168.04	32.43	534.26	424.58
CFNZ	6.15	0.051	0.53	31.02	165.70	30.15	468.90	432.10
Post Experimentation								
CFP	6.15	0.054	0.51	32.10	213.10	32.10	542.10	356.10
CFNZ	6.23	0.059	0.66	28.80	203.25	38.97	505.05	395.54
Soil Biological parameters	Bacteria	Fungi	Actino-mycetes	MBC[1]	FDA[2]	SR[3]	qMBC[4]	qCO_2[5]
Before experimentation								
CFP	10 x 10^4	11x 10^3	4 x 10^3	46.70	14.46	0.16	0.93	3.43
CFNZ	12x 10^4	9 x 10^3	6 x 10^3	45.8	13.2	0.17	0.86	3.71
Post Experimentation								
CFP	16x 10^4	9 x 10^3	6 x 10^3	45.5	15.10	0.15	0.89	3.30
CFNZ	59x 10^5	13 x 10^4	19 x 10^3	66.8	19.01	0.21	1.01	3.14

Note : [1]MBC; Microbial biomass carbon (micro gm biomass C/gm dry soil/hr), [2]SR:Soil Respiration, [3]FDA : Soil Fluorescein diacetate hydrolysis activity (µg/gm dry soil), [4]qMBC :Microbial Quotient, [5]qCO_2: Metabolic Quotient

Biological indicators further underscored the efficacy of the CFNZ program. There was a substantial increase in microbial populations, including bacteria, fungi, and actinomycetes, in CFNZ implemented fields. This microbial proliferation is attributed to the application of high-quality Novcom compost at 40 tonnes per hectare, which

provides a rich substrate for microbial growth. Enhanced microbial activity was evidenced by increased microbial biomass carbon (MBC) and fluorescein diacetate (FDA) hydrolysis activity, both of which are indicative of a dynamic and healthy soil microbial community. These biological enhancements are vital for nutrient mineralization and overall soil ecosystem functioning.

The comparative analysis clearly indicates that the CFNZ program fosters a more robust and resilient soil environment compared to conventional practices. By improving both chemical and biological soil properties, the CFNZ program not only enhances immediate soil fertility but also contributes to long-term agricultural sustainability. These findings align with broader research indicating that regenerative agricultural practices can significantly improve soil health and productivity.

GHG Mitigation under CFNZ program in different crops

Agriculture occupies a pivotal role in both generating GHG emissions and offering pathways for their mitigation through carbon sequestration. The 25.2-hectare Clean Food Net Zero (CFNZ) program in Mandya, Karnataka, India towards development of Regenerative Agri-Net Zero Model, which employs IRF Technology, exemplifies this dual potential. Through substantial carbon sequestration, notable emissions reductions, and the enhancement of ecosystem health, the CFNZ program illustrates how innovative agricultural practices can lead to net-zero emissions without compromising productivity.

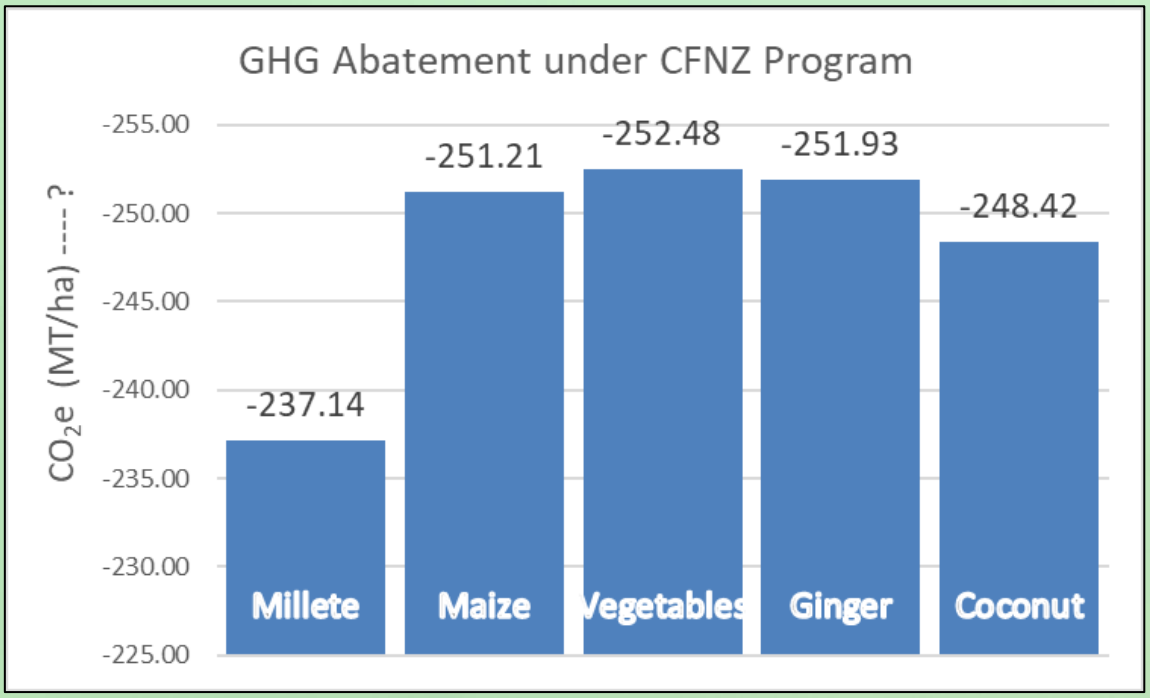

Fig 1 : GHG abatement potential under CFNZ program.

A GHG evaluation conducted using the ACFA (Version 2.0) tool demonstrated that replacing conventional farming practices (CFP) with the CFNZ program yields significant abatement of CO_2e per hectare across multiple crops. For instance, while CFP results for millet, maize, vegetables, ginger, and coconut registered at 1.14, 1.39, 2.65, 2.30, and –1.66 ton CO_2e/ha respectively, the corresponding CFNZ values dropped dramatically to –236.01, –249.83, –249.83, –249.63, and –250.08 ton CO_2e/ha. This translates to GHG abatement potentials of –237.14, –251.21, –252.48, –251.93, and –248.42 ton CO_2e/ha, respectively, thereby underscoring the significant environmental benefits of the CFNZ approach in fostering sustainable and climate-resilient agriculture.

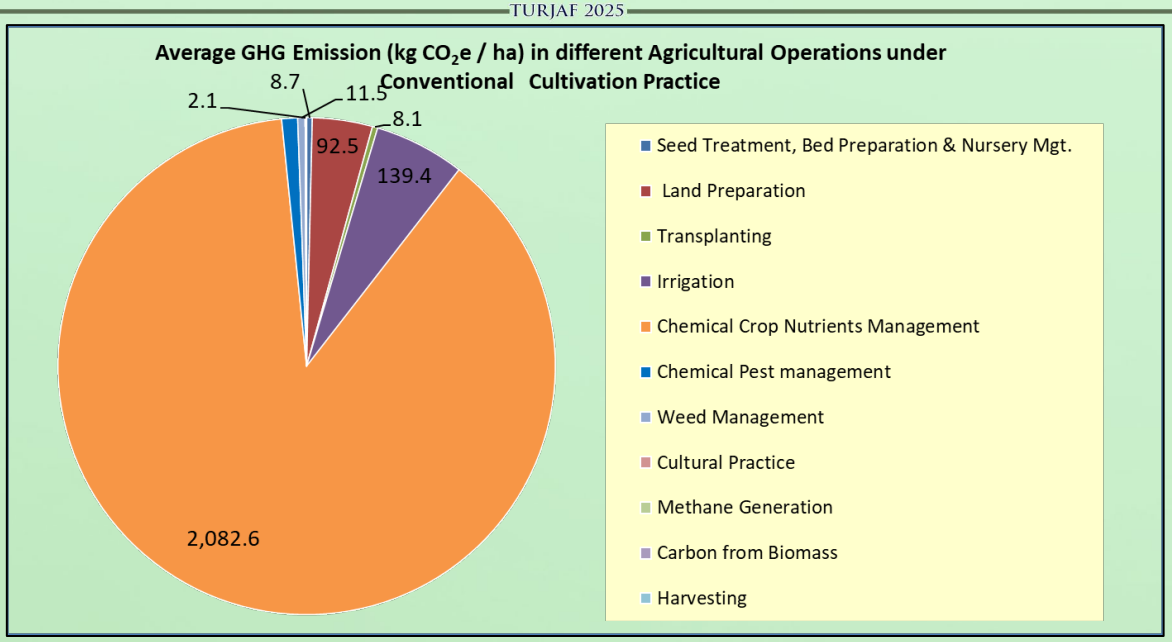

Fig 2 : Average GHG emission ($KgCO_2e$ /ha) of different agricultural operations under CFP at Mandya, India studied under IBM-IORF Sustainability Program

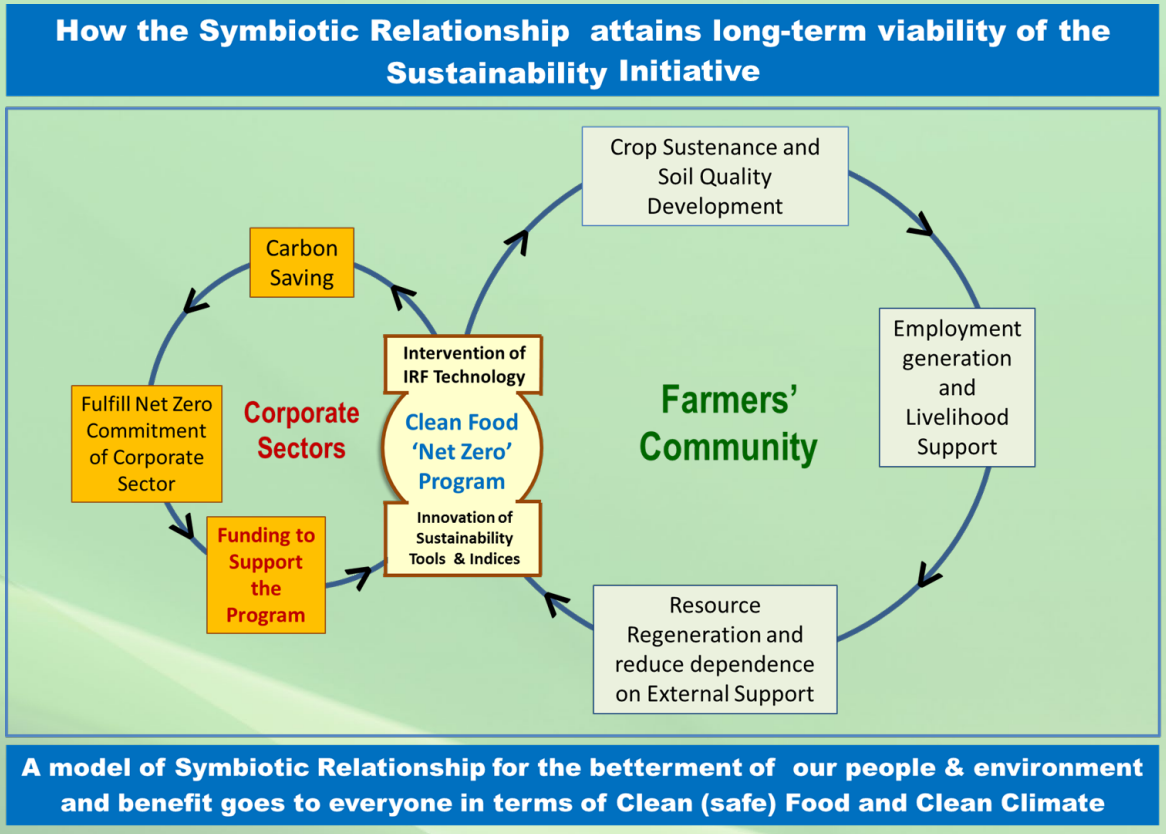

Fig 3 : The Regenerative Agri-Net Zero Model showed a symbiotic relationship between corporate net zero goal and farmers sustainability

Development of the Regenerative Agri-Net Zero Models

The Regenerative Agri-Net Zero Model represents an innovative framework that decouples economic growth from resource depletion and environmental degradation by closing the carbon cycle and promoting waste to compost development movement. This approach integrates waste recycling, resource efficiency, and renewable energy to conserve natural resources while actively mitigating greenhouse gas emissions, and it has been successfully implemented under the IBM-IORF Sustainability Project in Mandya, Karnataka—the first agro-net zero model in India certified by i-NoCarbon, UK. By combining Inhana Rational Farming (IRF) Technology with Novcom

Composting Technology, the project has transformed approximately 2000 tonnes of coir pith, a byproduct of coconut processing, into a high-quality compost applied at 40 tonnes per hectare over a 25.2-hectare area for two consecutive years. The rapid bioconversion process—completing within just 30 days—yields compost that is exceptionally rich in native microflora, which catalyzes soil microbial regeneration and effective carbon sequestration. Beyond enhancing soil health, this model sustains crop productivity, aligns with economic services, and facilitates the production of pesticide-free food, thereby securing sustainable livelihoods.

Moreover, it exhibits a very high carbon mitigation potential; GHG evaluations using the ACFA (Version 2.0) tool reveal that the model can mitigate approximately 250.39 metric tonnes CO_2 equivalent per hectare, in addition to the bioconversion process mitigating around 6000 tonnes CO_2 equivalent per 1000 tonnes of waste and further abating nearly 6300 tonnes CO_2 equivalent by eliminating synthetic nitrate fertilizers. This robust carbon abatement program not only support corporate net-zero and sustainability initiatives but also ensure that the program has no spillover effects or scope for greenwashing. In fact, the model's significant social and environmental footprint establishes it as one of the best decarbonization programs currently available, setting a scalable benchmark for sustainable, climate-resilient agriculture and advancing global sustainable development goals.

Multifaceted Impact Assessment of Regenerative Agri-Net Zero Model : Enhancing Sustainable Agriculture, Environmental Regeneration, and Livelihoods of Small and Marginal Farmers

The Clean Food Net Zero (CFNZ) program represents a transformative advancement in sustainable agriculture by integrating organic soil management, rapid waste bioconversion, and advanced plant health practices to deliver significant environmental, agronomic, and social benefits. Environmentally, the model achieves considerable greenhouse gas mitigation—up to 250 tons CO_2 equivalent/ha—while enhancing soil carbon sequestration by approximately 300 kg/ha/year through the conversion of diverse organic wastes into nutrient-rich compost in just 21 days. This rapid bioconversion process revitalizes degraded lands by boosting soil microflora and earthworm activity and supports pesticide residue–free food production in compliance with FAO-WHO-Codex standards, ultimately reducing chemical input burdens and promoting ecological sustenance across 100 hectares serving over 20,000 consumers. Agronomically, the CFNZ program drives a 15–25% increase in crop productivity relative to conventional practices, simultaneously achieving up to 32% lower energy input and over 60% higher energy productivity, which is further reinforced by the development of climate-resilient organic seeds that enhance farmers' adaptability to climate change. Socially, the model serves as a critical catalyst for the economic upliftment of small and marginal farmers by transferring sustainable crop technologies and comprehensive knowledge support, thereby fostering greater food security and income generation. Furthermore, by bridging the gap between grassroots farming and corporate sustainability efforts, the CFNZ program enables the integration of sustainable agricultural practices into supply chains, aligning corporate initiatives with broader net-zero objectives and Sustainable Development Goals. In summary, this integrated approach not only regenerates environmental health and boosts agricultural productivity but also delivers profound socio-economic benefits, establishing a scalable, win–win framework for sustainable development.

Economic viability of Agricultural Sustainable initiatives: A detailed insight and impact of carbon funding

An analysis of cultivation costs and income indicates that adopting any sustainable project involves extra expenses that erode profitability. Our experience shows that when sustainable practices fail to sustain crop yields or lack technological enhancements to improve system efficiency, the gap in the return on investment (ROI) widens further. Consequently, the cost and return aspects of sustainable projects are seldom discussed within the framework of hard economics, with the discussion taking a holistic view and typically focused on broader environmental benefits—such as enhanced soil health and ecological sustenance—rather than on direct financial outcomes.

Introduction of Inhana Rational Farming (IRF) technology reduces operational costs by sustaining crop productivity and lowering expenses associated with pest and disease management. However, the organic inputs required for sustainable soil management remain significantly more expensive than chemical fertilizers. The adoption of Novcom composting technology further cuts management time, enhances compost quality, and improves the efficacy of soil application. It is evident that conventional sustainable initiatives without technological intervention demand a premium of 80–100% to achieve net benefits comparable to conventional farming practices. In contrast, the introduction of IRF technology effectively narrows the return on investment gap, requiring only a 30–35% premium—particularly when following the Agri-Net Zero model with its intense carbon mitigation objectives. On the other hand, carbon funding under the Agri-Net Zero model can potentially boost net profits by more than 200%.

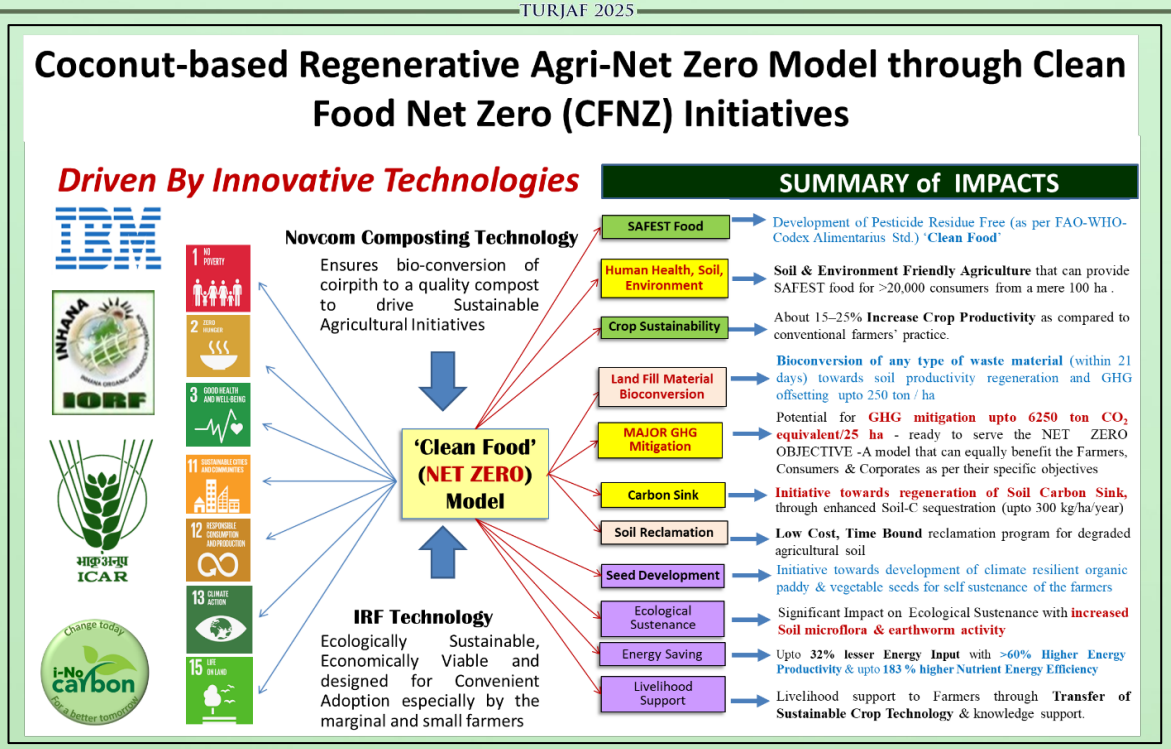

Fig 4 : The Regenerative Agri-Net Zero model driven by Clean Food Net Zero (CFNZ) program through the adoption of Inhana Rational Farming Technology exhibited a multifaceted social and environmental footprint.

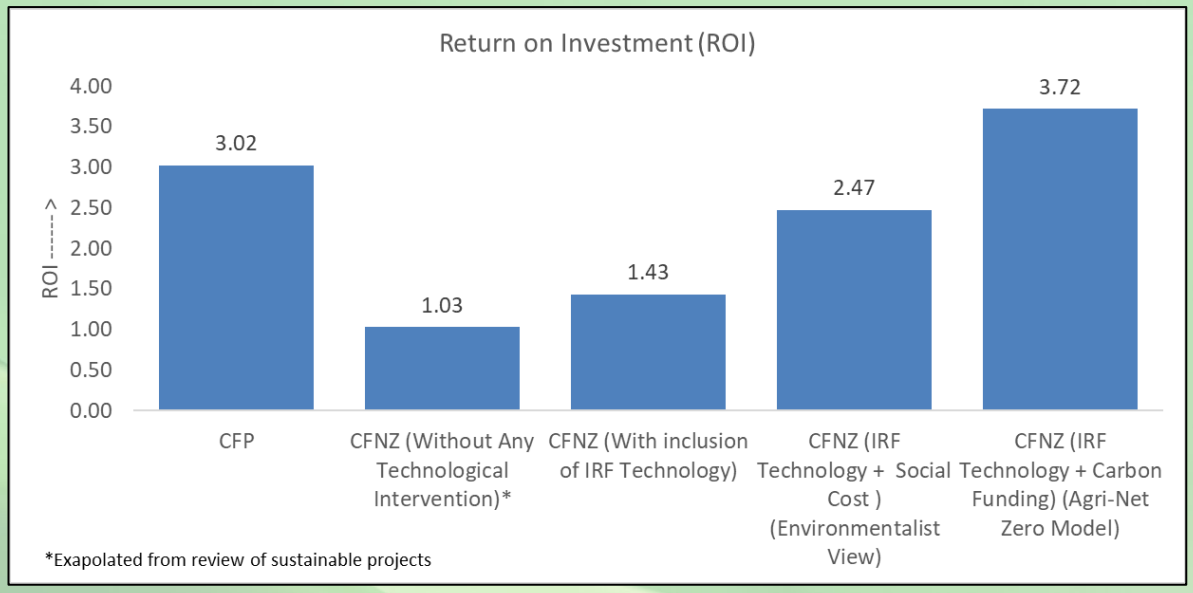

Fig 5 : Return on Investment (ROI) in sustainable initiative – a detailed Insite.

One of the most intriguing outcomes is the return on investment (ROI) in sustainable agriculture. Despite improvements in yield, reductions in pest and disease incidence, and enhanced energy productivity, the ROI for these initiatives remains lower than that of conventional farming—primarily due to the increased costs of sustainable soil management compared to chemical fertilizers. The Agri-Net Zero Model, integrated with climate-resilient regenerative agriculture, offers a promising solution by linking corporate sustainability commitments through CSR, ESG, and dedicated funding with farmers' practices via carbon mitigation objectives. Economic analyses indicate that when generated carbon credits are repurchased at a moderate price (around $60 per metric ton, even when international prices exceed $100), the Agri-Net Zero Model becomes significantly more viable, bolstering overall profitability. While environmental benefits such as improved soil health and long-term climate

change mitigation are critical and widely discussed among policymakers, agronomists, and environmentalists, the hard economic metrics of cost and return receive far less attention. For resource-poor farmers, who prioritize immediate operational sustainability over uncertain future gains, expecting them to shoulder these costs is impractical; instead, the lion's share of responsibility must be borne by policy makers, government bodies, and corporate institutions. Sustained support over a three-to-five-year period can further rejuvenate farming systems by gradually reducing soil management costs, enhancing productivity, and enabling fair market price realization, thereby driving the long-term viability of sustainable agricultural practices.

Conclusion

The study decisively establishes the Regenerative Agri–Net Zero Model as a scalable, economically viable, and scientifically robust framework for climate-resilient agriculture. By integrating advanced organic soil and plant health technologies—specifically Inhana Rational Farming and Novcom Composting—within a regenerative, circular bioeconomy, the model delivers transformative outcomes. It substantially enhances crop yields, nutrient use efficiency, and farmer incomes while restoring soil health through increased organic carbon sequestration and revitalization of microbial ecosystems. It achieves significant greenhouse gas mitigation, supports pesticide-residue–free food production, and reduces reliance on synthetic fertilizers—ensuring sustained ecological balance. Critically, the model bridges corporate sustainability goals with the resilience of small and marginal farmers, producing tangible co-benefits such as improved energy productivity, enhanced ecosystem adaptability, and access to carbon financing. Third-party certification affirms its environmental integrity, confirming the absence of greenwashing or negative spillover effects. To accelerate its impact, a clear policy directive is needed to promote nationwide adoption of the Regenerative Agri–Net Zero Model through targeted incentives, carbon credit integration, and its inclusion in corporate ESG frameworks—aligning agricultural sustainability with national climate goals. Altogether, the model sets a transformative benchmark, aligning with global Sustainable Development Goals and offering a future-ready blueprint for corporate ESG ambitions and rural livelihood sustainability.

Abstract

Global food systems are facing challenges in meeting the rising demand for food while also reducing their environmental impact, including carbon and water footprints. Artificial intelligence (AI) offers promising solutions to improve efficiency, effectiveness, and resilience throughout the food supply chain. However, the use of AI in food production, particularly in advanced industrial settings such as Industry 4.0 and 5.0, also presents its own environmental and social challenges. This study examines the potential benefits of AI in creating a sustainable food system, including better resource use, less waste, improved water efficiency, and enhanced crop protection. It also considers the significant energy needed to train and operate AI systems. To ensure AI-based technologies truly support sustainability in food production, we need a balanced approach that includes fair access, responsible resource management, and integrating AI with other sustainable agricultural practices. Future efforts should focus on making AI tools easier to use for a wider audience, implementing strong governance rules, and aligning AI advancements with environmental, economic, and social impacts. By preventing these challenges, AI can be used to develop a more efficient, resilient, and environmentally friendly food resource system, contributing to global sustainability goals.

Effects of Allantoin, A Stress-related Purine Metabolite, on Salt Stress Mitigation in Maize (*Zea mays L.*) During Early Germination Stage

Mst. Adia Sultana[1], Shobnom Mustary[1] , Maisha Rahman[1], Tahmina Akter[1], Md. Rezwanul Haque[1], Md. Arif Sakil[1*]

Abstract

Soil salinity is a major constraint on global agricultural productivity, particularly affecting salt-sensitive crops like maize (*Zea mays L.*). This study investigated the potential of allantoin, a purine metabolite, to mitigate salt stress during maize seed germination and early seedling development. Maize seeds were pretreated with varying concentrations of allantoin (0, 0.5, and 1 mM) and subsequently subjected to 150 mM NaCl stress under controlled conditions. Morphological parameters, including shoot and root length, fresh and dry weight, germination percentage, and vigor index, were assessed. Biochemical analyses quantified oxidative stress markers (malondialdehyde, hydrogen peroxide), photosynthetic pigments, protein content, osmolyte accumulation, and antioxidant enzyme activities. Salt stress significantly inhibited germination and seedling growth, increased oxidative stress, and disrupted biochemical homeostasis. However, allantoin pretreatment, particularly at 0.5 mM, effectively alleviated these adverse effects. Allantoin-treated seedlings exhibited improved germination, enhanced growth, reduced oxidative damage, and modulated biochemical responses. This research demonstrates that allantoin can enhance salt tolerance in maize during germination. These findings suggest that allantoin pretreatment represents a promising strategy for improving maize establishment and productivity in saline environments.

Abstract

Helminth infections, particularly those caused by soil-transmitted helminths (STHs), pose a substantial global health threat, affecting over 1.5 billion individuals, particularly in tropical and subtropical regions. These infections are common in impoverished communities, particularly in rural areas and urban slums of Bangladesh, which lack adequate sanitation systems. These infections impose a significant economic burden on developing countries by reducing livestock productivity and deteriorating animal health. The rise of anthelmintic resistance to conventional anthelmintics, particularly in livestock, and the potential for its spread to humans underscore the urgent need for alternative therapies. This review aims to explore the potential of medicinal plants in Bangladesh as alternative anthelmintic treatments by examining studies conducted over the past two decades, focusing on species native to the country. A comprehensive literature search was conducted across various databases, including PubMed and search engines like Google Scholar, to identify only full-length, English-language articles. The review identified fifty-six medicinal plants belonging to thirty-six different families, with Fabaceae (seven species),being the most diverse followed by Lamiaceae (four species), and Apocynaceae, Combretaceae, and Cucurbitaceae (three species each). The conservation status assessment revealed 29 plants classified as Least Concern (LC), 24 as Not Evaluated (NE), and 3 as Data Deficient (DD). A thorough literature review resulted in the development of a detailed table summarizing diverse anthelmintic evaluations. This table provides data on extract types, with aqueous and alcoholic extracts being the most prevalent, and testing methods, which include both in vitro and in vivo assays against parasitic and non-parasitic nematodes. Furthermore, it addresses assessment parameters such as egg hatch inhibition, larval migration inhibition, and paralysis induction. The review highlights the growing importance of Bangladeshi medicinal plants as alternative medications in the face of rising anthelmintic resistance. Further studies should focus on the extracts, fractions, and compounds derived from these plants, evaluating their efficacy as anthelmintic agents for use in livestock, companion animals, and humans. As traditional anthelmintics become ineffective due to resistance, medicinal plants offer a promising alternative, highlighting the need to explore their potential in humans, animals, and livestock.

Abstract

The chemical analysis and nutritional assessment of *Balanite aegyptiaca* seed cake (BASC) were investigated to evaluate the effect of using BASC as additive at 0 %, 10 %, 20 % and 30 % inclusion levels in catfish diets and performance. Two hundred and twenty-five *Clarias gariepinus* post juveniles (catfish) with initial weight ranging from 28.06±0.35g to 31.92±0.97g were divided into five experimental groups. Each group with three replicate of fifteen fishes stocked in 40-litre plastic bowls were fed twice a day at 3 % of their body weight with five formulated diets for 56 days. Diets 1 and 2 (standard feed and 0 % BASC) were used are control while diets 3, 4 and 5 containing respectively 10 %, 20 % and 30 % of BASC were the experimental diets. The protein content in the prepared feed increased gradually within the groups due to the high protein content (51.31±0.13%) of BASC. All the fish increased significantly ($P \leq 0.05$) in weight, length, nitrogen metabolism, condition factor, survival rate and in other growth parameters above the initial values with the highest percentage in 30% group. Haematological analysis showed a slight increments in the blood parameters (PCV, Hb, RBC WBC and MCHC) except for MCH, MCV and platelets ($p<0.05$). No significant differences were observed in ATP, AST, ALT, globulins and albumin in fish fed on BASC containing diets. Histology showed a mild congestion of the blood vessels in the Kidney of the control and 10 %, a moderate portal congestion and diffuse vacuolar degeneration in the liver of the control and 20%. No significant differences were observed in all gills, heart as well as in the kidney and liver of other experimental fishes. *B. aegyptiaca* seed cake could be a nutritional source without any toxic effect to *Clarias gariepinus* post juveniles (catfish).

Key Words: *B. aegyptiaca* cake, *C. gariepinus* post juveniles, growth performance, nutritional source

Evaluation of antibacterial efficacy of albedo of *Citrus medica* fruit against pathogenic microorganisms

Wajid Khan*1, Asad Ullah[1], Asif Nawaz[1], Muhammad Nazir Uddin[1] and Nabila Qayum[1]
[1]Center for Biotechnology and Microbiology, University of Swat, Pakistan
Correspondence email address: sherafghan.shah@gmail.

Abstract

The present study aimed to explore the antibacterial effect of the albedo of *Citrus medica* fruit. For this pursuit, extracts were prepared in methanol, ethyl acetate, n-hexane, cold water, and hot water. These extracts were then tested against both plant and human pathogenic bacterial species. The disc diffusion method measured the antibacterial activity of extracts from the albedo of fruit at different concentrations (1000µg/disc, 2000µg /disc, and 3000 µg /disc). The findings of the study showed that hot water and ethyl acetate extract formed the same zone of inhibition against *Escherichia coli* (*E. coli 0157:H7) and Citrobacter freundii* (53% ZI) at 3000 µg/disc. Similarly, ethyl acetate extract was active against *Agrobacterium tumefecien* and produced a 53% zone of inhibition at 3000µg/disc. Methanol and cold water extract at 3000µg /disc formed a 41% zone of inhibition against *Agrobacterium tumefecien* and *Xanthomonas oryzae*.

Ethyl acetate extract n-hexane was active against *Bacillus atrophaeus* and *Salmonella typhi* by producing 41% zone of inhibition. The ethyl acetate extract showed antibacterial potential against *P. aeroginosa* and formed a 41% inhibition zone at 3000µg/disc. Furthermore, the growth of *Rhizobacteria solani* was inhibited equally by methanol and n-hexane extract (33%ZI) at 3000µg /disc. Hot water extract produced a 41% zone of inhibition against *C. freundii* . However, ethyl acetate and n-hexane extracts formed 28 and 23% zones of inhibition against *Rhizobacter* and *C. freundii* respectively.

Unveiling the role of spirulina in the mitigation of sumithion-induced toxicity in Thai pangas, *Pangasianodon hypophthalmus*

Saudah Binte Ashraf, Md Ruhul Amin and Md Shahjahan

Laboratory of Fish Echophysiology, Department of Fisheries Management, Bangladesh Agricultural University, Mymensingh 2202, BANGLADESH
Corresponding author: mdshahjahan@bau.edu.bd

Abstract

Sumithion is an organophosphate insecticide, widely used in aquaculture ponds to eradicate aquatic insect (mainly tiger bugs), typically applied before stocking fish larvae. However, it adversely affects non-target aquatic organisms, particularly fish. This study was conducted to evaluate the potential toxicity of sumithion in Thai pangas (*Pangasianodon hypophthalmus*) as well as the role of dietary *Spirulina platensis* in mitigating the toxic effects of sumithion. Over a 42-day trial, a total 240 of striped catfish fingerlings were exposed to four different treatments: control (without Sumithion or Spirulina), sumithion (0.6 mg/L), Spirulina (50 g/kg feed) and combined treatment (sumithion + Spirulina) with three replicates each. Sumithion-treated fish exhibited altered hemato-biochemical indices (hemoglobin and glucose) as well as erythrocyte morphology such as cellular (teardrop, twin, fusion) and nuclear (nuclear bridge, nuclear buds, notch, karyopyknosis) abnormalities. Furthermore, the sumithion-treated fish exhibited a considerable difference in the expression levels of antioxidant genes with down-regulated of *SOD*, *CAT* and up-regulated of *GPx* as well as immune-related genes with up-regulated of *MHC-II* and *IFN-β2* and down-regulated of *IL-1β* and *IFN-α2* compared to control. Moreover, it has been found that Spirulina along with sumithion improves the immunological, anti-oxidative, and physiological conditions of fish. The present study unveiled the implementation of dietary Spirulina to be an effective approach to mitigate sumithion-induced stress and optimize health condition in striped catfish by improving haemato-biochemical index and immune-antioxidant genes expression.

*corresponding author: lerzanozturk@gmail.com

Abstract

Aphelenchus avenae Bastian 1865,and *Aphelenchoides clarus* Thorne and Malek, 1968, and *Aphelenchoides sacchari* Hooper 1958 are mycophagous nematodes belonging to the *Aphelenchida* order. These nematodes are highly distributed in vineyards in Turkey. In this study, the reproduction potential of these three nematodes was determined under in-vitro conditions using the fungi *Aspergillus niger, A. flavus,* and *Fusarium oxysporum.* The fungi used in the experiments were isolated from soils collected from vineyards and maintained on Potato Dextrose Agar (PDA) at 25°C. Nematodes were extracted from the soils using the modified Baermann funnel method. After one week of fungal growth, 30 females of each nematode species (*A. avenae, A. clarus* and *A. sacchari*) were hand-picked and inoculated into the fungal cultures, which were then incubated for about a month at 25°C. At the end of the month, all nematode species reproduced in the Fusarium oxysporum culture. The reproduction rate was the lowest in *A. avenae* (44 individuals, a 1.46-fold increase) and the highest *A. sacchari* (177 individuals, a 5.9-fold increase). However, none of the nematodes reproduced in the *A. niger* or *A. flavus* cultures. The juvenile populations of *A. sacchari,* and *A.clarus* were abundant in the fungal cultures, and in petri dishes where the nematode population increased significantly, fungal cultures showed visible deterioration and a decrease in biomass.

A comparison of different selection indexes for milk traits in Friesian cows by using different relative economic values.

Hussein, A,M[1].; Farrag, F.H[2].; El- Arian, M.N[2].; Omer. E.A[1]. and Khattab, A.S[3].

[1]Animal production Research Institute, Ministry of Agric., , Giza, Cairo 12618, Egypt, [2] Animal Production Department, Faculty of Agric., El- Mansoura Univ., Egypt and[3] Animal production Department, Faculty of Agric., Tanta Univ., 31527, Egypt.

Abstract

The data set contained 2181 normal lactation records of Friesian cows kept at Sakha Experimental Farm, Kafer El- Sheikh Government, belonging to Animal Production Research Institute, Ministry of Agriculture, Dokki, Cairo, Egypt were used to construct several selection indexes by using two relative economic values, actual relative economic value (REV_1) and one phenotypic standard deviation (REV_2). Variables studied were 305 day milk yield (305 d MY), 305 day fat yield (305 d FY) and 305 day Protein yield (305 d PY). Data were analysis by using MTDFREMAL Software. The model include the main effects of month and year of calving, parity and days open as covariate and random effects of animals, permanent environmental and errors.

The estimated means and standard deviations for 305 d MY, 305 d FY and 305 d PY were 2806 ±949 kg , 102 ±37 kg and 79 ±28 kg, respectively; and their estimated heritabilities 0.29±0.01, 0.24±0.02 and 0.29±0.02, respectively. Repeatability estimates were 0.37±0.05, 0.44±0.06 and 0.51±0.06 for 305 d MY, 305 d FY and 305 d PY, respectively. Phenotypic, genetic environmental correlations among different variables were positive and significant. Comparison of the two methods for estimating relative economic values explained no changes in any of the two methods for the expected genetic gain per generation for each variable. Our results indicate that, the two methods were succeeded in predicting the genetic progress per generation for the three variables studied. However, the second method (one phenotypic standard deviation) was recommended based on ease of estimation.

Key words: Selection indexes, milk, composition , Friesian cows

1. Introduction

Selection index is the best method of selection for several variables in livestock. It takes heritability of each variable, phenotypic variance of each variable, genetic and phenotypic correlations among variables and relative economic value of each variable **(Hazel and Lush, 1942).**

Relative economic values can estimate by different methods, actual economic value or net profit (**Khattab and Sultan, 1991; Atil et al, 2005; El- Awady, 2009 ; Kassab et al. 2024**), one phenotypic standard deviation **(Falconer and Mackay, 1996; Abosaq et al. 2017; Khattab et al. 2023; Kassab et al. 2024),** Lamont method (**Lamont, 1991; Abosaq et al., 2017 ; Khattab et al. 2023)** and one genetic standard deviation (**El- Awady, 2009** ;**Kassab et al. 2024).**

The main objectives of current study were to estimate phenotypic and genetic parameters for 305 day milk yield (305 d MY), 305 day fat yield (305 d FY) and 305 day protein yield (305 d PY) and constructed selection indexes by using two methods of relative economic values for Friesian cows.

2. Material and methods

Data were collected from Sakha experimental farm, belonging to the Animal Production Research Institute, Ministry of Agriculture, Dokki, Cairo, Egypt and comprising 2181 cows which completed one or more lactations. Animals were fed on Egyptian clover (*Trifolium alexandrinum*) during winter and spring season and during summer and autumn they were fed on concentrate ration and clover hay. Artificial insemination (AI) was used at random. Heifers were first inseminated at 18 months of age. In subsequent lactations, cows were initially inseminated 60 -70 days postpartum. Milking was performed twice daily at 7am and 4pm during the lactation period. Milk yield were recorded daily and milk components were analyzed weekly by using system of Milko–Scan 130 series, type 10900. Maintained at (ILMTC) related to Animal Production Research Institute (APRI), this have special program to estimate milk composition (fat and protein). Variables studied are milk, fat and protein yield in 10 months (305 d MY, 305 d FY and 305 d PY), respectively. Days open was computed as the interval between parturition and the date of successful mating.

Statistical Analysis:

Data were analysis by using MTDFREML Software Boldman et al. (1995), the statistical models included the fixed effects of month and year of calving and parity and days open as a covariate, and random effects of animal, permanent environmental effect and residual. Heritability (h^2) was estimated by using the following equation ($h^2 = \sigma^2a / \sigma^2a + \sigma^2pe + \sigma^2e$). Repeatability (t) was estimated by using the following equation ($t= \sigma^2a + \sigma^2pe/ \sigma^2a + \sigma^2pe + \sigma^2e$), where, σ^2a = additive genetic variance, σ^2pe= permanent environmental variance and σ^2e= random residual effects.

Selection Index Methodology:
Requires selection on an index or criterion (which correlates best with H):
$I = \sum_{i=1}^{n} (bi\ pi)$
I is selection index, b_i is a selection index weighing factor, p_i is a phenotypic measure and n is number of traits. The optimum set of selection index coefficients are those which maximize the correlation (r_{IH}) or minimize the squared deviation between the selection index and the aggregate genotype. The genetic and phenotypic parameters used for the calculation of the optimal index weights in all index calculations were those observed in the present study, Hazel (1943) proved that maximum r_{HI} is achieved when $Pb = Gv$, then The vector of optimal index weights (b) was calculated for each of the objectives as
$b = P^{-1}Ga$
where:
P^{-1} is the inverse of the phenotypic (co)variance matrix of the traits in the selection index, G is the genetic covariance matrix between traits in the selection goal and the selection index, and a is the vector containing the economic values for the goal traits.
Furthermore, the other different properties of the selection index were calculated as following:
Standard deviation of the index (σ_I) = $\sqrt{b'Pb}$,
Standard deviation of the aggregate genotype (σ_H) = $\sqrt{a'Ga}$
Correlation between the index and the aggregate genotype (accuracy)
$R_{IH} = \sigma_I / \sigma_H$

The genetic change per trait from selection ΔG (R_j) was calculated as:

$$\mathbf{R_j} = \frac{\mathbf{i^*b'^*G_j}}{\sigma_{\mathbf{i}}}$$

Where R_j = a vector with the genetic change per trait j, i is selection intensity (in the present study this was assumed to equal one), b′ is transpose of the vector containing the index weights, G_j is the j^{th} column of a G matrix containing the genetic covariance between the trait j and the index traits; and σ_i is the standard deviation of the index used. The expected response from selection using the objectives is illustrated in the present study as genetic gain following one cycle of selection with a standardized selection intensity of one.

Estimate of relative economic value (REV):
The economic values were calculated by two methods:
Actual relative economic value: The economic value for each variable was calculates based on the final actual net profit (Khattab and Sultan, 1991; Atil et al., 2005 ; Kassab et al. 2024).
One phenotypic standard deviation: Depending on the phenotypic standard deviation where $V_i = 1 / \sigma_p$. According to (Falconer and Mackay, 1996; Atil et al., 2005; Kassab et al., 2024). The weighted economic values according to the two methods of economic values are shown in Table 1.

Table 1. Relative economic values (REV) for different variables according to actual economic values ($REV_{1)}$ and one phenotypic standard deviation (REV_2).

Variables	REV_1	REV_2
Milk, kg	1	1
Fat, kg	12.60	20
Protein, kg	6.30	25.50

Results and discussion
Means, standard deviation (SD) and coefficient of variability (CV %) for the three variables studied are presented in Table 2. Means of 305 d MY, 305 d FY and 305 d PY were 2806 kg, 102 kg and 79 kg, respectively. The present means of the three variables were lower than those reported by **Kafidi et al. (1992), Atil and Khattab (2000), El- Awady et al. (2002), kadarmideen et al. (2003), Lazarevic et al. (2018), Amina Habib et al. (2020 and 2024) Estrada-León (2024) and Kassab et al. (2024)** worked on Friesian cows in different regions and ranged from 4490 to 9710 kg for 305 d MY , from 200 to 317 to for 305 d FY and from 158 to 296 to for 305 d PY. The variation in estimates of milk variables between our study and previous study may be due to the differences in breed composition, management, climate, feeding system, and models used in the analysis.
The CV % ranged between 33.82 to 35.97 % (Table 2). The estimates between 26.91 to 39.45 % for yield traits were reported **Amina Habib et al. (2020).** The higher CV % values of milk traits cause a great variation between individuals in important productive variables.

Estimates of direct heritability (h^2) for 305 d MY, 305 d FY and 305 d PY were 0.29±0.01, 0.24±0.02 and 0.29±0.02, respectively (Table 3). Our estimates are fall within the range calculated by many workers on different breeds of dairy cows in different regions. In this respect, Ahlborn and Dempfle (1992) with 178 Half-sib groups of 7345 Holstein – Friesian cows, stated that h^2 estimates for milk, fat and protein yield were 0.26, 0.26 and 0.28, respectively. El- Awady et al. (2002) with German Friesian cows, found that h^2 for 305 d MY, 305 d FY and 305 d PY were 0.32, 0.36 and 0.31, respectively. Rahayu et al. (2015) with Baturraden Dairy Cattle in Indonesia found that h^2 for MY, FP and PY were 0.20, 0.30 and 0.17, respectively. Uribe et al. (2017) with 64,029 complete lactation records of dairy cows in Southern Chile, using multi trait animal mode, found that h^2 estimates for milk yield, and fat and protein above 3% yield were 0.16±0.004, 0.44±0.007 and 0.42±0.006, respectively. Lazzrevic et al. (2018) worked on Holstein Friesian and Black and White cows, using mixed model, reported that h^2 estimates for MY, FY and PY were 0.291, 0.319 and 0.273, respectively. Amina Habib et al. (2024) with Holstein Friesian cows using MTAM reported that direct h^2 estimates for 305 d MY, 305 DFY and 305 d PY were 0.36, 0.30 and 0.23, respectively. While the present estimates are higher than those found by many authors. DeGroot et al. (2002) with Holstein cows, found that h^2 estimates for milk, fat and protein yield were 0.13 (0.02), 0.22 (0.08) and 0.09 (0.09) , they concluded that the small sample size could explain the small estimates of h^2 for milk and protein. El-Awady et al. (2002) with another set of that herd, using MTAM, found that direct h^2 estimates for MY, FY and PY were 0.017, 0.046 and 0.048. They concluded that lower estimates of h^2 could be due to higher percentage of permanent and residual environmental factors. Tohidi and Nazari (2023) with Iranian Holstein cattle, found that Heritability estimates using the repeated record animal model for 305 d MY, 305 d FY and 305 d PY were 0.19 ± 0.001, 0.15 ± 0.005, and 0.17 ± 0.006, respectively. Snedddon et al. (2015) worked on New Zealand dairy herds, using bivariate animal model, found that h^2 estimates for MY, FY and PY were 0.23+0.04, 0.15+0.04 and 0.14+0.03 respectively

Table 2. Means, standard deviation (SD) and coefficient of variability (CV%) for milk yield (MY), fat yield (FY) and protein yield (PY) in Friesian cows

	Means	SD	CV%
Milk yield (MY), kg	2806	949	33.82
Fat yield (FY), kg	102	37	35.97
Protein yield (PY), kg	79	28	35.46
No. of records 2181			

Table 3. Estimates of direct heritability (h^2_d) and repeatability (t) for 305 day milk yield (395 d MY), 305 day fat yield (305 d FY) and 305 day protein yield (305 d PY) for Friesian cows.

Variables	h^2_d	t
305 d MY	0.29±0.01	0.37±0.05
305 d FY	0.24±0.02	0.44±0.06
305d PY	0.29±0.02	0.51±0.06

Table 4. Additive genetic (rg), environmental (re) and phenotypic correlations (rp) for 305 day milk yield (305 d MY), 305 day fat yield (305 d FY) and 305 day protein yield (305 d PY) for Friesian cows.

Variables correlated	r_g	r_{pe}	r_e	r_p
305 d MY X 305 d FY	1.00	0.32	0.35	0.51
305 d MY X 305 d PY	1.00	0.14	0.34	0.52
305 d FY X 305 d PY	1.00	0.80	0.96	0.96

Standard errors ranged from 0.02 to 0.10

Repeatability estimates for 305 d MY, 305 d FY and 305 d PY were 0.37±0.05, 0.44±0.06 and 0.51±0.06, respectively (Table 3) and similar to those values reported by Tohidi and Nazari (2023) , being 0.38 ± 0.002, 0.34 ± 0.002, and 0.36 ± 0.002, for 305 d MY, 305 d FY and 305 PY, respectively.

The moderate h^2 estimates for milk, fat and protein yield, it can be concluded that the genetic improvement in milk yield and it is components can be achieved through selection breeding program, Also, According to moderate repeatability estimates for milk traits, culling of cows based on a single record as commonly practiced by commercial breeders of dairy cattle, would be recommended from a genetic standpoint.

Estimates of genetic correlations among the three variables were unity (Table 4) and were higher than phenotypic correlations which ranged from 0.50 to 0.96 (Table 4). Due to the high genetic correlations among milk yield and it is components, genetic selection for all traits can be achieved through selection for any of them. These results are agreement with previous studied (Ahlborn and Dempfle ,1992; Kafidi et al., 1992; DeGroot et al. 2002; El-Awady, 2002; Amina Habib et al. ,2020 &2024; Tohidi and Nazari (2023) and ranged from 0.68 to 0.995.

Estimates of direct additive genetic variance (σ^2a), permanent environmental variance, error variance (σ^2e) and phenotypic variance (σ^2p) and covariance among different variables which are used in construction selection indexes are presented in Table 5. Four selection indices were made according to REV_1 and REV_2 (Tables 6 and 7). The original index (I_1) included all the three variables (305 d MY, 305 d FY and 305 d PY), to be used for improving the aggregate genotype of the three variables, However, the reduced indexes (I_2, I_3 and I_4) include only two variables to select aggregate genotype.

For method 1 (REV_1) the expected genetic gain per generation in each variable (305 d MY, 305 d FY and 305 d PY) assuming a selection intensity 1 given in Table 6 . The expected genetic change per generation (EG) ranged from 285 to 305 kg for 305 d MY, from 12.22 to 14.0 kg for 305 d FY and from 10.41 to 11.93 kg for 305 d PY. Similarly for method 2 (REV_2) the expected genetic change per generation (EG) ranged from 285 to 305 kg for 305 d MY, from 12.22 to 14.0 kg for 305 d FY and from 10.41 to 11.93 kg for 305 d PY (Table 7).

Table 5. Estimates of (co) variance components for milk yield (MY), fat yield (FY) and protein yield (PY) for Frisian cows.

Estimates	Variables		
	MY	FY	PY
σ^2a	233103 (29%)	492 (23.64%)	358 (29%)
σa with MY		10709	9131
σa with FY			420
σ^2p_e	66527 (8.25%)	144(6.92%)	107(8.66%)
σp_e with MY		991	272
σp_e with FY			72
σ^2e	506780(62.75%)	1445(69.44%)	770(62.34%)
σ^2P	806419	2081	1235
σe with MY		21067	16422
σe with FY			1541

Table 6. Selection indices (I's) for different variables of Friesian cows, expected genetic changes per generation (EG) in each variable, correlation of index with aggregate genotype (R_{IH}) and the efficiency (RE) of different indices relatives to the original index (I_1) by using actual relative economic values (REV_1).

Indices	Variables						R_{IH}	RE%
	MY		FY		PY			
	b	EG	b	EG	b	EG		
I_1	0.3555	305	-9.2833	14.0	20.3613	11.93	0.63	100
I_2	0.3319	285	4.7620	13.1	----------		0.59	94
I_3	0.2368	298	----------		6.0717	11.67	0.62	98
I_4	----------		-3.6176	12.22	10.6254	10.41	0.55	87

Table 7. Selection indices (I's) for different variables of Friesian cows, expected genetic changes per generation (EG) in each variable, correlation of index with aggregate genotype (RIH) and the efficiency (RE) of different indices relatives to the original index (I_1) by using one phenotypic standard deviation (set_1).

Indices	Variables						R_{IH}	RE%
	MY		FY		PY			
	b	EG	b	EG	b	EG		
I_1	0.5680	305	-14.7984	14.0	32.4995	11.93	0.63	100
I_2	0.4033	285	5.78892	13.1	----------		0.59	94
I_3	0.3795	298	----------		9.7398	11.67	0.62	98
I_4	----------		-8.3589	12.22	24.6235	10.41	0.55	87

The present estimates are near similar to those reported by El- Awady et al. (2002) with German Friesian cow found that the expected genetic change per generation ranged between 338 kg and 344 kg for 405 d MY from 4.11 kg to10.81 kg for 395 d FY and from 7.55 kg to 7.98 kg for 305 d PY. Amina Habib et al. (2020) with another herd of Holstein Friesian cows reported that the expected genetic gain per generation ranged from 180 to 323 kg for 305 d MY, from 13.79 to 24.95 kg for 305 FY and from 13.79 to 24.95 kg for 305 PY). Ozturk et al. (2021) with Holstein Friesian cows in Turkey, found that the expected genetic gain for 305 d M was 111.5 kg/year. While Rahayu et al. (2015) with Indonesia cows found that the genetic gains of milk yield was 9.76 kg. Tohidi and Nazari

(2023) found that The regression coefficients of breeding values on calving years for 305 d MY, 305 FY and 305 DPY were 17.32 Kg, 0.51 Kg, 0.53 Kg, respectively.

The maximum genetic progress in 305 d MY, 305 d FY and 305 d PY was achieved by the original index (I_1) for both methods. The expected genetic gain in 305 d MY , 305 d FY and 305 d PY increased by 305 kg/generation, 13.0 kg/ generation and 11.93 kg/ generation, respectively (Tables 6 &7).

The index not including 305 d MY (I_4) showed a reduced accuracy (0.87) for both two methods. Therefore including 305 d MY with either 305 d FY or 305 d PY (I_2 and I_3) closed in accuracy to I_1 RIH (tables 6&7). Hence it would be desirable to include 305 d MY in an index incorporating 305 d FY and 305 d PY. Uribe et al. (2017) arrived at the same conclusion.

Compare of selection indices indicated that index I1, which incorporated 305 d MY, 305 d FY and 305 D PY and the third index I_3, which incorporated 305 d MY and 305 d PY are the best for both methods (R_{IH} = 0.98, Tables 6 &7).

The comparison of two methods of relative economic values revealed no differences among them for the economic gain (EG) of each trait, the relative importance hierarchy (R_{IH}), and the relative efficiency (RE) compared to the original index (I). Thus, the two methods effectively predicted the genetic gain per generation for the three traits under investigation. Therefore, it is recommended to use the second method, which involves one phenotypic standard deviation, as it is simpler to compute.

Conclusion

The present work suggested that the two methods of relative economic values predicted the genetic gain per generation for the three variables studied successfully and the second method (one phenotypic standard deviation) was recommended for ease of calculation

Abstract
This study was conducted to evaluate performance of rice seeds production among the beneficiaries of KSADP/SAA in Kano State. 156 community-based seed multipliers were randomly selected from 21 Local Government of Kano State. Structured questionnaire were used with the aid of android app kobocollect to collect the data for this study. Descriptive statistics, Cost estimation, Net profit, Operational ratio and Benefit cost ratio were used in the analysis of the data for this study. The study showed that seeds producers had a mean age of 45.27 years. Almost all (98.72% and 98.08%) of the respondents were males and married with a mean household size of 12. It was also found that 84.72% of them had a form of formal education and a mean years of experience in seeds production of 5.35 years. The results further revealed an average total cost of rice seeds production/ha of NGN571, 158.11. The revenue generated was NGN1, 743, 000.54 for with a net profit of NGN1, 171, 842.43. The return on investment on rice seeds production was 2.05. While the operational ratio was 0.29. The major challenges to rice seeds production were pest and diseases, unfavorable climatic condition and high transportation cost. It is concluded that rice seed production was profitable and cost-effective. It is recommended that researchers should refocus on development of high quality seeds that are resistant to drought and pest and diseases.

Keywords: *Profitability, rice, seeds, beneficiaries and Kano.*

Introduction

Agriculture is strategic to the Nigerian economy and plays a significant role of supplying food for the population, raw materials for industries, earning of high foreign exchange which is next only to that from crude oil, providing market for the industrial sector and a key contributor to wealth creation and poverty alleviation (National Seeds Policy (NSP), 2014). However, it is widely acknowledged that the most crucial tactic for increasing agricultural output and hastening the implementation of the National Food Security Programme is the deployment of higher quality crop cultivars by farmers for profitable farming (Ruma, 2008). Seed is widely considered as an essential ingredient for productive crop development. Farmers need enough high-quality seeds at the proper timing and cost to increase productivity (Umar, Sanni, Usman and Shu'aib, 2014). High-quality seeds help farmers meet their goals of increasing crop output and other applications (Chijoke and Akaninyene, 2019) and should be made readily available and effectively utilized to raise the standard of living of rural people and their income as well (Sapkota et al, 2018)

Therefore, as an alternative to the formal seed industry for distributing novel crop types, community-based informal seed manufacturing has grown in favour recently. This is due to the fact that most farmers can more easily get and afford farmer-produced seed than certified seed (Katuingi *et al*, 2011). To ensure regular supply of quality seeds at affordable price and poverty free society, some farmers were trained as community based seeds multipliers for which this study intended to describe the demographic variables, estimate the cost, revenue and profitability of rice seeds production and the possible challenges affecting rice seed production.

Methodology

Study Area

The survey area is Kano State, Nigeria. The State occupies an area of about 20,760 square kilometers out of which about 1,754,200 hectares of agricultural land and over 92,250 hectares of forest vegetation with a projected population of 13,969,085 (Male: 7,124,234 and Female: 6,844,852) (NPC, 2021). Kano State is located between latitudes 10˚ 30´N and 13˚02´N, and longitudes 8˚ 45´E and 12˚ 05´E. The State has a temperature ranging between 14.2˚C in January to about 40.3˚C in April being the warmest month with annual rainfall of 617mm. Relative humidity is high up to 80% in August, which drops to 23% in December and January. Two (2) major systems of crop production have been seen to be practiced in the State: the rain-fed and irrigation. Kano State is bordered by the States of Jigawa to the north and east, Bauchi to the southeast, Kaduna to the southwest, and Katsina to the northwest.

Sampling Procedure

Multi stage sampling technique was employed to select the respondents, in consideration of the SAA area of coverage and the seeds companies' area of coverage as well across gender. In the first stage, twenty-one (21) Local Government Areas of the State were purposively selected based on the intensity and preponderance of the beneficiaries of the SAA/KSADP. The LGAs selected include: Kura, Garunmallam, Tudunwada, Kumbotso, Gwarzo, Rogo, Danbatta, Kunchi, Tsanyawa, Dawakin Tofa, Bagwai, Kabo, Rimin Gado, Tofa, Minjibir, Ungoggo, Wudil, Warawa, Gezawa, Takai and Sumaila. List of the community-based seeds multiplication was sought from SAA. In the second stage, the sample frame obtained was used to generate the sample size by subjecting it to one of the Social Science research scientific sampling calculators that is Raosoft sample size calculator, at 95% confidence level and determined the sample size of 156 respondents. In the third stage, Simple Random Sampling was used to come up with the respondents.

Method of Data Collection

The data for this survey were obtained with the aid of structured questionnaire by well-trained enumerators in an android application kobocollect. Some of the information elicited include socioeconomic characteristics of the rice seeds producers (beneficiaries), costs of inputs used and output sold and the challenges encountered in rice seeds production.

Analytical Techniques

The analytical tools used in the analysis of the data for this study include descriptive statistics, cost and return estimation, net profit, operating ratio, benefit cost ratio and return on investment.

i. Cost estimation

Total cost = TVC + TFC …….... ……. (Equation 1)

Where:

TVC =Total Variable Cost associated with the seed multiplication (cost of seed, labour cost, watering, packaging etc) (₦)

TFC = Total fixed cost (₦)

ii. Return/total revenue generated

Total revenue (TR) represents the total income that farmers receive from selling the seeds to farmers. It comprises of the followings:

(i) Cash income is the value of sold products received in cash.

(ii) In-kind income is the value of the seeds for own usage, for charity or gift

TR = ∑ (income inflow in cash and in-kind)

Where: TR = Total Revenue (₦)

∑ = summation

iii. Net Profit

Net profit = TR – TC ……... (Equation 2)

Where:

TR = Total Revenue (₦)

TC = Total Cost of Seeds production/ha (₦)

iv. Benefit-Cost Ratio

Benefit-Cost Ratio (B/C ratio) is calculated by dividing the total present value of income earned after the activity by the total costs spent during the seed multiplication. The higher the value of operating ratio, the higher the profit margin. Hence, positive BC-ratio is always desirable and most recommended.

$$\text{Benefit} - \text{Cost Ratio (B/C ratio)} = \frac{\text{Total revenue}}{\text{Total costs}} \quad \text{……..... (Equation 4)}$$

v. Return On Investment (Return Per Naira Invested)

$$\text{ROI} = \frac{\text{Net profit}}{\text{Total cost}} \quad \text{……..... (Equation 5)}$$

Where: ROI = return on investment = return per Naira invested (₦)

vi. Operating Ratio

Operating Ratio: According to Eze *et al*., 2021, Operating Ratio measures how much profit is made after paying for variable cost. It is calculated using:

$$\text{OR} = \frac{\text{TVC}}{\text{TR}} \quad \text{……..... (Equation 3)}$$

Where: OR = Operating Ratio

TVC = Total Variable Cost associated with seed multiplication business

TR = Total Revenue generated after selling the seed produced

Results And Discussion

Socioeconomic Characteristics of CBSM Beneficiaries

The results of the socioeconomic characteristics of the community-based seeds multiplication beneficiaries are presented in Table 1 below:

Table 1: Socioeconomic characteristics of Community-based seeds multiplication beneficiaries

Variable	Category	Frequency	Percentage	Mean
Age of the CBSM beneficiaries				
	25 – 33	9	5.77	47.27
	34 – 42	44	28.21	
	43 – 51	56	35.90	
	52 – 60	40	25.64	
	61 – 69	7	4.49	
Gender of the beneficiaries				
	Male	154	98.72	
	Female	2	1.28	
Marital status				
	Single	3	1.92	
	Married	153	98.08	
Household size				
	1 – 8	49	31.41	12
	9 – 16	76	48.72	
	17 – 24	18	11.54	
	25 – 32	10	6.41	
	33 – 40	3	1.92	
Years of experience in seeds multiplication				
	1 – 5	109	69.87	5.35
	6 – 10	27	17.31	
	11 – 15	8	5.13	
	16 – 20	4	2.56	
	21 – 25	8	5.17	
Total		**156**	**100**	

Source: Survey data, 2023

Age of the CBSM beneficiaries: The results in Table 1 revealed that most (90%) of the CBSM beneficiaries were within the age group of 34 – 60 years, with average age of 47.27 years. This implies that majority of the CBSM beneficiaries of SAA/KSADP intervention were relatively young, agile with physical and mental ability to undertake seed multiplication enterprise as a business in the study area.

Gender and marital status of the beneficiaries: The results in Table 1 also showed that majority (98.72%) of the beneficiaries were males while the remaining 1.28 % were females. This indicated that seeds multiplication is male dominant and therefore, the CBSM program is highly gender biased, the need for incorporating many women is paramount as the business is very lucrative and therefore, alleviate poverty among gender. This finding agrees with Sakpota *et al*., 2017 who found that majority (74.2%) of maize seeds producers in Palpa District of Nepal were male. It was also found from the survey that majority (98.08%) were married.

Household size of the beneficiaries: Moreover, majority (80 %) of the CBSM beneficiaries had a household size of 1 -16 persons, with a mean household size of 12 denoting that the beneficiaries had a large household which is far greater than the national average of 5. It is obvious that large household size serves as a source of family labour which as a result, reduces cost of production and increase in the net income of the business.

Years of experience of the CBSM beneficiaries: The results in Table 1 further revealed that majority (70 %) of the beneficiaries had an experience of 1 – 5 years of seeds production, with an average experience of 5.35 years. This implies that the beneficiaries had some degree of experience in the business which will help them to have a good mastery of all the operations of the enterprise and to avert any form of risk associated with the enterprise as well.

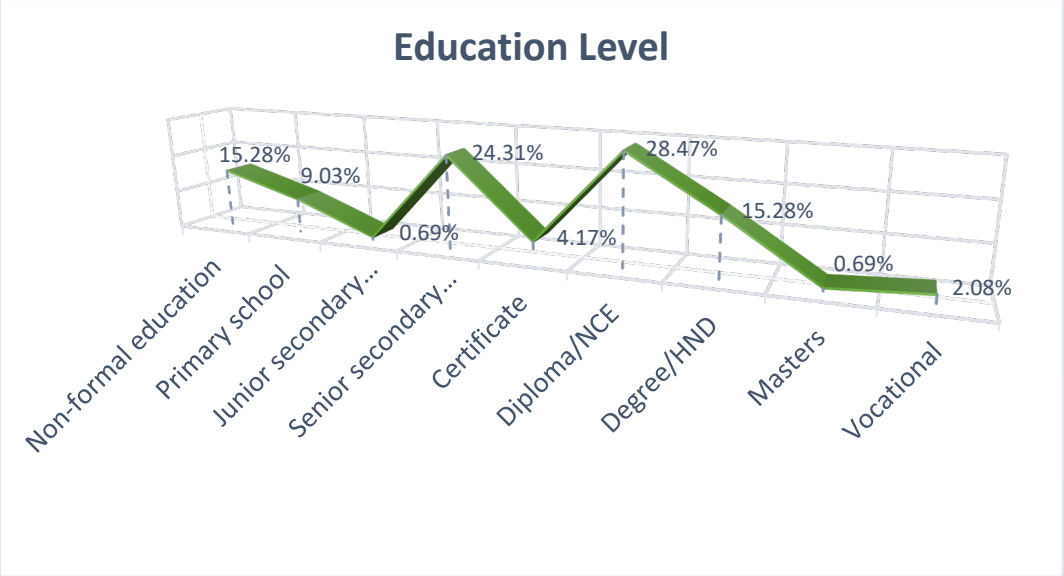

Figure 1: Educational level of the CBSM beneficiaries

Educational level of the beneficiaries: Figure 1 presents the educational level of the CBSM beneficiaries in the study area. 28.47% of them had diploma/NCE, 24.31% had attained SSCE certificate level, 15.28% each had a degree and non-formal education, 9.03% stopped only from primary school, 4.17% had certificate, 2.08% were vocational attendants and 0.69% each had junior secondary school and master's degree. This shows that majority (84.72%) of them had formal education which will assist them in reading instruction on chemical and fertilizer application and also in the adoption of innovation.

Cost Structure and Revenue of Rice Seeds Production among the Beneficiaries of KSADP/SAA in Kano State.

Rice seeds production incurred certain expenses of inputs and cost structure and revenue accrued from sales of rice seed are presented in Table 2 below:

Table 2: Cost structure and revenue of rice seed production among the beneficiaries of KSADP/SAA of Kano State

Rice seeds production			
Items	**Quantity (Kg/Ltr)**	**Amount (₦)**	**%TC**
Variable inputs			
Seeds	36.45	28,595.54	5.01
Fertilizer (NPK)	198.5	103,099.71	18.05
Fertilizer (Urea)	2	41,307.70	7.23
Fertilizer (USG)/Organic manure	75.7	26,062.45	4.56
Herbicides	4.71	18,301.69	3.2
Pesticides	2.19	8,710.55	1.53
Seed dress	5.92	1,796.48	0.32
Empty bags	54	14,530.86	2.54
Labour cost		253,703.80	44.42
Transportation cost		17,900	3.13
Loading and unloading		0.00	
Total variable cost		**514,009**	
Fixed inputs			
Depreciation on equipment		1,593.77	0.28
Rent		55,555.56	9.73
Total fixed cost		**57,149.33**	
Total cost of production		**571,158.11**	
Output			
Seeds	48.72	1,736,200.54	
Other grains			
Straw/Stover		6800	
Revenue		**1,743,000.54**	

Source: Survey Data, 2023

The results in Table 2 presents the cost structure and revenue of rice seeds production. The results showed a total cost of ₦571, 158.11 with an average revenue of ₦1, 743, 000.54. The results also revealed that labour constitutes the largest proportion of the total cost of rice seeds production (44.42%), followed by fertilizers (NPK, Urea and USG) which constitutes 29.84% of the total cost. While rent constitutes 9.73% and depreciation on equipment was the insignificant factor of rice seeds production with only 0.28%.

Profitability of Rice Seed Production among the Beneficiaries

Table 3: Profitability of rice seed production among the beneficiaries of KSADP/SAA

Items	Amount (₦)
Revenue	1,743,000.54
Variable cost	514,009
Total cost	571,158.11
Profit margin	67.23%
Net profit	1,171,842.43
Return on investment (RI)	2.05
Benefit cost ratio (BCR)	3.05
Operational ratio (OR)	0.29

Source: Survey Data, 2023

From the results in Table 3, there is an average revenue of ₦1, 743, 000.54 with a total cost of 571, 158.11. The net profit was estimated to be ₦1, 171, 842.43 with a margin of 0.6723 implying that profit constitutes 67.23% of the gross revenue. The benefit cost ratio was 2.05. This shows that for every ₦1 invested in rice seeds multiplication, all things being equal, there is a gross revenue of ₦2.05. The operational ratio of 0.29 implies that operating cost constitutes only 29% of the total revenue generated from rice seeds production while the remaining 71% is available to cover other cost such as interest, rent, premium etc. This shows that rice seeds production among the beneficiaries is cost effective.

Challenges Associated with Rice Seeds Multiplication

The community-based seeds multiplication beneficiaries are faced with various hitches affecting their seeds multiplication activities. The results for these challenges are presented in Figure 2 below:

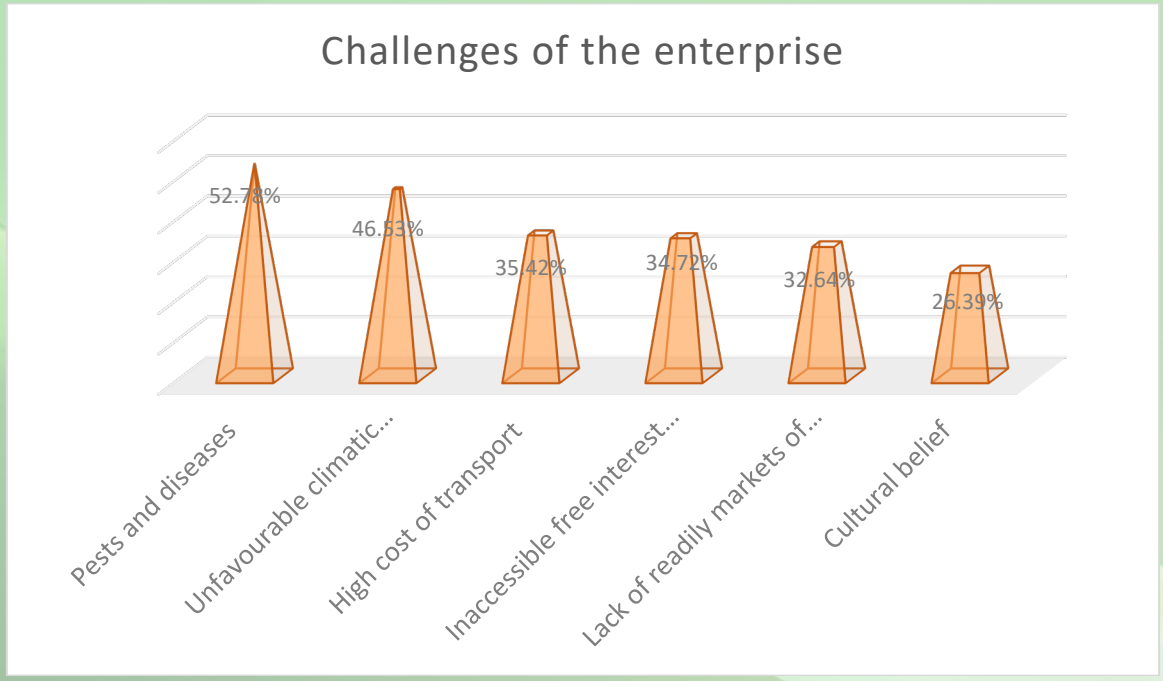

Figure 2: Challenges associated with community-based seeds multiplication (Multiple responses)

The results for the challenges of rice seeds production are presented in Figure 2 above. The results showed that 52.78% of the rice seeds producers (beneficiaries) indicated pests and diseases as one of the challenges affecting their seeds production activities, 46.53% reported unfavorable climatic condition, 35.42% and 34.72% reported high cost of transportation and inaccessible free interest loan respectively as their challenges, 32.64% showed lack of readily market of their product and finally 26.39% indicated cultural belief of the farmers to primitive seeds as their challenges to seeds multiplication enterprise.

Conclusion And Recommendations

Based on the findings of this study it can concluded that rice seeds production among the beneficiaries in the study area is a profitable enterprise and cost effectives. However, the enterprises is challenged by pests and diseases, unreliable climate and high cost of transportation. It is recommended that beneficiaries should adopt integrated pests management and climate smart production and also breeders should develop high quality seeds that are more resistant to pests and diseases and drought tolerant.

Ameliorative Role of Dietary *Spirulina platensis* on Sumithion-Induced Growth Suppression and Intestinal Histopathological Alterations in Striped Catfish (*Pangasianodon hypophthalmus*)

Md Ruhul Amin, Saudah Binte Ashraf, Mst Nusrat Jahan, Md Shahjahan*

Abstract

Sumithion is commonly used pesticides to eradicate tiger bugs from aquaculture ponds; nevertheless, it adversely affects non-target species, particularly fish. The microalga (*Spirulina platensis*) could mitigate the sumithion-induced adverse effects in fish. Regarding this, the investigation was executed to mitigate the adverse effects of sumithion by Spirulina supplementation in diet to striped catfish (*Pangasianodon hypophthalmus*). During the 42-days experimental period, a total 240 of striped catfish fingerlings (10.82±1.34 g) were reared to four different treatments, including control, sumithion (0.6 mg/L), Spirulina (50g/kg feed at 3-5% body weight) and combined treatment (Spirulina + sumithion) with three replicates each. Sumithion treatment resulted in considerably decreased ($p<0.05$) the levels of FBW, GW and SGR (%/day) as well as increased FCR. In contrast to the sumithion treatment, the Spirulina treatment resulted in significantly ($p<0.05$) higher FBW, WG, and SGR (%/day), along with a lower FCR value. However, sumithion treated fish exhibited impaired structure of intestine and decreased the goblet cells and enterocyte number. In contrast, Spirulina either alone or with sumithion, significantly ($p<0.05$) improved intestinal structure, growth and feed efficiency. The present study unveiled the implementation of dietary Spirulina to be an effective approach to mitigate sumithion-induced stress and optimize health condition in striped catfish by improving histological index of intestine and growth indices.

Keywords: pesticides, toxicity, bioremediation, Spirulina, striped catfish

Abstract

Background and aim of study: Subclinical mastitis (SCM) represents a major health challenge in Albanian dairy farms; however, its management is frequently overlooked, characterized by limited diagnostic monitoring and a predominant reliance on conventional antibiotic-based treatments. Preventive strategies and awareness regarding abiotic risk factors—such as mineral nutrition, milking hygiene, and housing conditions—remain minimal, despite their well-documented role in the environmental transmission of mastitis pathogens. To date, few studies conducted in Albania have systematically investigated these factors. This study aims to assess the influence of key risk abiotic factors, namely mineral nutrition, milking hygiene, and housing conditions on the prevalence of SCM under real production conditions in dairy farms across various regions of Albania.

Methodology: The study was conducted on nine Holstein dairy farms in Albania, located in both lowland and hilly regions (herd sizes ranged from 21 to 140 cows; daily milk yields ranged from 12 to 30 kg). Data collection extended over an eight-month period during lactation. On each farm, a group of 6 to 10 cows in early lactation was randomly selected and monitored throughout all three stages of lactation. To evaluate the association between abiotic factors (mineral supply, udder hygiene, and housing conditions) and the occurrence of subclinical mastitis (SCM), no changes were made to existing farm management practices. Data were collected using a standardized protocol that included structured questionnaires on farm characteristics and feeding practices, as well as on-farm assessments of housing conditions, udder hygiene, and the application of the California Mastitis Test (CMT). Mineral content in feed samples was determined. Variance and regression analyses using SPSS were conducted to evaluate the influence of biotic and abiotic factors on SCM.

Results: The observed average prevalence of subclinical mastitis (SCM), defined as the percentage of cows with a CMT score of ≥1+ relative to the total number of animals tested, was 37.2% (range: 6–72%). This prevalence was significantly influenced by the level of mineral nutrient intake, assessed through the concentrations of Ca, P, Zn and Se per kilogram of dry matter (DM) intake (average daily DM intake of 20.9 kg/cow). Higher dietary Ca concentrations were significantly associated with a reduction in SCM prevalence ($P = 0.013$). An increase in Se concentration resulted in a quadratic decrease in SCM incidence ($P = 0.066$), while elevated Zn intake showed a trend toward reduced SCM prevalence. In contrast, P concentrations showed no effect on SCM occurrence. Udder cleanliness and teat infection status were both significantly associated with SCM occurence ($P = 0.01$ and $P = 0.001$, respectively). Post-milking teat disinfection demonstrated a highly significant effect in reducing SCM prevalence ($P = 0.001$). SCM occurrence was significantly lower in free-stall housing systems compared to tethered systems ($P = 0.001$). The use of stationary milking systems was also significantly associated with a lower prevalence of SCM compared to mobile milking units ($P = 0.001$).

Amelioration of Microplastics-Induced Growth Inhibition and Stress in Nile Tilapia Using Multi-Species Probiotic

Mahadi Amin[1], Md Shahjahan[1]

Laboratory of Fish Ecophysiology, Department of Fisheries Management, Bangladesh Agricultural University, Mymensingh 2202, Bangladesh.
*Corresponding authors' e-mail: mdshahjahan@bau.edu.bd

Abstract

Microplastics (MPs) are emerging pollutants in aquatic ecosystems, known for their toxic effects on various physiological processes in fish. This study aimed to evaluate the potential of multi-species probiotics in mitigating the harmful impacts of MPs on Nile tilapia (Oreochromis niloticus). Fish with an initial weight of 3.02 ± 0.27 g were exposed to four treatment groups for 42 days: (1) control (no MP or probiotics), (2) MP exposure (10 mg/L), (3) probiotics only (1 ml/L), and (4) combined MP + probiotics. The results demonstrated that MP exposure significantly reduced growth performance and survivability, lowered haemoglobin levels, and increased glucose concentration in the blood. Additionally, erythrocytic cellular and nuclear abnormalities were more prevalent in the MP-treated group. Probiotic supplementation markedly improved these conditions by enhancing growth and survival and reducing haematological and cellular damage. Goblet cell frequency, which was reduced by MP exposure, was preserved in the probiotic-treated group. The relative mRNA expression revealed that MP exposure significantly upregulated antioxidant genes (*SOD* and *CAT*) and immune-related genes (*TNF-α*, *IFN-γ*, and *IL-1β*) in the liver. However, these expression levels were downregulated when probiotics were administered alongside MPs. Overall, the findings indicate that probiotics can alleviate microplastic-induced physiological stress and immune disruption, highlighting their potential as a protective dietary supplement in aquaculture.

Ameliorative Role of Spirulina on Sumithion-Induced Hematological and Molecular Altarations in Nile tilapia

A.K.M. Afzal Hossain[1], Md. Abu Rahad[1], Md Al-Emran[1], Md Mahiuddin Zahangir[2], Md Shahjahan[1*]

[1]Laboratory of Fish Ecophysiology, Department of Fisheries Management, Bangladesh Agricultural University, Mymensingh-2202
[2]Department of Fish Biology and Biotechnology, Faculty of Fisheries, Chattogram Veterinary and Animal Sciences University, Chattogram-4225, Bangladesh

Abstract

This study evaluated the ameliorative role of Spirulina in overcoming the adverse effects of the organophosphate insecticide sumithion on Nile tilapia (Oreochromis niloticus). Sumithion is extensively utilized in agricultural land and aquaculture ponds. The indiscriminate use poses a potential threat to many non-target organisms, including fish. For conducting the experiment, 240 Nile tilapia (O. niloticus) fingerlings, with an average weight (12.84 ± 0.09 g) were collected and randomly distributed in four treatments with three replications of each, namely T1 (Control), T2 (Sumithion; 0.3 mg/L), T3 (Spirulina; 50gm/kg), and T4 (Sumithion + Spirulina) for 42 days. According to the experimental outcomes, hemoglobin (g/dL) and blood glucose (mg/dL) levels were significantly ($p < 0.05$) altered in sumithion-treated fish. Regarding erythrocytic abnormalities, both cellular (teardrop, twin, spindle) and nuclear (nuclear buds, notched nuclei, karyopyknosis) abnormalities were most abundantly identified in sumithion-treated fish. Additionally, sumithion exhibited adverse effects on antioxidant and immune-related genes expression. In T2 (Sumithion), the expression of the antioxidant gene Superoxide Dismutase (SOD) was significantly ($p < 0.05$) downregulated, whereas the immune-related genes Tumor Necrosis Factor-alpha (TNF-α) and Interferon-gamma (IFN-γ) were significantly ($p < 0.05$) downregulated. However, Spirulina's protective role helped reverse the alterations that sumithion treatment induced. Consequently, Spirulina supplementation improved blood parameters, structure of erythrocytes, and expression of genes. The present study unveiled the implementation of dietary Spirulina to be an effective approach to mitigate sumithion-induced stress and optimize health condition in Nile tilapia by improving hemato-biochemical index and antioxidant-immune genes expression.

Abstract

This paper presents Agri-Net Zero as the optimal pathway for corporate net zero compliance, emphasizing its dual role in advancing climate action while ensuring sustainable livelihoods. In the wake of accelerating climate change and the urgent need to stabilize global warming within critical thresholds, the integration of direct emission reductions and nature-based carbon sequestration in agricultural systems emerges as a transformative solution. Agriculture is highlighted as both a significant contributor to greenhouse gas emissions and a uniquely positioned sector capable of acting as a large-scale carbon sink. Through regenerative practices such as agroforestry, sustainable livestock management, and advanced soil health techniques, Agri-Net Zero enables corporations to achieve immediate and measurable decarbonization in line with stringent IPCC guidelines.

The paper examines global trends and corporate commitments to net zero targets and ESG goals, contextualizing the role of agriculture within broader mitigation strategies. It further presents the Clean Food Net Zero (CFNZ) program under the IBM-IORF Sustainability Project as a practical demonstration of the multifaceted impact of Agri-Net Zero. The CFNZ program's innovative "waste-to-wealth" strategy and integrated sustainability tools not only reduce greenhouse gas emissions significantly but also enhance energy efficiency, resource utilization, and overall economic viability.

By repositioning agriculture from an emissions-intensive sector to a critical component of the global carbon cycle, Agri-Net Zero provides a comprehensive, scalable, and economically viable model. This paper argues that through proactive adoption of Agri-Net Zero, corporations can bridge the gap between environmental imperatives and sustainable development, simultaneously achieving robust net zero compliance and bolstering food and livelihood security in a climate-uncertain future.

Key words : *Carbon sink, Waste to wealth, Net Zero, ESG, CFNZ program*

Introduction

Corporates' commitments to achieve net-zero emissions and advance robust ESG goals are emerging as a linchpin in the global effort to combat climate change and ensure sustainable livelihoods, with Agri-Net Zero at the forefront as a transformative pathway. Scientific consensus underscores that global temperatures, which have already risen by 1.1°C above pre-industrial levels between 2011 and 2020, must be capped at 1.5°C to 2°C by 2050 to avert devastating impacts, yet projections indicate a potential 2.8°C increase if current measures remain insufficient (WMO, 2024). Globally, nearly 9,000 companies have pledged to reduce emissions—with approximately 3,500 targeting net-zero outcomes—while Europe leads with 2,998 firms, Asia follows with 1,846, and the UK accounts for 702 companies committed to Science-Based Targets. In India, despite contributing roughly 7% to global emissions, 127 corporates have embraced net-zero targets under the ICRA ESG Ratings framework, signalling a burgeoning awareness, particularly as sectors such as power, energy, and cement lag behind (ET World, 2024). The drive toward net zero is not solely an environmental imperative; it is also fuelled by escalating investor pressure, anticipated regulatory shifts, and evolving consumer preferences that favor sustainability, all of which compel companies to innovate in renewable energy, energy efficiency, and sustainable supply chain practices. Notably, even as more than one-third of the world's largest companies have endorsed net zero commitments, analyses suggest that without at least doubling the current pace of emissions reduction by 2030, 93% are at risk of failing to meet their targets.

Agri-Net Zero presents an exceptionally compelling pathway for corporates to meet their net zero commitments because it directly tackles one of the most significant yet often under-addressed sources of greenhouse gas emissions—agriculture. Agriculture accounts for approximately 10–12% of global anthropogenic emissions, contributing around 16 $GtCO_2e$ in 2020 and projected to climb to 30 $GtCO_2e$ by 2050. This sector stands at a critical crossroads, being both the largest vulnerability to climate change and the second largest contributor to GHG emissions, yet it remains uniquely positioned to drive both adaptation and mitigation. By integrating innovative sustainable practices Agri-Net Zero can transforms farmlands into effective carbon sinks, thereby restoring the natural carbon cycle and enhancing soil health. Studies suggest that with the implementation of these

measures, potential CO_2 reductions in agriculture could range from 0.21 to 2.0 $GtCO_2e$ per year under various scenarios—gains that are critical for limiting global warming to below 2 °C by 2100. Moreover, as population growth and changing dietary preferences in developing economies drive up emissions further, agriculture's role in climate mitigation becomes even more urgent. With approximately 80% of countries incorporating agriculture into their mitigation targets and 64% including it in adaptation strategies via Nationally Determined Contributions, the Agri-Net Zero approach not only aligns with global climate objectives but also offers tangible benefits for corporates. It provides measurable progress on sustainability, mitigates supply chain risks for industries reliant on agricultural inputs, and supports innovation that can lead to improved resource efficiency and long-term financial benefits. In essence, by simultaneously reducing emissions from crop and livestock production, enhancing carbon sequestration, and restoring ecological balance, Agri-Net Zero delivers a comprehensive, scalable, and economically viable strategy that positions corporations as key drivers of climate action while securing food and livelihood security in an increasingly climate-uncertain world.

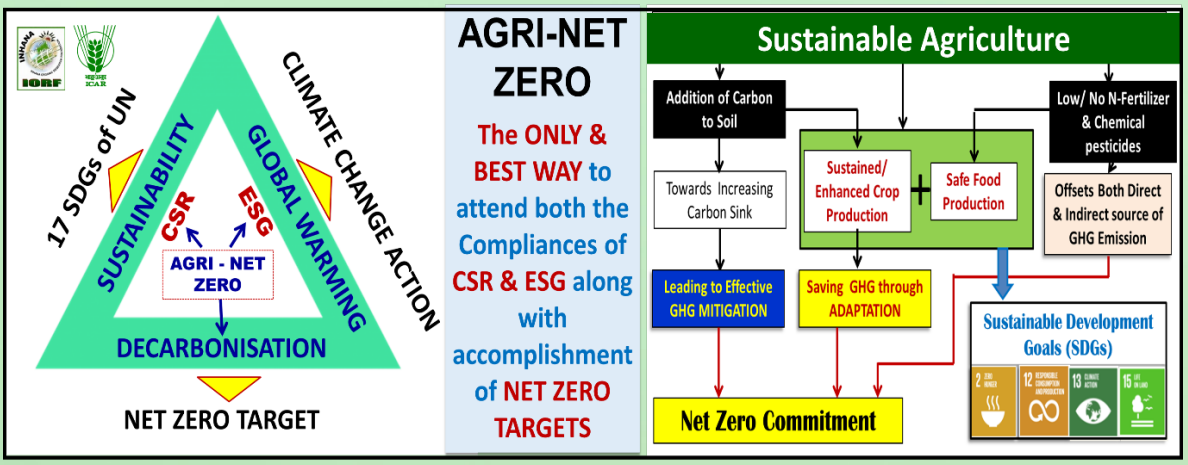

Fig 1 : Sustainable Agriculture can at a time attend the Net Zero Commitment & Sustainable Development Goals (SDGs)

Understanding Net Zero and Its Significance

The net zero concept represents a fundamental target in climate science and policy. It defines the state in which human-caused greenhouse gas (GHG) emissions are balanced by an equivalent amount removed from the atmosphere, effectively resulting in zero net emissions over multi-decadal timescales (IPCC, 2021). In essence, achieving net zero requires that every unit of CO_2 and other GHGs released by human activities is counterbalanced by removals through natural or engineered carbon sinks—such as forests, soil sequestration, or carbon capture and storage (CCS) technologies. This balance is critical because cumulative CO_2 emissions directly determine the extent of global warming. To keep warming within the 1.5°C threshold—an objective central to the Paris Agreement—the global carbon budget is estimated to be between 400 and 800 $GtCO_2$, implying that emissions must peak by 2030 and reach net zero by around 2050. Delays in reducing emissions not only erode the remaining carbon budget but also risk locking in long-term warming due to the persistent effect of CO_2 in the atmosphere.

Reaching net zero is both a scientific necessity and a moral imperative. Stabilizing global temperatures depends on halting the net addition of CO_2, while also addressing other potent, albeit shorter-lived, greenhouse gases like methane and nitrous oxide. The concept extends beyond a mere numerical target; it offers a comprehensive framework that demands aggressive, front-loaded emission reductions combined with rigorously verified removal strategies. A credible net-zero strategy is underpinned by several scientifically grounded attributes that ensure environmental integrity, equity, and effective climate action. First, emission reductions must be front-loaded, with immediate and substantial cuts to maximize the likelihood of limiting global warming to 1.5°C. Second, a comprehensive approach is required, addressing all emission sources, including those from hard-to-abate sectors such as heavy industry and agriculture. Third, reliance on carbon dioxide removal should be approached with caution, ensuring it does not detract from direct emission reduction efforts. Fourth, carbon offsets must be subject to stringent regulation to guarantee their environmental and social integrity, preventing misuse and ensuring real climate benefits. Fifth, the transition to net zero must be equitable, recognizing different national circumstances and providing necessary support to developing countries. Sixth, net-zero plans should align with broader socio-ecological objectives by integrating biodiversity conservation and sustainable development goals. Lastly, pursuing new economic opportunities through innovation and investment in clean technologies can drive sustainable growth and job creation. Together, these attributes form a robust framework for achieving net-zero emissions in a manner that is scientifically sound, socially just, and economically beneficial.

In summary, the scientific significance of net zero lies in its direct link to the global carbon budget and temperature stabilization. However, its practical implementation is a complex, multi-faceted process that bridges technological innovation, policy reform, and international cooperation. Adhering to this framework—with its emphasis on immediate, decisive action and robust verification—offers the most promising pathway to mitigate climate change and secure a sustainable future for all.

Agriculture's Dual Challenge of Sustainability and Climate Action

Agriculture occupies a central role in the global economy and environmental sustainability, underpinning human existence not only through its production of food but also by sustaining countless livelihoods. For example, in countries like India, roughly 60% of the population depends directly on agriculture, with about 80% of these individuals being small and marginal farmers (FAO, 2021a). This heavy dependency highlights both the vulnerability of the sector and its critical influence on driving equitable and sustainable development.

Unlike other sectors characterized by high emissions—such as energy, transport, or industry—agriculture's long-term sustainability is inherently linked to achieving net zero emissions. While many sectors can transition to cleaner technologies or switch energy sources without radically changing their operational models, agriculture relies directly on ecological stability, predictable weather patterns, and the overall integrity of natural systems (IPCC, 2023). Climate change imperils these essential foundations by increasing temperatures, altering precipitation patterns, intensifying extreme weather events, and facilitating the spread of pests and diseases. These threats not only jeopardize agricultural productivity but also intensify risks to global food security, making the pursuit of net zero a matter of survival rather than a mere environmental obligation.

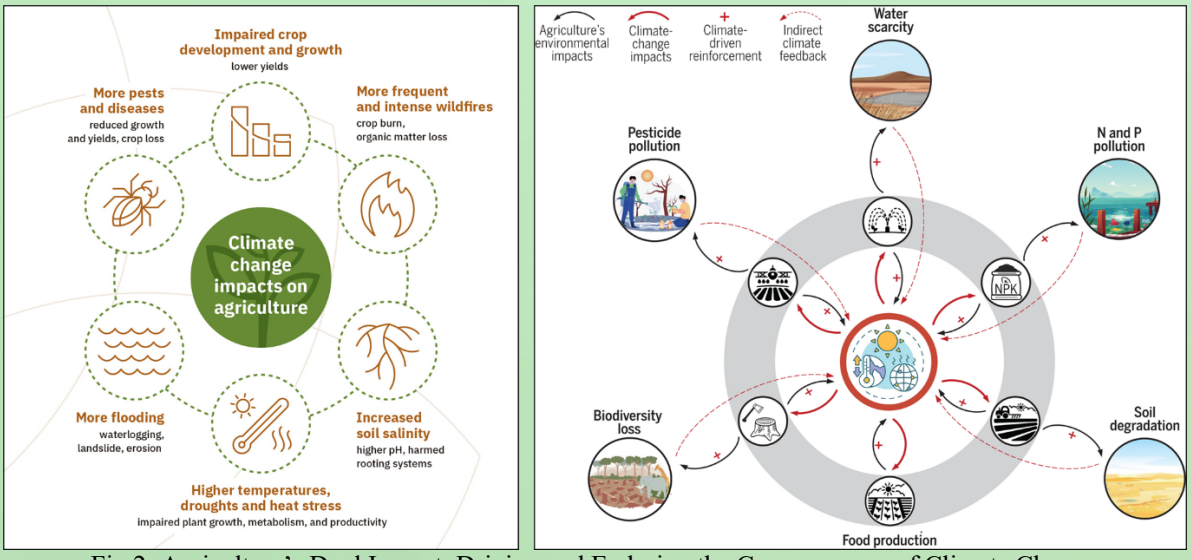

Fig.2: Agriculture's Dual Impact: Driving and Enduring the Consequences of Climate Change

Agricultural sustainability is also integral to achieving multiple Sustainable Development Goals (SDGs) such as Zero Hunger (SDG 2), Good Health and Well-being (SDG 3), Responsible Consumption and Production (SDG 12), Climate Action (SDG 13), and Life on Land (SDG 15) (United Nations, 2015). The sector now faces a dual challenge: feeding a growing global population—whose demand is projected to push food production up by approximately 50% by 2050 (FAO, 2017)—while simultaneously curbing its environmental impact. This tension is heightened in regions dominated by smallholder farming, where unsustainable practices have already emerged in agriculturally intensive and ecologically fragile areas.

Agriculture is uniquely positioned in the climate discourse; it is both a significant contributor to global greenhouse gas (GHG) emissions and one of the most vulnerable sectors to climate impacts. The sector is estimated to account for roughly 25–30% of global GHG emissions, primarily due to methane (CH_4) from enteric fermentation and rice paddies, nitrous oxide (N_2O) from synthetic fertilizer and manure applications, and carbon dioxide (CO_2) resulting from deforestation and land-use changes (IPCC, 2019). Moreover, the overuse of chemical inputs and extensive land conversion not only amplify emissions but also degrade ecosystems, reducing their capacity to act as natural carbon sinks (FAO, 2021). In India, for instance, agricultural activities contribute around 47% of total CH_4 and 80% of N_2O emissions, mostly from enteric fermentation, rice cultivation, and fertilizer use (MoEFCC, 2021; IPCC, 2019). These realities make it imperative to reform the sector—ensuring that the transition towards sustainable practices like climate-smart agriculture, agroecological methods, and improved resource management is supported by robust policy frameworks, financial investments, and international cooperation.

A promising aspect of agricultural ecosystems is their potential to mitigate climate change through soil carbon sequestration, with estimates suggesting that these systems could store up to 1 billion metric tons of carbon per

year—offsetting nearly 10% of global annual GHG emissions (Lal, 2020). However, this potential remains largely untapped due to the current lack of regenerative agricultural frameworks and the insufficient integration of carbon sequestration practices.

In summary, agriculture stands at a critical crossroads. It must navigate the dual imperative of meeting increasing food demands while drastically reducing its environmental footprint. The sector's decarbonization is not only a vital contribution to global climate goals but also a necessary path for its own longevity. By adopting deeply integrated strategies that encompass emission reductions, ecosystem restoration, and resilience-building, agriculture can pave the way for a sustainable future that concurrently addresses climate change and socio-economic development.

From Source to Sink: Repositioning Soil in the Climate Change Equation

Soil represents one of the largest natural carbon sinks on Earth, capable of storing more carbon than the atmosphere and terrestrial vegetation combined (Lal, 2004). This immense sequestration potential positions agriculture at the forefront of climate mitigation strategies, particularly in the context of achieving net zero. Agricultural soils, when managed sustainably, can absorb significant amounts of atmospheric carbon dioxide (CO_2) through processes such as enhanced organic matter input, cover cropping, conservation tillage, and agroforestry. However, conventional agricultural practices—characterized by intensive tillage, monocropping, and overuse of chemical inputs—have historically led to widespread soil degradation and carbon loss (IPCC, 2019). Transitioning to regenerative and climate-smart agricultural systems not only reduces ongoing emissions but also restores the soil's natural capacity to function as a long-term carbon sink. In this way, agricultural net zero initiatives go beyond short-term abatement; they contribute directly to the long-term stabilization of the climate system by embedding carbon back into terrestrial ecosystems. This dual functionality—emissions reduction and carbon sequestration—makes soil-centered agricultural strategies uniquely aligned with the IPCC's dual imperatives: curbing near-term warming and ensuring long-term climate resilience (IPCC, 2023). Hence, any credible pathway to net zero must prioritize agriculture not merely as an emitter to manage, but as a natural ally in climate restoration.

The IPCC Perspective: Positioning Agri-Net Zero within Net Zero Compliance Frameworks

The Intergovernmental Panel on Climate Change (IPCC) provides a foundational framework for achieving net zero emissions, emphasizing two core principles that are directly relevant to agriculture-based climate strategies. The first guideline identifies the need for an "entry point into longer-term emissions-reducing activities," stressing that any credible net zero compliance program must begin with immediate and significant reductions in absolute greenhouse gas (GHG) emissions—both direct and indirect (IPCC, 2023). This entry point is not merely about meeting near-term benchmarks but about initiating a robust and sustained trajectory of decarbonization. It necessitates the early adoption of mitigation strategies, investment in low-emission technologies, and structural shifts in policy and practice that drive continuous emission reductions over time. Agriculture offers a particularly strategic entry point in this context, given its potential not only to reduce emissions but also to serve as a large-scale carbon sink. Through integrated approaches that enhance both mitigation and sequestration, Agri-Net Zero emerges as a vital mechanism for aligning agricultural practices with net zero goals.

The second IPCC guideline focuses on the treatment of "impossible-to-abate" emissions—residual emissions from sectors where complete decarbonization is currently unfeasible due to technological or systemic limitations. In agriculture, this primarily includes methane (CH_4) emissions from enteric fermentation and nitrous oxide (N_2O) from fertilizer application and manure management, for which no zero-emission substitutes currently exist (IPCC, 2022). For these emissions, the IPCC framework mandates that carbon removals—whether through afforestation, soil carbon sequestration, or other nature-based solutions—be deployed judiciously and only as a compensatory measure for truly unavoidable emissions. Agri-Net Zero responds to this imperative by offering a responsible, science-aligned pathway that combines source-level emission abatement with landscape-scale sequestration. It prioritizes emissions reductions at the production level while leveraging the inherent carbon capture capacity of agricultural ecosystems. In doing so, it advances a balanced and ethically grounded net zero approach that neither delays mitigation efforts nor over-relies on offsets, but instead positions agriculture as a cornerstone in the global climate solution.

Emission Reduction Over Offsetting: Agriculture's Unique Decarbonization Advantage

In the pursuit of net zero, the global emphasis must shift from carbon offsetting mechanisms to actual emission reductions at the source. While many sectors rely heavily on offsetting—through afforestation, carbon trading, or external sequestration projects—to balance their emissions, these approaches often delay systemic change and create accountability gaps (IPCC, 2023). In contrast, agriculture stands out as a sector where internal emission reduction is not only viable but indispensable. Unlike sectors such as aviation or heavy industry, where decarbonization technologies remain limited or cost-prohibitive, agriculture offers a suite of nature-based and management-driven solutions that enable real-time reductions in greenhouse gas emissions (FAO, 2021c; Smith et al., 2019). These include practices such as improved livestock feeding strategies, reduced nitrogen fertilizer use, agroforestry, and enhanced soil carbon management—all of which lower emissions at the source while delivering co-benefits for biodiversity, soil health, and resilience. Therefore, agriculture represents a rare opportunity: a sector

capable of delivering authentic emission reductions without over reliance on external offsets. As climate accountability becomes more stringent, the credibility of agriculture's mitigation pathway—grounded in real emission reductions—positions it as a leading contributor to global net zero efforts.

Agricultural Net Zero: The Best Model for Achieving Climate and Sustainability Goals

Among the diverse pathways to net zero emissions, the agricultural net zero model offers the most holistic and achievable approach. Agriculture stands as the only sector where emission reductions, carbon sequestration, and sustainable land management practices can be integrated in a way that enhances food security, ecosystem services, and resilience to climate impacts. Unlike energy or industrial sectors that rely heavily on technological innovations or external carbon offsets, agriculture's capacity to both reduce emissions and actively cycle carbon back into the soil makes it an inherently productive, scalable, and natural carbon sink (IPCC, 2023; Lal, 2020). Regenerative agriculture, agroforestry, soil carbon management, and sustainable livestock systems provide a multi-pronged strategy that not only mitigates climate change but also regenerates vital ecological functions, such as soil health, biodiversity, and water management (FAO, 2021). Moreover, agriculture's direct relationship with food production ensures that net zero in agriculture is not an isolated goal but one deeply tied to global sustainable development targets—making it the most impactful and comprehensive net zero pathway. This synergy of climate action and food security makes agricultural net zero the best model for a sustainable future, combining environmental, social, and economic resilience in a single framework.

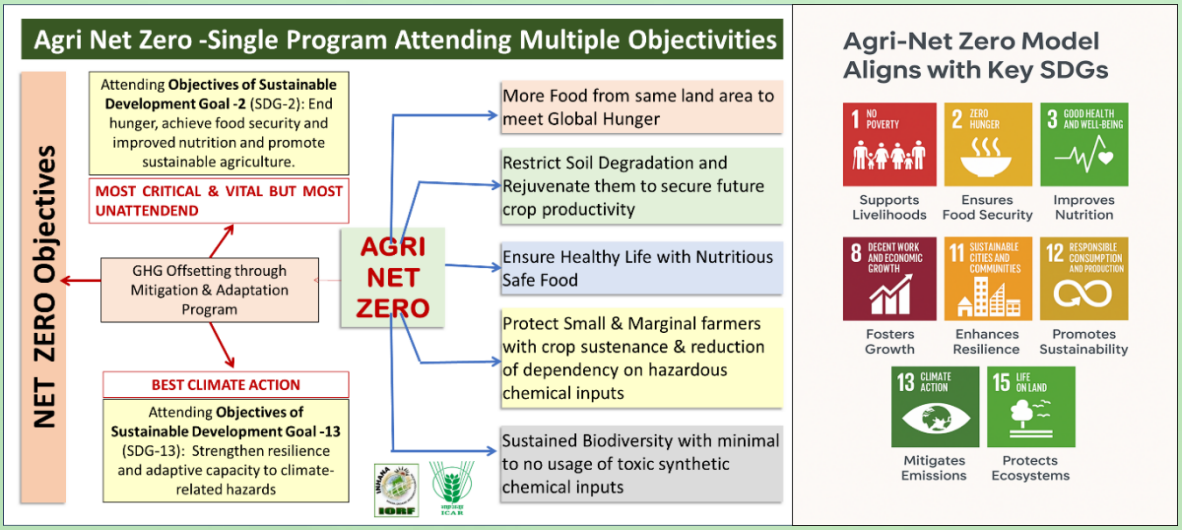

Fig.3: AGRI NET ZERO vital link in between Net Zero Objectives and Environmental & Social Goals

Agricultural Net Zero: The Only Pathway to Reintegration of Atmospheric Carbon

Among all major sectors, agriculture uniquely holds the potential not only to reduce emissions but to actively channel atmospheric carbon back into the terrestrial carbon cycle through biological processes. While sectors such as energy, transport, and industry focus primarily on reducing or avoiding emissions, agriculture—via soil carbon sequestration, biomass growth, and ecosystem restoration—can capture and utilize atmospheric CO_2 in ways that are intrinsic to its production system (IPCC, 2019a). Practices like agroforestry, regenerative tillage, organic matter incorporation, and pasture management serve as natural carbon drawdown mechanisms that reintegrate carbon into living systems and soils, where it contributes to soil fertility, water retention, and biodiversity (Lal, 2020). This makes agriculture the only sector where net zero is not solely an endpoint of balance, but also a functional mechanism for restoring the carbon cycle. Unlike engineered carbon capture, agricultural sequestration is inherently productive, cost-effective, and scalable—representing not just climate mitigation, but carbon utilization for long-term ecosystem and food system resilience. Achieving net zero in agriculture, therefore, offers the clearest pathway to align carbon removal with global sustainability and regenerative land use objectives.

Agri Net Zero: A Socially Inclusive Pathway for Livelihood Security and Rural Transformation

The Agri Net Zero can hold transformative potential not only for environmental sustainability but also for social equity and rural livelihoods. As agriculture continues to be the primary source of income for a majority of the rural population—particularly small and marginal farmers—transitioning to low-carbon, sustainable practices presents a unique opportunity for inclusive development (FAO, 2021). By promoting low-input farming systems that reduce dependency on expensive chemical fertilizers and pesticides, Agri Net Zero directly addresses rural indebtedness and economic vulnerability (World Bank, 2020). Moreover, the integration of regenerative and carbon-smart practices facilitates farmer participation in emerging carbon markets through carbon farming initiatives, creating new income streams via carbon credits (IPCC, 2023; Verra, 2022). In addition, the Agri Net Zero framework aligns

with national and global food security goals by improving soil fertility, ensuring year-round productivity, and enhancing the nutritional value of food outputs. These systemic improvements contribute to SDG-2 (Zero Hunger), SDG-1 (No Poverty), and SDG-10 (Reduced Inequalities), among others. Furthermore, empowering farmers with climate-smart knowledge and market access strengthens community resilience and fosters rural development through decentralized, sustainable economies. Thus, beyond emissions reduction, the Agri Net Zero model emerges as a powerful socio-economic lever for driving rural transformation, food system resilience, and equitable climate action.

Agri Net Zero: Pioneering Sustainable Agriculture for a Resilient, Net Zero Future

Agri Net Zero is the optimal net zero strategy because it addresses the twin imperatives of limiting global warming through direct emissions reduction and mitigating climate change by transforming sectors that are both major emitters and potential carbon sinks. The core net zero objectives emphasize reducing greenhouse gas (GHG) emissions from human activities and mitigating the broader impacts of climate change; however, since corporations cannot realistically achieve a 100% reduction across Scope 1, 2, and 3 emissions, they must rely on advanced technological interventions and strategic offsetting measures. Agri Net Zero leverages this approach by focusing on agriculture—a sector that, while responsible for substantial GHG outputs such as nitrous oxide and methane, also possesses the unique capacity for carbon sequestration through improved soil health, regenerative practices, and precision farming. Guided by IPCC recommendations, the strategy prioritizes decarbonization in areas where emissions are particularly challenging to abate and emphasizes long-term, sustainable measures that extend beyond short-term fixes. Moreover, Agri Net Zero not only enhances crop sustainability by reducing the reliance on chemical inputs like nitrate fertilizers but also integrates circular economy principles by converting agricultural waste into resources, effectively transforming the sector into a carbon-negative system. This approach is especially critical given that a significant portion of the global population—up to 70% in countries like India—relies on agriculture for their livelihoods, with a large percentage of small, resource-poor farmers at risk from the impacts of climate change. By aligning with Sustainable Development Goals such as SDG 13 (climate action) and SDG 2 (zero hunger), Agri Net Zero ensures that corporate efforts toward emissions reduction are simultaneously advancing social, economic, and environmental sustainability. In essence, Agri Net Zero integrates robust technological solutions, long-term ecological benefits, and comprehensive social responsibility, making it the most viable and impactful approach for achieving a resilient net zero future.

Practical Demonstration of Agri-Net zero Model- Clean Food Net Zero (CFNZ) Program under IBM-IORF Sustainability Project (2021-22 to 2023-24)

The IBM-IORF Sustainability Project (2021–22 to 2023–24) has successfully demonstrated a breakthrough Agri-Net Zero model through its Clean Food Net Zero (CFNZ) Program, which integrates nature receptives agronomic innovations for sustainable, pesticide-free, and carbon-negative food production. Developed by the Inhana Organic Research Foundation on the proven ECCES Model, the CFNZ model leverages IRF Technology for Plant Health Management—providing 360° support from seed treatment to production and enhancing crop productivity by up to 20%—in tandem with Novcom Composting Technology for Soil Health Management. Comprehensive field evaluations have shown that this integrated approach not only reduces the cost of cultivation through optimized resource utilization and enhanced plant immunity but also significantly improves energy efficiency, with recorded gains upto 432% higher crop productivity per unit energy investment and a 57% energy transition.

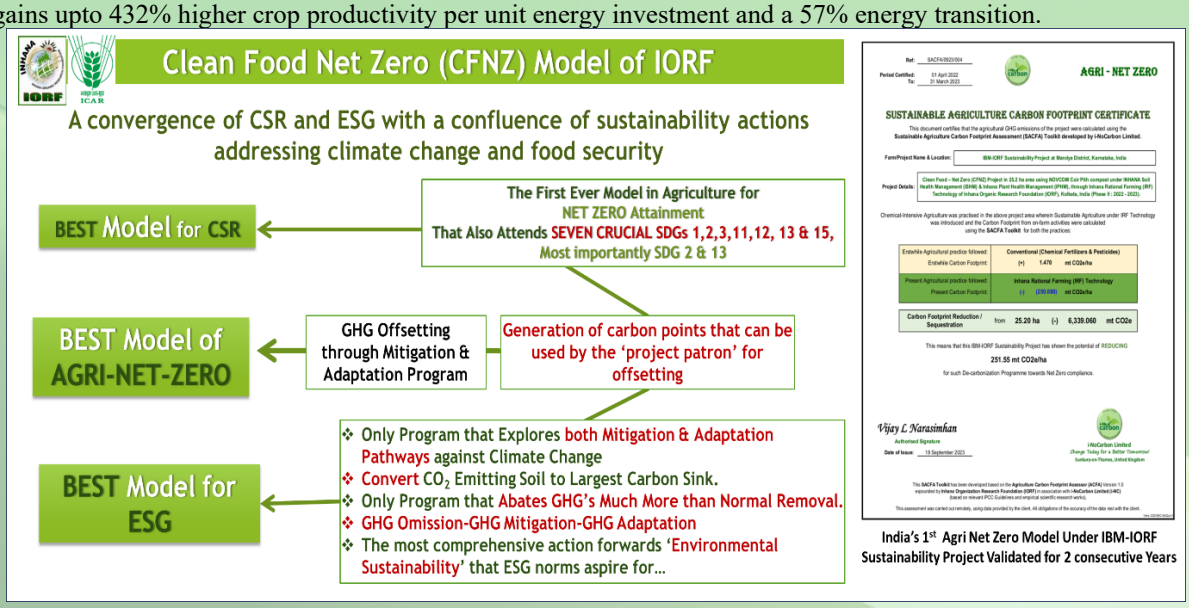

Fig 4 : The Clean Food Net Zero (CFNZ) program, under the IBM-IORF Sustainability Project, effectively showcased the extensive, multifaceted impact of the Agri-Net Zero model.

A pivotal innovation within the program is its "waste-to-wealth" strategy, wherein the conversion of coir pith—a byproduct of the coconut industry into Safe–Stable–Mature Compost can mitigate up to 250 MT CO_2e per hectare by transforming a high-methane-emitting waste into a valuable organic manure, thereby reducing methane emissions and enhancing soil organic carbon sequestration. Demonstrations on model farms in West Bengal and Karnataka revealed that a 100-hectare application of the CFNZ model can potentially offset between 24,833 and over 50,000 MT CO_2e per year, Furthermore, the project has developed unique sustainability tools viz. the Soil Health Proximity Model, the Pesticide Pollution Index, and the Carbon Footprint Indices—that provide quantitative assessments of soil quality, pesticide risk, and crop sustainability. By aligning with multiple Sustainable Development Goals (notably SDG 2 and SDG 13) and complementary government initiatives such as the Agriculture Accelerator Fund, GOBARdhan etc, the CFNZ model paves the way for transforming conventional, GHG-emitting agricultural practices into resource-independent, GHG sink systems, with scalable potential to register carbon abatement and to significantly contribute to corporate, net zero, and sustainability compliance in the agricultural sector.

Conclusion

Agri-Net Zero stands out as the best model for Corporate net zero compliance by seamlessly integrating direct emission reductions with nature-based carbon sequestration. This approach transforms agricultural landscapes—one of the most significant sources of greenhouse gas emissions—into dynamic carbon sinks, while concurrently enhancing soil health, ensuring food security, and mitigating supply chain risks. Unlike traditional offsetting methods that often delay systemic change, Agri-Net Zero implements regenerative practices such as agroforestry, sustainable livestock management, and advanced soil techniques that drive immediate and measurable decarbonization. Aligned with rigorous IPCC guidelines, this model tackles both direct emissions and "impossible-to-abate" emissions like methane and nitrous oxide through innovative, sustainable strategies. The practical success of initiatives like the Clean Food Net Zero Program under the IBM-IORF Sustainability Project further demonstrates its scalability, economic viability, and the substantial environmental co-benefits it offers—ranging from improved energy efficiency to significant cost reductions in resource utilization. By directly addressing emission reductions at the source and securing sustainable livelihoods for communities, Agri-Net Zero not only helps corporations meet their ambitious net zero targets but also reinforces their overall ESG commitments. In an era where rapid climate action is essential, Agri-Net Zero provides a transformative and comprehensive pathway that uniquely positions agriculture as a cornerstone in the global pursuit of climate stability and sustainability.

Impacts of Salinity Stress on the Physiology and Tissue Structure of Nile Tilapia

Shakil Ahmed[1], Md Shahjahan[1]

[1]Laboratory of Fish Ecophysiology, Department of Fisheries Management, Bangladesh Agricultural University, Mymensingh 2202, Bangladesh

Abstract

Salinity is considered one of the most important environmental factors, and stress induced by salinity negatively impacts aquaculture production. This study focused on hematological and histological alterations induced by different salinity levels in Nile tilapia (*Oreochromis niloticus*). The experiment was carried out with a total of 300 fingerlings exposed to 5 different treatments: T1 (control), T2 (3 ppt), T3 (6 ppt), T4 (9 ppt), and T5 (12 ppt) with three replicates each, over 42 days. The study revealed that hemato-biochemical parameters (hemoglobin and glucose) levels were increased at 9 and 12 ppt compared to the control. Regarding erythrocytic abnormalities, cellular (fusion, twin, teardrop, spindle) and nuclear (nuclear bridge, binuclei, notched nuclei, karyopyknosis) abnormalities were significantly more abundant in T4 and T5 compared to other treatments. Histological examination showed that the abnormalities of gills (epithelial lifting, hypertrophy of chloride cell, telangiectasia, deformed pillar system, hyperplasia), liver (hepatocyte hypertrophy, hemorrhage, blood congestion, hemosiderin, melano-macrophage centers), kidney (necrosis, shrinkage of renal corpuscle, hemorrhage, glomerular destruction, melano-macrophage centers) were found in 9 ppt, but markedly alterations were detected at 12 ppt with increasing the days of exposure. These findings are projected to be valuable in raising awareness about the importance of salinity levels for freshwater aquaculture species.

Key Words: *Salinity, Stress, Hematology, Histology, Tilapia*

Growth and Feed Utilization Responses of Nile Tilapia (*Oreochromis niloticus*) to Microplastics and Sumithion Co-Exposure

Mobassir Bin Anwar[1], Md Shahjahan*[1]

[1]Laboratory of Fish Ecophysiology, Department of Fisheries Management, Bangladesh Agricultural University, Mymensingh 2202, Bangladesh

Abstract

The widespread contamination of aquatic environment by microplastics (MPs) and chemical pollutants, including pesticides, pose a severe threat to aquatic organisms, leading to significant disruption in ecological health. This research investigates the cumulative toxicity of polyamide microplastics and the organophosphate pesticides sumithion on Nile tilapia (*Oreochromis niloticus*), a widely cultivated freshwater key species. Over the course of 42 days, the fish were subjected to three treatment groups; 10 mg/L microplastics, 0.3 mg/L sumithion, and a combined exposure to both microplastics and sumithion (MP + Sum). This investigation focused on evaluating growth parameters and tissue histopathology. Co-exposure to microplastic and sumithion led to a significant reduction in growth attributes including final body weight, weight gain, and specific growth rate (SGR), while feed conversion ratios increased, suggesting diminished feed efficiency. The histopathological changes observed in the intestinal tissues including degeneration of columnar epithelium, hyperplasia of intestinal mucosa, degeneration of lamina propria from epithelium, reinforced the severity of the combined exposure. The GH, IGF1, and IGF2 gene expression in Nile Tilapia exibited a consistent downward trend, where the control group exhibits the highest level, followed by a significant reduction in response to microplastic exposure, a further decline under Sumithion treatment, and the most profound suppression in the combined exposure group, detrimentally affecting the growth and development. Overall, the results of the present study highlights the urgent need for integrated approaches to pollution management in aquatic ecosystems to mitigate these synergistic effects.

Keywords: *Microplastics, Sumithion, Nile tilapia, Growth, Histopathology, Gene Expression.*

Abstract

In an increasingly interconnected global marketplace, the role of mathematics and data-driven strategies in shaping marketing and trade decisions has become indispensable. As e-commerce expands across borders and consumers shift toward digital engagement, businesses that leverage quantitative tools such as predictive analytics, optimization models, and machine learning algorithms are achieving strategic advantages. This paper explores how data-based methodologies are redefining global marketing and international trade dynamics in a rapidly globalising and technologically fluid environment. The paper provides a literature-driven foundation on the intersection of mathematics, data science, and global commerce, followed by a discussion on emerging practices, such as personalized marketing, dynamic pricing, inventory optimization, and real-time consumer behavior analysis. Case studies from global brands illustrate how mathematical tools enable better market segmentation, trade forecasting, and cross-border supply chain efficiency. The paper further argues for a more integrated role of data science in business curricula and policy frameworks, especially in emerging markets, where digital transformation is creating new opportunities. A shift toward data-driven global strategies not only enhances profitability but also supports more sustainable, inclusive, and responsive trade ecosystems. In the context of and food marketing systems, African farmers and and food marketers can adopt algorithms and data analytics to enhance market access, optimize production, improve supply chain efficiency, and make informed decisions that align with global trade demands.

Keywords: Algorithms, Analytics, Data driven, decision making, global marketing, trade

Introductıon

Global trade and marketing are no longer the domains of intuition and experience alone. In today's hyper-connected, data-saturated world, business strategies are increasingly informed—and in many cases, driven—by mathematics and algorithmic decision-making (Yazdi, 2024; Aneesha, 2024). From personalized recommendations on Amazon to dynamic pricing models in global airlines, data has become both a resource and a strategic compass. As digital platforms break down geographical barriers, the scale and complexity of international marketing demand robust quantitative tools (Addy et al., 2024). Simultaneously, global trade is affected by volatile consumer trends, supply chain disruptions, and geopolitical shifts—requiring companies to react with precision and speed (Celestin & Sujatha, 2024).

Mathematics plays a critical role in navigating this complexity. Algorithms enable customer clustering and sentiment analysis; optimization models streamline logistics; statistical tools support market research and predictive modeling; and machine learning algorithms allow businesses to adapt to shifting demand in real time (Rane et al., 2024).

In this paper, we aim to demonstrate the growing convergence of mathematical thinking and global commerce. The study surveys the relevant literature, then delves into contemporary applications in global marketing and trade, and concludes with practical insights and policy recommendations for businesses and institutions aiming to remain competitive in a data-driven global economy.

Mathematical Foundations of Decision-Making in Business

Mathematics forms the backbone of modern business decision-making. Tools like linear programming, decision theory, and game theory help optimize resource use and strategic choices, while trade models such as general equilibrium and gravity models simulate global trade flows (Bahiraie *et al*., 2024; Anderson & van Wincoop, 2003). In global marketing, the explosion of big data has fueled predictive analytics, enabling firms to mine insights using clustering, regression, and association rules (Han, Kamber & Pei, 2012). Machine learning techniques such as neural networks and decision trees support customer segmentation, churn prediction, and personalized targeting (Sharma & Lambert, 2021).

E-commerce giants like Amazon and Alibaba leverage collaborative filtering and matrix factorization for algorithmic personalization (Linden, Smith & York, 2003), while dynamic pricing models respond to real-time data shifts (Elmaghraby & Keskinocak, 2003). In supply chains, mathematical models like EOQ and the

newsvendor model improve inventory and logistics (Bazan *et al*., 2016), with AI-enhanced systems now forecasting disruptions and optimizing freight in real time (Ivanov & Dolgui, 2020).

Despite these advancements, ethical concerns are rising. Scholars warn of algorithmic bias, data privacy issues, and cultural insensitivity, especially in emerging markets (Eubanks, 2018; Noble, 2018). Algorithms trained on Western datasets may misrepresent diverse consumer behaviors, underscoring the need for inclusive and culturally informed models. As businesses become increasingly data-driven, ethical and localized approaches are vital for effective and equitable global marketing. This perspective has been illustrated in Figure 1.

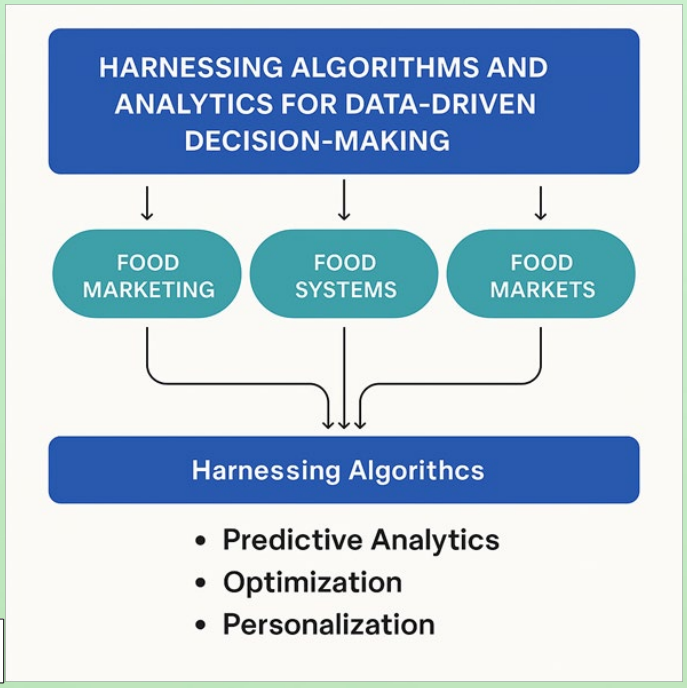

Figure 1. Authors' Proposed Framework

Figure 1, shows a framework highlighting how algorithms and analytics are transforming decision-making in food marketing and trade. Predictive tools and optimization models boost efficiency, forecast demand, and tailor strategies to consumer needs. Data-driven insights enhance policy, investment, and sustainability in agriculture. As data becomes foundational to global competitiveness, firms must invest in ethical, inclusive strategies, infrastructure, and culturally aware modeling to stay ahead.

The intersection of mathematics and global business is no longer optional, it is foundational. Companies that fail to adopt data-driven strategies risk falling behind in a world where agility, personalization, and efficiency define competitiveness. Yet, these strategies must also be inclusive and ethically grounded, ensuring that data use does not exacerbate inequality or erode consumer trust. Investing in data literacy, infrastructure, and culturally informed modeling is essential for both multinationals and local firms aspiring to compete globally. The practical application of mathematics in business decision-making is further illustrated below.

Price Forecasting using Basic Algorithm and Analytics

This section presents a simple illustrative example using a basic algorithm and analytics in the context of price prediction and market decision-making in global marketing and trade, particularly for agricultural exports from Africa.

Illustration: Price Forecasting Using Linear Regression (A Simple Algorithm)

Objective: Predict future export prices of cocoa based on historical data using a linear regression model.

Step 1: Historical Data (Simplified)

Assuming the following data for export prices of cocoa over 5 years, as presented in Table 1.

Table 1 Hypothetical Export Prices of Cocoa between 2020 and 2024

Year	Export Price (USD/ton)
2020	2,200
2021	2,300
2022	2,450
2023	2,600
2024	2,750

Source**:** Hypothetical dataset c*onstructed by authors for illustrative purposes.*

Table 1 presents hypothetical data set generated by the authors to illustrate the application of linear regression in predicting export prices.

Step 2: Apply Simple Linear Regression

The general formula of a linear regression model is:

$$y = a + bx$$

Where:

- y = predicted price
- x = year (treated numerically, e.g., 1 for 2020, 2 for 2021...)
- a = intercept
- b = slope

From the data, we calculate:

- Mean of x = 3
- Mean of y = 2,460

$$b = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sum(x - \bar{x})^2}$$

$$b = \frac{(-2)(-260) + (-1)(-160) + (0)(-10) + (1)(140) + (2)(290)}{(-2)^2 + (-1)^2 + 0^2 + 1^2 + 2^2}$$

$$b = \frac{520 + 160 + 0 + 140 + 580}{4 + 1 + 0 + 1 + 4} = \frac{1400}{10} = 140$$

$$a = \bar{y} - b\bar{x} = 2400 - 140(3) = 2460 - 420 = 2040$$

Prediction Model:

$$Price = 2040 + 140x$$

Step 3: Using the Algorithm for Decision-Making

Predict export price in **2025** (i.e., x=6):

$$Price_{2025} = 2040 + 140(6) = 2040 + 840 = USD2{,}880\ per\ ton$$

From the result, this simple model can help decision-makers to:

- Forecast future prices for planning production and marketing
- Advise farmers on when to harvest or sell
- Inform export contracts and trade negotiations

This illustration demonstrates that such algorithmic insights, when scaled and refined with real-time analytics, can give African farmers and marketers a strategic edge in global trade.

Applications and Case Studies

Global companies use mathematical tools to transform business: Alibaba analyzes demand trends with AI, Unilever optimizes supply chains using machine learning, and Amazon and Walmart apply predictive analytics for logistics and promotions. In Africa, Jumia leverages mobile data to reach underserved markets, guiding vendor engagement and logistics through insights from consumer behavior. These applications are illustrated in Figure 2.

Figure 2 illustrates how data-driven decision-making in global marketing and trade relies on predictive analytics, optimization models, and machine learning. These approaches support personalized marketing, inventory optimization, and trade forecasting with segmentation—enabling strategic advantage in a rapidly changing world.

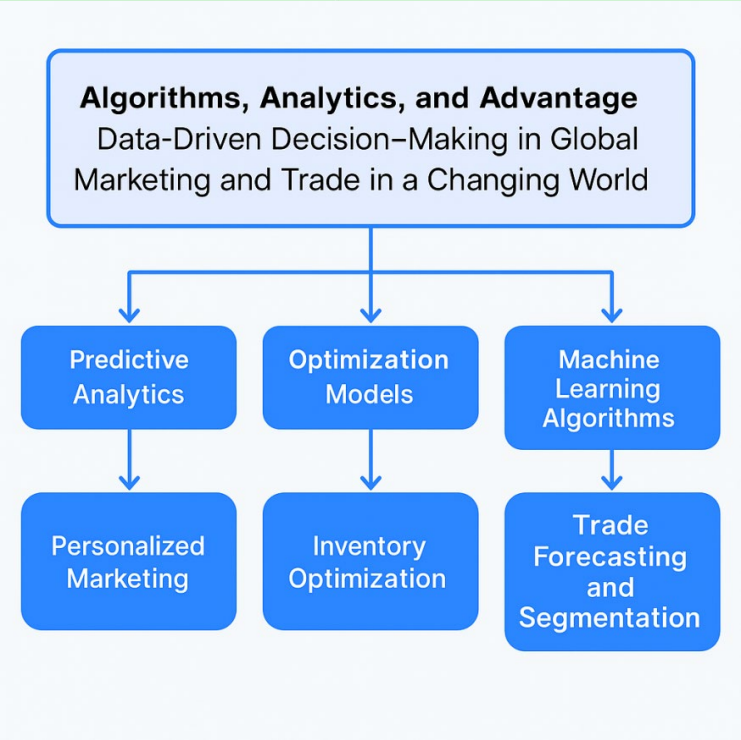

Figure 2. Authors' Proposed Framework

Algorithms, Analytics and Food Marketing Systems

The integration of algorithms and analytics into food systems has transformed how decisions are made across food marketing and trade. Recent studies underscore the pivotal role of data analytics in enhancing efficiency, transparency, and responsiveness within agri-food value chains (Klerkx & Rose, 2020). Predictive analytics and machine learning algorithms are now widely used to forecast consumer trends, optimize supply chains, and tailor marketing strategies in real time (van der Burg *et al*., 2019). In food marketing, big data enables segmentation and personalization, helping businesses respond to diverse consumer preferences, ethical concerns, and sustainability demands.

Moreover, in global food markets, algorithms support price prediction, demand estimation, and trade logistics, facilitating smarter and faster decision-making (Zhong *et al.*, 2020). For food systems, analytics contribute to risk management, climate resilience, and resource optimization by analyzing large datasets from farm-level sensors, satellite imagery, and market reports. As a result, digital intelligence enhances the adaptability of food systems in the face of volatility and global shocks. However, literature also highlights challenges such as data quality, digital inequality, and ethical considerations in algorithmic governance. Addressing these issues is essential to fully harness the benefits of analytics for inclusive and sustainable food system transformation. The framework illustrating how algorithm and data-analytics facilitate global marketing is shown in Figure 3.

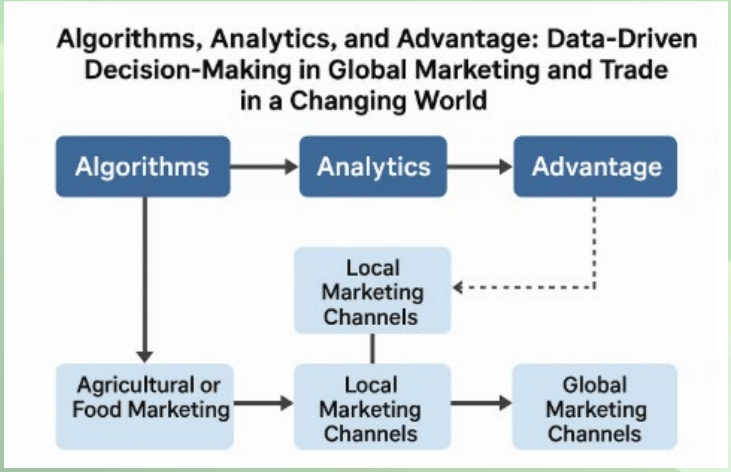

Figure 3. Authors' Proposed Framework

Figure 3 illustrates a dynamic, data-driven framework linking algorithms, analytics, and competitive advantage within the context of agricultural or food marketing. Algorithms initiate the process by generating insights from raw data, which are then processed through analytics to inform strategic decisions. These analytics support both local and global marketing channels by optimizing supply chains, identifying market trends, and enhancing consumer targeting. Agricultural marketing, as the entry point, is positioned to benefit from these insights, ensuring better market alignment. Local marketing channels serve as a crucial feedback loop, where real-time data informs further refinement of algorithms and strategies. This interaction enables producers especially farmers to scale operations, penetrate global markets, and adapt to changing trade environments. The framework emphasizes a continuous cycle of improvement, where informed decision-making leads to sustainable competitive advantage, fostering inclusive participation of African farmers in global trade networks.

Role of Algorithms and Data Analytics in Shaping Food Marketing in Africa

Food marketing in Africa has traditionally been localized, with most farmers relying heavily on product exchange at the farmgate. Therefore, leveraging algorithms and data analytics becomes essential to advance food marketing beyond the farm gate and into the global marketplace. The transformation of food marketing in Africa is increasingly driven by data and digital innovation. Traditional, fragmented supply chains are being reshaped by mobile platforms and algorithmic tools that enhance access to global markets. ICT plays a key role in connecting rural producers to international buyers (Aker, 2010; World Bank, 2020). Platforms like Twiga Foods and FarmCrowdy use real-time data and algorithms to optimize logistics, reduce waste, and improve pricing. Blockchain and traceability tools help meet global standards, fostering trust and market expansion (Kamilaris *et al*., 2019). Predictive analytics support inventory management, export forecasting, and targeting of niche markets (FAO, 2021; UNCTAD, 2022). However, challenges like digital divides and low data literacy persist, risking the exclusion of smallholders. Inclusive data ecosystems and public-private partnerships are essential to ensure equitable participation. Overall, data and algorithms serve as strategic enablers, positioning African food systems for global competitiveness.

Conclusion

In today's dynamic global landscape, mathematics and data science are essential for strategic decision-making in marketing and trade.

Businesses must embrace advanced analytics, ethical AI, and interdisciplinary collaboration to remain competitive. Strong industry-academic partnerships can foster innovation, shape curricula, drive market research, and develop data-informed strategies, especially in global and agricultural markets. Algorithms and analytics drive competitive advantage in global marketing and trade, supporting agricultural or food marketing, feeding into both local and global marketing channels. Analytics enhance these channels by refining strategies, while feedback from local markets informs further optimization. This data-driven cycle strengthens decision-making and global reach. In particular, African farmers and food marketers can harness the power of algorithms and data analytics to gain real-time market insights, predict demand trends, and improve production efficiency. By leveraging these tools, farmers can access broader markets, reduce post-harvest losses, streamline supply chains, and make data-driven decisions. This approach empowers both smallholder and commercial farmers to compete effectively in the global economy and respond proactively to shifting consumer preferences and trade dynamics.

Application of Different Phytosolutions on Germination and Growth Indices of Wheat

Iqtidar Hussain

Department of Agronomy, Faculty of Agriculture, Gomal University, Dera Ismail Khan, Khyber Pakhtunkhwa, Pakistan
iqtidarhussain453@yahoo.com

Abstract

Wheat (*Triticum aestivum* L.) is an important cereal grown in temperate and subtropical regions, mainly for food and animal feed. In Dera Ismail Khan, wheat planting is often delayed because sugarcane and cotton are prioritized. Late planting leads to poor wheat germination due to low temperatures or the presence of weeds, which can harm the crop. This issue is common across the country, affecting farming and causing wheat yields to stagnate. Increasing wheat production is a challenge. Recently, methods like seed treatment and synthetic plant growth regulators have gained popularity for boosting crop growth and ensuring wheat sprouts quickly. Allelopathy is another innovative approach that has gained attraction to mitigate biotic and abiotic stresses. The shift towards sustainable crop production is also supported by innovation in organic farming. The fallen leaves and stubble of some trees and weeds may influence emergence of wheat in the field. A study was performed at the Postgraduate laboratory, Department of Agronomy, Faculty of Agriculture, Gomal University, Dera Ismail Khan during the year 2024. Nine treatments were arranged in a completely randomized design including T1 (Control), T2 (Bitter apple), T3 (Lasoda), T4 (Parthenium), T5 (Garlic), T6 (Peelu), T7 (Conocarpus), T8 (Moringa), T9 (Algal water solution) and were compared for emergence and growth indices of wheat. Germination parameters i.e. day wise germination, germination count, germination (%), germination energy and growth indices i.e. coleoptile, root, shoot, plant length, root, shoot, whole plant fresh and dry biomass at 15 days interval were observed and found significant at 5% probability level. Leaf area, chlorophyll content, crop growth rate, net assimilation rate and photosynthetic efficiency were also noted and significantly different from control. Our results classified Moringa, Bitter apple and Algal solution as growth stimulator, while Parthenium, Conocarpus and Garlic proved as inhibitor because they hampered the wheat germination and growth indices. Moringa water solution at 10% is most effective and should be used to enhance the wheat germination and development of seedling especially in late sown wheat. Plantation of Conocarpus around the crop area should be avoided. Parthenium reduced germination and its indices, so it should be managed before wheat crop plantation.

Molecular characterization of brackish and marine water fishes of Sundarbans through DNA barcodes

Md. Mobarak Hossen

Fisheries biology and geneticsResearch Fellow at Bangladesh Agricultural University Mymensingh, Bangladesh

Abstract

The present study aims to apply a DNA barcoding tool through amplifying the mitochondrial candidate genes like COI for accurate identification of fish of Sundarbans mangrove wetland, to build a reference library of fish of the unique ecosystems. A total of 83 mitochondrial COI barcode sequences gene were obtained from 26 species of 26 genera, 23 families, 8 orders and one class; among the 26 species, 3 fishes were new records in Sundarbans ecosystem. The collected samples were first identified by examining morphometric characteristics and then assessed by DNA barcoding. The COI sequences of fishes were clearly discriminated among genera in their phylogenies. The average Kimura two-parameter (K2P) distances of COI barcode sequences within all fish species were 0.37 ± 0.01%. The base composition analysis for the COI sequence showed that the average percent T content was the highest and the average percent G content was the lowest; the AT content (53.60%) was higher than the GC content (46.40%). The GC contents at the first, second, and third codon positions for all fishes were 46.3%, 47.2%, and 45.7%, respectively. At the first codon position, the usage of C (18.7%) was the lowest, and the usages of the other bases were 23.00%, 27.10%, and 31.30% for T, A, and G, respectively. There were 36 haplotypes comprised this network. Each node of the network represents one unique haplotype and the bar across branches indicates the number of mutations separating two haplotypes. The overall haplotype diversity (Hd) was 0.979. The highest haplotype diversity was found 0.968 in perciformes fishes and the lowest haplotype diversity was found to be 0.000 in beloniformes, Synbranchiformes, Pleuronectiformes, Cichliformes and mugiliformes fishes. The overall nucleotide diversity (Pi) for all groups fishes were 0.37032. The nucleotide diversity was found to be highest (0.3961) in perciformes and lowest (0.000) in beloniformes, synbranchiformes, pleuronectiformes, cichliformes and mugiliformes samples. The present study describes the development of a molecular and morphometric cross-referenced inventory and assess the genetic variability of fishes of the Sundarbans. This inventory will be useful in future biodiversity studies and in forming future conservation plan. High efficiency and fidelity in species identification and discrimination were demonstrated in the present study by DNA barcoding, and we can be added that COI sequencing can be used as an authentic identification marker for Bangladesh brackish and marine fish species.

Evaluating Biometric Indices and Life-History Traits of Climbing Perch, *Anabas testudineus* of Baluhor Oxbow Lake in Southwestern Bangladesh: Implication for Sound Management

Sarower Mahfuj[1,*], Sk. Mohibulla Islam[1], Mst.Sabrin Akter[1]

[1] Department of Fisheries and Marine Bioscience, Jashore University of Science and Technology, Jashore, Bangladesh
[*] Corresponding author email address: sa.mahfuz@gmail.com

Abstract

In Bangladesh, the freshwater climbing perch, *Anabas testudineus*, is a food fish with significant economical and nutritional value. To create long-term management and conservation strategies for this species, it is essential to investigate the life-history characteristics of *A. testudineus*. The present research provides the comprehensive explanation of the life-history traits (LHT), containing length-frequency distribution (LFD), length-weight and length-length relationships (LWR and LLR), form factor ($a_{3.0}$), condition factors, length at first sexual maturity (L_m), natural mortality (M_w), maximum life span (t_{max}), optimum age, where fish reaches its maximum biomass and optimum catchable length (L_{opt}) of *A. testudineus* from the Baluhor Oxbow Lake in Southwestern Bangladesh. Fish samples (n=102) were collected from May to July 2024, using various types of traditional fishing gears. Digital slide calipers and an electronic balance with an accuracy of 0.01 cm and 0.01 g, respectively, were used to measure total length (TL) and whole-body weight (BW). During this investigation, 102 specimens with measurements ranging from 6.96-13.49 cm TL and 9.59-35.07 g BW were examined. The calculated b values of *A. testudineus* showed a trend of negative allometric growth ($b<3.0$). The LWRs were highly significant ($p<0.001$) with r^2 values >0.8117. Among the four categories of condition factors in the Baluhor Oxbow Lake, K_F represented the best for well-being of *A. testudineus*. Significant dissimilarity from 100 was found in a Wilcoxon sign-ranked test for WR, indicating that habitat is uneven of *A. testudineus*. The determined $a_{3.0}$ was 0.00861, and L_m was calculated as 8.2383 (~8.30) cm TL in the Baluhor Oxbow Lake. The M_w of *A. testudineus* was 1.26 $year^{-1}$, optimum age of maximum biomass was 2.60 years and maximum life span, t_{max} was 9.65 years according in this study. The outcomes sought to help Southwestern Bangladesh and its surrounding environments in effective management of *A. testudineus* species sustainably.

Abstract

Waste accumulation from industries and households poses the greatest challenge to environmental sustainability and public health in industrializing and urbanizing nations. Conventional technologies for treating waste, including landfill and incineration, are increasingly coming under attack for their environmental disadvantages and poor resource recovery capacities. In this context, biotechnology offers itself as a paradigm-breaking technology for valorization of waste to value-added products. In this mini-review, advanced biotechnological interventions—ranging from microbial digestion and enzymatic depolymerization to anaerobic fermentation and bio-electrochemical systems—are presented for recycling and valorization of heterogeneous waste streams. Emphasis is on engineering microbial consortia, synthetic biology for designing engineered enzymatic activity, and interfacing of bioprocesses with digital monitoring systems. Examples of case studies are microbacteria degrading plastics, upgradation of lignocellulosic biomass, biofuel, bioplastic, and organic fertilizer manufacturing. Reviewing also includes socio-economic and policy frameworks required for the adoption of bio-based circular economies, especially in low- and middle-income countries. Biotechnology offers relief to the environment as well as employment generation and propelling green innovation with furthering cross-disciplinary approaches and bridging the waste-resource gap.

Abstract

Microbial populations play a fundamental role in nutrient cycling and maintaining ecosystem resilience in environments with pollutants of anthropogenic origin. Through this mini-review, the adaptable capacity, ecological processes, biotechnological perspectives, and genomic insights of microbial consortia present in contaminated freshwater and terrestrial systems are investigated. Recent advances in metagenomics, transcriptomics, and microbial ecology have provided valuable insights into microbial survival strategies under chemical stress, such as horizontal gene transfer, quorum sensing, and biofilm formation. The review categorizes microbes based on their degradative potential (e.g., hydrocarbonoclastic, heavy metal-reducing, xenobiotic-tolerant) and elaborates on how these characteristics can be utilized for soil remediation, water purification, and atmospheric detoxification. Special focus is given to the functional interaction between native microbiota and supplemented bioengineered strains for enhanced bioremediation efficiency. Ecological restoration, climate change mitigation, and environmental policy design consequences are also discussed. Lastly, understanding microbial ecosystem resilience and utility provides a promising avenue towards sustainable environmental management.

Abstract

Achievement of global sustainability goals requires an immediate transition from fossil fuel-based energy systems to integrated renewable energy systems. This mini-review addresses the design principles, design considerations, and implementation strategies for integrated renewable energy systems—solar, wind, biomass, and small-scale hydropower—in the context of the emerging economies. It emphasizes how decentralised models, energy storage technologies, and hybrid grids can eradicate energy poverty and reduce greenhouse gas emissions. Key technological synergies are explored, such as solar-bioenergy coupling, optimization of the energy-water nexus, and AI applications to grid management. The review considers socio-economic factors such as financing models, gendered access to energy, and local capacity development. Policy settings and global cooperation are considered as the driving forces for sustainable transitions. Through the integration of renewable technologies that are appropriate to local resources and needs, new economies can promote simultaneously economic growth, energy security, and environmental integrity.

Keywords: *Integrated renewables, Energy transition, Decentralized systems, Climate-smart development, Sustainable energy policy, Emerging economies*

Abstract

Climate change poses severe challenges to global agriculture, disrupting crop productivity, increasing chemical dependency, and threatening the livelihoods of small and marginal farmers. This paper examines the impact of climate change on agricultural systems and the potential of regenerative agriculture to sustain crop yields, reduce pesticide loads, support farmers' livelihoods, and mitigate carbon emissions. By integrating the Clean Food Net Zero (CFNZ) Program with Inhana Rational Farming (IRF) Technology and utilizing advanced composting methods such as Novcom Composting, the study demonstrates that regenerative practices can enhance soil health, boost crop productivity by up to 22%, and significantly reduce greenhouse gas emissions through improved nutrient cycling and carbon sequestration. Field evaluations from West Bengal, India, underscore how these interventions not only lower emissions from conventional practices but also transform agriculture into a viable carbon sink while promoting safe, pesticide-free produce. Overall, the findings reinforce that adopting a net zero regenerative agriculture model is a viable strategy for addressing the multifaceted impacts of climate change, ensuring food security, and elevating the socio-economic conditions of farming communities.

Key words : *Novcom composting technology, IRF Technology, ACFA version 2.0, Agri-Net Zero model*

Introduction

Climate change poses multifaceted challenges to modern agriculture, severely impacting crop productivity through altered weather patterns, increased frequency of extreme events, and shifts in pest and disease dynamics (Subedi et al, 2023). These climate-induced stresses not only lead to reduced crop yields but also escalate production costs, thereby exacerbating the difficulties associated with ensuring food and nutritional security (Tchonkouang et al, 2024). Moreover, the agricultural sector occupies a paradoxical role in the climate nexus—it both contributes to greenhouse gas emissions and suffers from the adverse effects of climate change (Gupta and Pathak, 2016). In countries like India, where more than 80% of the farming community comprises small and marginal farmers who are resource-poor and highly vulnerable to climatic shocks, the stakes are even higher (Mubashir and Bhat, 2021). These groups often face compounded risks, including financial instability and limited access to resilient technologies, making them disproportionately affected by the escalating costs and productivity losses due to climate variability.

Against this backdrop, regenerative agriculture has emerged as a promising paradigm aimed at sustaining crop yields while simultaneously reducing reliance on chemical inputs such as pesticides. This approach underscores the importance of managing both soil and plant health to not only restore the ecological balance but also enhance the resilience of agricultural systems. By aligning farming practices with ecosystem services, regenerative methods aim to improve soil fertility, bolster biodiversity, and enhance carbon sequestration, all while being socially acceptable, easily adoptable, economically viable, and replicable on a large scale. The integration of regenerative agriculture practices represents a critical pathway for mitigating the twin challenges of climate change and the systemic vulnerabilities of conventional agricultural systems (Lal, 2020). Its holistic framework offers a sustainable solution that addresses the immediate needs of crop productivity and farmer livelihoods, while also contributing to long-term environmental stability and climate mitigation efforts (Chepngeno et al, 2024).

In this context, Nadia Krishi Vigyan Kendra, BCKV, ICAR, located in West Bengal, India, has joined hand with Inhana Organic Research Foundation (IORF), India, to initiate a pesticide-free, safe, and sustainable cultivation system. This collaborative effort infuses the principles of regenerative farming by implementing the Inhana Rational Farming (IRF) Technology—a nature-harnessed, sustainable package that advocates for the integrated management of soil and plant health as critical components for enhancing crop sustainability, economic viability, and carbon mitigation. The initiative aims to establish a comprehensive agricultural production system that not only bolsters crop productivity and nutrient uptake efficiency but also significantly reduces pesticide loads, facilitates energy transitions, uplifts soil quality, and mitigates carbon emissions. Ultimately, the present study seeks to develop and validate a regenerative agriculture model that promotes livelihood sustenance and contributes

to broader environmental benefits including carbon mitigation, thereby uplifting the overall socio-economic conditions of the farming community.

Materials and method

Study area

The study was done at the project site comprised five villages namely Satyapole, Bhabanipur, Panchkahaniya, Dhopagachi and Bansbona in the Haringhata block of Nadia district of West Bengal, India. The area belongs to hot, moist subhumid ecological sub region (15.1) (Sehgal, 1992). The climate of the study area is characterized by oppressively hot summer, high humidity and high rainfall during the monsoon.

Concept of Clean Food Net Zero (CFNZ) program

The Clean Food Net Zero (CFNZ) Program is a transformative and holistic initiative designed to revolutionize agricultural practices while significantly reducing greenhouse gas emissions. Central to its approach is the implementation of Inhana Rational Farming (IRF) Technology—a nature-harnessed, sustainable package that integrates comprehensive soil and plant health management (Bera et al, 2023). By doing so, IRF Technology enhances crop sustainability, increases yields through improved photosynthetic efficiency, and provides a robust mechanism for carbon sequestration and emission mitigation. One of the program's core principles is that its strategies must be aligned with ecosystem services, economically viable, socially acceptable, easily adoptable, and scalable on a large scale. In addition to driving environmental benefits, the CFNZ Program is committed to ensuring that safe, nutritious, and affordable food is available for all. Equally important, it seeks to sustain and uplift the livelihoods of small and marginal resource-poor farmers by providing them with cost-effective, sustainable farming practices that can be readily implemented. Together, these integrated objectives not only fortify food security and public health but also empower farming communities, thereby contributing significantly to both climate resilience and inclusive economic development.

Novcom composting technology

Novcom Composting Technology is an advanced bio-conversion process engineered to rapidly transform diverse biodegradable wastes—including agricultural byproducts and landfill residues—into nutrient-dense compost that is exceptionally rich in microorganisms (on the order of 10^{16} cfu per gram of moist compost). This technology distinguishes itself by achieving complete compost maturity in just 21 days, a notable improvement over conventional windrow methods, primarily due to its capacity to generate a substantially higher native microbial population within the compost heap. The accelerated microbial activity not only expedites the decomposition process but also enhances soil nutrient cycling and promotes vigorous plant growth (Seal et al, 2012). Moreover, the process meets five critical criteria—safety, speed, effectiveness, comprehensiveness, and economic viability—making it highly suitable for any biodegradation program. By optimizing these biological processes, Novcom Composting Technology significantly reduces greenhouse gas emissions, particularly methane, thereby mitigating the overall carbon footprint associated with organic waste management. This efficient, cost-effective, and environmentally friendly approach renders it a valuable tool in sustainable agriculture and climate change mitigation strategies (Bera et al, 2024).

Inhana Rational Farming (IRF) Technology

Inhana Rational Farming (IRF)T Technology is a comprehensive, nature-harnessed approach to agriculture that integrates advanced soil and plant health management practices to transform conventional, chemical-intensive farming into a more sustainable, resilient, and climate-friendly system (Seal et al, 2017a). By leveraging the synergistic interactions of native soil microbes, nutrient cycling, and plant physiological processes, IRF Technology enhances nutrient uptake and photosynthetic efficiency, thereby improving crop yield and quality. Its holistic methodology not only bolsters economic viability and crop sustainability but also promotes carbon sequestration and reduces greenhouse gas emissions by lowering dependency on artificial inputs. Designed to be economically viable, socially acceptable, and easily scalable, IRF Technology offers an adaptable pathway for small and marginal resource-poor farmers, ultimately contributing to a safer food supply and more resilient agricultural ecosystems (Seal et al, 2017b).

Analytical methodology for soil, compost, crop production, energetics and carbon footprint

Analytical measurements were performed across several components—compost, soil, crop productivity, energetics, and carbon footprint—to assess the impacts of the intervention. For compost quality, 20 samples from individual Novcom compost heaps made from different biodegradable waste viz agricultural farm waste, water hyacinth, poultry litter, vegetable market waste and cow dung were collected and analyzed for various parameters following the standard methodology of Seal et al. (2012), and a Compost Quality Index (CQI) was computed as described by Bera et al. (2013). Soil quality was assessed by collecting samples from the 0–30 cm depth both before the experiment and one year later; these were analyzed for physicochemical properties and fertility using conventional methods (Jackson, 1973), while microbial biomass carbon was estimated through the dichromate oxidation method (Vance et al., 1987) and soil respiration was quantified by chemically titrating trapped CO_2 and measuring fluorescein diacetate hydrolysis (Haney et al., 2008). Crop productivity was determined according to guidelines by Patrick (1999) and converted into coconut equivalent yield, leading to an estimation of total system

productivity as per the methods of Ghosh et al. (2021) and Naveen Kumar et al. (2017). Energetic parameters—including energy use efficiency, energy productivity, specific energy, energy intensiveness, and net energy—were calculated following Banaeian et al. (2011). Finally, the carbon footprint was evaluated using the ACFA (version 1.0) carbon computing standard, developed by the Inhana Organization Research Foundation (IORF), ICAR-ATARI, Kolkata (Zone-V), and i-NoCarbon Limited (i-NC), UK, which integrates relevant IPCC guidelines with empirical research findings.

Result and discussion

Analysis of Compost quality

Novcom compost quality was evaluated across diverse substrates—including agri-farm waste, water hyacinth, banana stump, and poultry litter—revealing distinct physical, chemical, and biological properties. Moisture contents ranged from approximately 59% to 64%, while pH values remained near neutral (7.24–7.8), ensuring a favorable medium for microbial activity. Electrical conductivity was highest in the poultry litter compost (2.84 dS/m), indicating a greater concentration of soluble salts. Organic carbon percentages were notably high in the banana stump (28.2%) and water hyacinth (27.1%) composts, and the C/N ratios varied from 11.6:1 to 15.2:1, reflecting moderate maturity and balanced nutrient availability. Although total nitrogen levels were relatively consistent (1.79–2.09%), total phosphorus and potassium contents varied, with poultry litter compost exhibiting the highest phosphorus (1.24%) and banana stump the highest potassium (1.51%). Microbial assessments showed bacterial counts ranging from 23 × 10^16 to 40 × 10^16, with substrate-specific variations also observed in fungal and actinomycete populations, suggesting differences in decomposition dynamics. The CO_2 evolution rate, an indicator of microbial metabolic activity and compost stability, was markedly higher in poultry litter compost (4.61 mg CO_2–C/g OM/day) compared to the 2.13–2.39 mg CO_2–C/g OM/day observed in the other substrates. Bioassay results further demonstrated that composts derived from agri-farm waste, water hyacinth, and banana stump supported robust plant growth, as evidenced by seedling emergence rates between 107–113% and germination indices exceeding unity (1.09–1.12), while the poultry litter compost showed slightly diminished performance (93% seedling emergence and a germination index of 0.89), indicating minor phytotoxicity. Overall, these findings illustrate that Novcom composts, particularly those made from agri-farm waste, water hyacinth, and banana stump, possess favorable qualities for sustainable agricultural application, balancing nutrient enrichment with microbial vitality and minimal phytotoxic risk**.**

Table 1 : Analysis of Novcom compost quality

Sl No	Quality parameters	On-Farm Novcom Compost			Poultry litter
		Agri-farm waste	Water hyacinth	Banana stump	
1	Moisture (%)	61.2	64.3	63.7	59/1
2	$pH_{(water)}$	7.61	7.24	7.41	7.8
3	EC (1 :5) dS/m	1.91	2.64	1.93	2.84
4	Organic carbon (%)	22.2	27.1	28.2	23.1
5	CMI[2]	2.17	1.83	1.91	2.37
6	Total nitrogen (%)	1.91	2.09	1.79	1.89
7	Total phosphorus (%)	0.57	0.97	0.91	1.24
8	Total potassium (%)	1.04	1.11	1.51	1.17
9	C/N ratio	11.6:1	13.0: 1	15.2:1	12.2:1
10	Total bacterial count[3]	31 x 10^{16}	40 x 10^{16}	33 x 10^{16}	23 x 10^{16}

15	Root elongation (% of control)	101	98	105	96
16	Germination index (phytotoxicity bioassay)	1.09	1.11	1.12	0.89

Crop productivity under conventional farmers practice and CFNZ program

In a comprehensive evaluation conducted over a cropping year, five major crop sequences were studied: CS 1 (Tomato–Cucumber–Coriander), CS 2 (Potato–Brinjal–Cauliflower), CS 3 (Potato–Okra–Cabbage), CS 4 (Brinjal–French bean–Spinach), and CS 5 (Pumpkin–Okra–Cabbage). Notably, the Potato–Brinjal–Cauliflower sequence (CS 2) demonstrated the highest productivity, yielding 52,125 kg/ha under conventional farmer practices (CFP) and increasing to 92,775 kg/ha under the Clean Food Net Zero (CFNZ) program. This was followed by the Potato–Okra–Cabbage sequence (CS 3), which achieved yields of 66,937.5 kg/ha under CFP and 82,125 kg/ha

under CFNZ. On average, the CFNZ program led to a 22% increase in crop yields compared to conventional practices. The observed yield improvements are scientifically attributed to the adoption of enhanced soil and plant health management practices, particularly through the integration of Inhana Rational Farming (IRF) Technology. This technology promotes a synergistic soil–plant interaction by boosting microbial biomass, nutrient cycling, and overall resource use efficiency, thereby enhancing photosynthetic activity and crop growth. Moreover, the methodological framework of the CFNZ program adheres to critical criteria—being aligned with ecosystem services, economically viable, socially acceptable, and readily scalable—which further supports its potential to deliver sustained productivity improvements while mitigating environmental impacts.

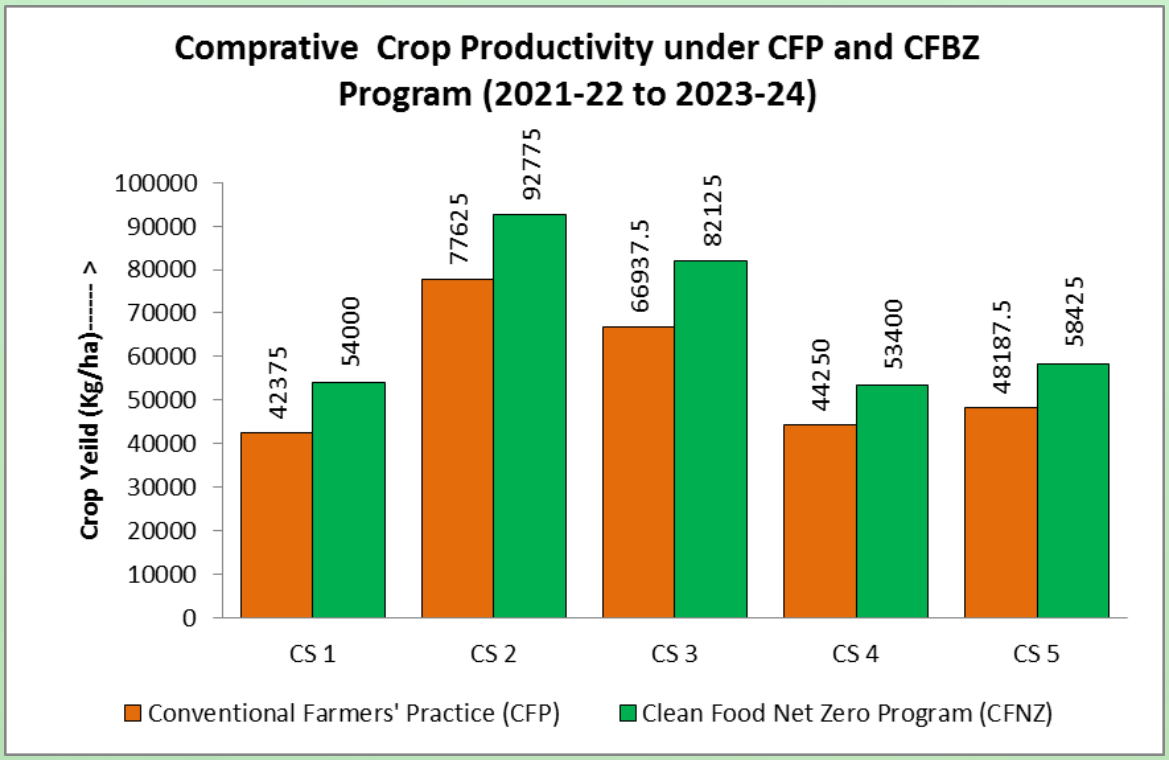

Fig 1 : Comparative evaluation of crop productivity under CFP and CFBZ program

The Status of Food Safety in India and how 'Clean Food' Safety correlates

In India, food safety is regulated by the Food Safety and Standards Authority of India (FSSAI) under standards aligned with the Codex Alimentarius Commission, setting a conventional maximum pesticide residue limit of 0.1 ppm in vegetables. However, for organic produce and the 'Clean Food' initiative, the limit is tightened to 0.01 ppm—not per individual pesticide, but as a cumulative ceiling irrespective of the number of pesticide groups present. From 2008 to 2018, analysis of 181,656 food samples revealed that 3,844 samples (2.1%) surpassed the prescribed limits. A focused study on 584 vegetable samples detected residues above 0.1 ppm in 83 samples (14.21%), with data showing that 34.93% of vegetables from conventional markets were contaminated, compared to only 3.85% of samples collected from the 'Clean Food' project area. Risk assessment further categorized vegetables into three groups: low/no risk (e.g., peas, cabbage, cauliflower, potato, onion, yam, spinach, and coriander with contamination in less than 20% of samples), moderate risk (e.g., French bean, cucumber, carrot, tomato, pumpkin, and ridge gourd with 20–50% contamination), and high risk (e.g., pointed gourd, brinjal, chilli, and okra with contamination in over 50% of samples). For vegetables in the high-risk category, the conventional market samples exhibited a 63.3% contamination rate, whereas those from the Clean Food project area recorded only 12.7%—an approximate 80% risk reduction. Additionally, while conventional market samples showed a single pesticide group presence in 21.6% of cases, along with 7.8% and 3.2% for two and three groups respectively, the Clean Food area reported only a 3.8% occurrence of a single pesticide group. This comprehensive data highlights that the 'Clean Food' standard stands as one of the most stringent and effective measures in minimizing pesticide exposure in India's vegetable supply.

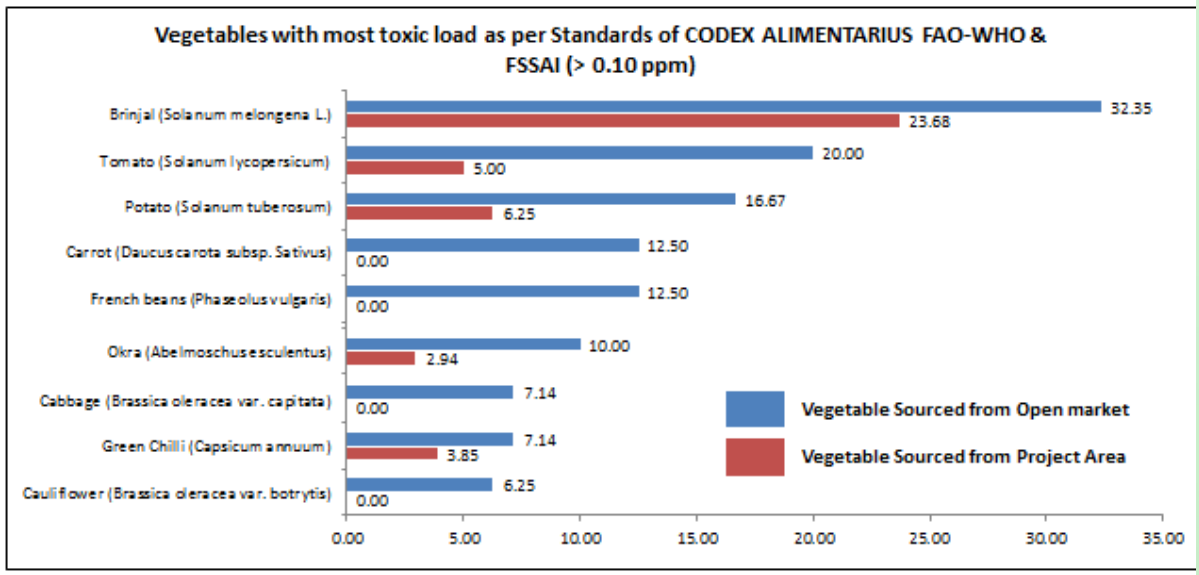

Fig 2 : Variation in percent vegetable samples having pesticide residue under conventional farmers practice and CFNZ program

Energy transition

Agriculture serves as both a consumer and producer of energy, providing bioenergy and food. The Green Revolution significantly increased energy use in agriculture due to the widespread adoption of chemical fertilizers, pesticides, and mechanization. Currently, the agri-food chain accounts for approximately 30% of global energy consumption, with a substantial portion occurring post-harvest and primarily derived from fossil fuels.This intensive energy use has led to environmental challenges, including soil and water pollution, and elevated CO_2 and N_2O emissions that contribute to global warming. Therefore, enhancing energy efficiency in agriculture is vital to minimize environmental impacts, conserve natural resources, and promote sustainable agricultural practices.

Energy analysis of agricultural ecosystems provides a concrete approach to assess energy use efficiency, identify environmental issues, and evaluate the sustainability of crop production systems. In this context, an assessment was conducted on various crop sequences under the 'Clean Food Net Zero' production model, comparing scenarios with 50% and 100% reductions in chemical nitrogen use against conventional farming practices. The study focused on five major cropping sequences prevalent in the project area: Tomato-Cucumber-Coriander, Potato-Brinjal-Cauliflower, Potato-Okra-Cabbage, Brinjal-French Bean-Spinach, and Pumpkin-Okra-Cabbage.

The energy footprint plays a crucial role in agricultural sustainability, as both direct and indirect energy inputs in farming directly impact carbon emissions, resource efficiency, and environmental resilience. High energy-intensive practices contribute to greenhouse gas emissions, accelerating climate change. Notably, about 30% of the world's energy is consumed within agri-food systems, and energy use is responsible for a significant portion of greenhouse gas emissions in this sector .

The study revealed that energy use efficiency (EUE) was notably higher under the 'Clean Food' production model, especially in the Potato-Okra-Cabbage and Potato-Brinjal-Cauliflower sequences. This finding is significant, considering that energy input was also considerably higher in these two cropping sequences. An EUE greater than 2.0, along with sustained crop productivity under 'Clean Food' production, underscores the model's potential for economic sustainability and greenhouse gas mitigation within safe and sustainable agriculture.

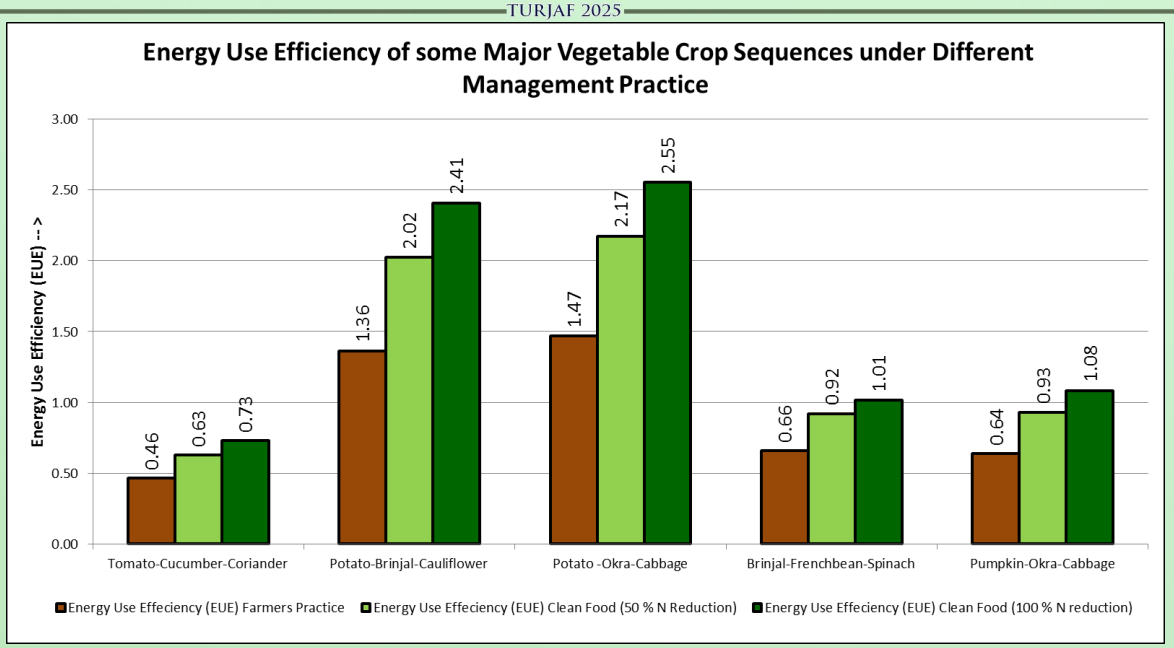

Fig 3: Comparative study of energy use efficiency under different management practice

Comparative GHG Emission and Mitigation in Conventional and Clean Food Net Zero Crop Sequences

A comparative analysis of different cropping sequences under varied management practices—Conventional Farmers' Practice (CFP) versus the Clean Food Net Zero (CFNZ) Program—reveals significant differences in GHG emission and mitigation potential. Using the Cool Farm Tool (Hillier, 2013), the study quantified the emissions in terms of kg CO_2 equivalent per hectare and per kilogram of produce. Under CFP, where chemical nitrogen fertilizers are used, the average GHG emission is positive—for instance, +0.13 kg CO_2-eq per kg produce—indicating net emissions. In contrast, the CFNZ approach, which incorporates either a 50% or 100% nitrogen reduction alongside the adoption of IRF Technology, achieves net mitigation, with average emissions of –0.05 and –0.23 kg CO_2-eq per kg produce, respectively. .

Table 2 : Agricultural Component wise GHG (kg CO_2 equv./ha/year) Footprint

Agricultural Operations (component-wise)	Farm Chemical Production Component wise	Crop GHG (kg CO_2 equv./ha/year) Footprint	CFNZ under IRF Technology	GHG (kg CO_2 equv./ha/year) Footprint
Seed, Seed Treatment & Nursery Management	Chemical Seed Treatment	8.28	IRF Seed Treatment	0.86
	Seed Bed & Nursery	3.08	Seed Bed & Nursery	1.5
	Direct Seed Sowing	12.38	Direct Seed Sowing	11.02
Transplanting		6.27		7.63
Land Preparation		373.06		376.11
Irrigation		463.82		488.48
Weed Management		5.56		5.72
Crop Nutrient Management	Chemical Nutrient Management	4934.97	Nutrient Management through Novcom Compost	(-) 15269
Crop Protectant	Chemical Crop Protection	431.29	Inhana Plant Health Mgt (IPHM)	16.86
Total GHG (kg CO2equv. /ha/year)		(+) 6238.7		(-) 14330.77

In the detailed crop sequence analysis, sequences such as Tomato-Cucumber-Coriander, Potato-Brinjal-Cauliflower, Potato-Okra-Cabbage, Brinjal-French bean-Spinach, and Pumpkin-Okra-Cabbage showed marked shifts from positive emission values under conventional practices (ranging from 4682.9 to 8254.5 kg CO_2-eq/ha) to substantial negative values under CFNZ (ranging from –13085.3 to –15275.9 kg CO_2-eq/ha). Moreover, when only chemical pesticides were completely eliminated—as captured in the Phase-II Project—the intervention yielded an additional 18–20% reduction in GHG emissions, underscoring that nitrogen fertilizers are the predominant GHG contributors under CFP. The highest emission reduction of 7100 kg CO_2-eq per ha per year was

observed in the Potato-Okra-Cabbage sequence, and in terms of per kilogram yield, the Tomato-Ridge Gourd-Spinach and Pointed Gourd–Cauliflower sequences emerged as the most carbon efficient (around 0.07 kg CO_2-eq per kg). Overall, the study demonstrates that transitioning from CFP to CFNZ—particularly with a 100% reduction in both nitrogen fertilizers and chemical pesticides—has the potential to transform agriculture from a net greenhouse gas emitter into a significant GHG sink

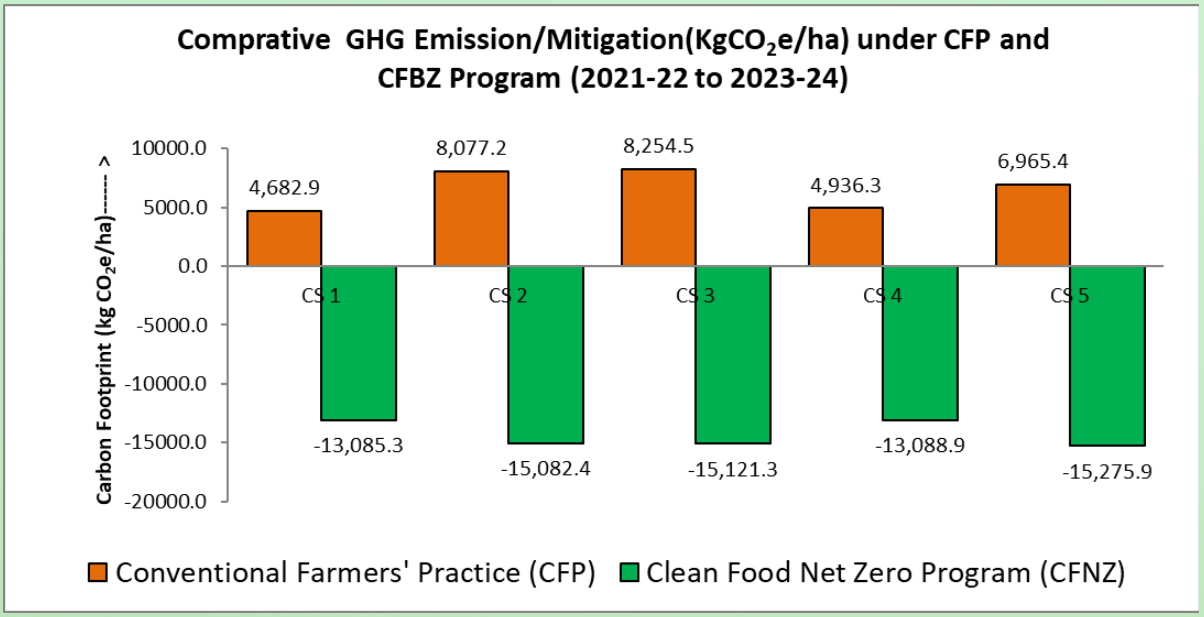

Fig 4 : Comparative assessment of Carbon footprint inder CFP and CFNZ management Program

Economics, employment generation

The impact of the Clean Food (CF) Model on employment generation and livelihood support is significant and multifaceted. A comparative study, as illustrated in Figures 16 and 17, indicates that adopting the CF Model can boost employment opportunities by up to 16.7 percent, demonstrating its potential to enhance local job markets and stimulate rural economies. In addition to creating more jobs, the CF Model also positively influences farmers' incomes. An analysis of gross income based on major cropping sequences—using a six-month average from December 2022 to May 2023 of farmers' procurement prices as reported by Sufal Bangla—revealed that even within conventional market frameworks, there is a potential income increase of up to 19.7 percent, even without implementing any value-added marketing strategies. This suggests that if a dedicated market chain were established for these pesticide-free, value-added products, the income potential for farmers could be amplified considerably. Such improvements not only underscore the CF Model's capacity to transform agricultural practices into more sustainable and profitable systems but also highlight its broader role in supporting rural livelihoods and contributing to overall economic development.

Development of net zero regenerative agriculture model for livelihood sustenance and carbon mitigation

The development of a net zero regenerative agriculture model for livelihood sustenance and carbon mitigation is a transformative approach that integrates sustainable farming practices with robust climate action measures. By merging strategies such as the Clean Food Net Zero (CFNZ) Program and Inhana Rational Farming (IRF) Technology, this model focuses on reducing reliance on chemical nitrogen fertilizers and pesticides, thereby lowering greenhouse gas emissions while enhancing soil health and crop productivity. Regenerative practices—bolstered by advanced technologies like Novcom composting—accelerate organic matter recycling, improve nutrient cycling, and promote microbial biodiversity, which in turn increases carbon sequestration and creates a net carbon sink. This holistic model not only improves yields by up to 22% and raises income potential by nearly 20% compared to conventional practices but also fortifies the socio-economic conditions of resource-poor, small, and marginal farmers. Ultimately, by aligning agricultural productivity with environmental resilience, the net zero regenerative agriculture model offers a sustainable pathway to secure both the livelihoods of farming communities and the long-term stability of the climate.

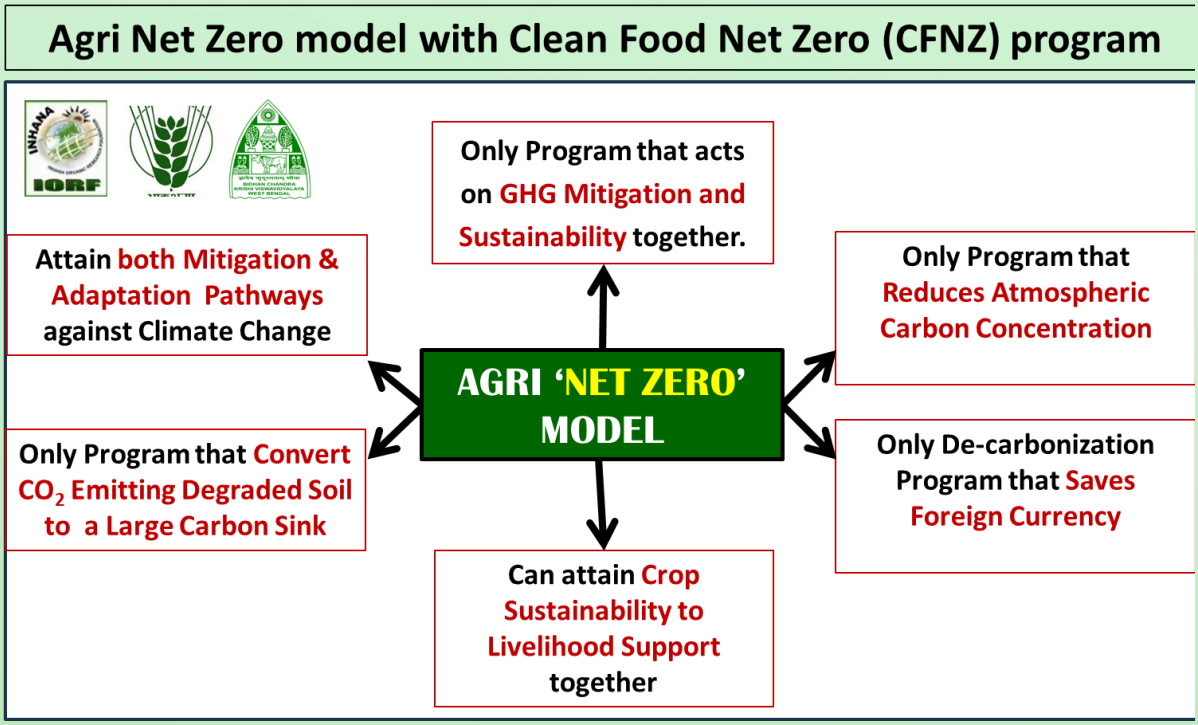

Fig 5 : Development of Agri-Net Zero model with adoption of CFNZ program

Conclusion

The comprehensive studies and analyses presented affirm that integrating a net zero regenerative agriculture model can substantially transform conventional farming practices into sustainable, climate-resilient systems. By adopting innovative practices such as the Clean Food Net Zero (CFNZ) program and Inhana Rational Farming (IRF) Technology, agriculture can transition from being a major greenhouse gas emitter to acting as a robust carbon sink. This transformation is supported by enhanced soil and plant health, exemplified by improved crop yields, nutrient cycling, and effective microbial activity as observed in advanced composting technologies like Novcom Composting. Furthermore, the integrated model not only mitigates environmental impacts—achieving marked reductions in greenhouse gas emissions—but also bolsters rural livelihoods by increasing employment opportunities and farmers' income. Ultimately, these findings underscore the viability of a regenerative agricultural framework that aligns economic sustainability with environmental stewardship, offering a replicable blueprint for addressing the twin challenges of climate change and food security on a global scale.

Abstract

Poultry production constitutes a pivotal component of the rural economy in Bangladesh, with indigenous chickens representing one of the most significant poultry species. This study was conducted across five Upazilas in the Barishal district of Bangladesh to investigate the behavioral patterns and welfare status of indigenous chickens within rural communities. Indigenous chickens are still regarded as xpre sources of income, food security, and employment for rural populations. However, the welfare of these chickens often remains overlooked due to a lack of knowledge and awareness among the people.

Key behavioral aspects such as dust and sand bathing, foraging, scratching, roosting, pecking, nesting, peck order, brooding, and hen-chick relationships were meticulously documented in this study. Welfare assessments concentrated on housing, feeding, drinking, and health conditions. The findings revealed that indigenous chickens exhibit a diverse array of behavioral patterns. Notably, 84.5% of the chickens engaged in foraging, while 82.6% participated in dust and sand bathing; 79.5% demonstrated roosting and perching behavior. Among social interactions, 73.9% of male birds displayed a peck order. Brooding, observed in 81.4% of the subjects, is also a pronounced reproductive behavior among indigenous chickens. A significant majority, 78.3%, exhibited mating behavior, and the hen-chick relationship, characterized by 80.1%, reflects a critical maternal instinct.

Nonetheless, welfare challenges pose significant constraints on the ability of indigenous chickens to xpress their natural behaviors. Inadequate feeding, drinking, housing, and healthcare facilities emerged as primary welfare issues. The study underscores that the appropriate expression of behavioral patterns and welfare conditions could enhance the production performance of indigenous chickens. Disseminating knowledge regarding the proper rearing of indigenous chickens and fostering awareness among rural communities about essential welfare tools such as improved housing, balanced nutrition, and vaccination programs can significantly elevate the production performance of indigenous chickens and contribute to the development of sustainable poultry production.

Keywords: *Indigenous chicken, behavior, welfare, food security, and sustainable development*

Introduction

Bangladesh possesses a rich historical legacy of rearing indigenous chickens. In rural communities, these chickens are raised not only for livelihood and income generation but also for ensuring protein security and alleviating unemployment among youth, women, and children. Despite the socio-economic and nutritional significance of indigenous chickens, issues surrounding their behavioral patterns and welfare have not garnered adequate scientific attention in Bangladesh.

Indigenous chickens in rural settings exhibit a diverse array of behaviors, including scavenging, dust bathing, sand bathing, perching, preening, egg laying, incubation, and hatching, among others. These behaviors can be categorized as general, social, productive, and reproductive in nature. Bracke and Hopster (2006) elucidated that the natural behavior of animals refers to the actions typically exhibited by these creatures when they are situated in environments that closely resemble their native habitats. Any deviation from these innate behaviors may result in psychological distress, such as depression, in chickens. Indigenous chickens, in rural settings, often forage around household premises to fulfill their nutritional needs; however, in many instances, proprietors provide only a meager quantity of feed, consequently failing to meet the birds' nutritional requirements, which contravene the principles of animal welfare. Behavior is a pivotal component of animal well-being. Ensuring that chickens can maintain and express their natural behaviors significantly contributes to their physical and psychological health. According to the Appleby *et al*., 2004, behavior reflects an animal's health and environment, studying behavioral patterns can be a useful tool for assessing welfare.

This study examines the current state of indigenous chicken behavior and welfare in the rural regions of Bangladesh. By identifying prevalent behavioral patterns and welfare challenges, the aim of the study was to explore the behavioral patterns and welfare status of indigenous chickens in rural Bangladesh and identify critical challenges and potential areas of improvement.

Materials and Methods

Selection of the Study Area

A comprehensive survey was conducted across five uapzillas in the Barishal district, namely Barishal Sadar, Babuganj, Agaljhara, Banaripara, and Gouronodi. The households were meticulously selected based on their behavioral patterns and the welfare status of indigenous chickens within the study area.

Experimental data collection

The study was conducted across five upazilas in the Barishal district, specifically Babuganj, Barishal Sadar, Anaripara, Agaljgara, and Gouronodi, with the objective of investigating the inherent behavioral patterns and welfare assessments of indigenous chickens. A total of 160 households were surveyed, comprising 32 households from each upazila, to facilitate the research. Data were meticulously collected through face-to-face interviews and direct observations.

Statistical Data Analysis

The quantitative and qualitative data was analyzed statistical analysis IBM SPSS version 20.0. Data were analyzed through descriptive statistics. The results were expressed in frequencies, mean, percentage and p value.

Behavioral Parameter

Following behavioral parameters were observed in the study area-

1. General behavioral pattern
a. Feeding
b. Drinking
c. Dust and sand bathing
d. Scratching
e. Foraging
f. Roosting/Perching
g. Pecking

2. Social behavior
a. Peek order
3. Productive and reproductive behavioral pattern
a. Mating
b. Nesting
c. Brooding
d. Hen-Chick- Relationship

Welfare Assessment Framework

Welfare assessment was based on the five freedoms framework (FAO, 2010)

1. Freedom from hunger and thirst
2. Freedom from discomfort
3. Freedom from pain, injury, or disease
4. Freedom to express normal behavior
5. Freedom from fear and distress

(a) (b) (c) (d) (e) (f)

Figure : (a) Poultry house, (b) Day basket, (c), Alert and active, (d) Scavenging feeding, (e) Dust bathing; and (f) Hen -chick -relationship

Results and Discussions

General behavior pattern of indigenous chickens

Behavior and welfare criteria of indigenous chickens primarily encompass general behavior, social interactions, and both productive and reproductive conduct, among other aspects. This study delves into various dimensions of behavioral patterns and welfare concerns pertaining to indigenous chickens within rural communities in Bangladesh.

Feeding

Table 1 showed a significant majority (89.39%) of the farmers in the study area reared indigenous chickens utilizing free-range scavenging systems. They provide a minimal quantity of feed to the birds, which is inadequate for their nutritional needs. Consequently, hunger is prevalent among the chickens, which contravenes the principles of animal welfare.

Drinking

Respondents in the study area (62.5%) provided no potable water for the birds; consequently, the avian resorted to consuming contaminated water from their surroundings or the effluent of tube wells (Table 1). As a result, dehydration is prevalent among indigenous chickens, which contravenes the principles of avian welfare.

Dust and sand bathing

Table 1 showed that 82.6% of flock observed dust bathing in the study area, especially during warmer period of the day which is significant.

Table 1: General Behavioral Pattern of Indigenous Chickens

No	3.125	4.375	1.25	2.5	3.125	14.37	

*=Significant ($p<0.05$)

Scratching

Scratching (80.1%) is a common behavioral practice among the birds. Significance number of birds showed scratching behavior (Table 1).

Foraging

Indigenous chickens exhibit a remarkable tendency for foraging, with an impressive 84.5% of their activity occurring in the surrounding environment (Table 1). They predominantly derive their sustenance from the abundant resources available in their external habitat.

Roosting or Perching

Roosting (79.5%) represents a prevalent behavioral pattern among indigenous chickens (Table 1). This practice not only enhances the physiological well-being of the birds but also mitigates soiling of the ground and diminishes incidences of cannibalism within the flock.

Social behavior

Pecking order

One of the most sociable behaviors exhibited by chickens is the establishment of a pecking order, or dominance hierarchy (73.9%). Chickens demonstrate this social stratification among their peers in free-range environments or within a flock. This characteristic is evident within a collective of birds or within a chicken community.

Productive and reproductive behavior

Nesting

Nesting is a prominent and fruitful behavior observed in indigenous chickens, constituting 79.5% of their overall activities (**Table 3)**. These chickens engage in nesting behavior prior to oviposition. To facilitate successful egg-laying, it is imperative to provide suitable nesting environments; consequently, the maintenance of an appropriate nest box significantly enhances egg production.

Mating behavior

Mating behavior is one of the reproductive behaviors of chicks. About 78.3% of birds showed mating behavior in the study area which isn't significant.

Brooding

Brooding behavior showed just after incubation of chicks. Brooding is a maternal instinct of indigenous chicken. About 81.4% of indigenous chicken showed brooding behavior and it's not significant.

Hen chick relationship

Indigenous chicken showed strong hen chick relationship. Most of the cases hen were roaming with birds often too long and showed stung imprint among them. About 80.1% birds showed hen chick relationship which is significant.

Welfare status of Indigenous Chicken

Housing

Poultry houses in the study area were traditional houses, kept miscellaneous poultry species together. This housing facilities don't meet the welfare criteria "freedom from discomfort" and birds were consequently perdition and exposure to environmental stress was common (Rahman *et al.,* 2017).

Table 2: Social behavioral pattern of indigenous chicken

Variables	Babuganj	Barishal Sadar	Banaripara	Gouronodi	Agaljara	Grand Mean	P Value
Pecking order							
Yes	14.375	15.625	15	15	13.75	73.75	0.224
No	5.625	4.375	5	5	6.25	26.25	

*=Significant (p<0.05)

Table 3: Productive and reproductive behavioral pattern of indigenous chicken

Variables	Babuganj	Barishal Sadar	Banaripara	Gouronodi	Agaljara	Grand Mean	P Value

Brooding							
Yes	16.875	15.625	17.5	18.75	12.5	81.25	0.008
No	3.125	4.375	2.5	1.25	7.5	18.75	
Hen-chick relationship							
Yes	18.125	15.625	13.75	18.75	13.75	80	0.007
No	1.875	4.375	6.25	1.25	6.35	20	

*=Significant (p<0.05)

Feeding and Drinking

Feeding practices in the study area predominantly consisted of scavenging (89.39%), with only 10.63% of participants providing nutritional supplementation to the birds. Consequently, the birds frequently experienced malnutrition. Access to clean drinking water was available in 37.50 % of cases, which consequently reflects the chickens' freedom from hunger and thirst (Hossen, 2010).

Bio-security and Health Status

Birds have been afflicted by various health concerns, including diseases, infections, and disorders. A mere percentage of respondents had access to veterinary services, and preventive health management practices were predominantly lacking (Rahman *et al*., 2017; FAO, 2010).

Housing

Birds have been afflicted by various health concerns, including diseases, infections, and disorders. A mere percentage of respondents had access to veterinary services, and preventive health management practices were predominantly lacking (Rahman *et al*., 2017; FAO, 2010).

Health status

No vaccination programme (68.1%) was maintained during rearing of indigenous chicken as a result highest mortality of chicks and adult birds was very common. This is also against welfare.

Conclusion

Indigenous chickens play a pivotal role in the rural communities of Bangladesh. Conducting a behavioral study of these indigenous birds is crucial, as their behaviors are indicative of their welfare status. A deficiency in behavioral expressions can signal significant welfare concerns. Inadequate housing, insufficient nutrition, and health complications pose serious threats to these birds. Conversely, the presence of adequate behavioral expressions contributes to the enhancement of their welfare. It can be concluded that a comprehensive behavioral analysis can significantly elevate the welfare standards of indigenous chickens.

Abstract

The intersection of agriculture, pharmaceutical innovation, and food science is giving rise to a transformative field: the use of edible plants as platforms for pharmaceutical production, commonly referred to as molecular pharming. This review explores the current advances, opportunities, and challenges associated with utilizing genetically engineered crops—such as lettuce, rice, maize, and tomatoes—to produce therapeutic proteins, vaccines, and antibodies. Compared to traditional bioreactor-based methods, plant-based expression systems can reduce production costs by up to 60% and lower the risk of contamination by approximately 80%. Key developments in chloroplast transformation, transient expression systems, and glycoengineering have improved protein yields to levels of 1.5–3.0% of total soluble protein in edible tissues. The review highlights successful case studies, including plant-derived vaccines for hepatitis B and Norovirus, which showed immunogenic responses in 75–90% of subjects during early trials. In addition to cost-effectiveness and scalability, these edible plant platforms offer the potential for oral delivery, eliminating the need for cold-chain logistics and sterile injection, which could increase global vaccine accessibility by over 40%. Critical discussions include the regulatory landscape, biosafety, and consumer perception—particularly concerning genetically modified organisms (GMOs) in the food chain. This review emphasizes that with standardized protocols and robust safety evaluations, molecular pharming can play a pivotal role in decentralizing pharmaceutical production, particularly in low- and middle-income regions.

Title: Harnessing Neglected and Underutilized Crop Species in Sub-Saharan Africa: A Pathway to Food Security and Sustainable Agriculture

Kurai Gareth Mawoneke [1], Humphrey Masimba Makumbirofa[2], Takudzwa Rusike [3]

[1]Department of Food Processing Technology, School of Industrial Sciences and Technology, Harare Institute of Technology, Belvedere, Harare, Zimbabwe
[2]Department of Pharmaceutical Technology, School of Allied Health Sciences, Harare Institute of Technology, Belvedere, Harare, Zimbabwe
[3]Department of Library and Information Services, Harare Institute of Technology, Belvedere, Harare, Zimbabwe

Abstract

Neglected and Underutilized Crop Species (NUCS) in Sub-Saharan Africa offer a promising avenue for enhancing food security, particularly in light of increasing climate variability and socioeconomic challenges. This review synthesizes current knowledge on the agronomic potential, nutritional benefits, and processing technologies associated with key NUCS, including fonio, teff, and amaranth (*Digitaria exilis*, *Eragrostis tef*, and *Amaranthus spp.* respectively). These crops, often overlooked in favor of major staples, demonstrate resilience to adverse environmental conditions and possess superior nutritional profiles, including high levels of essential amino acids, micronutrients, and dietary fiber. The review critically evaluates innovative food processing technologies, such as fermentation, extrusion, and milling, which can significantly improve the palatability, nutritional bioavailability, and shelf-life of NUCS. By integrating traditional processing methods with modern advancements, we propose a framework that not only enhances consumer acceptance but also promotes the commercialization of these crops. Furthermore, the review highlights case studies where successful processing techniques have revitalized local economies and contributed to sustainable agricultural practices. Key challenges facing the adoption of NUCS are addressed, including inadequate infrastructure, limited market access, and the need for supportive policy frameworks. This review advocates for a collaborative approach involving researchers, policymakers, and local communities to overcome these barriers. By prioritizing investment in NUCS research, education, and awareness initiatives, we can harness their potential to diversify diets, improve nutritional outcomes, and build resilience against food insecurity in Sub-Saharan Africa. Therefore, it is crucial to critically reassess agricultural priorities and champion Neglected and Underutilized Crop Species (NUCS) as vital cornerstones of sustainable food systems. By embracing their potential, we can significantly enrich the global dialogue on food security and agricultural sustainability.

Developing Short-Rotation Woody Biomass Feedstock in the Philippines: Strengths, Weaknesses, Opportunities, and Threats

Renato S. Pacaldo[1]

[1]College of Forestry and Environmental Studies, Mindanao State University-Main Campus, Marawi City, Philippines
Email: renato.pacaldo@msumain.edu.ph

Abstract

Biomass energy attracts the attention of researchers, investors, developers, and policymakers because of its potential to promote local and national economies, alleviate poverty, and mitigate climate change impacts. Most biomass power plants in the Philippines derive their fuels from agricultural wastes, such as rice hulls, bagasse, coconut husks, and other agricultural wastes. However, the seasonal and limited availability of these sources are limitations for ensuring a continuous flow of raw materials supply to support an uninterrupted operation of a biomass power plant. Developing an intensive biomass feedstock farming system using short-rotation biomass crops provides opportunities for increasing productivity of marginal areas and unproductive agricultural lands, ensuring the sustainability of biomass feedstock supply for the biomass energy sector in the country, alleviating poverty, promoting rural economy, and mitigating climate change impacts. The humid tropical warm climate in the Philippines offers a favorable growing environment for year-round biomass production of some fast-growing short-rotation woody biomass crops, such as Ipil-Ipil (*Leucaena leucocephala*) and Kakawati (*Gliciridia sepium*). The country also legislated enabling laws to promote renewable energy and marketing opportunities for biomass farmers and investors. The limited science-based information concerning the sustainability of biomass energy production and the lack of scientific investigation on the potential of developing short-rotation woody biomass crops result in poor outcomes and unsustainable biomass investments. Furthermore, the long waiting period for return on investments, large investment costs during establishment, and large area requirements needed for establishing biomass plantations must be addressed to ensure the profitability, participation of biomass farmers, and interest of investors. At present, the government's voluntary commitment under the Conference of Parties (COP) 21 to reduce greenhouse emissions by 70% for the next five years and the increasing market demands for biomass provide huge opportunities for biomass investments in the country. However, these opportunities could be influenced by the changing local, national, and geopolitical political dynamics and technological advancement of other renewable energy sources, like solar, wind, nuclear, and wave, affecting demands, markets, and prices. This study contributes to understanding the feasibility and sustainability of developing a large-scale short-rotation biomass feedstock production in the country, which is a vital piece of information for informed policy and decision-making and for promoting the biomass industry in the country.

Abstract

Salt is a daily staple food and an important source of minerals. However, contamination in salt can pose public health risks. This study aimed to determine the concentrations of essential (calcium, potassium, magnesium, iron, manganese) and non-essential elements (aluminum, boron, chromium, nickel) in 11 commonly consumed edible salts in Türkiye and evaluate their potential health risks and nutritional contributions. The element levels were determined using Inductively Coupled Plasma Mass Spectrometry (ICP-MS), health risk assessments were conducted, and the percentage contributions of the elements to daily dietary reference values were calculated. Element levels varied significantly among samples. For instance, aluminum levels ranged from 0.13 to 5.60 mg/kg. The highest calcium, potassium, magnesium, aluminum, iron, manganese, and nickel levels were found in S5 (Himalayan salt), while chromium was highest in S9 (rock salt). Hazard index values remained below the safety threshold, and all salts were evaluated as low risk. Although the risk assessment suggests no immediate threat based on the current data, the necessity for comprehensive element analyses of edible salts remains crucial. Moreover, despite the variations in mineral levels, the assessed salts are unlikely to meet the recommended daily intake levels for essential minerals.

Key Words: *Salts; Elements; Public health; Risk assessment; Food contamination*

Introduction

Salt is an essential source of minerals required by humans and is utilized in various industries, including metallurgy, textile, medicine, agriculture, and chemicals (Horasan and Öztürk, 2021). Table salt is commonly added to enhance the flavor of foods and serves as a preservative for many canned, salted, pickled, and fresh foods (Elias et al., 2020; Nagendra et al., 2020). While salt exists in liquid form in seas, lakes, and other water sources, it is classified as rock salt in its solid form. The sea is the largest global source of salt, with its salt content influenced by geographical structures, physical and chemical changes in rocks, evaporation, and climatic conditions. In Türkiye, raw salt production occurs from seawater, underground rock mining, lake water, and underground spring water (Türkiye Mineral Research and Exploration General Directorate, 2023).

Elements can be examined in two groups, essential and non-essential when evaluating their effects on human health (Demir et al., 2020). Essential elements have important functions in the human body, but they can be toxic at high consumption rates. However, essential elements have homeostatic mechanisms that increase or decrease absorption and excretion to maintain certain levels in the body. Insufficient essential element intake results in deficiency symptoms, while high intake can be toxic to metabolisms (Somuncu et al., 2025). On the other hand, non-essential elements have no known function in the human body, they can be toxic even at low concentrations and cause health problems. Long-term exposure to non-essential elements can lead to physical (i.e. blood pressure changes, changes in blood composition, chronic pain, etc.) and psychological (i.e. anxiety, passivity, etc.) disorders, neurodegenerative diseases, and cancer (Witkowska et al., 2021; Marquès et al., 2022; Jomova et al., 2024). The severity of their health impacts depends on several factors the dose, the route and the duration of exposure, and the degree of bioaccumulation in the body (Ali et al., 2018).

Since salt is a substance consumed daily, any contamination can have adverse effects on consumer health. The natural resources from which salt is obtained may sometimes contain high levels of essential and non-essential elements. These increased levels can adversely affect human health. Furthermore, industrial waste, pesticides, and other contaminants can increase the element levels in these sources (Lugendo and Bugumba, 2021). Factors such as the equipment and energy sources used in salt production, air, and water pollution in regions near salt beds, and the processing and packaging of salt can also contribute to its essential and non-essential element content (Chan et al., 2021; Di Salvo et al., 2023).

The World Health Organization (WHO) (2024) recommends a daily salt intake of less than 5 grams. However, the average daily salt consumption in Türkiye is around 10.2 g among individuals aged 15 and older (Republic of Türkiye Ministry of Health, 2019). The consumption of high salt content foods such as pickles, olives, cheese,

fermented cereal foods like tarhana and bread, along with a preference for salty flavors, may contribute to the elevated salt consumption in Türkiye. Despite public health campaigns, the slow adoption of salt reduction initiatives in food manufacturing and daily consumption practices contributes to continued high intake (Erdem et al., 2017). Therefore, the risk of people living in Türkiye being exposed to elements from edible salts is higher.
This study aims to determine the levels of some essential (calcium, potassium, magnesium, iron, manganese) and non-essential elements (aluminum, boron, chromium, nickel) in 11 different table salt products mostly consumed in Türkiye, employing the Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) method. Additionally, the findings are evaluated in the context of public health and nutrition.

Materials and Methods

Samples

A total of eleven different types of salt were analyzed, including three Himalayan salts, three rock salts, three spring salts, and two sea salts, all commonly consumed in Türkiye. Detailed information regarding the salt types and their origins is given in Table 1.

Analysis by ICP-MS method

0.3 g of each salt was weighed and dissolved in a mixture of 10 mL of nitric acid (%2 V/V) (Merck, Darmstadt, Germany) using a microwave digestion system (Cem Corporation MARS 5 Digestion). The resulting solution was then filtered. A 1 mL aliquot of each filtrate was diluted to 10 mL with ultrapure water. All samples were subsequently placed in the autosampler unit of the ICP-MS instrument (Thermo Scientific™ iCAP™ RQ) for analysis. Calibration solutions were prepared by serial dilutions using ICP-multi element standard solution-IV (1000 mg/L) (Supelco 1.11355.0100, Merck, Darmstadt, Germany). All reagents used were of analytical grade.

Health risks assessment

Salt consumption in Türkiye is twice the levels recommended by the WHO, and considering its sources, each sample needs to be evaluated in terms of Health Risk Assessment (HRA). HRA is a systematic process used to evaluate the potential adverse health effects associated with exposure to environmental, chemical, biological, or physical hazards. This multidisciplinary approach integrates toxicological, epidemiological, and statistical methods to estimate risk levels for individuals or populations.

To assess the health risks of elements in salts, the estimated daily intake (EDI) was calculated using the following formula:

$$EDI = (M \times C)/BW$$

where M is the daily salt intake (kg/day). C is the elemental concentration (mg/kg) of salts and BW is the body weight (Antoine et al., 2017). Health risks were calculated for 3 age groups: ≥21, 16 to < 21, and 11 to < 16 years.

The reference BWs estimated by The Agency for Toxic Substances and Disease Registry (ATSDR) (2023) were used to evaluate the health risks of these age groups. These values are 80, 71.6, and 56.8 kg, respectively.
Chronic daily intake (CDI) was calculated using the formula:

$$CDI = (EDI \times EDtot)/BW$$

where EDtot is the exposure duration (years). The Target Hazard Quotient (THQ) indicates the non-carcinogenic health risk caused by exposure to the relevant element (Chebli et al., 2024).

THQ was calculated using the formula:

$$THQ = CDI/RfDo$$

where RfDo is defined as consumers' daily oral exposure estimate over a long time without experiencing harmful effects and is a specific value for the trace element being assessed. The RfDo values used for Al, B, Cr, Fe, Mn, and Ni are 1, 0.02, 1.5, 0.64, 0.14, and 0.02 mg/kg/day, respectively (Antoine et al., 2017; United States Environmental Protection Agency, 2024). If THQ is <1, non-carcinogenic health effects are not expected. However, if THQ is >1 then there is a possibility that adverse health effects could be experienced.
To evaluate the cumulative risk, the Hazard Index (HI) was calculated by summing the THQ values of each element. If the HI is <1, the risk is acceptable and considered safe for human consumption, but if the HI is >1, consumption should be regarded as a potential health concern (Chebli et al., 2024).

Statistics

Statistical analyses were conducted using the SPSS software (Version 29.0 for Windows, Chicago, Illinois). The normality of continuous variables was evaluated with the Shapiro-Wilk test. For variables with a normal distribution, means and standard deviations were reported, while median values were provided for variables that did not conform to a normal distribution.

Table 1. Information about the analyzed salts in this study

Salt Samples	Type of Salts	Origin Country (Province)
S1	Spring Salt	Türkiye (Kırıkkale)
S2	Spring Salt	Türkiye (Tunceli)
S3	Spring Salt	Türkiye (Sivas)
S4	Himalayan Salt	Pakistan
S5	Himalayan Salt	Pakistan
S6	Himalayan Salt	Pakistan
S7	Rock Salt	Türkiye (Çankırı)
S8	Rock Salt	Türkiye (Yozgat)
S9	Rock Salt	Türkiye (Kars)
S10	Sea Salt	Türkiye (İzmir)
S11	Sea Salt	Türkiye

Results and Discussion

In this study, eleven edible salts commonly consumed in Türkiye were analyzed to determine their essential (calcium, potassium, magnesium, iron, manganese) and non-essential (aluminum, boron, chromium, nickel) element contents. The results showed considerable variation in elemental concentrations among the samples, as summarized in Table 2. The levels of essential and non-essential elements varied significantly among the salts. For instance, calcium concentration ranged from 36.53 mg/kg in S11 to 2,595.26 mg/kg in S5, while iron levels ranged from 1.91 mg/kg in S4 to 39.60 mg/kg in S5.

Table 3 shows the calculated daily intake of essential and non-essential elements level based on the WHO's recommended maximum daily salt intake of 5 g/day and the average daily salt consumption in Türkiye, which is 10.2 g/day. Among the analyzed salts, S5 contributed the highest amounts to the daily intake of calcium, magnesium, potassium, aluminum, boron, iron, manganese, and nickel. Salts S9, S10, and S11 were leading contributors to chromium intake.

The average concentrations indicate that calcium is the most abundant mineral across the samples, with a mean value of 1,046.05 ± 865.2 mg/kg, while manganese is the least abundant, with an average of 0.37 ± 0.37 mg/kg. Notably, sample S5 (a Himalayan salt) contained the highest concentrations of calcium (2,595.26 mg/kg), magnesium (2,457.46 mg/kg), potassium (3,612.00 mg/kg), aluminum (5.60 mg/kg), boron (2.76 mg/kg), iron (39.6 mg/kg), manganese (1.29 mg/kg), and nickel (1.40 mg/kg). Additionally, sample S9 exhibited the highest chromium concentration at 1.07 mg/kg.

Calcium is an essential mineral critical for numerous physiological functions in the body. Sufficient calcium intake is associated with preventing various health conditions, including osteoporosis, colorectal cancer, hypertensive disorders during pregnancy, and reducing LDL cholesterol levels and blood pressure (Cornick and Belizán, 2019). According to the Dietary Guidelines for Türkiye, the tolerable upper intake level (UL) for calcium has been established at 2500 mg/day for individuals aged 19 to 50 (Republic of Turkish Ministry of Health, 2022). In this study, the calcium levels of different types of salt were as follows: Himalayan salt contained 662.26-2595.26 mg/kg, spring salt contained 823.30-1853.27 mg/kg, rock salt contained 340.38-498.24 mg/kg, and sea salt contained 36.53-427.04 mg/kg. The highest calcium level was observed in S5, a Himalayan salt (2595.26 mg/kg). This was followed by S6, another Himalayan salt (2025.00 mg/kg). The lowest calcium level was found in S11, sea salt (36.53 mg/kg). However, in another sea salt, S10, it was 427.04 mg/kg. Himalayan salts are formed through the interaction of underground minerals and sea salt over hundreds of millions of years of geological compression and exposure to high underground temperatures. These ancient geological processes enriched the salts with minerals from the surrounding rocks, resulting in higher concentrations of calcium, magnesium, and potassium (Deng et al., 2023).

A significant proportion of potassium in the body is found within muscles and the skeleton, while the remainder is distributed among the central nervous system, intestines, liver, lungs, and skin. Extracellular potassium plays a crucial role in regulating cell membrane potential, as well as in nerve and muscle activities (D'Elia, 2024). In this study, the highest potassium levels were observed in Himalayan salts (848.63-3612.00 mg/kg), whereas the lowest was found in spring salts (3.30-39.63 mg/kg).

Magnesium is the fourth most abundant cation in the body and is essential for numerous physiological processes. It contributes to blood pressure regulation, myocardial and muscle contraction, neuromuscular transmission, glycemic control, energy production, synthesis of nuclear materials, transmembrane ion transport, and bone development (Al Alawi et al., 2018). In this study, the magnesium levels ranged from 582.88-2457.46 mg/kg in Himalayan salts, 18.57-26.54 mg/kg in spring salts, 33.35-239.02 mg/kg in rock salts, and 89.49-606.22 mg/kg in sea salts.

Aluminum constitutes approximately 8.8% of the Earth's crust by mass and is abundant in many rocks. Its presence in the environment is significantly influenced by natural weathering processes and anthropogenic activities such as coal burning, mining, vehicle exhaust emissions, and waste incineration. These activities contribute extensively

to environmental aluminum levels. The adverse health effects of aluminum exposure are primarily linked to neurotoxicity (Alasfar and Isaifan, 2021). Although the precise mechanism remains unclear, elevated aluminum levels have been detected in the brain tissues of patients with Alzheimer's disease and other neurodegenerative disorders (Charlebois and Pantopoulos, 2023). Aluminum exposure has also been associated with lung fibrosis, reduced lung function, bone disorders, kidney damage, hormonal imbalances, and various cancers (Bonfiglio et al., 2023). In this study, the average aluminum concentration in the analyzed salts was 1.23 mg/kg. Himalayan salts exhibited the highest aluminum levels, between 1.03 to 5.60 mg/kg. As shown in Table 3, sample S5 contributed the most to daily aluminum intake (0.057 mg/day). This equates to a weekly aluminum intake of 0.4 mg/week from this salt. According to the European Food Safety Authority (EFSA) (2008), the tolerable weekly aluminum intake for a 70 kg individual is 70 mg/week. None of the salts analyzed in this study exceeded this threshold.

Table 2. The essential and non-essential element content of salt samples (mg/kg) in this study

Salt Samples	Ca	K	Mg	Al	B	Cr	Fe	Mn	Ni

WHO: World Health Organization's maximum daily salt intake recommendation (5 g), THNS: Average daily salt intake for people aged 15 and over in Türkiye (10.2 g).

Boron, which has been shown to positively affect human health in recent years, is regarded as a potentially essential element (Sosa-Baldivia et al., 2016). The average daily intake of boron through diet and drinking water is approximately 1.85 mg/day (Kuru et al., 2018; Kuru et al., 2020). The United States Committee on Medicines, Food, and Nutrition (2001) has established the tolerable upper intake level (UL) for boron at 20 mg/day for adults, while the EFSA (2023) has set this value at 10 mg/day. Consuming boron in excess of 500 mg/day can result in toxicity symptoms, including headache, abdominal pain, nausea, vomiting, diarrhea, muscle contractions, weakness, disorders of the digestive and central nervous systems, glandular dysfunction, skin lesions, and shock. In this study, boron levels in different types of salt were found as follows: 0.06-0.85 mg/kg in spring salts, 0.37-2.76 mg/kg in Himalayan salts, 0.15-1.39 mg/kg in rock salts and 0.27-3.80 mg/kg in sea salts. The sample S10 contributed the highest amount to daily boron intake (0.039 mg/day). These findings indicate that it is not possible to exceed the established UL for boron through the consumption of the salts analyzed in this study.

Chromium is a potentially toxic metal released into water and groundwater from both natural and anthropogenic sources. Exposure to chromium poses serious health risks, affecting the skin, eyes, blood, respiratory and immune systems. At the cellular level, chromium exhibits genotoxic properties that can induce oxidative stress, and DNA damage, which can contribute to tumor formation (Tumolo et al., 2020). EFSA has found no convincing evidence that chromium is an essential element. One of the significant challenges in evaluating chromium deficiency is the absence of a recognized biomarker to assess chromium nutritional status (EFSA, 2014). Consequently, neither the UL nor the adequate intake level of chromium has been established. In this study, the highest chromium concentration was found in S9 (1.07 mg/kg), a rock salt, followed by S10 and S11 (1.04 and 1.05 mg/kg), sea salts with very close concentrations.

Iron is a crucial nutrient essential for oxygen transport and cellular respiration. Iron deficiency anemia remains a significant global health challenge, particularly affecting vulnerable populations such as indigenous communities, refugees, immigrants from low- and middle-income countries, and other disadvantaged groups. However, excessive iron levels in the body can lead to adverse health outcomes, primarily due to increased oxidative stress and resultant tissue damage (Vincent and Lukaski, 2018). In another study, the iron content in Himalayan salt was determined as 0.299 ± 0.0323 mg/kg using the ICP-MS method (Ercoşkun, 2022). In the present study, the iron levels ranged from 5.26 to 23.89 mg/kg in spring salt, 11.91 to 39.60 mg/kg in Himalayan salt, 5.46 to 7.99 mg/kg in rock salt, and 2.56 to 6.68 mg/kg in sea salt. The highest iron levels were observed in S5 (39.60 mg/kg), a Himalayan salt, followed by S6 (31.32 mg/kg), another Himalayan salt. The tolerable UL for iron is 45 mg/day (Republic of Turkish Ministry of Health, 2022). Based on the findings of this study, it is not possible to exceed this UL through the consumption of the analyzed salts.

Manganese is an essential trace element involved in the synthesis and activation of various enzymes in humans, as well as the regulation of glucose and lipid metabolism. Additionally, manganese is a critical component of manganese superoxide dismutase, an enzyme primarily responsible for scavenging reactive oxygen species during mitochondrial oxidative stress. Both manganese deficiency and toxicity have been linked to adverse metabolic and neuropsychiatric effects (Li and Yang, 2018). In this study, manganese levels ranged between 0.06-0.48 mg/kg in spring salt, 0.30-1.29 mg/kg in Himalayan salt, 0.06-0.19 mg/kg in rock salt, and 0.17-0.72 mg/kg in sea salt. The highest manganese level was in S5 (1.29 mg/kg), a Himalayan salt. The tolerable upper intake level (UL) for manganese is 11 mg/day (Republic of Turkish Ministry of Health, 2022). As shown in Table 3, it is unlikely that the examined salts would lead to manganese intake exceeding this threshold.

Nickel is a transition metal widely distributed in the environment, including air, water, and soil. Human exposure to nickel occurs through dietary sources, water, and inhalation. Nickel is present in fertilizers, vehicle exhaust, cigarettes, pesticides, industrial waste, and everyday materials such as jewelry, utensils, keys, and coins. Nickel exposure has been associated with allergic contact dermatitis, systemic contact dermatitis, and Systemic Nickel Allergy Syndrome (Conti et al., 2021). Although the precise molecular mechanisms remain unclear, the nervous system is one of the primary targets for nickel toxicity (Genchi et al., 2020). Recent studies have focused on nickel's role in enzymatic functions, its beneficial effects on nitrogen utilization in plants, its mechanisms of allergy induction, and its presence in food and biological tissues (Nielsen, 2021). The UL for nickel is 1.0 mg/day as soluble salts for individuals aged ≥14 years (ATSDR, 2024). Based on Table 3, it appears that the nickel content in the examined salts would not lead to intakes exceeding this UL. In this study, the lowest nickel levels were in S8, a rock salt (0.26 mg/kg), and the highest in S5 and S6, Himalayan salts (1.40 and 1.12 mg/kg). However, these Himalayan salts may not be suitable for individuals with allergic contact dermatitis, systemic contact dermatitis, or Systemic Nickel Allergy Syndrome.

Di Salvo et al. (2023) analyzed the calcium, aluminum, iron, chromium, manganese, and nickel content of 10 commercial gourmet table salts in Southern Italy using the ICP-MS method, reporting values of 3,129.34, 4.82, 5.31, 0.56, 2.17, and 2.71 mg/kg, respectively. In comparison, the values we obtained were 1,046.05, 1.23, 13.88, 0.75, 0.37, and 0.66 mg/kg, respectively, which are generally lower than those reported by Di Salvo et al (2023). Specifically, for Himalayan pink salt, their reported concentrations of calcium, aluminum, iron, chromium, manganese, and nickel were 2,926, 4.4, 2.6, 0.9, 0.0074, and 1.3 mg/kg, respectively, whereas our study found values of between 662.26-2595.26, 1.03-5.60, 11.91-29.60, 0.50-0.76, 0.30-1.29, and 0.43-1.40 mg/kg. While

chromium levels in their study were higher, our iron and manganase concentrations were significantly greater. These discrepancies may be attributed to differences in the salt source, mineralogy, salt type, geographical origin, geological features, or industrial activities surrounding the salt sources.

Table 4 presents the EDI and CDI levels of essential and non-essential elements from salts across all analyzed age groups, showing that these values remain below the RFD thresholds. Additionally, all THQ and HI levels are below 1, indicating no significant non-carcinogenic health risks associated with salt consumption in these age groups.

A study conducted in Pakistan found that salts obtained from the Sandpit salt fields, which receive untreated wastewater via the Lyari River, exhibited THQ values that were 2 to 6 times higher than the reference values, while HI values exceeded the acceptable threshold by of 20 times in terms of heavy metal contamination (Chan et al., 2021). Given the variability in salt sources and the potential health risks associated with elements, THQ and HI levels were conducted for the samples included in this study. The results indicate that aluminum, boron, chromium, iron, manganese, and nickel were present in varying concentrations across the analyzed salt samples. Notably, Himalayan salts contained the highest levels of aluminum (up to 5.60 mg/kg), iron (up to 39.60 mg/kg), and manganese (up to 1.29 mg/kg). However, despite these concentrations, HRA calculations demonstrated that the EDI and CDI of heavy metals remained below the reference dose (RfD) values for all age groups.

Table 5 provides the percentage contribution of each salt's consumption in our study to the daily dietary reference values, calculated based on the average daily salt intake in Türkiye (10.2 mg/day). These calculations were conducted using the Dietary Guideline for Türkiye (Republic of Türkiye Ministry of Health, 2022), the Summary Report on Nutrition Reference Values for Foods of the EFSA (2017), and the Food and Nutrition Board's Dietary Reference Intakes Review Committee (2019). The highest contributions to daily intake were observed for magnesium, calcium, and iron. S5, a Himalayan salt, provided the largest contribution to the Recommended Dietary Allowance (RDA) of calcium, potassium, magnesium, iron, and manganese. The contribution of S5 to the RDA of calcium in females and males ranged between 2.65-2.79%. In comparison, S11, a sea salt, contributed only 0.04% to the RDA of calcium. For potassium, S5 contributed between 0.78% and 1.42% in females, while males in 0.78% to 1.08%. Salts S1 and S2 had almost negligible contributions to daily potassium intake. The contribution of S5 to the RDA of magnesium was between 8.09-8.36% in females and 5.97-7.16% in males. In contrast, S2 only contributed 0.06% in females and 0.05% in males. The contribution of S5 to the RDA of iron was 2.24-2.52% in females and 3.67-5.05% in males. Regarding iron, S5's contribution to the RDA was between 2.24% and 2.52% in females and between 3.67% and 5.05% in males. In comparison, S11's contribution was almost one-fifteenth of S5's. Although the contributions of salts to the daily RDA are different, it is seen that salt consumption contributes minimally to overall daily nutritional requirements.

This study provides valuable insights into the essential and non-essential elements content of table salts commonly consumed in Türkiye. While Himalayan salts exhibited higher concentrations of essential elements, their contribution to daily nutritional intake remains limited. Importantly, the HRA confirmed that the determined element levels in the analyzed salts do not pose significant non-carcinogenic risks. However, continued monitoring and regulation of salt sources are essential to ensure consumer safety. Future research should focus on the potential interactions between essential and non-essential elements in food products and their cumulative health effects over time.

Consequently, in this study, the essential and non-essential elements levels in 11 salt samples frequently consumed in Türkiye were found to comply with the Dietary Reference Intake Levels and Codex Limits. While no adverse health risks were identified based on the HRA in terms of analysed elements it remains crucial to perform thorough element analyses before these salts are made available for consumption to ensure public health safety. Although the examined salts contained varying amounts of elements, their contribution to meeting daily adequate intake levels appears to be minimal.

Table 4. EDI, CDI, THQ, and HI levels of elements from salt across different age groups

Salts	Element	Estimated Daily Intake			Chronic Daily Intake			Target Hazard Quotient			Hazard Index		
		Age (years)			Age (years)			Age (years)			Age (years)		
		≥21	16 to <21	11 to <16	≥21	16 to <21	11 to <16	≥21	16 to <21	11 to <16	≥21	16 to <21	11 to <16

Valorization of Stale Bread in Tunisian Traditional Cookies: A Sustainable Approach to Maachech Formulation

Borhen Dahmen

Food industry engineering, Tunisia

The growing issue of bread wastage presents significant challenges to food security, environmental sustainability, and economic stability, particularly in regions like Tunisia. This study investigated a comprehensive strategy for the valorization of stale bread through its incorporation into *Maachech*, a traditional Tunisian cookie. The objective of the present work was to develop a sustainable, nutritious and sensorically acceptable food product within a circular economy framework.

Stale bread was staled at ambient temperature for 72 hours, processed into whole and crumb fractions, and subsequently milled into flour. Six different *Maachech* cookie formulations were prepared, featuring incremental substitution levels of wheat flour with stale bread flour (F0:0%, F1:10%, F2:20%, F3:30%, F4:40%, and F5:100%). Proximate composition (moisture, protein, fat, and sugars), CIE *Lab* color parameters (L*, a*, b*, Chroma, ΔE), techno-functional properties and microbial loads were determined for stale bread flour and cookie formulas. *Maachech* cookie caloric values were calculated utilizing the Atwater system. A hedonic sensory evaluation was performed with a panel of 61 volunteer consumers (mean age 25.7 ± 6.5 years, 96% female, university educated, 60% aware of environment, climate change and food waste issues) using a 7-point scale. Post-tasting, panelists' willingness to buy and underlying motivations were assessed via direct survey.

Analysis of the 3-day stale bread revealed the following characteristics: Humidity 28.39±0.23%, Dry Extract 75.22±0.26 g/100g, Proteins 6.25±0.02 g/100g, Fat 1.8±0.01 g/100g, Sugars 0.54±0.01 g/100g, Reducing Sugars 1.39±0.14 g/100g, and Acidity 0.0270±0.0001 g of lactic acid/ 100g of bread. Microbiological analysis indicated that the 3-day stale bread conformed to established food safety standards. It also exhibited high oil and water holding performance, making it suitable for reprocessing into flour for cookie development.

Findings showed that 30% substitution level (F3) was found to offer the best compromise between technological performance and consumer acceptability. The F3 *Maachech* cookies had a fat content of 27.62 g/100g, protein content of 18.7 g/100g, reducing sugars at 25 g/100g, and a total calorie value of 336.13 kcal/100g. Functionally, they displayed a water holding capacity of 10 g/g, an oil holding capacity of 7 g/g, and were microbiologically safe. Color values remained within the acceptable range (ΔE ≈ 2.3) at this level of incorporation, with visual differences only increasing at higher substitutions.

Sensory analysis confirmed F3 as the most preferred product in terms of texture, taste, appearance, achieving a mean global appreciation score of 5.96/7 and ranking first by the majority of the panel. Panelist survey analysis indicated that all (100%) expressed a willingness to buy *Maachech* cookies made with stale bread flour. The main motivations cited were: fighting food waste (83.6%), environmental responsibility (77%), support for local and artisanal production (70.5%), curiosity for new flavors and textures (63.9%), and religious values (16.4%).

Overall, this study demonstrated the feasibility and market acceptance of reusing stale bread in traditional cookie recipes, offering a practical integrated model for reducing bread waste while maintaining product quality, safety, and nutritional value. Through scientific validation and consumer-centered formulation, *Maachech* becomes a powerful example of zero-waste innovation rooted in tradition—an approach replicable in similar food systems worldwide.

Key Words: *Bread waste valorization, Traditional cookies, Sustainable food production, Sensory acceptability, Circular economy*

Effect of Nanoparticles Application on the Germination and Growth of Tunisian Durum Wheat Varieties (Dhabee, Kareem and Inrat100) Under Simulated water Stress Conditions

Mohammad Abed[1], Ayed sourout[1], Sharaf Al-Tardeh[2]

[1] National Agricultural Research Institute of Tunisia, Tunis, Tunisia
[2]Department of Applied Biology and Chemistry, Faculty, Palestine Polytechnic University, Hebron, Palestina

Abstract

This study discussed the effect of five sorts of nanoparticles, SiO2, ZrO2, MgO, ZnO, and TiO2 in the germination and growth of three varieties of Tunisian durum wheat (Triticum turgidum subsp. durum Desf.) (Dhabee, Inrat100, and Kreem) under the simulated stress conditions using poly ethanol glycol (PEG6000). Moreover, in this study, two levels of stress conditions were evaluated compared to control (distilled water). Also, the study checked the different concentrations of nanoparticles to determine their results on the germination, the root length, and the shoot length. The results declared that the water stress resulted in a significant decrease in the germination and growth rates. In addition to that the nanoparticles (TiO2, ZnO) get the highest efficiency in decreasing the side effects of the stress. The TiO2 NPs at the concentration of 100 proved their efficiency in enhancing germination and growth special under severe stress conditions of -3 bar. Furthermore, the varieties showed significant differences in stress conditions as Inrat100 declared exceeding in stress resistance. These results highlighted the possibility of using the NPs, to improve the performance of crops under drought conditions in rainfed Agriculture.

Key Words: *Nanoparticles, Durum wheat, Water stress, Germination,Sshoot length*

Integrated Agriculture-Aquaculture Systems for sustainable development in Rural Nepal

Dilip Kumar Jha

Department of Aquaculture, Faculty of Animal Science, Veterinary Science and Fisheries, Agriculture and Forestry University, Rampur, Chitwan, Nepal
dkjha@afu.edu.np

Abstract

Food security with sustainable development is a major issue being faced by the ever growing population in the world. Integrated Agriculture- Aquaculture (IAA) systems are increasingly recognized as vital for food and nutrition security particularly in the face of global challenges such as climate change, resource scarcity, and food insecurity. By harmoniously integrating crop farming with aquaculture practices, IAA systems enable efficient recycling of nutrients and water, reduce reliance on external inputs, and enhance overall farm productivity and resilience. Further, the integration of aquaculture into agricultural landscapes offers a practical pathway to circular economy practices and climate-smart agriculture. Aquaculture is a fast growing food-production sector that recently overtook fisheries as the main source of fish for human consumption. In Nepal different aquatic systems represent a total of 252 fish species. Among them 236 species are indigenous while 16 species are exotic. These species belong to 15 orders, 40 families and 120 genera. Carps of the order Cypriniformes are the major fishes cultivated in Nepal. These includes Indian Major Carps; Rohu (*Labeo rohita*), Mrigal (*Cirrhina mrigala*), and Chinese Major carps; Grass carp (*Ctenopharyngodon idella*), Silver carp (*Hypophthalmichthys molitrix*) and Bighead carp (*Hypophthalmichthys nobilis*). Two varieties of Common carp; Scale carp (*Cyprinus carpio var. communis*) and Mirror carp (*Cyprinus carpio var. specularis*) are cultivated also. Recently exotic catfish Pangas (*Pangasianodon hypophthalmus*) and exotic perch Nile tilapia (*Oreochromis niloticus*) are cultivated also. Annual fish production of Nepal is 113736 metric tons with the contribution of 92736 metric tons from aquaculture and 21000 metric tons from the inland capture fisheries, indicating per capita fish production 3.8 kg only. Pond fish culture accounts for 72.3% of the current total fish production. The Terai belt which makes up 88% of the entire pond area, is crucial to fish production due to its favourable environment. The support from the government certainly helped the expansion of fish farming to fulfil its potential to meet the national demand for nutritional support of the people and employment opportunities towards sustainable development of the nation.

Assessing the Economic Performance of Catfish Farming in Nsukka and Enugu Metropolis, Nigeria: A Comparative Perspective

Ikenna Charles Ukwuaba[1] Ileka Chikaosolu Maruqueen[1] Umeonuorah Tochukwu Georgina[1]

[1]Department of Agricultural Economics, Faculty of Agriculture, University of Nigeria, Nsukka, Nigeria
Corresponding author: ikenna.ukwuaba@unn.edu.ng

Abstract

Despite the significant contribution of catfish farming to Nigeria's agricultural sector, there is limited research on its economic viability and opportunities. This study presents a comparative analysis of the economic performance of catfish farming in both the Nsukka Local Government Area (LGA) and Enugu Metropolis, Nigeria. Specifically, it compared the socioeconomic characteristics of catfish farmers, evaluated the profitability of catfish production, and identified the constraints faced by farmers in these locations. A multistage sampling technique was used to select 120 respondents, and primary data were gathered using a structured questionnaire. Descriptive statistics and profitability indicators were employed to achieve the objectives. The results indicated that most catfish farmers in both locations are young, married, and have a formal education. The findings also revealed that catfish farming is a profitable venture in both Nsukka LGA and Enugu Metropolis, with mean gross margins of ₦662,534.45 and ₦861,733.22, respectively. The return on investment (ROI) for catfish farmers in Nsukka LGA was 1.09. In contrast, the ROI for Enugu Metropolis was 1.40, demonstrating greater profitability in that area. However, the enterprise faces significant challenges, including high feed costs, elevated interest rates on bank loans, inadequate access to quality fingerlings, and high-water supply costs. The study recommends strategic interventions to address these challenges and enhance the profitability and sustainability of catfish farming in the areas studied, including input cost management, better access to credit, and government support for research and development.

Keywords: *Catfish farming, Economic performance, Profitability, Investment, Nigeria.*

Introduction

Aquaculture has emerged as a vital sector in Nigeria's agricultural economy, playing a significant role in enhancing food security, providing a sustainable source of protein, generating employment, and contributing to household income for millions of people in urban and rural areas (Ogunji & Wuertz, 2023; Falola et al., 2022). The sector has witnessed substantial growth over the past few decades, particularly in urban and peri-urban regions where market access and infrastructure support aquaculture development. This growth has positioned Nigeria as a leading aquaculture producer in Sub-Saharan Africa (Adeleke et al., 2020; FAO, 2022), with southeastern states like Enugu experiencing a notable surge in catfish farming activities, driven by the proliferation of small and medium-scale farms. Among the various aquaculture practices, catfish farming has gained prominence due to increasing population, rising consumer preference for fish protein, declining capture fisheries, adaptability to diverse local environmental conditions, and relatively low production costs, as well as its fast growth rate (Abdel-Hady et al., 2024; Manyise et al., 2024; Mukaila et al, 2023). Catfish (*Clarias gariepinus* and *Heterobranchus spp.)* is one of the most cultivated fish species, contributing significantly to food security and livelihoods, particularly in urban and peri-urban areas in Nigeria (Olagunju, 2024; Adeleke et al, 2020).

Within Nigeria, different geographical regions demonstrate varying levels of catfish farming development and economic performance based on local conditions, market dynamics, and resource availability (Engle et al., 2022; Olagunju et al., 2022). Southeastern Nigeria, particularly Enugu State, has witnessed a proliferation of catfish farms, with Nsukka and Enugu Metropolis becoming key production hubs (Umaru et al., 2021). Nsukka and Enugu metropolis represent two distinct centers in southeastern Nigeria with different socioeconomic profiles, infrastructure development, and market characteristics that potentially influence catfish farming operations. Nsukka, a university town, characterized by its rural settings and limited market infrastructure, contrasts with Enugu metropolis, an urban centre, which serves as a major administrative and commercial hub in the region with a more diverse economic landscape and potentially different market demands and access to resources. These differences may significantly impact the structure, operation, and economic outcomes of catfish farming enterprises in both locations.

In addition, earlier studies (Arifa et al., 2022; Kumar et al., 2020; Diatin et al., 2020; Olagunju et al., 2022; Mukaila et al., 2023) showed several factors can influence the economic performance of catfish farming, including the socioeconomic characteristics of the farmers, the scale and intensity of production, access to inputs and credit, market dynamics, and the prevalence of constraints such as disease outbreaks, high feed costs, poor water management and inadequate infrastructure influence production efficiency, profitability, and overall economic viability. Thus, while catfish farming has proven profitable and contributes significantly to local economies in both locations, its operational dynamics, farmer characteristics, and challenges are likely shaped by their distinct

environments. Similarly, despite its growth, Ajagbe et al. (2024), Mukaila et al. (2023), and Mbokane et al. (2022) noted that catfish farming faces persistent challenges, including high feed costs, limited access to credit, inadequate water management, and inconsistent government policies, which vary across locations due to differences in infrastructure, market access, and farming practices.

Existing studies (Olagunju et al., 2022; Onyekuru et al., 2019; Akoh et al., 2025; Akure et al., 2024; Cheatham et al., 2023; Adelesi & Baruw, 2022) on catfish farming in Nigeria have largely focused on general profitability analyses or technical production challenges, with limited comparative studies specifically examining the socioeconomic and economic nuances between locations like Nsukka and Enugu Metropolis. Understanding these location-specific differences is crucial for formulating targeted policies and interventions to optimize resource utilization, improve market access, mitigate production risks for catfish farmers, enhance productivity, and the sustainability of the sector. This study, therefore, seeks to address this gap by comparatively assessing the socioeconomic profiles of catfish farmers in Nsukka and Enugu Metropolis, evaluating the profitability of their production systems, and identifying the key constraints they face. By providing evidence-based insights into these critical aspects, this research aims to contribute to the sustainable development of catfish farming in Enugu State and offer valuable lessons for similar agro-economic settings across Nigeria. The findings will be beneficial for policymakers, development agencies, extension services, prospective and current farmers, and other stakeholders in the aquaculture value chain.

Materials and Methods

The study was carried out in Enugu Metropolis and Nsukka Local Government Area (LGA) of Enugu State, Nigeria. Enugu metropolis is the capital city of Enugu State, and it comprises Enugu East, Enugu North, and Enugu South LGAs. Enugu State lies between latitudes 5°56'N and 7°36'N and longitudes 6°53'E and 7°55'E of the Greenwich Meridian (Enugu State Agricultural Development Project, ENADEP, 2009). A multi-stage sampling technique was used to select catfish farmers from Enugu Metropolis and Nsukka (LGA). The first stage was a purposive selection of six communities with a large number of catfish farmers from Enugu Metropolis and Nsukka LGA. The second and final stage was a random selection of 10 catfish farmers from the list of farmers in each of the 12 communities, giving a total of 120 respondents for the study, that is, 60 in Nsukka LGA and 60 in Enugu Metropolis.

Primary data was used for the study and was collected from the catfish farmers using a well-structured questionnaire. The questionnaire captured information such as the socio-economic characteristics of the respondents, costs incurred, and revenues obtained in catfish rearing and production constraints faced by the farmers. Descriptive statistics such as frequency distribution and percentages, gross margin, and net farm income techniques were used to achieve the objectives.

Model Specifications

Gross margin analysis was expressed as:

GM = TR -TVC

Where:
GM = Gross Margin (₦)
TR = Total Revenue (₦)

TVC = (Total Variable Cost) (₦)
NFI (Net Farm Income) = GM -TFC
TFC = Total Fixed Cost

$$\text{Return on Investment} = \frac{GM}{TVC}$$

Results and Discussion

Socio-economic characteristics of catfish farmers

The study revealed that catfish farming in both Nsukka LGA and Enugu Metropolis is predominantly male-dominated, with males constituting 68.3% and 76.7% of the respondents, respectively. The male dominance in catfish farming suggests potential barriers to women's participation, highlighting the need for initiatives to promote gender inclusivity. In terms of marital status, the majority of the respondents were married, accounting for 63.3% in Nsukka LGA and 68.3% in Enugu Metropolis. The high percentage of married respondents implies that family responsibilities may influence farming decisions, labour allocation, and income management. The age distribution showed that most farmers in both locations fell within the 21-40 age range, with 45% in Nsukka LGA and 51.7% in Enugu Metropolis. The mean ages of 41 and 43 years in Nsukka LGA and Enugu Metropolis, respectively, suggest that the catfish farmers are relatively young and energetic, which could contribute to innovation, productivity, and sustainability of the catfish business. The result aligns with a study by Omeje *et al.* (2021) among

catfish farmers in Kainji Lake Basin, Nigeria. Regarding household size, the majority of respondents in both locations had household sizes ranging from 1 to 4 persons, accounting for 48.3% in Nsukka LGA and 60% in Enugu Metropolis. The mean household sizes were 6 and 5 persons in Nsukka LGA and Enugu Metropolis, respectively. The result is in agreement with Jimmy et al (2024) and Gbigbi (2021) that the mean household size of Catfish farmers is between 6 and 8. The educational qualifications of catfish farmers differed between Nsukka LGA and Enugu Metropolis. In Nsukka, 3.3% had no formal education, while in Enugu Metropolis, all farmers had formal education. The mean years of schooling were 11 years in Nsukka and 13 years in Enugu, indicating that the farmers can manage catfish production effectively. However, additional training or support could further enhance productivity.

Table 1: Socioeconomic Characteristics of the Catfish Farmers

Socio-economic Characteristics	Nsukka (*n=60*)		Enugu (*n=60*)	
	Frequency	Percentage	Frequency	Percentage
Gender

30,000-60,000	9	15.0	4	6.7
61,000-100,000	39	65.0	41	68.3
101,000-250,000	12	20.0	15	25
Mean	89,151.75			105,148.02

The result is consistent with Jimmy et al. 2024 and Solomon and George (2019), who reported relatively high literacy levels among catfish farmers. The study also revealed that catfish farmers in both locations had significant experience, with a mean year of experience being 11 years in Nsukka LGA and 12 years in Enugu Metropolis. This level of experience is in line with a study by Enwelu *et al. (*2023) and suggests that the farmers are well-equipped to handle challenges and make informed decisions, which can enhance their productivity and overall success in catfish farming. The study found that the majority of respondents in both Nsukka LGA (63%) and Enugu Metropolis (71.7%) were full-time catfish farmers, indicating that catfish production is their primary source of livelihood. The high percentage of full-time catfish farmers suggests that many households in both locations depend on catfish farming for their livelihood. This highlights the importance of supporting and sustaining the catfish industry.

In terms of scale, most respondents in both locations operated medium-scale catfish farms, with 58.3% in Nsukka LGA and 68.3% in Enugu Metropolis. The dominance of medium-scale catfish farms suggests opportunities for growth and expansion into larger-scale operations, which could increase productivity and income. The income analysis showed that the majority of respondents in both locations earned between ₦61,000 and ₦100,000 per month. However, farmers in Enugu Metropolis had a higher mean monthly income of ₦105,148.02 compared to ₦89,151.75 in Nsukka LGA. The difference in mean monthly income between Nsukka LGA and Enugu Metropolis may be attributed to factors like market access, production costs, or demand. Understanding these factors could help bridge the income gap.

Profitability of catfish production

Tables 2a and 2b present the cost and return analysis of catfish farmers in Nsukka LGA and Enugu metropolis. Results in Table 2a showed that the mean quantity of catfish produced and sold within a production cycle in Nsukka LGA was 805.3, and the average price per kg of catfish was ₦1,580.5. The result further showed that the mean total cost of catfish production was ₦669,526,80, and the mean total revenue was ₦1,272,776.65. Therefore, the results of the gross margin (₦ 662,534.45) and the Net Farm Income (₦603,250.85) analyses indicated that catfish farming was both viable and profitable in Nsukka LGA. The return on investment of the catfish farmers was 1.09, implying that catfish farmers in the Nsukka LGA returned ₦1.09 for every 1.00 Naira invested in the business. This result is in agreement with the findings of Ikechukwu (2023), who found that catfish production was a profitable enterprise with a return on investment of ₦1.11 for every capital invested. However, the result disagrees with the findings of Enimu and Edet (2018) in Delta state, which found that the return on investment was less than ₦1.

The results in Table 2b indicated that the mean quantity of catfish produced and sold within a production cycle in the Enugu metropolis was 912.4, and the average price per kg of catfish was ₦1,620.3. The average total cost of catfish production was ₦678,256.60, and the average total revenue generated was ₦1,478,361.72. Therefore, the results of gross margin (₦861,733.22) and the Net Farm Income (₦800,105.12) analyses in Enugu metropolis showed that catfish farming was a profitable enterprise. The return on investment (ROI) of the catfish farmers was 1.40, implying that catfish farmers in the Enugu metropolis returned ₦1.40 for every 1.00 Naira invested in the business. The result is consistent with the findings of Enwelu et al. (2023), who noted that catfish production was profitable in Anambra State with a return on investment of ₦2.47 for every capital invested. However, it also disagrees with a study by Enimu and Edet (2018), which found a return on investment of 0.48 among catfish farmers in Delta State, Nigeria.

Comparatively, from Tables 2a and 2b, catfish farming was found to be more profitable in the Enugu metropolis when compared to that of Nsukka LGA. Though the cost of feed contributed more than 50% of total expenditure in both locations, the enterprise generated more revenue and consequently more profit and more return on investment in the Enugu metropolis. Therefore, catfish farmers had a higher return on investment (1.40) than those in Nsukka LGA, who had only 1.09 as a return on capital investment. This could be attributed to the fact that the Enugu metropolis had more full-time catfish farmers than Nsukka, as reported in Table 1. Catfish farmers who are full-time operators tend to be more dedicated and committed, and monitor any challenges that can reduce the efficiency of catfish production (Esiobu et al, 2022). Thus, the more time devoted to the enterprise, the higher the propensity to earn more. It can also be linked to the fact that the Enugu metropolis, being the state capital, may have more premium consumers who have more income than those in relatively rural Nsukka LGA.

Constraints faced by Catfish farmers

The constraints militating against the catfish production in Nsukka LGA and the Enugu metropolis are presented in Table 3. The results in the Table showed that the cost of feed (100%) was the major constraint in the catfish production. This is a further confirmation of the high cost of feed reported in Table 1, in which feed accounted for over 50% of the total cost of production in both Nsukka LGA and Enugu metropolis. The result is in agreement with that of Alawode and Ajagbe (2020), who ranked the cost of feed as the most important factor that militates against the level of profitability in cattish production. This suggests that if the cost of feed is reduced drastically, the welfare of the catfish farmers would increase due to increased profit levels.

Table 2a: Cost and Return of Catfish producers in Nsukka LGA per production cycle

	Average Quantity/Cost (₦)	% Share	Price per Kg (₦)	Total (₦)
Revenue				
Catfish	805.3		1,580.5	**1,272,76. 65**
Variable Cost:				
Catfish feeds	340,500.7	50.86

Gross Margin (TR -TVC)				**861, 733. 22**
Net farm income (TR-TC)				**800, 105. 12**
ROI/RCI GM/TVC				**1.40**

Aside from the cost of feed, the other major challenges facing catfish production in Nsukka LGA, as stated in Table 3, include high interest rate on bank loans (95%), high spread of pests and diseases (95%), lack of quality supply of fingerlings (85%), high cost of water supply (83.3%), high mortality rate (81.7) and inadequate capital (80%). As regards the Enugu metropolis, the major hindrance to catfish production, in addition to the high cost of feed as indicated in Table 3, include high cost of labour (95%), high cost of water supply (93.3), interest rate on bank loan (91.7%), high mortality rate (86.7), high spread of pests and diseases (85%), and lack of quality and supply of fingerlings (85%).

Comparatively, the result further suggests that whereas high interest rate on bank loans (95%) and high spread of pests and diseases (95%) were the second and third most important constraints in Nsukka LGA, the case was not the same with that of Enugu metropolis, in which high cost of labour (95%) and high cost of water supply (93.3%) were ranked as the second and third most important constraints to catfish production. However, catfish producers in both Nsukka and Enugu metropolises ranked the lack of an organised market as the least contributor to inefficiencies in catfish production, with 31.7% and 18.7%, respectively.

Table 3: Constraints Against Catfish Production in Nsukka LGA and Enugu Metropolis

Items	Nsukka		Enugu	
	Frequency	Percentage	Frequency	Percentage
High cost of feed	60	100.0	60	100.0
Inadequate capital	48	80.0	35	58.3
High cost of fingerlings	34	56.7	27	45.0
High cost of water supply	50	83.3	56	93.3
High spread of pests and diseases	27	45.0	21	35.0
High cost of labour	33	55.0	57	95.0
High cost of transportation	47	78.3	55	91.7
Lack of organised market	19	31.7	10	16.7
High spread of pests and diseases	57	95.0	51	85.0
Poorly trained extension Personnel	42	70.0	21	35.0
Lack of Access to credit	44	73.3	38	63.3
High mortality rate	49	81.7	52	86.7
Lack of quality supply of fingerlings	51	85.0	51	85.0
High interest rate on a bank loan	57	95.0	55	91.7
Poor Extension Coverage	28	46.7	32	53.3
Poaching	20	33.3	27	45.0

Multiple Responses*

Conclusions and Recommendations

Catfish farming is a profitable enterprise in both Nsukka LGA and Enugu Metropolis, with higher profitability in Enugu. The industry has significant economic potential, contributing to livelihoods, food security, and employment. However, challenges such as high feed costs, interest rates, labor costs, pests and diseases, poor fingerling quality, and water supply costs hinder its viability. Strategic interventions are necessary to address these challenges and ensure sustainable growth, efficiency, and profitability in catfish farming. Therefore, to enhance catfish farming in Nsukka LGA and Enugu Metropolis, several key measures are recommended. These include promoting cost-effective feed alternatives, improving access to affordable credit, and breeding quality, disease-resistant catfish. Additionally, training farmers to detect pests and diseases early, addressing water scarcity issues, and establishing organized markets with marketing support can help lower costs, increase profitability, and ensure the industry's sustainability.

Abstract

Sooty mould, *Capnodium* spp., a saprophytic fungus from the phylum Ascomycota, produces dark-coloured colonies on plant surfaces smeared with honeydew of coconut whitefly. This study explains eco-friendly biorationals, comprising plant extracts, organic materials, and microbial agents, to control the growth of *Capnodium* spp. Morphological analysis revealed distinct hyphal septation and conical black spores, providing insights into *Capnodium* fungal development. Experiments were conducted using 35 plant extracts, of which 12 showed significant antifungal properties. Inorganic pesticides cannot be sprayed on coconut to control whitefly, as the spray may reach the households, especially waterbodies at households. Extracts of *Acorus calamus* (Sweet flag) exhibited the highest inhibition (98.61% at 50% concentration), followed by *Allium sativum* (Garlic, 84.06%) and *Asparagus racemosus* (Shatavari, 84.72%). In contrast, extracts of vermicompost tea showed no inhibitory effects, while fermented cow urine and distillery spent wash reached 100% inhibition of fungal growth. In microbial agents, *Trichoderma* spp. completely inhibited fungal growth, whereas *Pseudomonas* fluorescens exhibits no effect. The results explained that plant extracts with organic compounds or microbial agents provide solutions as an alternative to chemical fungicides. Combining extracts could provide an eco-friendly and sustainable strategy for managing *Capnodium* spp., reducing crop losses and increasing agricultural sustainability. These findings contribute to the growing body of research supporting biorational approaches as viable, environmentally safe options for fungal management. Field-scale applications are to be tested, and the effect of the biorationals on coconut whitefly also has to be determined.

Keywords- *Acorus calamus, biorational control, Capnodium, Sooty mould, Trichoderma spp.*

Introduction

Sooty mould are saprophytic fungi from Ascomycota, typically with dark-coloured hyphae, resulting in seemingly brown to black colonies on live plants. These types of moulds are frequently connected to whitefly and other producers of honeydew, albeit they can also happen in their absence. Sooty moulds can develop into a pseudoparenchymatous crust, a pellicle, a velutinous growth, or a thin network of hyphae on leaves and smaller twigs. Many sooty mould hyphae have a distinctly mucilaginous outer wall that serves as an adhesive, and quickly absorbs water surely keeping the leaf surface moist for a longer amount of time. Upon bigger branches and trunks the growths are typically stronger and could appear as spongy or lumpy pseudoparenchymatous stromata (Hughes, 2018).

The most frequent genera of fungi that cause sooty mould on garden and landscape plants are *Fumago, Scorias* and *Capnodium*. A few less frequent genera are *Antennariella, Limacinula, Fumiglobus and Aureobasidium.* The kind of presence of sooty mould-causing fungi depends on several factors, including the host, habitat and insect species. A few certain plants or insects are preferred by specific species of sooty mould. Whereas other mould species might grow on a variety of surfaces and make use of honeydew made by several insect species (Ipm 2006). Sooty moulds decrease plants' photosynthetic potential by large mycelial networks, resulting in chlorosis under the mycelia. Hence, sooty moulds hurt crop output and quality (Haituk et al., 2022) especially it over grow on the fruits that cause low market value.

To lessen the negative effects of chemical fungicides on the environment, which can damage non-target organisms, contaminate soil and water, and cause pesticide resistance, eco-friendly management of sooty mould is crucial. Sustainable substitutes that support ecological balance and agricultural sustainability include plant extracts, organic materials, and microbiological agents. They also provide longer-lasting, safer solutions.

The following objectives were developed for the study

i. To conduct a morphological study of the sooty mould fungus colony for a better understanding of its growth characteristics.
ii. To explore eco-friendly alternatives to chemical fungicides for the management of sooty mould.
iii. To assess the antifungal potential of microbial agents in controlling sooty mould fungus.

Materials and methods

These experiments were carried out at the JICA - Plant Protection Laboratory of the Department of Agricultural Biology, Faculty of Agriculture, University of Jaffna.

Isolation and identification of the sooty mould fungus

Isolation and inoculation of sooty mould

Whitefly infested leaves of coconut were collected from a home garden at Iranaimadu, Kilinochchi. The leaves were cut into small pieces and rinsed in distilled water. Then the sample was inoculated into 9 cm Petri dishes containing PDA. Plates were incubated at room temperature (30ºC) for five days. The pure culture of the fungal isolate was maintained in PDA plates and stored in the refrigerator at 4°C for further use. Mycelial growth rate, colour and spore characters of the colony were measured after 3 days of inoculation.

Screening of plant botanicals against sooty mould fungus

For this experiment, thirty-five kinds of plant extracts were tested on sooty mould as a preliminary experiment, however only 09 extracts were found to prominently inhibit mycelial growth higher than 50%.

Selection of plant extracts

Based on the literature research, thirty-five medicinal plants (Table 1)bthat show antifungal properties were identified and selected for *in-vitro* screening against sooty mould fungus.

Table 1: Screening of botanicals to determine their suppressive effect on Sooty mould fungus

Treatment	Botanicals	Family	Plant part used
T1	*Acorus calamus*	Acoraceae	Leaves

T35	*Solanum trilobatum*	Solanaceae	Leaf

Preparation of plant extracts

Plant parts which are having higher antifungal properties were collected from different field locations based on the literature (Table 2) and washed with running tap water to remove adhered impurities and rinsed with distilled water, and the surface was sterilised using 3% NaOCl for five mins and thereafter rinsed with distilled water.

The plant parts of the collected plants were sun-dried and made into powder separately using a sterilized grinder. The aqueous extracts were prepared by mixing 10g plant powder with 100 ml of water, if it had the suppression effect then the extracts were prepared into different concentrations to check the suppression effect depending on the concentration of the extracts. The mixture was kept overnight in the shaker to mix well the sample. Then the mixture was filtered through the membrane filter. The supernatant was kept separately. 3.9 g of PDA powder was added with 20 ml of water and sterilized. The autoclaved PDA was mixed with plant extract.

(a) (b)

Plate 1: Procedures for getting plant extract to inhibit the growth of Sooty mould (a): Shaking the powdered plant parts with a shaker (b): centrifuged plant extract

Antifungal activity of plant extracts

The food poisoning technique (Sah et al., 2021) was used as a method to check the inhibitory effect of plant extracts on sooty mould. 15ml of PDA with plant extract was poured into the Petri plate and allowed to solidify. 5mm diameter discs were obtained from a 140-day-old pure culture of sooty mould using a cork borer. The mycelial segment was transferred to plant extracts or organic matter mixed PDA medium. Petri dishes containing PDA without plant extracts were used as a control. The treatments were replicated four times. The inoculated Petri dishes were sealed by parafilm and incubated at room temperature (30ºC). The diameter of growing colonies of the fungus was recorded from 24 hours after inoculation to the time taken for the fungus to fully cover the 9 cm Petri dish.

The percentage growth inhibition (I) was calculated using the formula given below (Sivakumar, 2002)

I%=(C-T) / C

I= Percentage of inhibition of fungus by plant extracts

C=Radial growth in control

T=Radial growth in the treatment

Collection and Preparation of Distillery spent wash, Fermented cow urine and Vermi tea

Distillery Spent Wash (DSW)

One litre of distillery spent wash was obtained from the Araly distillery unit, Jaffna. The collected distillery spent wash was kept in two conical flasks. One is maintained as unsterilized. Another conical flask with distillery spent wash was sterilized with the help of an autoclave at 121° C for 15 minutes. 10%,30%, and 50% of the concentration of the distillery spent wash was taken from sterilized and unsterilized ones, with each concentration having four replicates. and these measured DSW were added to PDA.

Fermented urine

One litre of fermented urine was obtained from the farm of the Faculty of Agriculture, University of Jaffna. The collected fermented cow urine was kept in two conical flasks, from which one was sterilized with an autoclave at 121ºC, 15 psi for 15 mins. The other one was kept as unsterilized. Different concentration (10%, 20%, 50%) of fermented cow urine was taken from sterilized and unsterilized conical flasks. and added into the petri dish with 15ml of sterilized PDA. Each treatments with different concentrations was maintained with four replicates.

Preparation of Vermi tea

Vermicompost was made with bedding material made up of cow dung. Then the vermicompost was sieved and 500 grams of fresh vermicompost was weighed by the electrical balance. That was soaked in one litre of non-chlorinated water and blended thoroughly to create the vermi tea. An aquarium pump was used to aerate the

solution during a 1–2-hour brewing period. Following that, the suspension was filtered through muslin cloth and stored in a sterile glass for use as a treatment to control the sooty mould fungus.

The prepared vermi tea was kept in two conical flasks one was maintained as sterilized with the help of an autoclave. Other is maintained as unsterilized. Different concentration of the vermi tea (10%, 30%,50%) were poured into the 15ml of PDA with four replicates in each concentration.

Effect of different biocontrol agents *Trichoderma* sp. and *Pseudomonas* spp on mycelial growth of sooty mould

Effect of *Trichoderma* spp on Sooty mould

Under *in-vitro* conditions "Dual Culture Technique" was used as described by (Morton and stroube,1955). For the experiment 15ml of sterilized PDA medium were poured aseptically into sterilized petri dishes under laminar flow. 5mm disc of antagonist and test organism were cut from 14 days old culture by sterilized cork-borer and was placed opposite in Petri dishes containing PDA medium.

The disc was placed in a straight line at one centimetre from the corner of the Petri dishes. Potato Dextrose Agar plates inoculated with sooty mould alone were treated as a control. Four replications were maintained. The inoculated Petri dishes were maintained at room temperature and radial growth of *Trichoderma* and sooty mould was recorded for five days from inoculation. The inhibition zone was estimated based on the formula given by Vincent (1947), as the percentage of inhibition

I%=(C-T)/C x 100

I=Inhibition of mycelial growth

C = Growth of pathogen in control plate (cm)

T= Growth of the pathogen in dual cultures (cm)

Plate 2:Pure culture of *Trichoderma*

Effect of *Pseudomonas* sp. on Sooty mould

Suspension of *Pseudomonas* was streaked in the nutrient agar medium. After that the plates were incubated for 24 hours at 30^{O}c.

For dual culture, 20 ml of sterilized PDA medium was poured into the sterilized Petri dishes under the laminar flow condition. The antagonistic bacteria were streaked one cm from the edge of PDA in a 9 cm diameter Petri dish as shown in the Plate 3. After 24 hours of incubation at 28˚C, a 5 mm disc of an actively growing 14 days old culture of sooty mould was inoculated at the centre. Plates inoculated with alone sooty mould were maintained as a control. Plates were incubated for three days at 28°C and the percentage of inhibition of radial growth (PIRG) was recorded using the following formula (Sariah, 1994).

PIRG = (R1-R2)/R1 ×100

R1= Radial growth of sooty mould

R2=interacting with antagonistic bacteria

Plate 3: Pure culture of *Pseudomonas*

Analysis

Statistical Analysis

Each experiments were arranged according to the Complete randomized design (CRD) in two factor factorial and the data were statistically analyzed using SAS package 3.81 (Enterprise edition). Post hoc test was performed using the Duncan Multiple Range Test (DMRT) at 95% of the confidence level**.**

Correlation Analysis

Correlation analysis was performed to understand the relationships between different plant extracts and organic materials based on their inhibitory effects against sooty mould. This analysis aimed to determine if there were any associations between the inhibitory patterns of various treatments, which could suggest common bioactive compounds or similar modes of action.

The Pearson correlation coefficient (r) was calculated to measure the linear relationship between inhibition rates of different treatments at varying concentrations. The value of r ranges from -1 to +1:

- +1 indicates a perfect positive linear relationship.
- -1 indicates a perfect negative linear relationship.
- 0 indicates no linear relationship.

The correlation coefficients were calculated separately for each concentration (10%, 30%, and 50%) to observe how the relationships changed with varying levels of the treatment. A heatmap was created to visualize the correlation matrix, using color gradients to represent the strength and direction of the correlations. Darker shades indicated higher positive or negative correlations, while lighter shades indicated weaker correlations. Correlations with p-values less than 0.05 were considered statistically significant, indicating that the observed relationships were not due to random chance.

Based on these correlation patterns, treatments with r values close to +1 were identified as having similar inhibitory patterns, while treatments with low or negative correlations suggested distinct inhibitory properties.

Results and Discussion

This chapter describes the findings of the experiments conducted to determine the objectives proposed to find a solution and discusses the literature obtained from the published research papers and sources which are documented in Chapter 3.

Colony morphological characters of sooty mould culture

Sooty mould grown in PDA is shown in Plate 1. It had a full growth in a 9cm petridish within 3 days, specific growth rate of this fungus is not reported in any reports because the growth rate may be affected by environmental conditions (Smith et al., 1980). It first created white colour mycelium but after 7 days it turned into black colour. The texture of the colonies was primarily in velvety but some of the areas displayed a powdery appearance. The surface of the colonies was smooth with slight radial grooves visible under magnification. Circular-shaped colonies were observed but after one-week irregular edges were also observed in the colony similar report byAguirre-hudson et al. (2014). After 3 days of incubation at 30ºC, 9cm of growth is observed. The pigmentation was higher in the center compared to the periphery of the colony. Spore production was started after 10 days of inoculation. The spores were observed as scattered small black dots on the upper surface of the colony.

The morphological characters were also observed in the microscope by doing the hanging drop technique. The septation was observed in the hyphae of the fungus. The spores was in black with a conical shape, these microscopic characters are alinged with (Hughes 2018) observed characters.

Evaluation of plant extracts with different concentrations against Sooty mould fungus

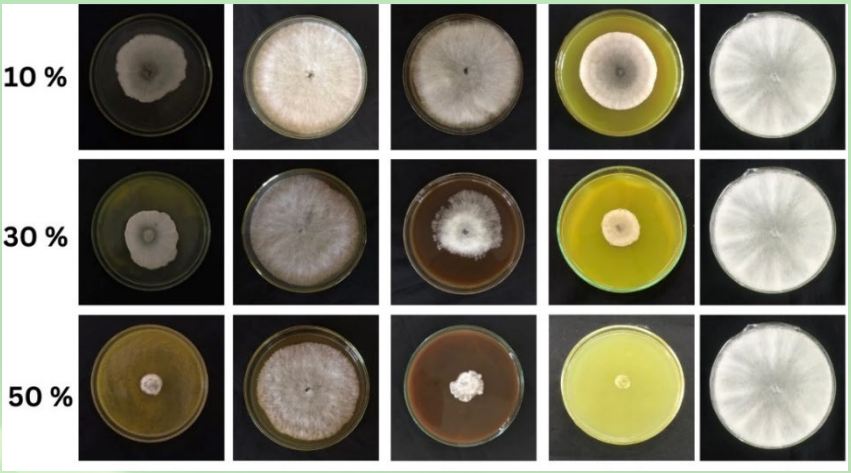
Table 2: Inhibition percentage of different plant extracts at different concentrations against sooty mould fungus (*Capnodium* spp) under *in vitro* condition

Plant extract	Inhibition percentage (%)		
	10%	30%	50%
1. Sweet flag	79.69±0.73^{a}	83.14±0.77^{a}	98.61±1.67^{b}
2. Khus	0^{d}	46.08±0.36^{c}	64.86±2.37^{a}
3. Pepper	0^{d}	0^{d}	4.38±1.35^{d}
4. Turmeric	40.22±2.98^{c}	53.39±2.69^{e}	75.83±2.62^{a}
5. Wild turmeric	41.86±2.9^{c}	52.92±2.28^{e}	81.25±0.52^{a}
6. Asparagus	30.86±2.25^{c}	52.92±2.82^{e}	84.72±1.66^{a}
7. Lesser galangal	0^{d}	22.61^{f}	42.22^{c}
8. Garlic	45.83±6.11c	65.47±1.39^{g}	84.06±1.75^{a}
9. Indian winter cherry	0^{d}	50.83±4.19^{e}	63.97±3.29^{g}
10. sickle senna	28.81±3.27^{c}	32.64±1.38^{c}	43.89±1.92^{c}
11. Gliricidia	0^{d}	16.75±2.04^{f}	51.94±2.62^{e}
12 .Mugwort	3.75±3.18^{d}	42.22±1.92^{c}	52.22±2.46^{e}

Values having the same letters in a column are not significantly different according to DMRT at 0.05 α

The inhibition percentage of different plant extracts with different concentrations is shown in Table 3 From the 35-plant extracts only 12 plant extracts showed inhibitory effects against the Sooty mould fungus, those 12 plant extracts performance are described in Table 3. From twelve plants, only nine plant extracts shown an inhibitory percentage of more than 50%. The highest inhibition (98.61±1.66%) was observed in sweet flag plant extract .at the concentration of 50% as of inhibition. And 10% concentration of this plant extract show 79.69±0.733% inhibition and 30% of this plant extract shows 83.14±0.766 % inhibition. These results revealed that chemical compounds which are present in the sweet flag plant have high antifungal properties against the sooty mould fungus compared to other tested plant extracts. Next to the sweet flag significant inhibition percentages found in the asparagus (84.72%) and garlic (84.06%). turmeric (75.83%) wild turmeric (81.25%), turmeric (75.83%).

Other than this plant extracts like *Colocasia*, neem, liquorice, country almond, castor, Bermuda grass, *Centella*, ginger, teak, pomegranate, eucalyptus, bidi leaf tree, milkweed, jamun, moringa, holy basil is didn't contribute to the suppression of the sooty mould. Which means there is no significance in these treatments. So chemical compounds which are present in these plants are not suitable for the control of sooty mould or the concentration is may not be enough for the growth of the inhibition of the growth of the fungus. So the further study need to optimize the concentrations wants to see the efficacy of the chemical compounds to suppress the fungus.the chemical compounds that show antifungal properties against sooty mould fungus depend on the concentrations.



When the concentration increases in higher percentages their inhibitory property also will increase in higher levels, which is also reported by (Dellavalle et al. 2011). For example, the wild turmeric which shows 41.86% as its

inhibition percentage, changes to 65.47% when the concentration is increased from 10% to 30% and then reaches a higher inhibition percentage of 81.25% at 50% concentration. Indian winter cherry had 0% inhibition in 10% concentration of the plant extract suddenly reaches the inhibition percentage of 50.83% when the concentration at 30%. The results revealed that inhibition efficacy of the plant extract correlate with the plant extract concentration.

Correlation Between Plant Extract Based on Inhibition Percentage

The primary purpose of conducting correlation analysis on the antifungal activity of various plant extracts against sooty mould is to identify potential synergistic effects and relationships among the extracts. By examining correlation patterns, researchers can determine whether certain plant extracts share similar inhibitory properties, which may indicate the presence of complementary or overlapping bioactive compounds.

This analysis helps in understanding the interactions between different extracts and can provide insights into developing effective botanical mixtures with enhanced antifungal activity. Additionally, the correlation analysis can reveal unique properties of specific plant extracts that show weaker or distinct inhibition patterns, suggesting that these extracts might require different concentrations or combinations for optimal effectiveness. The findings from such an analysis are essential for guiding future research on optimizing the use of plant-based bio-fungicides in eco-friendly agricultural practices.

The idea of utilizing correlation analysis in evaluating the effects of plant extracts is supported by the research conducted by Dellavalle et al. (2011) and Singh et al. (2023). Studies have shown that synergy among bioactive compounds in plant extracts can significantly enhance their antifungal properties compared to their individual effects. The concept of synergistic effects and correlation analysis in plant extracts has been previously reviewed in other phytochemical studies that aim to understand plant–fungus interactions and to improve the efficacy of natural fungicide (Díaz Dellavalle et al. 2011);(Singh et al. 2023)

The high correlation coefficients (0.99 or 1) observed between Sweet Flag, Turmeric, Wild Turmeric, Asparagus, and Garlic indicate that these extracts exhibit highly similar inhibitory patterns against sooty mould. However, it is important to note that similar inhibition percentages do not necessarily imply similar chemical compositions or modes of action. For instance, different sets of bioactive compounds could produce comparable inhibition results due to varying mechanisms, such as disrupting cell walls or inhibiting fungal enzyme activity.

However, based on the work of Dellavalle et al. (2011) it can be intuitively expected that the bioactive chemicals contributing to the inhibitory potential of these various extracts could be complementary or overlapping. There aren't many relationships between Pepper and Indian Winter Cherry and other plant extracts. Pepper exhibits poorer correlations than the other extracts, particularly with Khus (0.72) and Indian Winter Cherry (0.66). This could mean that Pepper has a distinct mode of action or less potent inhibition than the other extracts. Indian Winter Cherry also correlates less with others, suggesting unique properties of its inhibitory action. These results suggest that these extracts might not be as effective overall or that they might require other chemicals or amounts to act as an inhibitor.

While Khus's correlations with most extracts are moderate (0.72 with Pepper, 0.88 with Wild Turmeric, and 0.87 with Sickle Senna), which suggests that its inhibition potential is not as strong as extracts like Sweet Flag, Turmeric, or Garlic, it still shows notable inhibition, particularly in specific concentrations. Gliricidia and Mugwort show moderate correlations (0.9–0.95) with most extracts, indicating that their overall inhibitory potential is slightly lower than that of other extracts like Garlic and Sickle Senna, with slightly weaker inhibition potential overall. When compared to highly correlated plant extracts like Sweet Flag and Turmeric, Pepper and Indian Winter Cherry stand out in terms of their correlation patterns. These outliers show that Pepper and Indian Winter Cherry may have unique inhibitory profiles and may not follow the same trends as the other more correlated extracts.

To make definitive conclusions regarding the similarity of bioactive chemicals, further phytochemical analysis and studies comparing the chemical profiles of these extracts would be necessary. Without such evidence, it is not possible to conclusively state that these extracts contain overlapping or complementary compounds. Thus, while the inhibition patterns observed are noteworthy, further research and references are required to confirm any claims regarding chemical similarity or mode of action.

Evaluation of inhibition of organic materials in the growth of sooty mould fungus.

Table 3: Inhibition percentage of organic materials at different concentrations against sooty mould under *in vitro* condition

Organic material	**Inhibition percentage**		
	10%	**30%**	**50%**
Distillery spent wash (Sterilized)	100[a]	100[a]	100[a]
Distillery spent wash (Unsterilized)	100[a]	100[a]	100[a]
Fermented urine (Sterilized)	100[a]	100[a]	100[a]
Fermented urine (Unsterilized)	100[a]	100[a]	100[a]
Vermi tea (Sterilized)	0[b]	0[b]	0[b]
Vermi tea (Unsterilized)	0[b]	0[b]	0[b]

All the values in each column having the same are not significantly different according to DMRT at 0.05.

Table 4: Evaluation of different parameters of fermented cow urine, distillery spent wash, vermi tea

Organic material	**TDS (mg/l)**	**PH**
Distillery spent wash (Sterilized)	1741	6.4
Distillery spent wash (Unsterilized)	1734	6.2
Fermented cow urine (Sterilized)	1600	5.8
Fermented cow urine (Unsterilized)	1587	5.6
Vermi tea (sterilized)	500	7.0
Vermi tea (unsterilized)	400	6.8

Fermented cow urine both sterilized and unsterilized was shown a 100% inhibition rate against the sooty mould fungus, it indicates strong antifungal properties. This effect may be due to the presence of bioactive compounds like phenols, ammonia, and other antimicrobial compounds which are present in the cow urine and also nutrient in a rich condition due to higher TDS (Singh Rawat et al. 2020).

Distillery spent wash also contribute to the complete inhibition of the fungus. This also due to the high organic compound content (higher TDS) and also presence of organic acids and alcohols that possess antifungal property (Kaushik et al. 2018). In contrast vermi tea's inhibition percentage is 0. It may be due to the absence of specific chemical compound/ nutrient which is required to inhibit the sooty mould fungus. The results suggest that the antifungal activity is influenced by both the chemical composition and the pH of the organic materials.

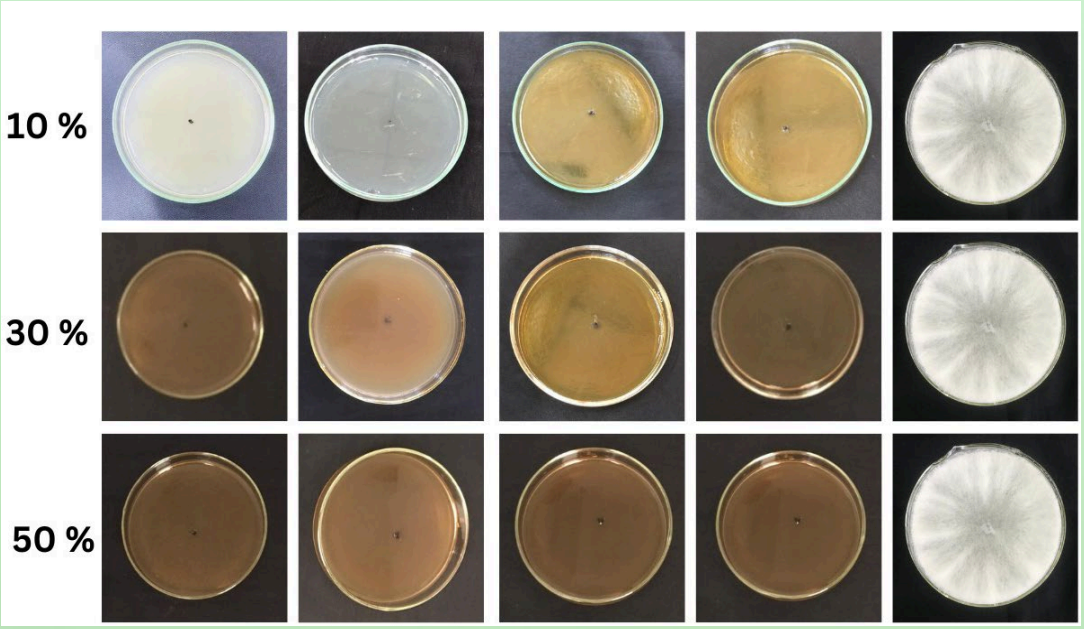

Plate 8: Comparison of growth of sooty mould in different plant extract and in control (a) Distillery spent wash(sterilized) (b) Distillery spent wash (unsterilized) (c) Fermented cow urine (Sterilized) (d) Fermented cow urine (unsterilized) (e) Control

These images indicates in plate 7 ,that there is no growth of Sooty mould in the treatments. Zero growth rate is observed.

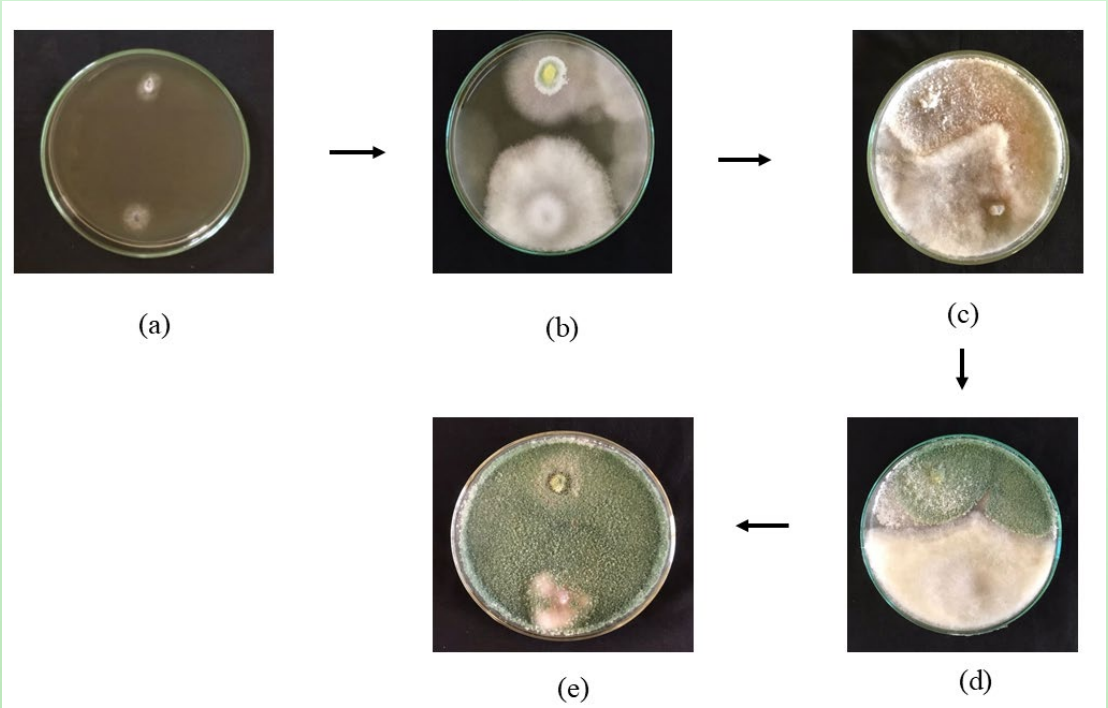
Figure *1*:Inhibition percentage of Sooty mould in organic material at different concentration

Figure 3 shows the inhibition of Sooty mould using the fermented cow urine, distillery spent wash with different concentration of inhibition but the inhibition percentage remain as 100% even though the concentration is reduced.

Evaluation of Antifungal activity of *Trichoderma* species against Sooty mould fungus

Table *5*:Day by day growth of *Trichoderma* against Sooty mould

Organism	**Growth (cm)**				
	1st DAC	**2nd DAC**	**3rd DAC**	**4th DAC**	**5th DAC**
Trichoderma sp	1.5	2.6	3	4.7	9
Sooty mould	2.5	5.2	6	4.4	0



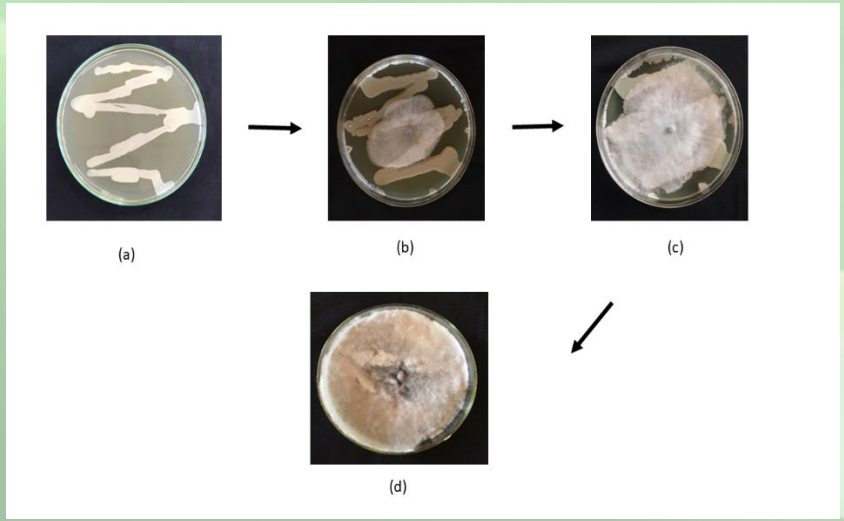


Plate 9: Gradual growth of *Trichoderma* in Dual culture with Sooty mould (a) 1 DAC (b) 2 DAC (c) 3 DAC (d) 4 DAC (e) 5 DAC

The colony of *Trichoderma* and Sooty mould grow normally without any interruption until the second day after inoculation. The third day Sooty mould mycelial growth is slightly inhibited by the *Trichoderma.* Because normally the growth of Sooty mould will reach 9cm after 3 days of incubation. but the mycelium was only reached 6cm and other spaces of the Petri dish was encroached by *Trichoderma*
Gradually *Trichoderma* was spread to the petri dish fully and suppress the sooty mould. Growth of Sooty mould in control is 9cm and the growth of Sooty mould in dual culture in 0. So the results revealed that the inhibition percentage of the *Trichoderma* to Sooty mould fungus is calculated as 100%. So the *Trichoderma* fully control the sooty mould. Sooty mould have the antifungal activity against many fungus through their mechanisms such as mycoparasitism, competition and production of antifungal compounds (Mukhopadhyay and Kumar 2020).

Evaluation of the antifungal activity of *Pseudomonas* species against sooty mould fungus

Table *6*: Day-by-day growth of Sooty mould in control and in *Pseudomonas* inoculated culture plate

	Colony diameter cm		
	1st DAC	**2nd DAC**	**3rd DAC**
Dual culture	2.7	5.2	9
Pure culture	2.9	5.8	9

Sooty mould culture was grown normally like the control one without any interruption in the dual culture . Within three days the fungus was grown fully to 9cm in diameter and covered the petri dish fully.There is no suppression effect of *Pseudomonas* for sooty mould fungus. So radial growth of the pathogen in control and the radial growth of the pathogen in dual culture were equal of 9 cm (0% inhibition).0. *Pseudomonas* inhibit many fungus species (Goswami et al. 2015). Due to the superficial growth and environmental conditions may be unsuitable for controlling of the sooty mould with *Pseudomonas* bacteria.

Abstract

Bean (*Phaseolus vulgaris*) is widely grown crops with high nutritional and commercial value that are staples on several continents. However, common bacterial blight (CBB), which is caused by *Xanthomonas axonopodis* pv. *phaseoli* is one of the most critical seed-borne destructive diseases of beans, having a major adverse effect on dry bean production, resulting in yield and quality losses. This study was conducted to examine the efficacy of biological control agents and a copper-based treatment in managing CBB under *in vitro* and *in planta* controlled conditions. In this study, various bacterial treatments, including *Bacillus subtilis* (Bs), *Pseudomonas fluorescens* (Ps), and a mixed treatment (Bs+Pf), were tested and compared to copper hydroxide (Ch) and control treatments. Disease incidence, disease severity index, and plant growth parameters such as plant height, number of leaves, root length, and weight, were evaluated to determine the effectiveness of each treatment. According to the results, there was a significant difference among treatments ($p<0,01$), as Bs demonstrated efficient *in vitro* inhibition (34.00 mm) and achieved 71% disease control in the *in planta* study. In the *in planta* study, the mixed treatment of Bs+Pf was the most significant among all treatments, reducing CBB to 10.33 and controlling the disease by 83.94%. Additionally, it inhibited the pathogen *in vitro* with a zone of inhibition measuring 23.66 mm. In comparison, Pf and the Ch control achieved 58.00% and 65.80% disease control, respectively. The mixed treatment yielded the greatest plant height (71.33 cm), while Bs produced the highest number of leaves (69.00) and the longest root length (19.00 cm). These findings underscore that integrating beneficial bacterial strains, particularly the combination of Bs and Pf, has strong potential as an eco-friendly alternative to pesticides for managing CBB in dry beans.

Keywords: *Xanthomonas axonopodis pv. phaseoli, biological control, Bacillus, Pseudomonas, bean*

Kuru Fasulyelerde Yaygın Bakteriyel Yanıklık Hastalığına Karşı Biyolojik Kontrol Ajanlarının Karşılaştırmalı Çalışması

Özet

Fasulye (*Phaseolus vulgaris*), birçok kıtada temel gıda maddesi olan, yüksek besin ve ticari değere sahip, yaygın olarak yetiştirilen bir üründür. Bununla birlikte, *Xanthomonas axonopodis* pv. *phaseoli*'nin neden olduğu yaygın bakteriyel yanıklık (CBB), kuru fasulye üretimi üzerinde büyük olumsuz etkiye sahip olan ve verim ve kalite kayıplarına yol açan, fasulyelerin en kritik tohum kaynaklı tahripkar hastalıklarından biridir. Bu çalışma, biyolojik kontrol ajanlarının ve bakır bazlı bir uygulamanın, *in vitro* ve *in planta* kontrollü koşullar altında CBB'yi yönetmedeki etkinliğini incelemek için yürütülmüştür. Bu çalışmada, *Bacillus subtilis* (Bs), *Pseudomonas fluorescens* (Ps) ve karışım bir uygulama (Bs+Pf) dahil olmak üzere çeşitli bakteriyel uygulamalar test edilmiş ve bakır hidroksit (Ch) ve kontrol uygulamalarıyla karşılaştırılmıştır. Her bir uygulamanın etkinliğini belirlemek için hastalık insidansı, hastalık şiddeti endeksi ve bitki boyu, yaprak sayısı, kök uzunluğu ve ağırlığı gibi bitki büyüme parametreleri değerlendirilmiştir. Sonuçlara göre, uygulamalar arasında önemli bir fark ($p<0,01$) bulunmuş, Bs *in vitro* da önemli inhibisyon göstermiş (34,00 mm) ve *in planta* çalışmada %71 hastalık kontrolü sağlamıştır. *In planta* çalışmasındada, Bs+Pf'nin uygulaması tüm uygulamalar arasında en önemli olanıydı, CBB hastalık şiddetini 10,33'e düşürerek ve hastalığı %83,94 oranında kontrol etmiştir. Karşılaştırma olarak, Pf ve Ch kontrolü sırasıyla %58,00 ve %65,80 hastalık kontrolü sağlamıştır. Karışım uygulama en uzun bitki boyunu (71,33 cm), Bs ise en fazla yaprak sayısını (69,00) ve en uzun kök uzunluğunu (19,00 cm) sağlamıştır. Bu bulgular, özellikle Bs ve Pf kombinasyonu olmak üzere faydalı bakteri türlerinin entegre edilmesinin, kuru fasulyelerde CBB'yi yönetmek için pestisitlere çevre dostu bir alternatif olarak güçlü bir potansiyele sahip olduğunu vurgulamaktadır.

Insights into the Apple Tree Microbiome: Determination of Pathogenic and Beneficial Bacteria

Sukriye Melis OZSARAC[1], Kubilay Kurtulus BASTAS[1,*]

Dept. of Plant Protection, Faculty of Agriculture, Selcuk University, Campus/Konya, Turkey
*Corresponding author: kbastas@selcuk.edu.tr

Abstract

In this study, the phyllospheric and rhizospheric microbiota of apple trees (***Malus domestica*** L.), one of the most significant crops in pome fruit cultivation, were investigated using a standardized sampling methodology. Genomic DNA was extracted from the collected samples utilizing the F-Spin Bacterial Fecal/Soil DNA Isolation Kit. Molecular identification was performed through the amplification of the V4 hypervariable region of the 16S rRNA gene using the primer set 533F-805R. In addition to molecular analyses, soil and leaf samples were cultured under laboratory conditions at the Molecular Plant Bacteriology Laboratory, Department of Plant Protection, Selcuk University, where biochemical characterization and pathogenicity assessments were conducted. According to the findings, the bacterial communities exhibited varying compositions across different orchards, with members of the phyla ***Proteobacteria***, ***Bacteroidetes***, ***Actinobacteria***, and ***Firmicutes*** being predominant. Importantly, several key apple pathogens were identified, including ***Erwinia amylovora***, ***Pseudomonas syringae*** pv. ***syringae***, and ***Rhizobium radiobacter***. The results suggest that the interactions between pathogenic and beneficial bacterial agents within the apple microbiota, under natural environmental conditions, differ across regions and climatic zones. These insights are anticipated to provide a foundational basis for the development of novel biological control strategies.

Elma Mikrobiyomuna Bakış: Patojenik ve Faydalı Bakterilerin Belirlenmesi

Özet

Bu çalışmada, yumuşak çekirdekli meyveciliğinin en önemli ürünlerinden biri olan elma (*Malus domestica* L.) ağaçlarından, standart örnekleme metodu kullanılarak filosferik ve rizosferik mikrobiyotasının incelenmesi amaçlanmıştır. Laboratuvara ulaşan örneklerden genomik DNA, F-Spin Bacterial Fecal/Soil DNA izolasyon kiti kullanılarak elde edilmiş moleküler tanılama 16S rRNA genine ait V4 bölgesi 533F-805R primer dizileri ile amplifiye edilmiştir. Toprak ve yaprak örnekleri aynı zamanda Selçuk Üniversitesi Bitki Koruma Bölümü Moleküler Bitki Bakteriyoloji Laboratuarında kültüre alınmış, biyokimyasal tanıları ve patolojik özellikleri belirlenmiştir. Elde edilen bulgulara göre; farklı bahçelerde farklı oranlarda Proteobacteria, Bacteroidetes, Actinobacteria ve Firmicutes'in hakim olduğu bakteriyel yapıda, başta *Erwinia amylovora*, *Pseudomonas syringae* pv. *syringae*, *Rhizobium radiobacter* olmak üzere önemli elma patojenleri de belirlenmiştir. Çalışma kapsamında, elma mikrobiyatasında belirlenen bakteriyel patojen ve faydalı bakteriyel etmenlerin doğal koşullarda etkileşimleri farklı iller ve iklimsel koşullar düzeyinde belirlenirken yeni biyolojik mücadele olanaklarının araştırılmasına da temel olacak sonuçlara ulaşıldığı düşünülmektedir.

Anahtar kelimeler: *elma, biyolojik kompozisyon, toprak, yeşil aksam, teşhis*

[2]Biosystems Engineering Department, Faculty of Agriculture, Van Yuzuncu Yil University, Van, Turkey

Abstract

Salinity is one of the greatest threats to global food security and is recognized as the largest source of abiotic stress in agricultural production. Rutin is a natural flavonoid found in advanced plants and has a stimulatory effect on the defense mechanism against abiotic and biotic stresses. This study conducted a pot experiment in a climate chamber to determine the effect of rutin flavonoid in lettuce plants under salinity stress. In the study, 4 saline water doses (0, 1.2, 2.4, and 3.6 dS m^{-1}) and control (Non-rutin) and 1 mmol L-1 rutin treatment (Rutin) were applied. Leaf dry matter content, electrolyte leakage, and relative water content were analyzed. As a result of the study, it was determined that increasing saline irrigation stress significantly decreased dry matter and leaf relative water content and increased leaf electrolyte leakage. On the contrary, rutin application alleviated the stress by significantly reducing electrolyte leakage. Based on the study's results, it is concluded that rutin application can be used as a stress mitigant for the sustainable commercial cultivation of lettuce.

Key Words: *Electrolyte leakage, Relative water content, Rutin, Salinity stress*

Introduction

Lettuce *(Lactuca sativa* L.) is one of the most widely consumed leafy vegetables and has significant economic value, especially in the restaurant and food processing sectors (Kim et al., 2016). It is becoming increasingly popular, especially among younger generations worldwide, where it is consumed as a significant ingredient in ready-to-eat meals. However, like other vegetable crops, lettuce production faces significant challenges due to salinity stress (Cakmakci et al., 2022; Gruda et al., 2024). Increasing salinity levels in soil and irrigation water worldwide significantly threaten agricultural production (Sahin et al., 2016). Increasing soil salinity, global warming, erosion of minerals, rising sea levels, and over-fertilization in agriculture contribute to the salinity problem. Also, decreasing arable land and agricultural productivity due to climate change threatens millions of people with poverty and under-nourishment (Pradhan et al., 2017).

In recent years, elicitors against stress factors have been widely recognized as a tested technological tool to improve quality and yield in agricultural production (Kazemi, 2014; Javanmardi and Akbari, 2016). Elicitors or biostimulants can be defined as substances that stimulate the defense mechanism in any plant, triggering or enhancing the biosynthesis of secondary compounds of nutraceutical value (Baenas et al., 2014; Gorni et al., 2021). Furthermore, biostimulants can improve plant growth by stimulating different physiological processes (Gorni et al., 2021). This comprehensive definition of stimulants includes both pathogen-derived substances (exogenous stimulants) and compounds released from plants by the action of the pathogen (endogenous stimulants) (Angelova et al, 2006). Rutin is an allelochemical of the flavonoid family, which is considered to be a plant-produced signaling molecule naturally found in developed plants, possessing antioxidant properties and stimulating the defense mechanism against biotic and abiotic stresses (Merewitz and Liu, 2019; Gorni et al., 2022). Rutin application promoted plant growth by reducing oxidative damage in quinoa and broad bean plants (Ismail et al., 2015). Rutin promoted plant growth by reducing oxidative damage in quinoa and broad bean plants (Ismail et al., 2015). Another study reported that rutin synthesis in grass promoted plant growth under heat stress and protected against stress (Merewitz and Liu, 2019). In addition, rutin is also known to play an important role in various physiological processes such as photosynthetic activity, energy transfer, UV protection, antibacterial activity, growth, and development in plants (Singh et al., 2017; Merewitz and Liu, 2019).

Based on the literature, this study hypothesized that rutin-treated plants under salinity stress conditions would increase plant growth and development and alleviate salinity stress damage. To test these hypotheses, the study aimed to determine the dry matter content, membrane damage index, and leaf proportional water content of rutin application under salinity stress.

Materials and Methods

Material

The experiment was carried out in the climate chamber of the Department of Horticulture, Faculty of Agriculture, Van Yüzüncü Yıl University. The experiment used standard lettuce (Lactuca sativa) as plant material. The temperature and relative humidity inside the climate chamber were monitored using an automatic weather station

(HOBO, Campbell Scientific INC., USA). The average daily temperature was 22±2 °C, and the relative humidity was 65±5 %. Lettuce seeds were sown in a randomised experimental design with three replications, producing 24 pots with four plants in each replicate.

Rutin and salinity treatments

In the study, 2 rutin (R) applications (R0: control; R1: 1 mmol L-1) were applied. Rutin in powder formulation was applied by foliar spray for three consecutive days (20 days after seed planting). For Rutin solution, Rutin was weighed on a precision balance, dissolved in methanol (10 mL), and finally added to 1000 mL of 0.02% Tween solution prepared with distilled water. Leaves of control plants were sprayed with water only.

For salinity stress, NaCl was applied as a saline water source. Threshold values and yield loss levels of lettuce plants were taken into consideration while determining salt doses (Ayers and Westcot, 1976; 1985; 1989). In the study, water with 4 different irrigation water salinities (Sw-0: 0.60 dS m^{-1}, control; Sw-1.2: 1.2 dS m^{-1}; Sw-2.4: 2.4 dS m^{-1}; Sw-3.6: 3.6 dS m^{-1}) were used. The salinity of the irrigation water was prepared and applied before each irrigation. Salinity applications started when the plants reached 4-5 true leaf stage.

Dry matter ratio (DM)

Lettuce leaves were separated from the stems, weighed to obtain fresh weight, and recorded. Subsequently, the same leaf samples were dried in an oven at 65°C for 48 h, weighed again, and obtained. The dry weight ratio to fresh weight was calculated to determine the plants' dry matter content (DM).

Electrolyte leakage (EL)

Electrolyte leakage was calculated by measuring the outflow of electrolyte from leaf cells (Shi et al., 2006). Samples taken as discs (10 mm diameter) from each plant leaf before harvesting were placed in 50 ml tubes containing 30 ml de-ionised water for 24 hours at room temperature, and then the electrical conductivity of the water in the tube was measured, and the EC1 value was obtained. Then, the tubes containing the sample were kept in a water bath at 95 °C for 20 minutes, cooled to room temperature, and the electrical conductivity of the water in the tube was measured again, and the EC2 value was obtained. Using the EC1 and EC2 values found, the electrolyte leakage (MZI) will be determined with the help of the following Equation.

$$EL = (EC1 / EC2) \times 100$$

Leaf relative water content (LRWC)

To determine leaf relative water content (LRWC), fresh weights (LFW) of leaf samples taken 10 mm in diameter before harvesting were weighed on a precision balance and recorded as LFW. Leaf turgor weights (LTW) were recorded by soaking the same samples in distilled water for 4 hours. Leaf dry weights (LDW) were determined by drying and weighing the samples in an oven at 65°C for about 48 hours. LRWC was calculated from the obtained weights using the following equation (Smart and Barss 1973, Ors et al., 2021):

$$LRWC\ (\%) = 100 \times (LFW - LDW)/(LTW - LDW)$$

Statical Analaysis

All multivariate analyses were performed with IBM SPSS Statistics version 21.0. One-way analysis of variance (One-way ANOVA) was performed for data comparison, and Duncan's multiple comparison test (at 0.05 % probability) was used to determine the differences between groups. All values were presented as mean ± standard deviation (SD).

Results and Discussion

Rutin treatments caused an increase in lettuce leaf dry matter ratio, but this effect was not found to be significant statistically (Fig. 1). The rutin increased dry matter ratio by 0.5% compared to control plants. On the other hand, the salt stress affected DM negatively, but these differences were not statistically significant. Also, 3.6 dS m-1 of saline water application decreased the dry matter ratio by 2%. No significant interaction was found between rutin and salinity treatments. The highest DM (93.4%) was found in control SW-0 and rutin-treated plants. Biostimulants play important roles in plant growth and development, and these properties can be associated with improving photosynthesis and carbohydrate accumulation in plants (Siddiqui et al., 2020; Gorni et al., 2020). An increase in leaf dry matter content was observed in lettuce plants treated with a 1 mmol L-1 dose of rutin. In a previous study, rutin application increased growth and development parameters such as leaf number, leaf area, fruit, and shoot weight in tomato plants (Gorni et al., 2022). Another study reported that exogenous application of rutin decreased total reactive oxygen species and improved the growth of rice plants (Singh et al., 2017). These responses may be related to increased photosynthetic activity (Hussain and Reigosa, 2016; Singh et al., 2017) and interaction with hormones (Hussain and Reigosa, 2014) and may be associated with increased dry matter in lettuce plants.

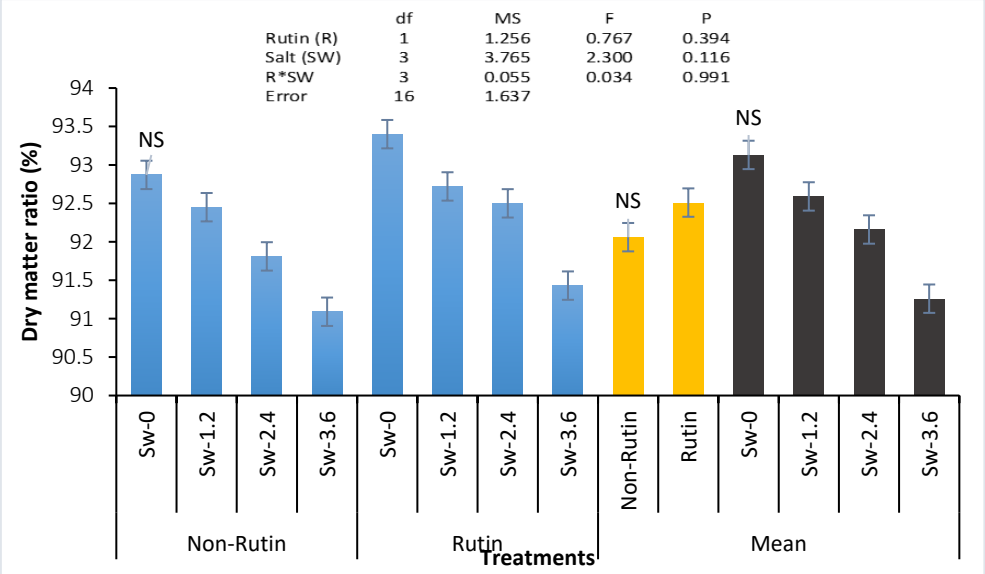

Figure 1. Effect of rutin treatment to dry matter ratio on lettuce plant under salinity stress. **Sw-0**: 0.60 dS m^{-1}, control; **Sw-1.2**: 1.2 dS m^{-1}; **Sw-2.4**: 2.4 dS m^{-1}; **Sw-3.6**: 3.6 dS m^{-1}. **R**: Rutin **Sw**: Saline water. Different letters indicate significant differences between treatments at P<0.05 according to Duncan's multiple range test. "NS" indicates not significant.

Electrolyte leakage (EL) value caused by oxidative damage caused by salinity stress was significantly decreased by rutin treatments ($p<0.01$) (Fig 2). Rutin application reduced the EL value by approximately 15% compared to the control. On the contrary, the EL value increased progressively with increasing saline irrigation applications. To clarify, Sw-1.2, Sw-2.4, and Sw-3.6 salinity stress treatments increased the EL value of lettuce leaves by approximately 1.5, 2, and 3-fold, respectively, compared to the control. Also, the interaction between rutin and saline irrigation treatments was not significant. In previous studies, applying rutin to bean leaves improved tissue tolerance, reduced the harmful effects of salinity on leaf photochemistry, and activated the antioxidant defense mechanism (Ismail et al., 2015). Another study demonstrated that exogenous application of rutin in corn seedlings alleviated the harmful effects of salinity stress (Muslu, 2024). These beneficial effects of rutin are attributed to improved potassium uptake and increased Na+ pumping rate from cells (Ismail et al., 2015). Additionally, rutin, a natural flavonoid, enhances antioxidant resistance by promoting the binding of free radicals. In this study, EL induced by salt stress was significantly reduced with rutin application, suggesting that stress was alleviated in lettuce leaves.

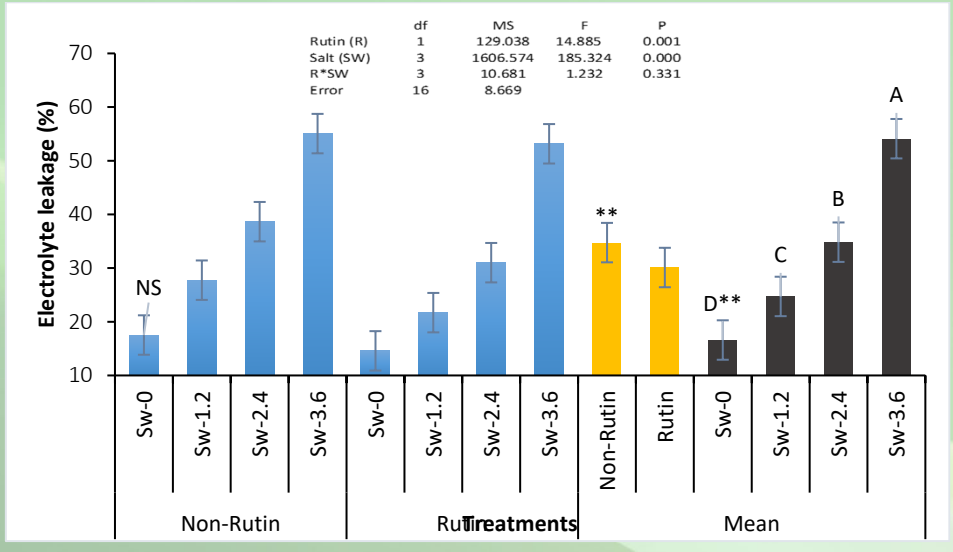

Figure 2. Effect of rutin treatment to electrolyte leakage on lettuce plant under salinity stress. Sw-0: 0.60 dS m^{-1}, control; Sw-1.2: 1.2 dS m^{-1}; Sw-2.4: 2.4 dS m^{-1}; Sw-3.6: 3.6 dS m^{-1}. R: Rutin Sw: Saline water. Different letters indicate significant differences between treatments at P<0.05 according to Duncan's multiple range test. "ns" indicates not significant.

Increasing doses of salinity treatments negatively affected leaf relative water content (LRWC) in lettuce leaves (Fig. 3). Increasing doses of salinity treatments negatively affected leaf relative water content (LRWC) in lettuce leaves. Salinity treatments at doses of 1.2 dS m^{-1}, 2.4 dS m^{-1}, and 3.6 dS m^{-1} decreased LRWC by about 4%, 11%, and 30%, respectively, compared to the control. On the other hand, rutin treatment increased LRWC by about 2% compared to the control, but this effect was not statistically significant. Furthermore, no significant interaction was found between rutin and saline irrigation treatments. LRWC is a valuable measure of the physiological water status of plants (Gonzalez and Gonzalez-Vilar, 2001). In this study, salt stress significantly reduced the LRWC of lettuce. Previous studies have demonstrated decreased LRWC values in lettuce under salt stress (Ekinci et al., 2012; Yildirim et al., 2015). As observed in the present study, the increase in LRWC is known as osmotic adjustment. Osmotic adjustment is one of the factors that can increase salt tolerance (Ashraf 2004; Raza et al. 2006).

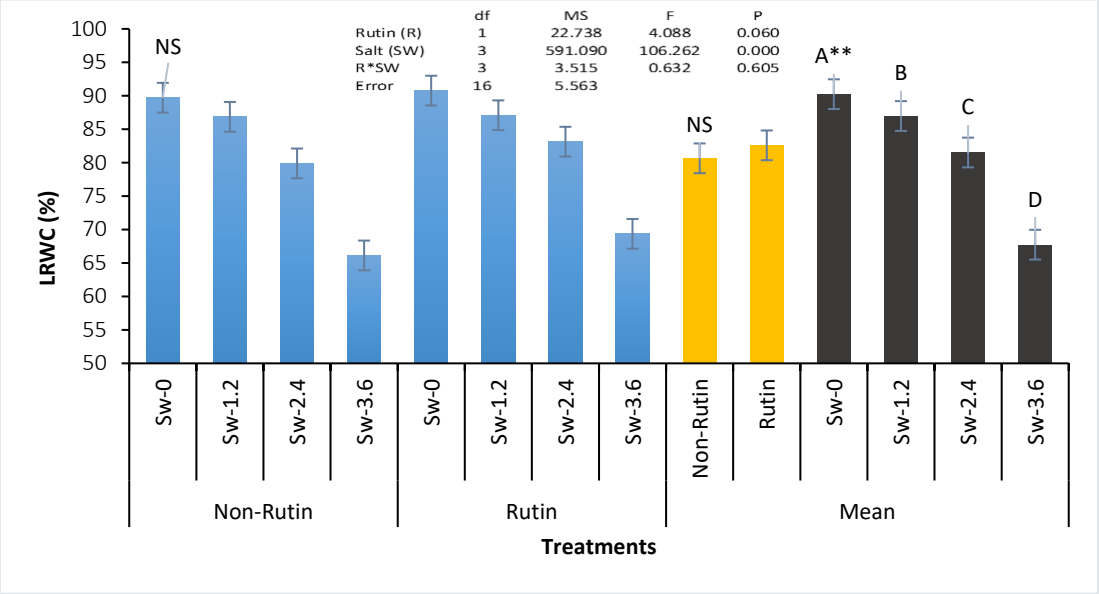

Figure 3. Effect of rutin treatment to leaf relative water content (LRWC) on lettuce plant under salinity stress. Sw-0: 0.60 dS m^{-1}, control; Sw-1.2: 1.2 dS m^{-1}; Sw-2.4: 2.4 dS m^{-1}; Sw-3.6: 3.6 dS m^{-1}. R: Rutin Sw: Saline water. Different letters indicate significant differences between treatments at $P<0.05$ according to Duncan's multiple range test. "ns" indicates not significant.

In summary, the present study concluded that the exogenous application of rutin had beneficial effects on lettuce plants and alleviated the damage caused by salinity stress. The data revealed that rutin promotes plant growth and increases the leaf dry matter content. Based on these results, the application of rutin in lettuce cultivation is recommended. Additionally, it is anticipated that rutin could be used as an alternative to biofertilizers to develop effective plant growth promoters and maximize their use under field conditions.

Abstract

Global agricultural systems are undergoing rapid transformation due to increasing food demand. Precision agriculture technologies such as GPS-guided machines, drone and satellite imagery, and IoT-based sensors have emerged as key solutions to optimize farming practices. These technologies increase crop yields, improve resource use efficiency, and support economic profitability. Thanks to these technologies, all processes are data-driven, facilitating decision-making. When all these features are considered together, it is obvious that they also promote environmental sustainability. However, access to these technologies is not the same in every country. Demonstrating the status of access to these technologies, especially in developing countries, will contribute significantly to studies on food security around the world. This review examines the impact of precision agriculture technologies on modern cropping systems, focusing on ways to provide precise control over water, fertilizer, and pesticides, thereby minimizing environmental impacts and input waste. The article also discusses the challenges that smallholder farmers face in adopting precision agriculture technologies, such as high initial costs and limited technological expertise. Recommendations are made to increase the accessibility of precision agriculture technologies through government funding, educational initiatives, and infrastructure improvements. Addressing these barriers is critical to the global adoption of precision agriculture.

Key Words: *Precision agriculture technologies1, Yield optimization2, Resource efficiency3, Sustainability3, GPS-guided machinery5*

Introduction

The agricultural sector is central in the global economy; mainly in the developing countries, it forms part of the economic bedrock. Nevertheless, these countries have various problems in the agricultural sector, such as food shortages, weak farmers' markets, inadequate infrastructure, and adaptive outcomes of climate change (Connolly-Boutin and Smit, 2015). With regard to the agricultural sector, the obstacles to development in the developing regions, including Nigeria, include factors such as low productivity and improved technology and techniques (Adeyemo *et al.*, 2024). The world's population in the future is expected to rise to 9 to 10 billion, and this requirement for food production for the future population calls for enhancements in agricultural productivity of between 60% and 99% (Seelan *et al.*, 2003). Agricultural development, on the other hand, has also accelerated environmental degradation in the last few decades, making the food security mission more challenging (Roberts *et al.*, 2021). A new idea called "smart farming" uses cutting-edge information technology to increase the effectiveness and efficiency of agriculture. The most recent developments in artificial intelligence, automation, and networking allow farmers to administer exact treatments that are decided by machines with superhuman accuracy and to monitor every procedure more effectively (Unal, 2020). For maximum crop yield and quality, smart farming techniques are incorporated into nearly every stage of the growing and even marketing processes. Agriculture production may now be enhanced because of smart farming techniques (Ünal and Kızıldeniz, 2023). The challenges facing the agricultural sector, particularly in the developing world, are daunting given increasing population and climate variability, coupled by scarcer resources. Such challenges have led to the adoption of better farming practices, which replace traditional farming practices. For these complex challenges, mainstream agricultural management strategies have been complemented by precision agricultural technologies, including new sensing tools and hi-tech ICT solutions (Loudjani, 2014). Based on the doctrine of 'getting more out of more', precision agriculture, which is also referred to as precision farming or smart farming, has the potential to reduce the agriculture difficulties encountered by the developing nations. The precision agricultural technologies would increase efficiency and enhance yields with the view to eliminating food insecurity as well as making primary production more sustainable (Erickson and Fausti, 2021). Precision agriculture technologies are employed at critical phases of the agricultural growth cycle, including soil preparation, seeding, crop management, and harvesting. Moreover, precision farming technology have not only helped agricultural and fruit cultivation but have also positively impacted livestock rearing practices. Precision agriculture can be categorised into two segments: precision crop farming, which involves the utilisation of precision farming technologies to address spatial and temporal variability for enhancing crop performance and environmental quality, and precision livestock

farming, which focusses on employing advanced technologies to maximise the productivity of each animal. The farmer seeks to attain improved outcomes in livestock production using this "per animal" methodology (Bucci et al., 2020). Precision crop farming and precision livestock farming are presently influenced by two predominant technical trends: big data and sophisticated analytics capabilities, alongside aerial images, feeding and milking robots, and intelligent sensors. This review article uses secondary sources to analyze various published reports and articles on precision agriculture in developing countries. It aims to provide a comprehensive overview of the topic, identify key findings, trends, and gaps, and propose effective implementation strategies. The review examines the role of precision technologies in increasing crop yields, their effects on resource efficiency, environmental benefits, economic impacts, and challenges and opportunities for future adoption in developing countries, with a particular focus on Nigeria. This paper therefore seeks to examine the adoption of precision agriculture technologies for the development of Nigeria and other developing countries. Specifically, it will draw attention to the difficulties, repercussions, constraints, and direction for applying these technologies. The study can be used as a reference for research and literature for both researchers and farmers to understand how to incorporate technology in the agricultural field.

2. Precision Agriculture Technologies

Precision agriculture has gained tremendous topicality when it comes to the discussion of the new generation of farming techniques. Through the use of GPS autonomously controlled machines, drones, satellite tools, and IOT sensors in cropping systems, information has been swiftly applied in the correct physical application of agricultural inputs with compromise to wastage or overapplication. Several precision technologies stand out in their contribution to modern cropping systems:

1. GPS-Guided Machinery: This was followed by advancements in planting, fertilizing, and spraying systems, which, with the help of GPS, can be sectioned very precisely. These tools provide a way of applying inputs in areas of need while avoiding overlaps and deficit areas. (Randal K. Taylor et al., 2013) study shows that GPS-steered systems help in increasing yields by 15% for crops like corn through consistent application of inputs.
2. Remote Sensing and Drones: Technologies such as drones and satellites allow for quick monitoring of details like crop condition, moisture levels in the soil, and much more. These insights help farmers to intervene whenever possible and probably reduce losses since all the available resources are optimally utilized.
3. IoT-Based Sensors: Some of the significant areas that relate to the use of Internet of Things (IoT) technologies include resource management, soil moisture, and environmental sensors. These sensors supply timely information in protracted intervals with respect to the soil status, hence useful in setting irrigation schedules. Using soil moisture sensors, (Lakhiar *et al.*, 2024) noted that there was a 30% saving of water used in agriculture, meaning that this was an environmental-saving method that also saved money.

2.1 Role of Precision Agriculture on Cropping Systems

Analysing these Precision agriculture technologies, they proffer several benefits to crop management i.e yield increase and better use of resources and environment. Precision yield management uses GPS-controlled application technology and related remote sensing tools for the accurate distribution of fertiliser, herbicide, or water. The distribution of required quantities at the right time benefits both crop yield and balancing the production process across various crops. Studies have shown that it leads to beneficial changes because crops require proper input to produce optimum yield (Sishodia, Ray and Singh, 2020; Lu *et al.*, 2022; Gawande *et al.*, 2023). In the field of resource utilisation and input, Precision agriculture technologies give basic information on the state of the soil, crops, and the general environment. It helps farmers in managing the resources such as water, fertilisers, and pesticides for increasing production and with least reproachable influence on the environment. Connected sensors for the specific and combined water and drone management offer precise procedures, which considerably decrease the wastage of farm resources and increase farm yield (Alahmad, Neményi and Nyéki, 2023; Rajak *et al.*, 2023). IoT technology might have a lot to offer the agricultural sector. To begin with, IoT gives farmers the ability to gather data in real time on the development and health of their crops, giving them important new information. This makes it possible to intervene proactively and make timely modifications to pest control, fertilizer application, and watering techniques. Second, by gathering comprehensive data on meteorological conditions, crop physiology, and growth patterns, IoT technologies improve the precision of yield prediction models (Kour *et al.*, 2024). As concerning the overall environmental impact, precision agriculture reduces the utilisation of agrochemicals as well as the utilisation of natural resources. Precision farming involves the application of a small amount of pesticides different from conventional methods, hence reducing pollution of soil and water. In this regard, they enable a higher or optimum eco-efficient, or least disruptive, yield per unit area relative to conventional practices (Gawande et al., 2023). These technologies have the attributes of tremendous promise for increasing the yield and also for protecting the environment in which farmers conduct their businesses.

2.2 Economic Implications

Precision agriculture technologies entail several advantages in the economic aspect. Although, implementation of precision technologies involves high initial capital investment the returns associated with investment is normally greater. The influx of precision agriculture technologies into a farming operation is often associated with gainful

heights, through the possible gains from subsequent input cutbacks and upticks in product yields. For example, GPS-controlled equipment enables the farmer to minimize seeding rates or overuse fertilizers due to costs of seeds and chemicals (Lu et al., 2022; Randal et al., 2013). Likewise, Smart technologies such as IoT sensors in farming improve irrigation, thereby reducing emission of water and, thus avoiding crop failure because of inadequate water (Rajak *et al.*, 2023).

Furthermore, the precise settings in precision agriculture result from data analysis, which makes it easier to anticipate and predict the ideal time and way of doing things within a farming season (Tantalaki, Souravlas and Roumeliotis, 2019). This ability can lead to more stable income levels, and decreased monetary volatility generally attached to agriculture especially with regard to climate turbulence and unfavourable weather conditions(Monteiro, Santos and Gonçalves, 2021).

2.3 Adoption of Precision Agriculture Technologies in Developing Countries

In developing countries, there are still many problems in agriculture, including low yields, ineffective resource management, and limited accessibility to modern inputs (Bjornlund et al., 2020). Precision agricultural technologies have the potential of reforming this terrain since they provide efficiency solutions to resource poor producers, boost productivity per unit area, and reduce environmental depletion (Balafoutis *et al.*, 2017). As used in many developing countries, high costs and a lack of technical knowledge have slowed the use of precision agricultural technologies, although some countries are starting to show the possibilities of how these technologies might help (Taylor, 2023).

3. Nigeria: A Case Study

Nigeria, with its complex agricultural practices and an increasing population, continues to embrace precision agriculture technologies with the aim of increasing food production and fixing food insecurity and climate change challenges, among others (Bolaji *et al.*, 2024). A number of approaches and pilot-action have been developed to introduce established technologies such as GPS-operated equipment, drones, and IoT sensors in small-holder producers (Ajewole and Oladipo, 2010). In Nigeria, study shows that machinery that utilises GPS is already applied in enhancing the land preparation, planting, and harvesting practices. With this technology, farmers can apply fertilisers or pesticides at the nearest probability, thereby cutting costs and equal amounts of waste (Abdullahi and Sheriff, 2017). For instance, in Northern Nigeria, where commercial farming of crops like maize, wheat, and rice is practiced on a on a large scale, GPS tractors are used for correct planting spacing as well as proper distribution of seeds and fertilizers (Kamai *et al.*, 2020). This has resulted in increased crop yields and decreased input costs for those farmers who can fund such technology. Some state governments have also collaborated with private firms to finance the purchase of GPS-equipped tools for smallholder farmers (Abdullahi and Kumar, 2022). The element of drone technology that has gained significant traction with farmers in Nigerian agriculture is in crop surveillance and pest eradication (Dinrifo *et al.*, 2022). The inspectors that are incorporated into these drones are designed to generate real-time feedback on the status of the crops, the condition of the soil, and the presence of threats from pests and diseases. The gathered information assists the farmers in decision-making processes such as whether and when to irrigate, apply fertiliser, or spray for pesticides. In the southern area of Nigeria, where cocoa and cassava farming are dominant, the apparatus is being employed in surveillance of large plantations (Wossen et al., 2017). In other areas, drones help the farmers to focus on where to make the application, thus increasing productivity and at the same time reducing the usage of agrochemicals. IoT-based sensors have been adopted in various pilot projects in Nigeria concerning water management, mostly in arid regions that receive little or no rain to support irrigation (Sharpe *et al.*, 2022). These sensors measure soil moisture content and inform farmers when to water their crops cross-sectionally. This has been experienced in the northern zones of Nigeria within vegetable production of smallholder farms using IoT sensors to regulate water consumption (Akpan-Etuk, 2024). Due to over irrigation and the use of rollers, the farmers have been able to save water and have healthy crops grown. Moreover, even international organisations like the Food and Agriculture Organisation (FAO) have been funding projects that augment the use of IoT technology in projects that encourage the use of water in regions that are most affected by drought.

3.1 Increased Yield

One of the greatest advantages of using precision agricultural technologies is the gradual augmentation of crop yield in precision agriculture. Precision agricultural technologies' adoption has the potential of reducing food insecurity because in developing countries like Nigeria, small-holder farms dominate the agricultural sector. These have been evidenced by yields of between 5 and 20 percent credited to technologies like GPS auto-steered planting equipment, satellite imagery, and other complementing precision farming technologies (Randal et al., 2013). Smallholder corn farmers in Nigeria who adopted GPS agriculture on planting practices recorded better seed placement, hence better competition for nutrients and water, hence better yields (Taylor et al., 2013). Furthermore, the use of drones proves useful in the development of developing countries as well. For pesticide spraying in the rice production in Nigeria, it has been observed that drones serve the purpose without underlining the crops and enhancing the growth and yield (Hafeez *et al.*, 2023). This is well applicable, especially in the developing countries where pest attacks and unfavourable crop handling are widespread. Drones not only open possibilities for the

efficient usage of pesticides but are also capable of recording the process and enabling farmers to act in a way that would increase productivity (Rejeb *et al.*, 2022). In other parts of Africa, precision agriculture technologies, in as much as they have been implemented appropriately, have resulted in increases in the yields in farming. This shows how precision agricultural technologies are not only recommendable but can also work to transform food production in areas of inadequate resources while helping farmers refine their decisions that would affect the productivity of crops.

3.2 Resource Utilization Efficiency

Enhancement of resource use productivity is the other advantage of precision agricultural technologies, especially for water-constrained and low-nutrient availability areas, common in developing nations. Smart embedded IoT soil moisture sensors and remote sensing technology enable water efficient application, and optimising the use of fertilisers greatly reduces the cost and is eco-friendly (Morchid *et al.*, 2024). Fields that grow vegetables in Nigeria utilising IoT sensors have seen the rate of watering decrease as data from the soil informs the farmers only when the watering is necessary (Douglas et al., 2016). This has led to the cutting down of water usage by 30%, meaning there is no hindrance in crop production (Rajak *et al.*, 2023). The same was the case with precision irrigation. In almond trees in California For at least 30%, water was saved while production rates were kept intact (Christian et al., 2012). It suggests that such countries facing the issue of water scarcity can adopt a policy of water conservation, a significant factor in most of the developing countries. In regions such as the northern part of Nigeria, which is faced with a scarcity of water, the use of IoT-based devices for irrigation has been identified as sustainable in the improvement of water use efficiency in agriculture (Familade et al., 2016).

In addition, there is an added advantage of precision agricultural technologies in that the application of the nutrients is made more accurate. Because several farmers in the developing countries fail to use fertilisers properly because of inadequate training, precision agricultural technologies enable costly fertiliser usage, therefore eliminating chances of nutrient leaching, which causes pollution. Numerous experiments have demonstrated the potential for the precision method of nutrient application to cut input costs by 10–25% on different farming practices, thereby increasing its profitability and efficiency (Hedley, 2015). This is especially relevant when cultivating crops and livestock in high-risk areas that impel smallholder farmers to work under severe budget constraints and with minimal capital.

3.3 Environmental Benefits

The technologies used in precision agriculture have a vital part in reducing the negative effects of concentrated agricultural activities on the environment (Getahun, Kefale and Gelaye, 2024). As these technologies allow input application to be targeted, these decreases the instances whereby fertilizers and pesticides are used in amounts that can pollute nearby ecosystems (Dehghani *et al.*, 2024). For example, (Wang *et al.*, 2019) showed that precision application of fertilizers lowered nitrogen leaching to a significant level, hence saving water bodies from pollution by nutrients. In addition, precision farming enables farmers to reduce the addition of inputs onto the soil, which has negative effects on the quality of the soil (Monteiro, Santos and Gonçalves, 2021) In the same way, agricultural Precision agriculture technologies also cause the carbon footprint of agriculture to be minimized through decreasing the usage of heavy agriculture tools and enhancing the wise utilization of natural resources in line with climate change (Sanyaolu and Sadowski, 2024).

3.4 Economic Gains

It has been realised that the adoption of precision agricultural technologies involves certain overall costs, which are nevertheless paid off in the long run by the stable advantages that are accorded to the shrewd users of these technologies of precision agriculture. A paper by (Munz and Schuele, 2022) shows that farmers who adopt precision technology use fewer inputs, produce many sellable outcomes, and therefore generate more revenues. As examples, IoT-implemented irrigation systems and GPS-navigated machinery have been proven to decrease input waste and increase operational efficiency and total yield. Comparative cross-sectional case studies indicate that it is possible to recover the initial investment cost of precision agriculture equipment in two to three years from the onset of pilot projects (Robertson et al., 2007). In the economies of developing countries such as Nigeria, the implication of precision agricultural technologies is observed in aspects of market prediction and management of agricultural businesses. Many IoT-based systems for irrigation, levee control, and GPS-based machinery have helped farmers in making intelligent decisions about the use of resources and better resistance to weather fluctuations (Familade et al., 2016).

This operational resilience results in a relatively stable income stream, which cushions the shocks that smallholder farmers generally experience due to climate change and poor physical infrastructure. Nonetheless, some studies have hypothesised that precision agricultural technologies may have positive effects on the economics of crops (Robertson et al.,2007; Munz and Schuele, 2022); nonetheless, numerous challenges persist for the application of Precision agricultural technologies, mainly because of the high costs of establishment, which are relatively high for final consumers and especially the smallholders in the developing countries. Precision agriculture technologies are capital intensive in terms of equipment, knowledge, and parts for maintenance, which most smallholder farmers cannot access. In sub-Saharan Africa, the majority of farmers practice small-scale farming, and, therefore, they are

unable to obtain capital and financing sources to purchase these technologies. This limiting factor reduces viability and causes an imbalance of access, with large-gain commercial farms and resource-poor smallholders. However, the expense of using precision technologies can aggravate their applicability in smallholder farmers' context: the cost of operation. Some of these technologies depend on internet connections, especially on infrastructure, which unfortunately is not a strong point in the rural areas of developing countries. With poor investment in infrastructure and technical support, the total economic benefit of precision agricultural technologies can plateau, and this is a disadvantage to the smallholder farmers. In order to overcome the above challenges, there require subsidies assumed by governments and/or international organisations or cheaper credits to support the development of precision agricultural technologies accessible to small farmers more easily. Moreover, joint initiatives of private entities, non-governmental organisations, and the government can ease actual cost restrictions by offering such options as shared technology or cooperation, allowing smallholders to buy precision technologies collectively without bearing the full expense. However, this is not all because the long-term strategic benefits of implementing precision agricultural technologies and betterment in economic prospects are positive signs. Appropriate qualitative financial and physical inputs assist in increasing smaller-holder farmer incomes, decreasing input costs, and improving yields, thereby bringing improvements in the economics of developing countries.

3.5 Challenges to Adoption

Despite benefits achievable through Precision Agriculture Technologies, which include higher yields, effective use of resources, and profitability, their uptake is limited by several constraints, especially in the developing world. These are mainly high initial costs, technology inaccessible, and poor infrastructure that hampers smallholder farmers as well as hinders wide implementation of precision agricultural technologies. The first and perhaps one of the main challenges is that the use of Precision agricultural technologies—GPS—to control machinery, IoT sensors, and drones, among other applications, is expensive to acquire and integrate (Talaviya *et al.*, 2020). These technologies demand large capital investments, most of which smallholder farmers in developing countries cannot afford (Say *et al.*, 2017). Despite the ability to lower input costs and ramp up profitability in the long run, the high up-front cost dooms most farmers to missing out on these opportunities. Now, there is no subsidy or funds from other independent sources for the small-scale farmers in the developing countries, such as Nigeria, to afford to purchase and maintain those precision technologies. A further issue is the difficulty of the technical know-how in terms of running and managing Precision Agriculture instruments. Smallholders in developing countries are often not trained enough to understand the data from GPS and IoT sensors and other modern tools (Tey and Brindal, 2012). Inadequate access to educational programs and agricultural extension services also enhances this problem because it becomes hard for farmers to optimally utilise precision agricultural technologies. It also helps to avoid adopting new technologies, as farmers are reluctant to spend money on instruments with which they are unfamiliar. Thus, lack of facility and the cost of acquiring and implementing precision agricultural technologies remain major impediments to their adoption in developing nations. Some of the precision agriculture technologies, especially those based on IoT technologies, depend on internet connectivity to operate efficiently. But in the remote and rural areas of the developing world, internet connections can be scarce or totally non-existent (Kumar *et al.*, 2024). This lack of fundamental investment complicates the application of technologies whose effectiveness depends on wired data links or real-time tracking, for example, IoT sensors to monitor irrigation needs or drone coverage for crop concerns. Besides, the existing transport and energy infrastructure in the rural areas poses additional challenges to the usage of precision agricultural technologies (Gbadamosi and Olorunfemi, 2016). Equipment like UAVs and tractors that form part of precision agriculture applications need to be powered constantly, an aspect that is always elusive in many developing countries. Lack of infrastructure and the relevant necessary equipment means poor application of the technologies that precision agriculture offers to farmers, mostly in rural areas. These challenges, in addition to a lack of equal access to technology and the possibility of uses of digital technology to augment and expand inequalities identified between large commercial farms and smallholder farmers, paint the future of African agriculture with potential inequalities. While large-scale, well-endowed farms are able to embrace and incorporate precision agricultural technologies, smallholder farmers, who could also benefit enormously from improved productivity, do not get service. Adoption of IoT technology in agriculture is not without its obstacles. One factor preventing IoT device adoption has been noted as being a lack of technical expertise. To properly integrate IoT technology into their agricultural methods, farmers might need assistance and training (Jabbari *et al.*, 2023). Meeting these challenges calls for collective action from governments, non-governmental organisations, and intergovernmental organizations. Subsidies—in the form of cash injection, cheap credit, or grants—could assist smallholder farmers to cover a major proportion of Precision agricultural technologies upfront costs. Also, expenditures on education and training would help farmers acquire the technical know-how to manage precise instruments productively. Lastly, sustainable advancement in rural physical capital, particularly internet and reliable energy, is important in improving the use of precision agriculture technologies in the developing countries.

4.0 Conclusion

The findings presented in this work highlight the prospects of the modern cropping systems based on the principles of precision agriculture. On this basis, Precision agriculture technologies demonstrate a progressive action plan that would lead to improved crop yields, better uses of resources and generally the sustainability of the environment

in agricultural production. Nevertheless, issues concerning the cost of implementing these technologies such as, infrastructure, or technical know-how affects the farming fraternity and should be dealt with, in order to make the realized benefits a reality at all levels of farming across the globe.

4.1 Recommendations

i. Government and Policy Support: Tax credit rebates or affordable interest rates on funds required for precision agriculture technology should be offered by governments. The Precision agricultural technologies should also feature in government food production, sustainable agriculture, and climate change policies.

ii. Training and Capacity Building: To operate and maintain precision devices, farmers require special education and training. Various farmers, with the help of agricultural extension services, universities, and international agricultural organisations can provide such programs.

iii. Infrastructure Development: Precision agricultural technologies that introduce the use of IoT require a stabilised framework; this consists of the internet. Therefore, expenditure in these technologies can yet aid the extension of rural digital facilities.

iv. Financing and Subsidy Models: Policies should also be proposed to supply capital for small farmers to purchase Precision agricultural technologies by cooperatives or through public, non-private partnerships. Asking to "premium" risks, small farmers could coordinate an order of precise technology and divide the gains in efficiency and productivity.

v. Research and Development: More studies should develop literature on how to improve Precision agricultural technologies acceptance, how to reduce the cost of the materials, and adapt them to the different production systems prevalent in the developing world. Second, empirical examination of the resilience of Precision agricultural technologies on power dynamics in the rural labour market and economy has to be done.

Abstract

Biotransformation technologies are one of the most promising fields in sustainable waste management, where farm and municipal waste is transformed into high-value bioproducts. This review explores the latest advances in microbial, enzymatic, and thermochemical processes that facilitate conversion of biomass and organic residues into bioenergy, bioplastics, biofertilizers, and bio-based chemicals. Scalable technologies such as anaerobic digestion, composting, fermentation, and gasification are emphasized with emphasis on process optimization and energy efficiency. The application of genetically engineered microbes and synthetic biology in enhancing conversion efficiency and product selectivity is examined. In addition, decentralized biorefineries are proposed as an economic model for circular bioeconomies to incorporate into local waste systems. The paper also examines key challenges that must be addressed, including heterogeneity of feedstock, microbial contamination, economic barriers, and policy uncertainty. Socio-economic and environmental impacts are evaluated using sustainability metrics and case studies from elsewhere. Future research directions stress the need for hybrid technologies, integrated systems, and real-time monitoring technologies in order to maximize the use of resources with the maximum possible efficiency and minimum possible environmental effects.

Keywords: *Anaerobic digestion, Bio-based products, Biorefineries, Biotransformation, Organic waste, Sustainable waste management*

Abstract
The exponential growth of electronic waste (e-waste) has become an urgent environmental and public health concern due to its toxic composition and propensity for illegal disposal. This review synthesizes e-waste generation, composition, and policy responses globally. It discusses the toxicological risks posed by heavy metals, brominated flame retardants, and persistent organic pollutants contained in the majority of end-of-life electronics. The paper then goes on to discuss emerging green technologies for e-waste recycling such as hydrometallurgical leaching, bioleaching, supercritical fluid extraction, and microfactory systems that minimize environmental damage while maximizing material recovery. It also explores the impact of producer responsibility, integration of the informal sector, and eco-design on the evolution of sustainable e-waste management systems. Global policies, for example, Basel Convention and WEEE Directive, are critically discussed alongside problems of transboundary dumping, informal recycling hazards, and inadequate public enlightenment. The article concludes by propounding multi-stakeholder frameworks towards creating secure, efficient, and equitable circular e-waste systems.
Keywords: E-waste, Toxicity, Recycling technology, Bioleaching, Producer responsibility, Circular electronics

Abstract
Nanotechnology has been a breakthrough technology in wastewater treatment and resource recovery because it possesses high surface area, reactivity, and selectivity in adsorption. This review discusses the most recent nano-enabled methods for the removal of contaminants including heavy metals, pharmaceuticals, pathogens, and microplastics from industrial and domestic wastewater. Nanomaterials such as carbon nanotubes, graphene oxide, metal-organic frameworks (MOFs), and magnetic nanoparticles are emphasized in the context of action mechanism, regeneration ability, and environmental safety. Hybrid systems that incorporate nanomaterials with membrane filtration, photocatalysis, and electrochemical treatment for optimal use are discussed in the article. Special consideration is given to the recovery of useful resources like nutrients and rare earth elements during treatment. Environmental risk assessment, regulatory barriers, and lifecycle concerns are also addressed to achieve responsible deployment and development of nano-based technology. This review concludes by proposing future directions such as green synthesis, AI-driven nano-design, and decentralized nano-filtration units for smart and sustainable wastewater management.

Keywords: Nanotechnology, Wastewater treatment, Nanomaterials, Resource recovery, Water purification, Environmental safety

Abstract

There is a growing body of psychological evidence that demonstrates the profound benefits of nature connection for human well-being and ecological action. This review paper discusses how environmental education generates ecological empathy and pro-environmental behavior through psychological mechanisms. Based on the synthesis of environmental psychology research, social cognition, and education science, the paper explores experiential change of nature-based learning experiences influencing children's and adults' sense of identity, emotional well-being, and ecological citizenship. Relevance includes forming biophilia, the role of sensory immersion, and cognitive reorganization achieved through experiential learning in natural settings. The article also examines barriers such as urbanisation, screen addiction, and socio-economic deprivation, which limit access to nature and undermine learning outcomes. Moreover, the paper examines how teachers, mentors, and role models are engaged in facilitating emotional connection to the environment. Through international case studies and educational programs analysis, the review demonstrates that fostering a psychological sense of nature connection improves not only environmental learning outcomes but also other mental health goals. The paper proposes that fostering ecological empathy through systematic and informal educational interventions is essential to facilitate progress in community and institutional sustainability transformations.

Abstract

The integration of ecopsychology into environmental education is a worthwhile approach to building sustainability by tapping cognitive knowledge and emotional affinity with nature. This review examines ecopsychological principles grounded on the human-nature relationship embedded within formal and informal curricula for ecological literacy and psychological wellbeing. The essay chronicles ecopsychology's evolution as well as the relevance of its framework in modern socio-environmental challenges of climate distress, eco-grief, and emotional detachment from the natural world. An integrative review of ecopsychological pedagogies such as mindfulness in nature, eco-art therapy, and reflective journaling shows their efficacy in building emotional resilience and environmentalism. Grounded on a multidisciplinary integration, this review shows how ecopsychological interventions in schools can initiate heightened awareness, sense of responsibility, and long-term commitment to taking care of the environment. It also presents case study examples from different learning environments—schools, universities, and community programs—highlighting their challenges and achievements. The paper concludes by proposing a model curriculum that incorporates ecopsychological approaches into sustainability education in order to connect the psychological and ecological dimensions of learning. Last but not least, this initiative instills a new paradigm for environmental education—one where students are empowered not only to know the environment but to experience and care for it.

Abstract
Phytoremediation has been acknowledged as an environment-friendly and cost-effective method for avoiding environmental contamination, particularly in contaminated soil and water. However, the plant uptake capacity limit and stress resistance limit prevent its large-scale application as a green technology. Current advances in genetic engineering offer promising answers to overcome these limitations through enhanced metal uptake, detoxification processes, and biomass yield. This review compiles the latest breakthroughs in molecular engineering, including CRISPR/Cas-mediated genome editing, overexpression of metal transporter genes, and transgenic insertion of antioxidant pathways. Omics tools such as transcriptomics, proteomics, and metabolomics have expedited the identification of novel gene targets associated with hyperaccumulation and resistance. Furthermore, synthetic biology is also enabling the development of modular genetic circuits to control phytoremediation reactions under different environmental conditions. The review also examines biosafety concerns, ecological impact, and regulation of genetically engineered phytoremediators. Overall, biotechnology application in phytoremediation not only increases its potential for remediation of the environment but also results in the development of circular and robust biotechnologies towards sustainable development across the globe.

Abstract

Rhizosphere is a dynamically biological interface where plant roots intimately interact with microbes in soil and form complex synergistic interactions influencing nutrient turnover and pollutant transformation. For phytoremediation, the plant-microbiome interface is also critical in controlling contaminant bioavailability and detoxification. This review highlights recent advances in the use of plant growth-promoting rhizobacteria (PGPR), mycorrhizal fungi, and endophytes to make phytoremediation more efficient. Some functions are microbial pollutant transformation, increased root surface area, induction of stress-responsive genes, and secretion of chelating agents. Microbiome engineering strategies like inoculation with pollutant-degrading bacteria consortia or microbiome transplant from stress-resistant ecosystems are also addressed in the review. Special emphasis is placed on microbial-assisted remediation of heavy metals, hydrocarbons, and emerging contaminants like PFAS. Future directions include metagenomics and synthetic microbial communities (SynComs) to address the manipulation of rhizosphere functions. Leverage and knowledge of such subterranean partnerships can lead to ecologically safe and highly effective phytoremediation processes.

Keywords: Rhizosphere, Microbiome, PGPR, Soil remediation, Mycorrhizae, Endophytes

Abstract

Constructed wetlands (CWs) leverage the phytoremediation potential of aquatic vegetation to remove polluted water through natural biological processes. This current review offers a comprehensive overview of different CW types—free water surface, subsurface flow, and hybrid systems—and their efficiencies in removing nutrients, pathogens, heavy metals, and organic contaminants. Special emphasis is laid on the selection of appropriate macrophytes such as *Phragmites australis*, *Typha latifolia*, and *Eichhornia crassipes* with elevated uptake and tolerance capacity. The mechanisms of pollutant removal are through sedimentation, root zone filtration, microbial breakdown, and uptake by the plant. Urban landscape and agriculture landscape case studies highlight efficient CW usage in wastewater treatment, stormwater management, and industrial effluent regulation. The integration of CWs with green infrastructure and urban planning is a term used to explain a sustainable decentralized wastewater treatment system. The invasiveness of plants, seasonality, and long-term maintenance issues are also clarified. CWs present an environmentally friendly, low-energy, and cheap option in congruence with water security and sustainable development strategies.

Keywords: Constructed wetlands, Aquatic phytoremediation, Macrophytes, Wastewater treatment, Green infrastructure, Nature-based solutions

Abstract
Hyperaccumulator plants possess the unique ability to absorb exceptionally high concentrations of heavy metals without exhibiting any symptoms of phytotoxicity. This property renders them strong candidates for phytoextraction and phytomining—ecological technologies for the remediation and resource recovery. This review chronicles the latest advances in the discovery, cultivation, and commercialization of hyperaccumulator species such as *Alyssum murale* and *Noccaea caerulescens*. Principal physiological traits, including metal transport mechanisms, chelator production, and vacuolar sequestration, are described. Novel field trials indicate the potential for nickel, cadmium, and rare earth element recovery in mining and post-industrial settings. Economic assessments indicate that phytomining could yield economic advantages to land owners and restore poor soils. Agronomic management, harvesting technologies for increased metal uptake and yield, and soil amendments are also presented in the review. As global demand for critical minerals rises, hyperaccumulators offer a sustainable option to conventional mining, fitting environmental rehabilitation alongside economic viability.

Keywords: Hyperaccumulators, Phytoextraction, Phytomining, Critical minerals, Soil remediation, Resource recovery

Abstract

As the list of environmental pollutants increases, phytoremediation is faced with new challenges in the remediation of recalcitrant and complex emerging pollutants such as pharmaceuticals, personal care products (PPCPs), per- and polyfluoroalkyl substances (PFAS), and microplastics. Traditional remediation techniques are often not effective in removing these compounds from the environment, whereas phytoremediation is a green and sustainable option. This review provides a current synthesis of how some plant species can take up, degrade, or immobilize such emerging contaminants. The emphasis is placed on the processes of phytotransformation, phytodegradation, and rhizodegradation, particularly in riparian and wetland ecosystems. The synergistic role of rhizosphere microorganisms in the degradation of complex chemical compounds is discussed. Case studies demonstrate success with *Vetiveria zizanioides*, Populus spp., and *Lemna minor* species for reducing contaminant load in wastewater and river sediments. The challenge of bioaccumulation, toxicity of metabolites, and detection by analysis are addressed, and suggestions for future research on transgenic and hybrid systems are made. Phytoremediation is shown to be an intriguing solution for combining environmental rehabilitation with contaminant-specific detoxification strategies.

Keywords: Emerging contaminants, PFAS, Pharmaceuticals, Microplastics, Phytodegradation, Wastewater treatment

Abstract

Nanotechnology is revolutionizing phytoremediation by enhancing plant-microbe interaction, pollutant bioavailability, and detoxification mechanisms. This review examines the synergistic potential of combining nanoparticles with plants for promoting the uptake and degradation of heavy metals, pesticides, and organic pollutants. Engineered nanoparticles such as nano-iron, nano-TiO_2, and carbon-based nanomaterials are shown to trigger root exudates, enhance enzyme activities, and modulate redox conditions in the rhizosphere. The review also discusses nanoparticle-mediated delivery systems for plant growth regulators and microbial inoculants. Problems of nanoparticle toxicity, persistence, and ecotoxicological impacts are viewed critically. Case studies demonstrate the effectiveness of nanotechnology-enhanced systems over classical phytoremediation systems in contaminated soils, water, and sediments. This combinatorial concept opens new fields in environmental nanobiotechnology and offers promise for real-time site-specific remediation with improved efficacy and control.

Keywords: Nanotechnology, Nanoparticles, Hybrid phytoremediation, Nano-iron, Environmental nanobiotech, Plant-nano interactions

Abstract

Degradation of soil due to heavy metal contamination and industrial effluents is a critical threat to soil fertility, microbial diversity, and ecosystem services. Phytoremediation, in addition to removing pollutants, can restore soil health by improving physicochemical properties and enhancing biological activity. The review discusses how phytoremediation influences soil pH, organic carbon, and nutrient cycling, leading to microbial biomass development and enzymatic activities being enhanced. Brassica juncea and Helianthus annuus are some of the plants that facilitate recolonization by microbes as they exude sugars, amino acids, and secondary metabolites that promote microbial growth. Co-remediation strategies like composting, biochar, and microbial consortia are also addressed. Such treatment has the potential to facilitate soil recolonization, trigger plant-facilitative microbe interaction, and increase crop productivity following remediation. Soil health indicator monitoring is highlighted in phytoremediation assessment protocols. By establishing a biologically active and resilient microbial community in the soil, phytoremediation can be an integral part of sustainable land management and ecological rehabilitation.

Keywords: Soil fertility, Microbial diversity, Soil enzymes, Co-remediation, Soil health, Land restoration

Abstract
The largest enclosed inland water body in the world, the Caspian Sea, is undergoing unprecedented change due to climate change, local hydrological perturbations, and anthropogenic stressors. This review presents an extended critique of how climate-related changes—though temperature changes, precipitation regimes, evaporation rates, and river inflows—are reshaping the hydrology and ecology of the Caspian Sea basin. Long-term satellite data and hydrological models predict alarming sea level drops, threatening coastal ecosystems, biodiversity, and infrastructure. Southern and eastern littoral zone ecosystems are particularly vulnerable, with migratory bird species, endemic fish, and benthic communities being more susceptible to habitat destruction, salinization, and pollution concentration. Socioeconomic effects include the disruption of fisheries, port infrastructure, agriculture, and traditional livelihoods. Furthermore, reduced water run-off from big rivers such as the Volga, Kura, and Ural, coupled with damming and irrigation, intensifies basin-wide water stress and geopolitics tension among littoral states. This review also investigates the feedback mechanisms relating climate change to sediment transport, wetland shrinkage, and invasive species proliferation. Significantly, it highlights knowledge gaps and emphasizes the need for regional climate-resilient policy, transboundary cooperation, and investment in early warning systems. Adaptive measures such as integrated water resource management (IWRM), nature-based solutions (NbS), and ecological restoration of deltas and wetlands are proposed as pathways toward mitigation. Overall, the Caspian Sea is a vulnerable socio-ecological system where climatic change, human activity, and governance intersect—calling for cooperative, multidisciplinary action.

Keywords: Caspian Sea, climate change, hydrological alteration, loss of biodiversity, regional cooperation, resilience of ecosystems

Abstract

Aflatoxins, highly toxic and carcinogenic Aspergillus-produced mycotoxins, represent a global threat to world food safety and public health. Recent biotechnology and nanotechnology advances hold auspicious opportunities for aflatoxin detection and detoxification. Molecular detection techniques, including enzyme-linked immunosorbent assay (ELISA), polymerase chain reaction (PCR), and new biosensors, have dramatically improved aflatoxin detection speed and sensitivity in foodstuffs and feed. These technologies and new nanomaterials, including nanoparticles, carbon nanotubes, and graphene oxide, are fast becoming potent tools for aflatoxin extraction from tainted foodstuffs and agricultural crops. Nanomaterials possess unique features such as high surface area, functionalization, and reusability, which enable more efficient and sustainable detoxification processes. Moreover, nanomaterial-based systems can also be employed in food packaging and storage systems to reduce aflatoxin contamination. In this review, the latest molecular techniques and the potential of nanotechnology in aflatoxin detoxification are highlighted, as well as a general overview of their application in food safety, environmental monitoring, and agricultural sustainability. By examining the unique advantages of nanomaterials, this paper highlights the potential for scalable, cost-effective solutions to prevent aflatoxin contamination at large scales.

Keywords: Aflatoxins, molecular detection, biotechnology, nanomaterials, biosensors, detoxification.

Abstract

Bioremediation, utilizing microorganisms and enzymes to degrade toxic pollutants, has proven an effective method of minimizing aflatoxin contamination. This article focuses on new developments in the microbial degradation of aflatoxins, explaining the function contributed by bacteria, fungi, and yeast strains to the degradation of such toxic compounds by enzymatic mechanisms. Individual enzymes such as cytochrome P450 monooxygenases, laccases, and peroxidases are essential to aflatoxin detoxification, catalyzing the conversion of aflatoxins into non-toxic metabolites. Microbial consortia synergistically degrading aflatoxins have also been shown with greater efficiency compared to individual species. Recent developments in enzyme engineering and synthetic biology may further improve the effectiveness of bioremediation by producing more stable and targeted enzymes for aflatoxin degradation. The review also takes into account the factors influencing the process of bioremediation, including environmental factors, nutrient availability, and microbial community dynamics. Besides, problems such as scalability and effectiveness of such methods in real field conditions are also addressed, with the solutions being microbial consortia and genetic engineering. A comprehensive review of the microbial and enzymatic methods of aflatoxin degradation has been given in this paper, highlighting their sustainability and eco-friendliness as effective alternatives to chemical detoxification processes.

Keywords: Bioremediation, aflatoxins, microorganisms, enzymes, degradation, detoxification.

Abstract

Aquatic ecosystems are increasingly threatened by the emergence of newly industrializing pollutants such as personal care products, pharmaceuticals, and endocrine-disrupting chemicals. The majority of these pollutants are not effectively removed by traditional wastewater treatment and accumulate in rivers, lakes, and coastal waters, posing gigantic threats to aquatic organisms and human health. This review addresses the monitoring of newly identified pollutants in aquatic environments, focusing on the use of advanced analytical techniques, such as liquid chromatography-mass spectrometry (LC-MS) and high-resolution mass spectrometry (HRMS), for the identification of trace concentrations. It also addresses the risk assessment of these contaminants, with emphasis on the challenges in assessing their long-term environmental and ecological impacts. Green remediation technologies, such as phytoremediation, bioremediation, and natural sorbents, offer green alternatives to chemical remediation. The overview presents a comprehensive overview of the effectiveness and limitations of these technologies, with focus on applicability for large-scale use in industrial settings. Furthermore, the application of bioindicators in assessing ecosystem health as well as pollutant bioaccumulation is addressed. This article ends by urging for holistic monitoring and remediation models that combine cutting-edge technologies with green approaches to address the new challenges posed by industrial contaminants in aquatic ecosystems.

Keywords: Industrial contaminants, aquatic ecosystems, monitoring, risk assessment, green remediation, bioindicators.

Abstract

Geohealth is a new interdiscipline of study that investigates how geological conditions affect public health and ecosystem integrity. This review takes into account the ways in which the fabric and composition of geological substrates—mineralized rocks, volcanic soils, sedimentary basins—can influence environmental quality and, consequently, human health. Natural impurities like arsenic, fluoride, and heavy metals typically have geogenic sources and leach into groundwater or concentrate in agricultural products, thus inflicting long-term health issues like carcinogenesis, fluorosis, and organ damage. In industrial belts and mining regions, anthropogenic activities are likely to initiate geological vulnerabilities, releasing toxicants that enhance environmental and health hazards. By using examples of case studies from Iran, India, and Sub-Saharan Africa, this paper provides regional variation in geological exposure to risk. New advances in geo-mapping, remote sensing, and isotopic fingerprinting now enable accurate spatial correlation of geologic substrates with disease clusters for early intervention. Further, the inclusion of geological data in environmental risk models enhances the accuracy of ecosystem health assessment and land-use planning. This review proposes a geohealth strategy based on cross-sectoral collaboration among geologists, ecologists, and public health experts to predict and mitigate environmental hazards. The novelty of this work lies in its emphasis on proactive integration of geological data into health monitoring systems, policy, and climate adaptation planning.

Keywords: Geohealth, geological substrates, environmental risk, heavy metals, groundwater, disease mapping.

Abstract

Soil is an integral part of the global carbon cycle and a key factor in climate regulation. This review identifies regenerative soil management (RSM) as a revolutionary approach under climate-resilient agriculture for increasing soil carbon sequestration, restoring degraded lands, and developing resilience against environmental stresses. Leading RSM practices—such as conservation tillage, agroforestry, biochar incorporation, green manuring, and composting—not only improve soil structure and soil fertility but also allow for long-term stabilization of atmospheric CO_2 in soil organic matter. Developing studies indicate that RSM can potentially raise soil organic carbon (SOC) content by up to 1.5% annually, which is a considerable input towards global climate change mitigation goals. The review also brings to the fore the central role played by soil microbiota, particularly arbuscular mycorrhizal fungi, in facilitating carbon stabilization and nutrient cycling. Cutting-edge predictive tools, including RothC and CENTURY models, provide strong frameworks for simulating SOC dynamics under various regenerative scenarios. However, widespread scaling up of RSM is constrained by insecure land tenure, low farmer uptake, and policy support deficits. This review suggests the incorporation of RSM in national climate action plans, sustainable development agendas, and carbon trading schemes. Notably, it provides a region-specific analysis of the feasibility of RSM in arid and semi-arid areas, where it has immense potential in reversing desertification, improving soil health, and supporting food security. The novelty of this study is its integrative approach that connects biophysical processes and socio-economic enablers to demonstrate the co-benefits of soil rejuvenation for climate resilience, biodiversity conservation, and rural livelihoods.

Keywords: Regenerative agriculture, soil carbon, carbon sequestration, climate change, agroecology, land restoration.

Abstract

Arid and semi-arid regions face enhanced food insecurity due to rising climate variability, land degradation, and water scarcity. Climate-smart agriculture (CSA) has an integrated approach to enhancing the environment sustainability, productivity, and resilience of crops under such tight conditions. From this review, CSA strategies, including precision irrigation (e.g., drip irrigation system), drought-tolerant cultivars, conservation agriculture, mulching, and organic soil manures, improve soil retention capacity, reduce erosion, and stabilize yield under changing climate. In addition, soil microbiome enhancement through the use of biofertilizers and microbial consortia is an area to advance drought resistance. Case study-based context-specific adaptations in Iran, the Sahel, and the Indian Thar Desert are highlighted, such as zai pits, sand mulching, and fog-harvesting. The review also mentions the deployment of digital agriculture—remote sensing, artificial intelligence-based weather forecasting, and sensor-based monitoring of soil—to enable decision-making. Socio-economic barriers to CSA adoption, including access to finance, knowledge transfer, and land tenure insecurity, are examined. Policy frameworks for inducing CSA using incentives, extension, and integrated watershed management are also discussed. The importance of context-specific and participatory approaches to CSA is discussed in this paper. Its novelty lies in the integration of indigenous ecological insights with new climate-resilient technologies for adaptive capacity building and food system resilience in risk-prone lands.

Keywords: Climate-smart agriculture, soil resilience, arid lands, drought adaptation, precision farming, microbial biofertilizers.

Abstract
Technology involve in encapsulating nutrients is one of the reliable tools in ruminant nutrition that provide a better way in which nutrients are efficiently utilized, animal performance enhancement with a minimal negative effects to the environment. This study reviews the economic and practical implications of nutrient encapsulation in ruminant nutrition with an emphasis on its potential in bioactive compounds protection, controlled release of nutrients and feed efficiency improvement. Despite the benefits incorporation of encapsulation technology in ruminant nutrition brings such as sensitive nutrients stability enhancement and their systematic delivery in the ruminant digestive system, its uses in ruminant nutrition is associated with scalability limitation, high costs and practical challenges. The costs involved in encapsulation is higher when compared with the conventional additives because of the complexity of the materials involved in processing. Its integration relied on production scalability, stable storage and conformity with traditional feeding. Its economic feasibility depends on its importance in the performance and health of ruminant animals, or its environmental impact. Challenges involved in its practical application include consistency, technical know-how, and variability in performance of encapsulated products. Further researches are very important to reduce the costs and improve its delivery. Therefore, the encapsulation technology advancement in ruminant nutrition is reliant on achieving a balance between innovative solutions, cost-effectiveness and implementation practically at the farm level.
Keywords: Encapsulation, Economic, Costs, Ruminant, Nutrition

Introduction

Ruminant animals plays important in maintaining global food security, by providing meat, milk and other products that care for human nutrition (Xie et al., 2021). Nevertheless, the ruminant production is faced with several challenges such as inefficiencies in nutrient use, pollution to the environment, and rising costs related to feed. Therefore, enhancing feed efficiency and reducing losses of nutrients are very vital in ensuring ruminant production sustainability and productivity.

Encapsulation technology improves ruminant nutrition in a way of protecting and ensuring the targeted delivery of additives in feed. The process include enclosing the nutrient or additive in a protective layer of material ensuring that it bypass the rumen to the targeted digestive site (Garba & Fırıncıoğlu, 2023). It also ensures that unpalatable odors of the additives are masked and also protect sensitive nutrients and additives from degradation (Wei et al., 2022).

Studies from previous researches suggested the possible importance of encapsulation in improving ruminant nutrition. Example rumen protected amino acids (lysine, methionine) encapsulation was reported to improve milk production and synthesis of protein in dairy cattle (Zanton et al., 2014). Also the encapsulation of polyunsaturated fatty acids has been reported to increase their chances of integration into milk and meat without compromising rumen function (Jenkins et al., 2008). Encapsulation was also used to protect probiotics, enzymes, and phytogenic additives therefore, improving their efficiency and stability in ruminant diets (McAllister et al., 2011).

Encapsulation technology methods such as spray drying, coacervation, and extrusion have presented a wide range of application in ruminant nutrition. For example, encapsulation by spra-drying was used to protect essential oils which possesses an antimicrobial properties from rumen degradation (Benchaar et al., 2015). Coacervation encapsulation method was also used to protect vitamins and minerals ensuring their stability and bioavailability in diets of ruminant animals (Sanchez et al., 2017).

However, despite all these developments, there is a limited adoption of encapsulation technology in ruminant nutrition. With high costs of production, scalability and performance of encapsulated products variability, the commercialize application of these technology is difficult. There is also lack of standardized methods for evaluation of economic feasibility and efficiency of encapsulation technologies in ruminant nutrition.

While the potential benefits of encapsulation in ruminant nutrition are well-documented, several knowledge gaps remain. First, there is limited understanding of the interactions between encapsulation materials and rumen microbes, which can influence the release and utilization of encapsulated nutrients. Second, the long-term effects of encapsulated products on animal health and productivity require further investigation. Third, there is a need for cost-benefit analyses to evaluate the economic feasibility of encapsulation technologies in large-scale ruminant production systems. Finally, the environmental impacts of encapsulation materials and processes have not been thoroughly assessed.

The purpose of this paper is to provide a comprehensive review of the economic and practical considerations of encapsulation in ruminant feeding systems. By synthesizing existing literature, this paper aims to identify key factors influencing the efficacy and feasibility of encapsulation technologies, highlight potential challenges, and propose future research directions to optimize their use in ruminant nutrition.

Encapsulation Technology

Encapsulation is a technology in which nutrients, bioactive compounds and other nutrients components are enclosed in a protective coat or matrix. The technology is important in ruminant nutrition because of its ability to allow a targeted deliverance of vital feed and nutrients bioactive components and protecting them from rumen degradation hence ensuring their release in the lower digestive tract (Garba & Fırıncıoğlu, 2023). Biovailability, stability and efficiency of nutrients can be improve by encapsulation leading to the overall animal performance improvement and minimal environmental effects (Garba & Fırıncıoğlu, 2023).

Diiferent methods of encapsulation have been reported with each showcasing a promising advantages. Spray drying is particularly employed for heat sensitive compounds like essential oils, vitamins and probiotics through forming a dry particles often rapid drying (Ré, 1998). Coacervation is used for hydrophobic compounds such as fatty acids in which a separate colloidal phase is used to encapsulate the substances (Dong et al., 2011). Extrusion works for enzymes and probiotics (Kailasapathy, 2002). Liposome encapsulation technique uses lipid bilayers to enclose sensitive nutrients like vitamins (Mozafari et al., 2008), while emulsion-based methods help stabilize PUFAs and lipids (McClements, 2012).

Encapsulation of rumen protected methionine and lysine was reported to boost milk yield and milk protein content in dairy cows (Zanton et al. 2014). PUFAs encapsulation also enhance their transfer into milk and meat without compromising rumen function (Jenkins et al., 2008). This technology also allows for controlled nutrient release, improving absorption. Encapsulated starch, for example, provides post-ruminal energy, supporting better growth in beef cattle (Huntington et al., 2006). Additionally, encapsulation safeguards probiotics and enzymes, enhancing their stability and effectiveness. Protected probiotics have been shown to improve rumen health and overall animal performance (McAllister et al., 2011). Phytogenic additives such as essential oils often degrade in the rumen, but encapsulation ensures they reach the lower digestive tract intact, maximizing their antimicrobial and antioxidant benefits (Benchaar et al., 2015).

Economic Considerations

Production Costs: The high production costs associated with the implementation of encapsulation process is one of the factor that hinder its widespread adoption in ruminant nutrition especially by the small scale farmers (Xie et al. 2021). These high costs result from the complex nature of the encapsulation process because of the need for a specialized equipment and machines and the encapsulation materials (Xie et al., 2021). For example high quality lipids or polymers to be used in encapsulation can increase costs of production tremendously (Sánchez et al., 2017).

Cost-Benefit: Encapsulation allows nutrients such as amino acids, vitamins, minerals, enzymes, and probiotics to bypass rumen degradation and be released at optimal sites in the digestive tract. Nutrient bioavailability is increased by the target delivery which leads to better conversion of feed, weight, and milk production (Almassri et al. 2024: Garba & Fırıncıoğlu, 2023). Feed accounts for up to 70% of total cost of production in ruminant nutrition, therefore any improvement in feed efficiency can save cost and increase profit (Almassri et al. 2024). While encapsulation technologies can improve nutrient utilization and animal performance, their economic viability depends on the cost-benefit ratio. For example, the use of rumen-protected amino acids may be economically justified in high-producing dairy cows but not in low-producing animals. Similarly, the cost of encapsulating essential oils or probiotics must be weighed against the potential benefits in terms of improved animal health and productivity (Benchaar et al., 2015).

Scalability: Another important factor that influence the economic feasibility of encapsulation technology in ruminant nutrition is scalability, even though there is a cost effectiveness in a laboratory-scale encapsulation procedures, scaling up the processes for commercial production pose a challenge and it is expensive. For example, the production of encapsulated probiotics or enzymes on a large scale requires specialized equipment and stringent quality control measures, which can increase production costs (McAllister et al., 2011).

Practical Considerations

Technical challenges: The implementation of encapsulation technology in ruminant nutrition is faced with challenges involving the technical know-how including the appropriate encapsulation material selection, encapsulation process optimization and product stability and efficiency evaluation. The encapsulation material choice have effect on the release rate of the compounds encapsulated which also affects its efficiency in the rumen (Sánchez et al., 2017).

Variability in Performance: Encapsulation material type, size and structure of capsules, rumen condition are the factors that influence the performance of the encapsulated products. This variability makes it difficult to determine

the encapsulated products efficiency in different feeding systems. McAllister et al. (2011) reported that probiotics encapsulated efficiency may vary depending on the rumen microbial activity and pH.

The impacts of encapsulation materials and process on the environment have not been thoroughly evaluated. Biodegradability and environmental persistence as a result of the use of synthetic polymers as an encapsulation material may raise environmental concern. The production of encapsulation materials may also generate waste and emissions leading to environmental pollution (Sánchez et al., 2017).

Conclusion

Encapsulation technology offers several importance in ruminant nutrition such as improved nutrient utilization, animal performance enhancement and minimal environmental impacts. Nevertheless, its adoption in ruminant nutrition is hindered by high costs of production, technical know-how, and limited scalability. It's recommended that future studies should focus on finding and developing a cost-effective and scalable encapsulation processes, long-term effects of encapsulated products on animal health and productivity evaluation as well as evaluating the impacts of encapsulation material and processes to the environment

Abstract

Over the last decade, there has been a surge of interest in natural feed additives as sustainable alternatives to antibiotics in poultry nutrition. The global restriction on the use of antibiotic growth promoters (AGPs) in animal nutrition has accelerated the search for safe, effective natural alternatives. Among various phytogenic additives, *Nigella sativa* (black cumin) has emerged as a promising alternate owing to its diverse pharmacologically active compounds, including thymoquinone, dithymoquinone, thymol, carvacrol, nigellicine, and nigellidine. These bioactive constituents exhibit a broad spectrum of biological activities, such as antibacterial, antioxidant, anti-inflammatory, immunomodulatory, hepatoprotective, and digestive-enhancing effects. In poultry, dietary supplementation with *Nigella sativa* seeds has demonstrated considerable improvements in growth performance, feed conversion ratio, carcass yield, and meat quality, as well as enhanced immune responses and intestinal health. It effectively reduces intestinal pH and pathogenic load while promoting beneficial gut microbiota. In layer birds, supplementation is associated with enhanced egg quality and improved overall health status. Beyond productivity metrics, the antioxidant properties of black cumin contribute to better meat preservation and shelf-life by reducing oxidative spoilage. Its antimicrobial activity against both Gram-positive and Gram-negative bacteria highlights its potential as a natural substitute for synthetic antibiotics and preservatives. Optimal inclusion levels ranging from 1–2% have been shown to yield beneficial outcomes without adverse effects. This review consolidates current findings on the efficacy of *Nigella sativa* in poultry diets, emphasizing its role in promoting growth, improving meat and egg quality, and supporting sustainable poultry production. Future research should aim to standardize inclusion levels, investigate synergistic effects with other natural additives like probiotics, and evaluate its long-term effects under diverse management systems.

Key Words: *Nigella sativa, black cumin, poultry nutrition, growth performance, meat quality, natural antioxidants, gut health, feed efficiency, sustainability*

Introduction

Text The global poultry industry serves as a vital source of high-quality animal protein, facing increasing demands as world population growth necessitates 60% greater food production by 2050 (Asghar et al., 2021; Akram et al., 2019; Al-Beitawi et al., 2008; Hanboonsong et al., 2013). This protein crisis has led to concerning practices, including the widespread use of synthetic chemicals and antibiotics as growth promoters in poultry production (Asghar et al., 2022; Akram et al., 2021; Güler and Dalkiliç, 2009; Miles et al., 2006; Naımatı et al., 2022). While these substances effectively control pathogenic microorganisms like Salmonella, Escherichia coli, and Enterococci, their routine use has led to alarming consequences including antibiotic resistance and tissue residues in animal products (Schwarz et al., 2001; Sierżant et al., 2023; Tauseef et al., 2017).

In recent years, the poultry industry has witnessed growing interest in phytogenic feed additives, driven by consumer demand for natural and residue-free animal products. Among these, *Nigella sativa* (black cumin) has emerged as particularly noteworthy due to its rich phytochemical composition and multifaceted therapeutic properties. With a history of traditional use in herbal medicine, this remarkable botanical has demonstrated antioxidant, antimicrobial, immunomodulatory, and growth-promoting characteristics that position it as an ideal candidate for sustainable poultry nutrition (Asghar et al., 2022)

The European Union's 2006 ban on antibiotic growth promoters Toghyani et al., (2010) has accelerated research into natural alternatives, particularly following evidence linking antibiotic residues in meat and eggs to human health risks (Rahmatnejad et al., 2009; Issa et al., 2012). This regulatory shift has forced the industry to reconcile production efficiency with evolving consumer preferences for food products containing beneficial bioactive compounds (Asghar et al., 2024; Cofrades et al., 2008; Sajid et al., 2023; Jia et al., 2021). Modern consumers increasingly prioritize not only food safety but also nutritional quality seeking products with natural antioxidants,

optimal fatty acid profiles, and reduced chemical additives (Hygreeva et al., 2014; Pisulewski et al., 2005; Capitani et al., 2013; Decker et al., 2010).

Scientific investigations have consequently focused on various natural alternatives including essential oils, phytobiotics, and medicinal plants (Elgayyar et al., 2001; Valero et al., 2003; Jamroz et al., 2002; Jang et al., 2004; Ramakrishna et al., 2003). These substances offer the dual advantage of antimicrobial activity without promoting resistance while potentially enhancing digestive function (Jamroz et al., 2002; Jang et al., 2004; Ramakrishna et al., 2003). The search for effective alternatives has gained urgency as dietary patterns shift toward healthier options that may reduce risks of cardiovascular disease, cancer, and obesity (Hygreeva et al., 2014; Pisulewski et al., 2005; Capitani et al., 2013; Decker et al., 2010).

Nigella sativa distinguishes itself among phytogenic options through its exceptional nutritional profile, containing high-quality proteins, essential amino acids, vital minerals (calcium, potassium, phosphorus, magnesium) El-Ghorab et al. (2003); Sultan et al. (2009), and an impressive array of bioactive compounds including thymoquinone, carvacrol, and thymol (Nasir, 2005). These components confer numerous benefits including antimicrobial activity (Oroojalian et al., 2010), antioxidant capacity (Attia et al., 2019; Baghban-Kanani et al., 2019; Khoobani et al., 2019), gastrointestinal protection (Jamroz et al., 2002), and growth promotion potential (Al-Beitawi et al., 2009).

The essential oil fraction of black cumin contains at least 18 bioactive compounds, predominantly carvone (66%) and limonene (50%), along with gamma-terpinene, cuminaldehyde, and various flavonoids (Jalilzadeh-Amin et al., 2011; Moghtader et al., 2009; Yalçın et al., 2009)[27-29]. These compounds exhibit diverse pharmacological activities including antimicrobial (Oroojalian et al., 2010), anti-inflammatory (Hajhashemi et al., 2011), and muscle relaxant effects (Jalilzadeh-Amin et al., 2011), making *Nigella sativa* a comprehensive natural solution for poultry production challenges.

This review systematically evaluates current knowledge regarding *Nigella sativa* supplementation in poultry nutrition, with particular emphasis on its effects on growth performance, carcass characteristics, and meat quality parameters in broiler chickens and laying hens. By synthesizing existing research, we aim to clarify the mechanisms of action, optimal inclusion levels, and practical applications of this promising phytogenic additive in modern poultry production systems.

Phytochemical Composition of *Nigella sativa*

Nigella sativa, commonly known as black cumin, is a flowering plant of the Ranunculaceae family that has garnered considerable scientific attention due to its complex and potent phytochemical profile. The seeds of N. sativa contain a wide array of biologically active compounds that contribute to its therapeutic efficacy and functional role as a phytogenic feed additive in poultry nutrition. The most significant constituent of N. sativa seeds is thymoquinone (TQ), a monoterpene compound that accounts for the majority of its pharmacological activity. Thymoquinone exhibits strong antioxidant, antimicrobial, anti-inflammatory, anticancer, and immunomodulatory effects, making it a key contributor to the plant's functional applications (Nasir, 2005; Attia et al., 2019; Baghban-Kanani et al., 2019; Khoobani et al., 2019). In addition to thymoquinone, other notable constituents include dithymoquinone, thymohydroquinone, thymol, carvacrol, nigellidine, nigellicine, and α-hederin, all of which have demonstrated bioactivity in both in vitro and in vivo studies (Al-Beitawi et al., 2009; Jalilzadeh-Amin et al., 2011; Moghtader et al., 2009). The essential oil content of N. sativa seeds ranges from 0.4% to 2.5%, and its composition varies depending on geographical origin, cultivation conditions, and extraction methods. Major volatile compounds include carvone (up to 66%), limonene (approximately 50%), p-cymene, γ-terpinene, trans-anethole, cuminaldehyde, and β-pinene, many of which contribute to the plant's antimicrobial, digestive-stimulant, and anti-inflammatory properties (Jalilzadeh-Amin et al., 2011; Moghtader et al., 2009; Yalçın et al., 2009; Oroojalian et al., 2009).

Apart from volatile oils, N. sativa seeds are also a rich source of fixed oils (up to 35–38%), composed primarily of unsaturated fatty acids such as linoleic acid (50–60%), oleic acid (20–30%), and smaller quantities of palmitic and stearic acids (Hajhashemi et al., 2011). These fatty acids contribute to the plant's nutritional value and are beneficial for energy metabolism, lipid regulation, and cellular function in poultry. Additionally, the seeds contain significant amounts of proteins (20–25%), dietary fiber, saponins, alkaloids, and phenolic compounds, including flavonoids and tannins. These molecules play important roles in modulating oxidative stress, enhancing nutrient absorption, and improving gut health (Gilani et al., 2004; Ferdous et al., 1992; ElKamali et al., 1998). Mineral content is also substantial in N. sativa, with appreciable levels of calcium, potassium, magnesium, iron, phosphorus, zinc, and selenium, which are essential for skeletal development, enzyme function, and overall physiological balance in poultry (El-Ghorab et al., 2003; Sultan et al., 2009).

In summary, the phytochemical richness of N. sativa underpins its multifaceted biological activities. The synergistic action of its bioactive compounds supports its efficacy as a natural growth promoter, antimicrobial agent, antioxidant, and immune enhancer, reinforcing its potential as a sustainable alternative to conventional feed additives in poultry nutrition.

Effects of N. sativa on Feed intake and Growth Performance

Numerous studies have demonstrated that dietary supplementation with *Nigella sativa* (commonly referred to as black cumin seed, BCS) positively influences average daily weight gain (ADWG) and overall growth performance in poultry. Research conducted over the past two decades consistently indicates improved body weight parameters across various poultry species and production systems following BCS inclusion in feed (Osman, 2002; El-Bagir et al., 2006; Guler et al., 2006; Durrani et al., 2007; Abu-Dieyeh and Abu-Darwish, 2008; Al-Beitawi et al., 2009; Ashayerizadeh et al., 2009; Erener et al., 2010; Ismail, 2011; Khan et al., 2012; Yatoo et al., 2012; Saleh, 2014; Jahan et al., 2015). For instance, Osman (2002) reported a significant increase in ADWG in broiler chickens supplemented with BCS oil. El-Bagir et al. (2006) found that the inclusion of BCS at levels of 10 or 30 g/kg significantly improved final body weight in laying hens. Guler et al. (2006) observed that broilers fed diets containing both BCS (10 g/kg) and antibiotics achieved the highest ADWG compared to the control. Likewise, Abu-Dieyeh and Abu-Darwish (2008) showed that diets containing 10 and 15 g/kg BCS led to significantly enhanced ADWG over a four-week feeding period. Similar improvements were reported by Erener et al. (2010), Khan et al. (2012), and Yatoo et al. (2012), with the latter highlighting the highest gains in groups receiving 0.5% BCS.

These growth-enhancing effects are potentially linked to improved nutrient digestibility, stimulated bile secretion, and activation of pancreatic enzymes, resulting in more efficient fat digestion and nutrient absorption (Kumar et al., 2017a). Key active components of BCS, including thymoquinone (approx. 60%), carvone, anethole, carvacrol, and 4-terpineol, exert antibacterial and antioxidant actions, while simultaneously stimulating digestive enzyme activity in both intestinal mucosa and pancreas (Abu-Dieyeh and Abu-Darwish, 2008). Additionally, Mandour et al. (1998) suggested that BCS may elevate thyroxine levels, thereby enhancing basal metabolic rate and contributing to growth.

The feed intake response to BCS supplementation, however, remains inconsistent across the literature. Some studies reported a significant increase in average daily feed intake (ADFI) following BCS inclusion (Osman and El-Barody, 1999; Abou-El-Soud, 2000; Erener et al., 2010; Ismail, 2011; Yatoo et al., 2012). For example, Osman and El-Barody (1999) noted increased ADFI with powdered BCS at inclusion levels ranging from 2 to 10 g/kg. Similarly, Yatoo et al. (2012) observed increased feed intake across all growth phases in broilers fed 1% BCS, while Abou-El-Soud (2000) reported the highest ADFI in quail chicks supplemented with 2% whole crushed BCS. In contrast, other investigations documented a decline in ADFI upon BCS supplementation. Osman (2002) and Abbas and Ahmed (2010) noted reduced feed intake in broilers receiving 1–2% BCS oil, while Szczerbińska et al. (2012) and Çetin et al. (2008) observed dose-dependent decreases in ADFI in quail and partridges, respectively. Durrani et al. (2007) and Shewita and Taha (2011) also reported significant reductions in feed intake at higher BCS inclusion levels. Several other studies found no significant impact of BCS supplementation on feed intake (Denli et al., 2004; Guler et al., 2006; Ashayerizadeh et al., 2009; Khalaji et al., 2011; Ghasemi et al., 2014; Al-Mufarrej, 2014; Saleh, 2014). These divergent findings may be attributed to variations in BCS form (whole seed, oil, extract), dosage, poultry species, and experimental conditions, including feed composition and rearing environment.

With regard to feed conversion ratio (FCR), most studies indicate a favorable effect of BCS supplementation. Significant improvements in FCR have been reported in trials by Guler et al. (2006), Durrani et al. (2007), Abu-Dieyeh and Abu-Darwish (2008), Erener et al. (2010), Toghyani et al. (2010), Yatoo et al. (2012), and others. Guler et al. (2006) showed that 1% BCS improved FCR by approximately 5% over the control group, while Abu-Dieyeh and Abu-Darwish (2008) achieved the best efficiency with 1.5% BCS supplementation. Nonetheless, not all studies found a consistent or significant effect on FCR. For instance, Nasir and Grashorn (2010) and Abbas and Ahmed (2010) reported non-significant improvements, and Majeed et al. (2010) even observed a deterioration in FCR with 0.25% BCS inclusion. Similarly, Al-Beitawi and El-Ghousein (2008) reported dose-dependent declines in feed efficiency at BCS inclusion rates above 1.5%. The variability in FCR responses may relate to several factors, including baseline diet composition, bird health status, housing conditions, and potential interactions between BCS bioactives and gut microbiota. It has been proposed that the benefits of phytogenic additives such as BCS are more pronounced under suboptimal conditions, where the antimicrobial and digestive-stimulatory effects may compensate for environmental or dietary challenges (Lee et al., 2003).

In conclusion, while the majority of studies support the growth-promoting and feed efficiency-enhancing effects of *Nigella sativa* supplementation in poultry, the impact on feed intake appears to be context-dependent. Differences in experimental design, dietary formulations, and the form and level of BCS supplementation likely account for the observed inconsistencies. Further research is warranted to define optimal inclusion rates and to elucidate the mechanisms underpinning these performance improvements.

Effects on Carcass Traits

The inclusion of *Nigella sativa* (Black Cumin Seed, BCS) in poultry diets has demonstrated variable yet generally beneficial effects on carcass traits and internal organ development. Several studies have reported improvements in dressing percentage, breast muscle yield, and reductions in abdominal fat deposition, suggesting enhanced protein

metabolism and modulation of lipid pathways. For instance, Guler et al. (2006) and Toghyani et al. (2010) observed significant increases in carcass yield, as well as the weights of the liver, breast, thigh, wing, and neck in broilers supplemented with 1% BCS. However, heart weight remained unaffected. Similarly, studies such as those by Erener et al. (2010) and Saleh (2014) confirmed increases in carcass and breast muscle weights, though some found no significant changes in liver or edible organ weights. On the contrary, several researchers have reported inconsistent or non-significant effects. For example, El-Ghammry et al. (2002) and Abbas and Ahmed (2010) observed a decrease in dressing percentage with BCS inclusion, while Ismail (2011) noted no significant changes in most carcass parameters, including dressing yield, edible organ weight, and abdominal fat.

In terms of fat metabolism, Durrani et al. (2007) and Abaza et al. (2008) highlighted BCS's lypolytic effects, especially the significant reduction in abdominal fat when BCS oil was added at low concentrations (e.g., 0.1%), indicating a potential diversion of energy from fat deposition toward more beneficial physiological processes. Nonetheless, conflicting evidence also exists. Some studies, such as those by Al-Beitawi and El-Ghousein (2008) and Khalaji et al. (2011), reported no significant differences in internal organ weights or carcass traits across varying levels of crushed or uncrushed BCS. Moreover, while an increase in breast meat weight was consistently observed in multiple studies (Jahan et al., 2015), parameters like thigh and wing weights, skin, and drumstick weights often varied depending on BCS concentration, bird age, and experimental conditions.

Additionally, several studies have indicated that while meat composition—such as protein and fat content—might be altered positively by BCS supplementation (Hermes et al., 2009, 2011), there are often no significant effects on attributes like meat tenderness, pH, shear force, or electrical conductivity (Majeed et al., 2010; Khan et al., 2012). Some negative impacts were also reported, such as increased cooking losses and decreased dressing percentage with 1% whole-ground black cumin (Ismail, 2011). The disparities in results may be attributed to differences in BCS form (oil, meal, crushed or uncrushed seeds), inclusion levels, bird genetics, and environmental or management factors. Nevertheless, the frequent observation of increased breast muscle yield suggests that BCS positively influences protein metabolism and mineral bioavailability in poultry, making it a promising natural additive for improving carcass traits under controlled dietary strategies.

Effects on Meat Quality, Chemical Composition, and Antioxidant Properties in Poultry

The inclusion of BCS in poultry diets has shown a promising impact on meat quality attributes, primarily through its antioxidant mechanisms. These effects are attributed to bioactive compounds such as thymoquinone, carvacrol, anethole, and 4-terpineol, which help delay lipid oxidation, reduce microbial load, and extend shelf life. Improvements in meat quality parameters have been consistently reported, including enhanced meat color—likely due to the stabilization of myoglobin—better water-holding capacity and tenderness, and reduced lipid peroxidation. Studies have demonstrated that BCS supplementation leads to increased dry matter (DM), crude protein (CP), and ether extract (EE) content in breast and thigh muscles, with the most significant results observed at 10 g/kg diet (Kumar et al., 2018). Similar findings were reported by Al-Beitawi and El-Ghousein (2008), who noted improved DM and CP levels in breast meat with 15 g/kg BCS inclusion, though leg meat was less responsive.

The antioxidant effects of BCS are also evident at the biochemical level. Supplementation has been shown to elevate antioxidant enzyme activities such as glutathione peroxidase and superoxide dismutase in thigh muscle, while simultaneously decreasing malondialdehyde (MDA) levels, a key marker of lipid peroxidation (Rahman and Kim, 2016; Guler et al., 2007). Kumar et al. (2018) observed increased ferric reducing antioxidant power (FRAP) in serum and meat, suggesting an improved oxidative stability, especially after storage at 4°C. While the peroxide values in thigh meat remained largely unaffected, breast meat showed decreased lipid peroxidation when ether extract content was considered, reinforcing the meat-protective effects of BCS. Moreover, these antioxidant properties may be linked to the influence of BCS on endocrine function, particularly thyroid activity, which affects protein synthesis and energy metabolism (Hermes et al., 2011).

In addition to improving oxidative stability, BCS influences the fatty acid profile of poultry meat. Though research is limited, some studies indicate increased polyunsaturated fatty acid (PUFA) content and reduced fat oxidation in BCS-treated meat (Kumar et al., 2018). PUFA enrichment is particularly beneficial, given its susceptibility to oxidative degradation and its importance in human nutrition. Methanolic extracts of BCS have revealed high phenolic content—such as syringic acid, hydroxybenzoic acid, and p-coumaric acid—which exhibit potent in vitro antioxidant activity (Mariod et al., 2009). The capacity of BCS to scavenge free radicals, inhibit cyclooxygenase and lipoxygenase pathways, and regulate enzymes like glutathione S-transferase and catalase has been confirmed in both poultry and rodent models (Badary et al., 2003; Tuluce et al., 2009). Notably, diets containing 0.5–1% BCS significantly reduced erythrocyte MDA levels and increased glutathione concentrations, reflecting decreased oxidative stress and enhanced cellular defense mechanisms.

Collectively, these findings underscore the potential of *Nigella sativa* as a natural feed additive to enhance meat quality in broilers. Its integration into poultry diets not only improves physicochemical properties and nutritional value of meat but also supports oxidative stability, thereby contributing to better shelf life and consumer acceptability.

Effects on Immunity and Health Status

Numerous studies have investigated the immuno-potentiative activity of Black Cumin Seed (BCS) in poultry, highlighting its potential role in enhancing immune responses and overall health. Kumar et al. (2017a) demonstrated a quadratic increase in antibody titres against Newcastle Disease Virus (NDV) in broiler chickens supplemented with BCS at 5, 10, and 20 g/kg diet at 35 days of age, although no significant difference was observed at 28 days. Similarly, Al-Beitawi et al. (2009) reported a significant enhancement in antibody titres against NDV and Infectious Bursal Disease Virus (IBDV) at 42 days of age following BCS supplementation in chickens vaccinated at appropriate intervals. Durrani et al. (2007) also noted increased antibody production when BCS was included at 40 g/kg diet. In contrast, other studies (Toghyani et al., 2010; Shewita and Taha, 2011) reported no significant changes in antibody titres against NDV and influenza virus, attributing these results to the use of lower BCS doses or reduced concentrations of active compounds in the BCS formulations used.

In terms of lymphoid organ development, findings remain inconsistent across studies. Kumar et al. (2018) observed that spleen weight decreased linearly while bursa weight increased linearly with increasing BCS supplementation. Toghyani et al. (2010) found that lymphoid organ weights were positively influenced at 2 and 4 g/kg of BCS. Al-Mufarrej (2014) reported enhanced immune responsiveness with 10 or 14 g/kg BCS supplementation; however, no significant differences in bursa or spleen weights were observed at 21 and 35 days post-vaccination. Other investigations, such as those by El-Deek et al. (2009) and Yatoo et al. (2012), failed to find statistically significant differences in immune organ weights, although some variation was noted, possibly due to external factors such as feed contamination by mycotoxins (Cazaban et al., 2015).

Several bioactive compounds in BCS, including thymoquinone, carvacrol, nigellimine, thymol, and nigellicine, are believed to contribute to its immunomodulatory effects due to their antibacterial, antioxidant, and anti-inflammatory properties. These compounds likely stimulate immune cell activity, promote antibody production, and offer protection against oxidative stress and pathogenic microorganisms. Supporting this, El-Tahir et al. (1993) found that supplementation of BCS in human volunteers enhanced immune function by improving the helper T cell to suppressor T cell ratio and increasing natural killer cell activity. Similarly, Dorucu et al. (2009) observed significantly elevated serum protein and immunoglobulin levels in rainbow trout fed with BCS.

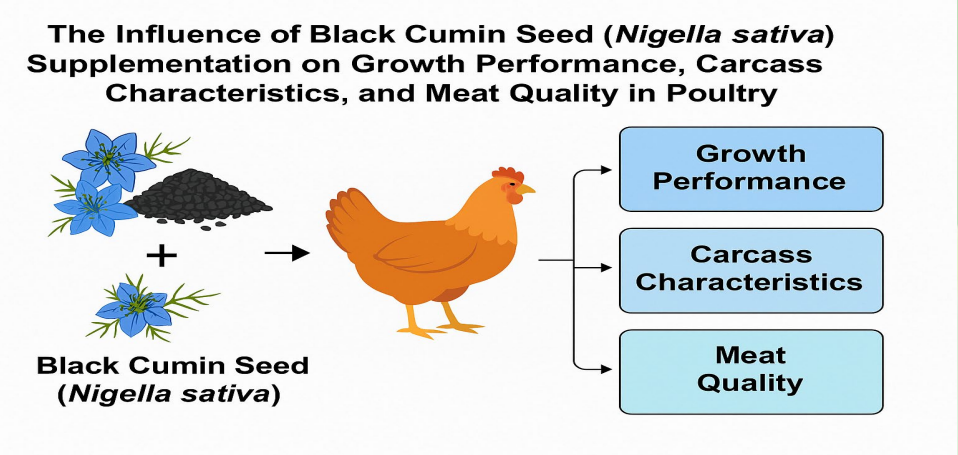
BCS also demonstrated the potential to reduce poultry mortality rates. Supplementation with 1.5% BCS in layer diets decreased mortality from 16.67% to 4.17%, while 1% BCS in broiler diets reduced mortality from 3.5% to 2% (Al-Jabre et al., 2003). Moreover, Hermes et al. (2011) noted improved bird survival and health under heat stress conditions with BCS supplementation, attributing the effects to enhanced immunity and antimicrobial action. However, some studies, such as Ismail (2011), reported no significant effect on mortality rates, reflecting the variability in outcomes depending on the dosage, environmental factors, and health status of the flock.

In summary, while the immunomodulatory potential of BCS is supported by several studies—particularly in enhancing NDV and IBDV antibody titres, supporting lymphoid organ development, and reducing mortality—the findings are not universally consistent. Variations in dosage, form of BCS used, bird age, vaccination schedule, and environmental conditions appear to significantly influence the outcomes. These inconsistencies underscore the need for standardized protocols in future research to better elucidate the immunological benefits of BCS in poultry nutrition.

Effects of *Nigella sativa* on Egg Production and Quality in Laying Poultry

The impact of *Nigella sativa* (black cumin) on egg production and quality in laying poultry has been widely studied, with results often showing variation depending on the dosage, form, and species involved. Several studies have reported positive outcomes; for instance, supplementation with 1.5% powdered black cumin or 3% whole seeds has significantly enhanced egg production in laying hens. Conversely, El-Bagir et al. (2006) observed a reduction in egg production by approximately 9% and 16% with the inclusion of 1% and 3% black cumin, respectively, without any influence on egg dimensions. This decline was attributed to increased final body weight, suggesting that the energy from N. sativa oil may be directed more towards weight gain than egg output. Another possible explanation is the associated decrease in egg yolk cholesterol, as lower cholesterol levels—essential for egg formation—can negatively affect egg production. Elkin et al. (1993) demonstrated that a 30% reduction in yolk cholesterol via a synthetic HMG-CoA reductase inhibitor resulted in a 20% drop in egg production, implying a critical threshold for cholesterol levels below which normal egg production cannot be sustained.

In terms of egg quality, supplementation with black cumin has shown promising results. A 1.5% inclusion increased egg weight from 54 to 58 grams, and 1% black cumin extract was effective in enhancing both egg weight and shell characteristics in quails. Additionally, diets with 2–3% black seed were associated with significant improvements in shell thickness and strength, whereas 1% or lower did not yield similar benefits. However, some studies reported no significant effect on egg production or composition. For example, Bolukbasi et al. (2009) found that N. sativa oil did not influence egg weight, production, or the proportion of yolk, albumen, and shell, although a 3 ml/kg inclusion reduced the Haugh unit, a measure of egg albumen quality. Notably, a 3% black cumin seed diet resulted in reductions in egg yolk total lipids, cholesterol, phospholipids, and triacylglycerols by 34%, 45%, 11%, and 20%, respectively—an outcome considered beneficial for human consumption. The exact mechanism of



cholesterol reduction remains unclear, though it is hypothesized that N. sativa inhibits de novo cholesterol synthesis or lowers serum cholesterol levels.

Albumin quality has also been reported to improve with N. sativa supplementation, although its effect on yolk index appears to be negligible. Medicinal plants like N. sativa, known for their bioactive compounds, have the potential to support reproductive tissue health in laying poultry. For example, Boka et al. (2014) demonstrated that black cumin seed supplementation (1–3%) did not significantly affect laying rate or yolk cholesterol but positively influenced intestinal E. coli counts, blood biochemistry, and immune parameters. At doses above 2%, enhancements in egg production, weight, and shell strength were observed. On the other hand, Yalçin et al. (2012) reported a significant reduction in egg weight following N. sativa supplementation, with no notable changes in shell thickness, egg index, albumen height, or Haugh unit. Similarly, studies by Aydin et al. (2008) and Szczerbińska et al. (2012) found no effects on the live weight of hens.

Other researchers have highlighted the favorable influence of N. sativa on overall hen performance and egg quality parameters. Rich in unsaturated fatty acids like linoleic and oleic acids, black cumin seed inclusion up to 15 g/kg has been associated with improvements in egg weight, cholesterol levels, and yolk fatty acid composition. Bölükbaşi et al. (2009) confirmed that N. sativa oil can reduce intestinal E. coli, although its administration at 3 mg/kg may adversely affect the Haugh unit. In Aydin et al. (2008) trial, laying hens fed 3% black cumin seeds produced more eggs compared to controls, and eggs from hens fed 2–3% black cumin exhibited superior shell thickness and strength. Additionally, eggs from these groups showed a significant reduction in cholesterol content. As dietary fatty acid composition plays a key role in modifying egg lipid profiles, N. sativa proves to be a promising feed additive. Elkin et al. (1993) previously noted a cholesterol reduction from 30% to 20% through dietary modification without compromising egg weight. Supporting these findings, Hossain et al. found that dietary supplementation with 1.5%–2% black cumin significantly decreased yolk cholesterol without adverse effects on egg production or weight. Overall, evidence suggests that black cumin can positively influence various aspects of egg quality and production, although inconsistencies across studies highlight the need for further controlled investigations.

Optimal Inclusion Levels and Safety

In poultry nutrition, determining the optimal inclusion levels of additives like Black Cumin Seed (*Nigella sativa*) is crucial to maximizing their benefits while ensuring safety. Research on *Nigella sativa* supplementation in poultry diets suggests that inclusion levels typically range from 0.5% to 2%, depending on the desired outcomes and specific poultry species. These levels are generally considered safe and effective, providing significant improvements in growth performance, carcass characteristics, and meat quality without compromising feed intake or bird health. At lower inclusion levels (0.5% - 1%), Black Cumin Seed supplementation tends to offer benefits without adversely affecting feed palatability, while higher inclusion levels (1% - 2%) may enhance performance but could lead to reduced palatability or even potential negative effects if overused. Excessive inclusion can result in undesirable outcomes such as digestive disturbances, reduced feed consumption, or toxicity from exceeding safe nutrient thresholds (Asghar et al., 2022). Therefore, ensuring proper formulation of poultry diets with Black Cumin Seed is essential to achieve the desired effects on growth and meat quality without compromising safety. This requires careful calculation of inclusion levels based on the birds' age, growth stage, and environmental factors. Formulating diets with the appropriate balance, along with considering the bioavailability of the active compounds in *Nigella sativa*, ensures that the supplementation promotes optimal performance. Adhering to regulatory guidelines and safety protocols set by authorities like the FDA or EFSA is also critical in determining safe inclusion levels. In conclusion, optimizing the inclusion levels of Black Cumin Seed in poultry diets is key to improving growth performance, carcass traits, and meat quality while maintaining bird health and productivity.

This graphical abstract illustrates the impact of dietary supplementation with *Nigella sativa* (black cumin seed) on poultry performance, carcass characteristics, and meat quality. The diagram highlights the functional bioactive compounds of *Nigella sativa* and their physiological roles in enhancing digestion, immunity, and antioxidant status. These effects collectively contribute to improved growth performance, better feed efficiency, enhanced carcass yield, and superior meat quality in poultry production systems.

Challenges and Future Perspectives

Despite the well-documented benefits of *Nigella sativa* supplementation in poultry nutrition, several challenges continue to limit its widespread and standardized use in commercial production systems. One of the primary concerns is the lack of standardization in the active compounds, such as thymoquinone, which can vary significantly between different seed sources and extraction methods. This variability makes it difficult to ensure consistent efficacy across studies and applications. Additionally, geographic and environmental factors play a significant role in influencing seed quality, composition, and potency, further contributing to inconsistencies in performance outcomes. Another practical challenge is the cost-effectiveness of *Nigella sativa* supplementation at a commercial scale, particularly when high-quality or processed forms such as oils or extracts are used. These issues highlight the need for continued research and innovation in this area. Future studies should explore advanced delivery systems, such as nano-formulations or encapsulated extracts, to improve the bioavailability and stability of active compounds in the digestive tract. Moreover, the potential synergistic effects of combining *Nigella sativa* with other feed additives such as probiotics, enzymes, or other phytogenics should be investigated to enhance overall efficacy and reduce costs. In addition, molecular and genetic expression studies are essential to gaining deeper insight into the metabolic and physiological mechanisms through which *Nigella sativa* exerts its effects on growth performance and meat quality. Such research could pave the way for precision feeding strategies and the development of optimized formulations tailored to specific production goals. Overall, addressing these challenges through targeted research and innovation will be key to fully realizing the potential of *Nigella sativa* in modern poultry production.

Conclusion

In conclusion, *Nigella sativa* represents a highly promising natural feed additive with substantial potential to enhance poultry growth performance, carcass yield, meat quality, and overall health status. Its rich profile of bioactive compounds, particularly thymoquinone, contributes to its antimicrobial, antioxidant, immunomodulatory, and growth-promoting effects, positioning it as a compelling alternative to synthetic growth promoters. The multifaceted benefits observed across various studies highlight its role in improving not only production efficiency but also the quality and safety of poultry products. However, for *Nigella sativa* to gain wider acceptance in commercial poultry production, key challenges such as the standardization of active constituents, variability in seed quality, and cost-effective inclusion strategies must be addressed. Continued research focusing on improved formulations, such as nano-delivery systems and synergistic combinations with other phytogenics or probiotics, will be crucial in optimizing its efficacy. Ultimately, with proper standardization and strategic application, *Nigella sativa* holds strong potential to become an integral component of sustainable and health-oriented poultry nutrition programs.

Farklı Yetiştirme Sistemlerinde Barındırılan Atak-S Erkek Civcivlerinin Et Kalite Özellikleri

Beyhan Yeter[1,*], Hasan Eleroğlu[2]

[1]Kahramanmaraş Sütçü İmam Üniv. Ziraat Fak. Zootekni Bölümü, Kahramanmaraş, Türkiye, byeter@ksu.edu.tr, https://orcid.org/0000-0002-1741-4635
[2]Sivas Cumhuriyet Üniversitesi, Sivas Teknik Bilimler Meslek Yüksekokulu, Sivas, Türkiye, eleroglu@cumhuriyet.edu.tr, https://orcid.org/0000-0002-1032-9833

Özet

Bu çalışmada, yumurtacı bir hat olan Atak-S yumurtacı hibritlerin, cinsiyet ayrımı yapılarak itlaf edilen erkek civcivlerinin kapalı ve serbest (free range) yetiştirme sistemlerinde et kalitesi incelenmiştir. Her muamele gurubunda 3 tekerrür kullanılmış, her tekerrürde 28 adet muamele başına 84 adet, toplam 168 adet civciv kullanılmıştır. Kapalı yetiştirme sistemi (KYS) ve serbest yetiştirme sistemi (SYS) muamele guruplarında civcivler, kümeste yer bölmelerinde (3,7 civciv/m^2) büyütülmüştür. SKS muamele grubu için ise, kapalı bölmelere ek olarak yonca ekili açık alanda 3. haftadan itibaren civcivlere serbest dolaşma ve otlanma (0,9 civciv/m^2) imkânı verilmiştir. Çalışma, Kahramanmaraş Sütçü İmam Üniversitesi, Hayvansal Üretim Uygulama ve Araştırma Merkezinde 12 hafta süre ile yürütülmüştür. Deneme boyunca tüm civcivler aynı yemlerle sınırsız beslenmiştir. İki farklı yetiştirme sisteminde et kalitesi incelenen Atak-S erkek civcvilerinin göğüs ve but etlerinde ham kül, protein, nem, su tutma kapasitesi, yağ, Renk (L, A, B) Hue, Chroma, ΔE, kolesterol ve yağ asitleri kompozisyonu karşılaştırılmıştır. SYS ve KYS'nin but ve göğüs eti nem değerleri, su tutma kapasitesi, yağ oranı, renk L, renk A, renk B, Hue değeri, Croma değeri ve ΔE üzerine etkisi önemsiz ($p>0,05$) bulunmuştur. SYS ve KYS'de ham kül değerleri arasında fark önemli ($p<0,05$) olarak hesaplanmış, but ve göğüs etlerinin ham kül değerleri arasındaki farkta önemli bulunmuştur ($p<0,01$). But ve göğüs eti protein içeriği, yetiştirme sistemlerinden önemli derecede ($p<0,01$) etkilenmiştir. But ve göğüs eti protein içerikleri birbirlerinden farklı bulunurken ($p<0,01$) yetiştirme sistemleri ile et bölgesi arasında interaksiyona rastlanmamıştır($p>0,05$). But ve göğüs eti kolesterol içeriği de yetiştirme sistemlerinden önemli derecede ($p<0,01$) etkilenmiştir. But ve göğüs etlerinin kolesterol değeri arasındaki fark ta önemli bulunurken ($p<0,01$) yetiştirme sistemleri ile et bölgesi arasında interaksiyona rastlanmamıştır. Yağ asitleri kompozisyonları bakımından yetiştirme sistemleri arasındaki fark ise bazı yağ asitlerinde önemli bulunurken bazıları önemsiz bulunmuştur.

Anahtar kelimeler: Yetiştirme sistemi, Atak-S, Et kalitesi

Özet

Bu çalışmada, yavaş gelişen karışık cinsiyette Hubbard Red JA57 etlik piliç genotipi, kapalı ve serbest (free range) yetiştirme sistemlerinde incelenmiştir. Çalışma, Kahramanmaraş Sütçü İmam Üniversitesi, Hayvansal Üretim Uygulama ve Araştırma Merkezinde 12 hafta süre ile yürütülmüştür. Kapalı yetiştirme sistemi (KYS) ve serbest yetiştirme sistemi (SKS) muamele guruplarında civcivler, kümeste yer bölmelerinde (3,7 civciv/m2) büyütülmüştür. SKS muamele grubu için ise, aynı ölçülerde kapalı bölmelere ek olarak yonca ekili açık alanda 3. haftadan itibaren civcivlere serbest dolaşma ve otlanma (0,9 civciv/m2) imkânı verilmiştir. Her tekerrürde 28 adet civciv muamele başına 84, toplam 168 civciv her muamelede 3 tekerrür kullanılmıştır. Deneme boyunca tüm civcivler aynı yemlerle sınırsız beslenmiştir. İki farklı genotipin iki farklı yetiştirme sisteminde; et kalitesi incelenmiştir. Göğüs ve but etlerinde ham kül, protein, nem, su tutma kapasitesi, yağ, Renk (L, A, B) Hue, Chroma, ΔE, kolesterol ve yağ asitleri kompozisyonları karşılaştırılmıştır. Çalışmada; Hubbard Red JA57 piliçlerinin but ve göğüs etlerinde yetiştirme sistemleri arasındaki fark; ham kül, su tutma kapasitesi, yağ içeriği, renk değerleri ve kolesterol bakımından önemsiz ($p>0,05$) bulunurken, protein ($p<0,05$) ve nem ($p<0,01$) bakımından önemli bulunmuştur. Yağ asitleri kompozisyonları bakımından yetiştirme sistemleri arasındaki fark ise bazı yağ asitlerinde önemli bulunurken bazıları önemsiz bulunmuştur. Yetiştirme sistemleri ile cinsiyet ve yetiştirme sistemleri ile et bölgesi arasında interaksiyon ham kül, protein, nem değeri, su tutma kapasitesi, yağ, Renk (L,A,B), HUE değerleri, CHROMA, ΔE, Kolesterol önemsiz bulunurken, cinsiyet ile et bölgesi arasında interaksiyon sadece ham kül değerinde önemli ($p<0,05$) bulunurken diğer özelliklerde yine önemsiz bulunmuştur.

Anahtar kelimeler: Yetiştirme sistemi, Hubbard Red JA57, Et kalitesi

Abstract
Global food systems are facing challenges in meeting the rising demand for food while also reducing their environmental impact, including carbon and water footprints. Artificial intelligence (AI) offers promising solutions to improve efficiency, effectiveness, and resilience throughout the food supply chain. However, the use of AI in food production, particularly in advanced industrial settings such as Industry 4.0 and 5.0, also presents its own environmental and social challenges. This study examines the potential benefits of AI in creating a sustainable food system, including better resource use, less waste, improved water efficiency, and enhanced crop protection. It also considers the significant energy needed to train and operate AI systems. To ensure AI-based technologies truly support sustainability in food production, we need a balanced approach that includes fair access, responsible resource management, and integrating AI with other sustainable agricultural practices. Future efforts should focus on making AI tools easier to use for a wider audience, implementing strong governance rules, and aligning AI advancements with environmental, economic, and social impacts. By preventing these challenges, AI can be used to develop a more efficient, resilient, and environmentally friendly food resource system, contributing to global sustainability goals.
Keywords: Sustainability, environmental footprints, carbon and water footprints, AI-integrated food production, zero waste and water efficiency

Introduction

The integration of AI into agrifood production systems presents a dual narrative regarding sustainability and environmental footprints. While AI offers substantial promise in optimizing resource utilization, minimizing waste, and enhancing the precision of agricultural practices – thereby potentially reducing the environmental burden associated with conventional farming (Shamshiri et al., 2018; Hussain et al., 2024). The development and deployment of AI technologies themselves carry inherent environmental and social costs that necessitate careful consideration (Rolnick et al., 2019). A comprehensive understanding of the sustainability implications of AI in agrifood requires a nuanced evaluation that encompasses both the benefits derived from its application and the environmental and ethical considerations of its implementation (van Es and Woodard, 2017). AI-driven solutions in agriculture, such as precision farming techniques, have demonstrated the capacity to optimize the application of water, fertilizers, and pesticides, leading to significant reductions in resource consumption and environmental pollution (Shamshiri et al., 2018; Hussain et al., 2024). Furthermore, AI applications in monitoring crop health, predicting yields, and managing livestock can contribute to increased efficiency and reduced waste across the food production chain (Kamilaris et al., 2018; Wolfert et al., 2017). These advancements align with the goals of sustainable agriculture by enhancing productivity while minimizing negative ecological impacts. However, the sustainability benefits of AI integration must be weighed against the environmental footprint associated with AI technologies, including the energy consumption for training complex models and the resource demands for hardware production and data storage (Rolnick et al., 2019).

Addressing the sustainability and environmental footprints of AI-integrated agrifood systems requires a holistic approach that considers the entire lifecycle of both the AI technologies and the agricultural practices they enable. Future research and development should prioritize energy-efficient AI algorithms, the use of low-carbon infrastructure for AI deployment, and the establishment of ethical and environmentally responsible design principles (Rolnick et al., 2019). Furthermore, comprehensive life cycle assessments (LCAs) are needed to quantify the environmental impacts of AI in agriculture, from the manufacturing of sensors and AI hardware to the energy used in data processing and the disposal of obsolete equipment. By adopting a balanced perspective that maximizes the sustainability benefits of AI while mitigating its potential environmental and social costs, the agrifood sector can move towards a more resilient and environmentally sound future (Ahmed and Shakoor, 2025). This paper explores the potential of AI to revolutionize agrifood production for enhanced sustainability, resource optimization, waste reduction, and crop protection, while also addressing the associated environmental and social challenges and outlining future directions for accessible, governed, and impactful AI integration.

The Challenge of Global Food Systems

Global food systems today face a complex set of challenges that intersect with environmental sustainability, socio-economic equity, and political governance. As the global population continues to grow, current agricultural practices are increasingly being scrutinized for their impact on natural resources and their contribution to climate change. Feeding an estimated 9.7 billion people by 2050 requires a food systems transformation that not only ensures food security but also addresses sustainability and equity. Traditional and intensive agricultural practices have been reported to lead to biodiversity loss, soil degradation, and water resource depletion (Godfray et al., 2010; Tilman et al., 2011). These challenges call for an integrated approach that simultaneously addresses production efficiency and ecosystem protection.

One of the key challenges is inadequate food distribution. Although global food production is sufficient to feed the entire population, more than 828 million people were reported to be undernourished in 2021 (FAO, 2022). At the same time, food waste remains a widespread problem. Approximately one-third of all food produced globally is lost or wasted each year (Gustavsson et al., 2011). In addition to these problems, market volatility, trade restrictions and economic volatility also contribute to difficulties in accessing food. Foley et al. (2011) reported that innovative policy measures and collaborative management models that promote food supply are needed. Adaptive strategies such as climate-smart agriculture, improved infrastructure and sustainable land use should be prioritized to build resilience to environmental shocks (Wheeler and von Braun, 2013). Transforming the global food system requires a holistic approach that integrates environmental sustainability, economic viability and social justice. As the EAT-Lancet Commission stated, “a global transformation of the food system is urgently needed” to protect both human and planetary health (Willett et al., 2019). To overcome the multidimensional challenges of feeding the world sustainably, international collaborative efforts based on science and equity will be crucial.

The Promise of Artificial Intelligence in Agrifood Production

AI holds transformative potential for the agrifood sector, promising increased efficiency, sustainability, and resilience in food production systems. As global agriculture faces escalating pressures due to climate change, labor shortages, and the need for more precise resource management, AI-driven technologies are emerging as critical tools to address these challenges. According to Kamilaris et al. (2018), AI applications in agriculture including machine learning, computer vision, and robotics are facilitating more accurate crop monitoring, yield prediction, pest detection, and autonomous machinery operation, thus enabling data-driven decision-making at unprecedented scales.

One of the most significant contributions of AI is its role in precision agriculture. AI-powered platforms analyze large datasets from satellites, drones, and IoT sensors to provide real-time insights on soil conditions, crop health, and weather patterns. These insights allow for targeted interventions that minimize input waste and enhance productivity. For instance, Liakos et al. (2018) highlight the use of machine learning algorithms in predicting crop yields and optimizing irrigation, which not only conserves water but also reduces the environmental footprint of agricultural activities. In livestock farming, AI systems are employed to monitor animal behavior and health, improving welfare and early disease detection (Wolfert et al., 2017). Despite these advancements, the integration of AI in agrifood systems is not without limitations. Challenges such as high initial costs, lack of digital infrastructure in rural areas, and concerns over data privacy and ownership remain significant barriers to widespread adoption. Moreover, the ethical implications of AI deployment especially in smallholder farming contexts demand careful consideration to ensure inclusivity and equity. As van Es and Woodard (2017) suggest, the development of AI solutions should be accompanied by policies that support technological access and capacity-building, particularly in developing regions.

Sustainability Benefits of AI Integration

The integration of AI across sectors has shown tremendous promise in enhancing sustainability by optimizing resource use, minimizing waste, and supporting climate adaptation strategies. AI technologies facilitate real-time monitoring, predictive analysis, and intelligent automation that collectively contribute to more sustainable systems in energy, agriculture, transportation, and urban planning. AI can be a powerful tool for mitigating climate change if developed and implemented responsibly, particularly through applications such as energy optimization, precision agriculture, and smart logistics (Rolnick et al., 2019). In the energy sector, AI enables significant efficiency gains by predicting demand and managing supply in real time. Smart grids powered by AI dynamically adjust electricity flow, more effectively integrate renewable energy sources, and reduce transmission losses (IEA, 2021). For example, Google’s DeepMind successfully reduced data center cooling energy usage by 40% using AI-based control systems and demonstrated the scalability of AI for sustainable infrastructure management (Evans and Gao, 2016). Such applications not only reduce carbon footprints but also promote cost-effective energy practices.

AI in agriculture supports sustainable practices by enabling precision farming that reduces water, fertilizer, and pesticide use. Machine learning models can predict crop yields, detect disease outbreaks, and recommend site-specific treatments that maintain productivity while reducing environmental impacts (Shamshiri et al., 2018). In

sustainable agriculture, AI contributes to the efficient management of water, fertilizer, and pesticides through precision farming techniques. These advances not only increase crop yields but also minimize environmental degradation. It has been found that irrigation planning systems based on machine learning can reduce water usage by up to 30% without compromising productivity (Hussain et al., 2024). Despite its potential, the sustainability of AI must also be addressed, particularly in terms of energy consumption associated with model training and data storage. Sustainable AI development requires the use of energy-efficient algorithms, low-carbon infrastructure, and policies that prioritize ethical and environmentally responsible design.

Resource Use Optimization through AI

AI transforms resource optimization in cloud computing and software systems, increasing efficiency, scalability, and cost-effectiveness. AI techniques such as machine learning (ML), deep learning (DL), and reinforcement learning (RL) offer powerful tools for dynamic resource allocation, workload prediction, and cost management. For example, Artamonov and Balych (2024) state that neural networks provide high accuracy in resource acquisition and response times, improving data center performance by 20%, especially in cloud infrastructures. These systems prevent unnecessary consumption by distributing resources such as processors, memory, and storage according to real-time needs. Rao (2023) emphasizes that AI-based solutions reduce energy waste by up to 15%, especially in large-scale cloud platforms. This is a critical development in terms of both economic and environmental sustainability. Deep learning models, especially Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks, stand out in energy efficiency and resource management. Kristian et al. (2024) show that LSTM models provide 90% accuracy in workload predictions based on time series data, thus reducing energy consumption in data centers by 12%. For example, in a cloud-based software system, LSTM networks automatically adjust server capacity by predicting user demands, thus reducing both costs and carbon footprint. Similarly, CNNs optimize resource usage in infrastructure monitoring systems that require visual data analysis (e.g., server temperature control with thermal cameras). However, the high computational requirements of these models are a disadvantage. Reinforcement learning (RL) stands out as another important AI technique in terms of cost management and flexibility. Kumar and Gore (2024) showed that an RL-based system dynamically optimized resource allocation in cloud environments, reducing operating costs by 25% and reducing service outages by 30%. RL enabled the system to learn through trial and error, enabling it to quickly adapt to variable workloads. For example, in an e-commerce platform, RL instantly scaled server capacity against sudden demand increases during holiday seasons. Artamonov and Balych (2024), state that such systems are 40% more flexible than traditional methods, especially in hybrid cloud architecture. This flexibility perfectly suits the dynamic nature of cloud computing. While AI-based solutions revolutionize resource optimization, they also present some challenges. Rao (2023) lists high initial costs, data privacy concerns, and a lack of expert personnel as the main obstacles to the widespread adoption of AI. Furthermore, Kristian et al. (2024) emphasize that the energy consumption used in training complex deep learning models may conflict with sustainability goals. To overcome these problems, open-source AI frameworks (e.g., TensorFlow, PyTorch), lightweight models, and energy-efficient algorithms are being developed.

Waste Reduction and Improved Water Efficiency with AI

AI is contributing to sustainability goals by revolutionizing waste management and water efficiency. AI technologies such as machine learning and artificial neural networks have optimized waste separation and resource recovery processes, increasing recycling efficiency by 15% and reducing operational costs by 20% (Li Wei Ming et al., 2024). In Singapore, in particular, AI-powered waste management systems have increased recycling rates by 25% (Hernandez et al., 2024). These innovations reduce the amount of waste going to landfills, preventing environmental pollution and supporting the conservation of water resources. Real-time data analytics of AI transform waste management into a more efficient and environmentally friendly process. AI applications in agriculture reduce water use by 30% and increase crop yields (Hernandez et al., 2024). AI-based systems analyze sensor data to optimize irrigation processes and ensure targeted use of water. This is an important step in combating global water scarcity, as 1.1 billion people worldwide lack access to clean water. In addition, the role of AI in agricultural waste management reduces soil and water pollution by facilitating the recycling of organic waste. However, challenges such as infrastructure limitations and the need for specialized personnel must be overcome for these technologies to become widespread. In wastewater treatment processes, AI increases the potential for water reuse and increases efficiency. AI systems integrated with the Internet of Things (IoT) determine the suitability of water for irrigation by monitoring water quality parameters (Narayanan et al., 2023). AI models exhibit high accuracy (R^2 value between 0.64 and 1.00) in predicting the removal efficiency of pollutants and effectively monitor water quality in wastewater treatment plants (Nagpal et al., 2024). These systems support environmental sustainability by reducing energy consumption and optimizing treatment processes. The success of AI in this area both saves water and contributes to global water management policies.

AI-Driven Crop Protection Solutions

AI and ML revolutionize crop protection strategies, enhance precision farming, pest management, and harvest optimization. These technologies enable real-time monitoring, predictive analytics, and data-driven decision-making, improving resource efficiency and reducing environmental impacts (Gustavo A. Mesías-Ruiz et al., 2023). AI applications in agriculture include big data analysis, pest and disease forewarning models, and ICT-based crop advisory systems (M. Pratheepa et al., 2023). Advanced crop protection techniques incorporate innovative chemical formulations, bio-PPPs, and AI-driven disease detection systems (A. Balafoutis et al., 2021). Integration with IoT and autonomous farming equipment further enhances productivity and minimizes labor costs (Danish Gul & Rizwan-ul-Zama Banday, 2024). However, data quality, infrastructure limitations, and implementation costs persist, particularly for small-scale farmers in developing regions (Danish Gul & Rizwan-ul-Zama Banday, 2024).

Environmental and Social Challenges of AI Implementation

AI is a general term used for a wide range of machine intelligence systems that can copy people's behavior. AI and Big Data have emerged as the defining features of the fourth industrial Revolution (IR). AI has developed tools. Due to innovation, the study of IR, AI and their environmental impact is still in the early stages of research (Adnan et al., 2024). Human-caused climate change and the degradation of our natural environment are critical problems. Advanced technologies such as AI offer the potential for the development of solutions. Machines that learn by acquiring information and perform human-like tasks can help humans reduce their intensive use of natural resources and improve environmental governance for more sustainable living (Taghikhah et al., 2022). The application of AI in environmental monitoring offers accurate disaster forecasts, pollution source detection, and comprehensive air and water quality monitoring (Olawade et al., 2024).Actually, the use of AI technology in environmental management, especially in terms of pollution, has emerged as a remarkable breakthrough in transforming our methodology for monitoring the environment. It has been given many advantages not only for developing AI hardware that focuses on sustainability by reducing energy use and using environmentally friendly materials, but also for improving of climate prediction models and environmental monitoring systems using AI (Adnan et al., 2024). In the other words, with the global energy sector under increasing pressure to support sustainability, the function of AI in improving Environmental, Social and Governance (ESG) performance is of great interest (Wang and Zhang, 2025). Carbon capture, utilization and storage (CCUS) are emerging as a promising solution to reduce global CO_2 emissions from the industrial and energy sectors (Elaouzy and Zaabout, 2025).

The social and environmental effects of developing productive AI. These include environmental challenges such as energy and resource consumption, and social issues such as working conditions and accessibility gaps, which highlight the systemic resource demands and socio-economic consequences of productive AI (Hosseini et al., 2025). As organizations continue to embrace the use of AI systems, it is very important to ensure that these AI systems can be trusted. However, there is still a significant gap between AI research and its application in real-world applications (Cousineau et al., 2024). Firstly, companies should prioritize integrating AI technologies into their ESG strategies by promoting a synergy between green innovation and AI through investments in AI-oriented sustainability solutions and cross-functional cooperation. Secondly, policymakers should provide specific support and incentives such as financial subsidies, tax incentives and technical assistance. In addition, differentiated policy measures are required to meet the specific needs of different types of enterprises, direct kits to pilot large-scale AI-oriented ESG projects, and support SMEs through capacity building and specialized AI tools. Finally, strengthening corporate ESG information disclosure and oversight mechanisms, including standard reporting frameworks and independent audits, is crucial to ensure transparency and accountability (Weng et al., 2025).

Towards Sustainable AI in Food Production: A Balanced Approach

The growing universal population and the growing demand for food are putting significant pressure on the global agricultural system to increase production. However, the expansion of agricultural land often comes at the expense of wildlife habitats, escalates human-wildlife conflicts as crops are damaged by animals, and threatens food security. In addition, the use of unsustainable deterrent methods can harm biodiversity. Current crop protection methods fall short of supporting sustainable agriculture goals (Abed et al.,2025). Agriculture and the food system are facing challenges related to climate change, biodiversity loss, agricultural pollution and food security. Food security at the international and national levels needs to be developed in an environmentally and resource-friendly way. Digitalization and AI provide opportunities to overcome these challenges and facilitate the transformation of agriculture and the food value chain (Wepner et al., 2025). One study used image-based experimental methods to explore the intersection of sustainability, gastronomic tourism and AI, with a focus on promoting ‘climate-conscious food’. This term refered to food produced with environmentally friendly practices. Despite the benefits of climate-conscious foods for individuals, the environment and local tourism, their adoption remained limited. This conceptualized research on visual information processing consists of two studies that use bottom-up and top-down processing. It confirmed that the type of content in the images generated by AI, especially the “Food

Presentation" versus the "Preparation Process", significantly affected consumers' perceptions of food quality and purchasing intentions (Chan et al., 2025). Indeed, the widespread use of chemical fertilizers on small farms has helped to increase crop yields, support food security and economic growth. However, recent studies have showed that these fertilizers are often used inefficiently and inconsistently. This leads to environmental damage, unstable soil nutrients and low-quality food production (Pandian et al., 2024). Infrastructure limitations, high implementation costs and data privacy concerns must be resolved to promote fair access and widespread adoption. Standardization of interoperability and quality control protocols is also critical to ensure accurate measurement and reporting of emissions. Future research should further refine ML models to address local variability in climate, soil, and farm practices, while exploring collaborative frameworks that protect data privacy (e.g., unified learning). Moreover, integrating policy incentives, capacity building programs and stakeholder collaborations can accelerate the use of IoT and Big Data tools in real-world agricultural environments. By addressing these issues, the agricultural sector can benefit from digital innovations to reduce its carbon footprint, increase resilience to climate change, and advance global sustainability goals (Ahmed and Shakoor, 2025). In the context of greenhouse agriculture, the integration of AI is being evaluated in terms of its potential to improve sustainability and crop production efficiency (Hoseinzadeh and Garcia, 2024). The relationship between developments in Industry 4.0 technology such as AI and their impact on the earth, the environment, humans and biological ecosystems needs to be taken into account more consideration. One article addressed the challenge of monitoring the indicators of the 17 SDGs by taking advantage of Industry 5.0 developments. It offered practical verification of the framework through use cases in energy and water management. The results showed how the framework can improve the sensitivity, transparency and scalability of SDG monitoring while providing useful information to stakeholders. (Hassan et al., 2025).

Future Directions: Accessibility, Governance, and Impact Alignment

Future directions necessitate a focus on critical areas such as accessibility, governance, and impact alignment with the widespread adoption of AI and related technologies. Particularly, with the increasing prevalence of AI-driven solutions in environmental monitoring and sustainable agriculture practices, ensuring these technologies are accessible to all stakeholders is of paramount importance. As emphasized by Ahmed and Shakoor (2025), the effectiveness of Internet of Things (IoT), Big Data, and AI-based smart agriculture technologies in supporting sustainability hinges on their ease of adoption and implementation by farmers and other users in rural areas. Furthermore, as noted by Cousineau, Dara, and Chowdhury (2024), AI systems must be operated within a transparent and accountable governance framework, considering the challenges and opportunities faced by AI developers in creating trustworthy AI applications. The meticulous evaluation of the environmental and socioeconomic impacts of AI technologies and their alignment with sustainability principles is also a priority among future directions. The research by Hosseini, Gao, and Vivas-Valencia (2025) underscores the need for a comprehensive analysis of the social and environmental impacts of generative AI. Similarly, Wang and Zhang (2025) highlight the importance of innovation, collaboration, and proactive sustainability strategies to enhance the environmental, social, and governance performance of AI-enabled supply chains in the energy sector. In this context, minimizing the environmental footprint, promoting social justice, and establishing robust governance mechanisms are critical considerations in the development and implementation of AI applications. Lastly, an interdisciplinary approach is essential for aligning AI technologies with sustainable development goals. The study by Pandian et al. (2024) emphasizes the significance of synergistic conservation strategies that address the interconnections between soil health, food security, and human health. In this regard, collaboration among experts from various disciplines and the adoption of a holistic perspective towards sustainability goals are necessary during the development and implementation of AI applications. As indicated by Wepner et al. (2025), the exploration of digitalization's impacts on the sustainability of agri-food systems through diverse scenarios will guide the effective utilization of AI and digital technologies.

Conclusion

The global food system faces significant interconnected challenges spanning environmental sustainability, socio-economic equity, and political governance, demanding a transformative shift to feed a growing population responsibly. AI emerges as a powerful catalyst in this transformation, offering promising solutions for enhanced efficiency, sustainability, and resilience across the agrifood value chain. From precision agriculture optimizing resource use to AI-driven crop protection and waste reduction, the integration of AI technologies presents substantial benefits for environmental stewardship and resource management. However, the widespread and equitable adoption of AI in agrifood production is not without its hurdles. Issues such as high initial costs, infrastructure limitations, data privacy concerns, and the energy consumption of AI models themselves must be carefully addressed. Ensuring accessibility for smallholder farmers, establishing robust governance frameworks, and aligning AI development with broader sustainability principles are crucial for realizing the full potential of AI in creating a more sustainable and equitable food future. Moving forward, a balanced approach is essential. This involves fostering international collaboration, promoting open-source AI solutions, developing energy-efficient

algorithms, and implementing supportive policies that prioritize inclusivity and capacity building. Future research should focus on refining AI models for local contexts, exploring collaborative data governance frameworks, and integrating policy incentives to accelerate the adoption of sustainable AI practices in agriculture. Ultimately, by thoughtfully navigating the challenges and strategically leveraging the opportunities, AI can be a transformative force in building a global food system.

Determination of Amino Acid Profile of Sea Bass Cooked in Microwave Oven

Adem Savaş[1]

[1]Hazelnut Specialisation Coordination Office, Prof. Ahmet Taner Kışlalı Street, Giresun University, Giresun, Türkiye

Abstract

It is evident that fish and fish products constitute a significant dietary source of animal origin for humans, playing a crucial role in the human nutrition. These products are of esential importance in ensuring adequate and balanced nutrition. The nutritional value of fish is subject to variation depending on the species; however, it is widely considered to be an excellent source of protein. In addition, fish products contain significant levels of omega-3 and other fatty acids necessary for our body. The present research aimed to determine the amino acid profile and some quality parameters of sea bass cooked using microwave. While the average pH value of the sea bass fish used in the study was 6.39, their moisture content was determined as 73.58%. Additionally, fifteen different amino acids were examined in the study. The amino acid content of the sea bass samples was found to vary between 1.97 and 178.22 µg/g. Major amino acids were determined as lysine, glycine, glutamate, alanine, proline and phenylalanine.

Key Words: *Fish, microwave, sea bass, cooking, amino acid profile*

Introduction

It is an irrefutable fact that foods of animal origin (such as red meat, chicken and fish) are indispensable products of human nutrition. Notably, fish constitutes a significant protein and nutrient source, essential for maintaining a healthy diet (Savaş et al., 2021; Savaş et al., 2023; Borrull et al., 2025). The nutritional composition of fish and its products is subject to variation due to a number of factors, including species, genus, age and geographical location. As is well documented, fish products boast a highly sophisticated composition in terms of both macro and micro components. Notably, fish proteins are distinguished by their complete amino acid profile, which is indispensable for the protection and development of body tissues (Turan et al., 2006).

Türkiye has the potential to become a significant producer of fish products. The region's strategic positioning, encompassed by seas and boasting approximately 25 million hectares of arable land conducive to aquaculture, confers a series of substantial benefits. Sea bass (Dicentrarchus labrax), a highly regarded fish product, is one of the fish species produced and consumed in Turkey and the Mediterranean countries (Alpaslan and Baygar, 2009; Karahan, 2009).

The consumption of meat products is typically followed by a process of cooking. While the cooking process provides both flavour and aroma to meat and meat products, it also contributes to the production of a microbially consumable product. However, in addition to the loss of nutrients due to inadequate cooking conditions, there is also the formation of mutagenic and/or carcinogenic compounds (Savaş et al., 2021; Savaş et al., 2023).

A substantial number of epidemiological studies have been published which demonstrate the significant role that nutrients and dietary habits play in certain diseases to which the societies is exposed. Consequently, there is an increasing awareness of the necessity to adopt a more conscious approach to eating. In this context, the number of studies on fish with a high nutritional composition continues to increase. In the present study, the analysis of sea bass fish was conducted in accordance with a range of quality parameters and amino acid profiles, utilising a microwave oven as the primary analytical instrument.

Materials and Methods

The sea bass (Dicentrarchus labrax) used as raw material in the research were obtained from the fish market in Giresun province. Special care was taken to ensure that the weight and size of the purchased fish were similar.

Cooking process

Samples of fish were transferred to the laboratory in a refrigerated environment and then subjected to a meticulous cleaning process to remove any internal organs. The fish samples were divided into two parts and cooked in a

microwave oven (MD 211DG, Arçelik, Turkey) with skin for a duration of 14 minutes. No oil and spices were used during the cooking process.

Water content ve pH analysis

Water content and pH values of the samples were determined according to the methods of Gokalp et al. (2010).

Free Amino Acid Screening with LC-MS/MS

The extraction of free amino acids from the samples was conducted as follows: 0.5 g of each sample was homogenised with 40 ml of 0.1 M HCl solution. The homogenate was then stored at 4°C for a period of 12 hours. Subsequently, the samples were subjected to centrifugation (MR 23i, Thermo Fisher Scientific) at 10000 g for 50 minutes at 4°C. Following extraction, the samples were filtered through a PTFE filter (Isolab 0.45 um) and transferred to a capped vial (Antoine et al., 1999; Oz, 2018).

Analyses were performed using a combined system of liquid chromatography (Spark Holland) and tandem mass spectroscopy (AB SCIEX 4000 QTRAP). The conditions for chromatographic analysis were; a C18 type column (Inertsil ODS-3V 250 mm x 4.6 mm, 5 µm), injection volume 10 µL, flow rate 0.700 mL/min and column oven temperature 30°C.

Statistical analysis

The present study was conducted using a completely randomised design with three replicates. All the data were presented as the mean ± standard deviation of the mean.

Results and Discussion

The water and pH values of the sea bass (Dicentrarchus labrax) used as raw material in the research were determined as %73.58±0.79 and 6.39 ± 0.03, respectively. Indeed, a preponderance of studies conducted hitherto have yielded analogous results (Türkkan et al., 2008; Sumi et al., 2025).

The amino acid profile of sea bass samples subjected to microwave-based cooking techniques in the present study is outlined in Table 1. In the present study, the amino acid composition of sea bass samples was analysed. The amino acid content of the samples exhibited a range from 1.97 to 178.22 µg/g. Subsequent analysis of the results yielded the determination that the predominant amino acids were lysine, glycine, alanine, glutamate, methionine, leucine, isoleucine and phenylalanine. Similar studies have been conducted in the literature (Baki et al., 2015). Sumi et al. (2025) determined seventeen different amino acids in their study on cultured and wild sea bass and reported that the amino acid contents of the samples varied between 17.11 mg/g and 116.03 mg/g.

Table 1. Amino acid profile of sea bass fish samples

Amino acid profile	Sea bass (µg/g)
Lysine	29.93±0.96
Histidine	1.99±0.10
Glycine	178.22±4.92
Serine	2.07±0.18
Alanine	137.29±3.72
Glutamic acid	72.44±1.55
Cysteine	6.83±0.14
Aspartic acid	18.94±1.13
Proline	16.96±0.77
Methionine	91.06±1.90
Leucine	29.93±0.88
Isoleucine	18.68±0.12
Tyrosine	5.29±0.17
Phenylalanine	57.85±1.03
Tryptophan	1.97±0.06

Conclusion

It is evident that fish and fish products constitute a significant component of the human diet, representing a vital source of animal protein. As is well documented, fish products exhibit a rich fatty acid profile and constitute a significant protein source. Furthermore, it is a rich source of essential and non-essential amino acids. The present study investigates the amino acid profile of sea bass fish. In this study, the amino acid profile of sea bass was examined after cooking it using microwave and fifteen different amino acids were determined. The effect of cooking on the nutritional composition of meat and meat products is significant. Consequently, there is a necessity for further research to ascertain the most suitable cooking methods.

Aflatoxins in Hazelnuts and Their Effects

Adem Savaş[1]

[1]Hazelnut Specialisation Coordination Office, Prof. Ahmet Taner Kışlalı Street, Giresun University, Giresun, Türkiye

Abstract

Hazelnuts are considered a significant component of human nutrition. They occupy a significant position in the classification of nuts, particularly with regard to production and consumption volumes. The leading producers of this commodity include Turkey, Italy, Azerbaijan, Georgia and other countries. Hazelnuts are consumed raw and also processed into a wide variety of food products. However, a significant challenge for hazelnuts and their products is the presence of aflatoxins. Aflatoxin and its metabolites pose a significant risk to human health as carcinogenic substances. Sensitive and rapid detection and detoxification of aflatoxins is invaluable in food safety, environmental monitoring and risk assessment. Aflatoxins produced by *Aspergillus flavus* and *Aspergillus parasiticus* are among the most toxic mycotoxins. And the formation of these mycotoxins is affected by many parameters such as environmental environment, temperature, humidity. In this context, the current research has compiled the presence of aflatoxins in hazelnuts and their products, detoxification methods and their effects on human health.

Key Words: *Hazelnut, aflatoxins, detoxification, health, nuts*

Introduction

Nuts are a class of foodstuffs that are included in human nutrition and possess both nutritional content and functional properties. Hazelnut (*Corylus avellana* L.), which occupies a significant position in this food group, is distinguished as one of the most produced and consumed nuts globally. As it is known, hazelnut is a plant from the birch family and among the most important producers are Turkey, Italy, Georgia, Azerbaijan, USA and other countries. Hazelnuts can be consumed both raw and used as raw material in many areas, especially in the chocolate industry. On the other hand, mycotoxins have been identified as a fundamental factor contributing to significant quality issues in hazelnut products, which are characterised by their high content of bioactive components, fatty acids, and antioxidants (Zhao et al., 2023; Savaş, 2024b, Savaş, 2024a).

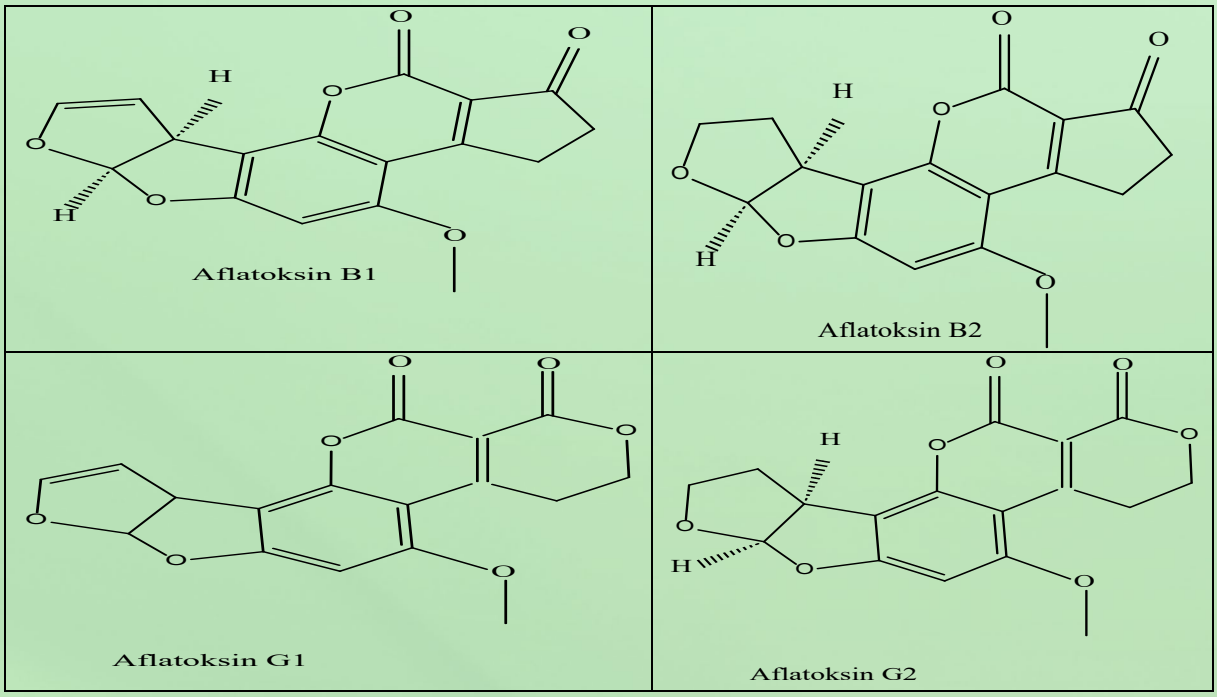

Figure 1. Hazelnut samples with and without aflatoxin

Mycotoxins are defined as secondary metabolites with the capacity to affect human health. To date, more than 400 mycotoxins have been identified, which have toxic effects on animals, including humans (Savaş, 2024; Pokoo-Aikins et al., 2024). The most well-known of these are aflatoxins (AFs), zearalenone (ZEA), deoxynivalenol (DON) and ochratoxin (OTA). Furthermore, these toxins have been observed to accumulate in the organs or tissues of animals upon ingestion, and consequently, they can be transferred to foods of animal origin(Juan et al.,

2019; Alaboudi et al., 2022). Especially among these mycotoxins, aflatoxins with difuran and coumarin skeletons are among the most toxic mycotoxin representatives(Yang and Wang, 2021; Kang and Zhao, 2025).

Aflatoxins, of which twenty types have been identified, are important toxins produced by *Aspergillus flavus* and *Aspergillus parasiticus*. The identification of aflatoxins is based on a combination of molecular differences, fluorescence properties under ultraviolet light, and chromatographic mobility (Catanante et al., 2016; Kang and Zhao, 2025). As has been demonstrated by numerous studies, the presence of aflatoxins has been identified in spices, nuts and fermented products, particularly in cereals. It has been asserted that the toxicity of aflatoxin B1 is significantly higher than that of potassium cyanide (10 times) and arsenic (68 times). Aflatoxin and its metabolites have been demonstrated to pose a significant risk to human health as carcinogens. Moreover, it is also stated that they have various effects such as hepatotoxic, genotoxic and mutagenic. (Kang and Zhao, 2025). However, aflatoxins, which are classified as hepatocarcinogens, are mostly stated to have uncertain effects on tissues other than the liver (Yang and Wang, 2021). In this context, Herzallah (2013) reported that aflatoxin B1 residues were detected in eggs and meat of chickens fed with aflatoxin B1-contaminated feed and egg production decreased. The chemical structures of the most common aflatoxins are presented in Figure 2.

Figure 2. Chemical structures of aflatoxin B1, B2, G1 and G2

The ingestion of aflatoxin-contaminated foodstuffs or animal products has been demonstrated to engender a range of health risks. The most prevalent methods of detoxification of aflatoxins are physical, chemical and biological. (Wang et al., 2025). Due to the thermal stability of aflatoxins, it is stated that AFB1 cannot be destroyed by normal cooking processes. However, various studies in the literature have reported that aflatoxins can be detoxified from different food products. For example, Wang et al. (2025) reported that AFB1 can be removed from peanut oil at different levels in their study. Şen et al. (2019) reported that cold plasma and gamma irradiation methods detoxify AFB1 at different levels in hazelnut samples. On the other hand, it has been revealed by various studies that aflatoxins can be detoxified. However, it is a fact that detoxification methods have various disadvantages in terms of high cost and side effects.

The impact of mycotoxins on human health has been elucidated through in vivo, in vitro and epidemiological studies. In particular, aflatoxins, which constitute one of the most significant toxic classes among mycotoxins, have been demonstrated to exert effects on reproduction and development, neurotoxicity, intestine and metabolism by in vivo, in vitro and epidemiological studies (Kousar et al., 2024; Wang et al., 2025). In this context, it is hypothesised that the consumption and formation conditions of foods containing aflatoxins should be prevented.

Conclusion

Nowadays, there is a growing interest in healthier, functional foods. However, various toxic compounds, including aflatoxins, may occur as a result of improper harvesting, storage, transport and applied processes. A review of the extant literature reveals numerous studies addressing the presence of aflatoxins in hazelnuts and various food groups. In particular, it is thought that the formation levels of aflatoxins should be at a minimum level due to their health effects and carcinogenicity, and more focus should be placed on control mechanisms and detoxification studies.

Serbest ve Zenginleştirilmiş Kafes Sisteminin Yumurta Mineral Madde Ve Yağ Asitleri İçeriğine Etkisi

Mehmet Zahit DEMİR, Hasan ELEROĞLU

Özet

Bu araştırmada serbest ve zenginleştirilmiş kafes sisteminin yumurta mineral madde içeriğine etkisi üzerinde durulmuştur. Çalışma, zenginleştirilmiş kafes sistemi ve altlıklı yer sisteminde yetiştirilen Atak-S kahverengi yumurtacı hibritlerden elde edilen yumurtalar üzerinde yürütülmüştür. Toplanan yumurtaların Palmitik Asit (PA), Stearik Asit (SA), Oleik Asit (OA), Linoleik Asit (LA), α-Linoleik Asit (ALA) ve Miristik Asit (MA) içerikleri analiz edilmiş, yetiştirme sistemlerinin bu özellikler üzerine etkisi bulunmamıştır ($p>0,05$). Toplanan yumurtaların ağır metal içeriklerini belirlemek amacıyla Demir (FE), Bakır (CU), Çinko (ZN), Kurşun (PB), Kadmiyum (CD) ve Krom (CR) analizleri yapılmıştır. Yetiştirme sistemlerinin toplanan yumurtaların ağır metal içeriği üzerine etkisi bulunmamıştır ($p>0,05$). Yumurta kalitesinin artırılması yönünde yapılacak çalışmalara kaynak oluşturacak bu araştırma sonuçları dikkate alındığında, serbest gezinmeli sistem ve zenginleştirilmiş kafes sisteminde barındırmanın yumurta iç kalitesi üzerine farklılık meydana getirmediği dikkate alındığında, zenginleştirilmiş kafes sisteminin açık sisteme benzer yumurta iç kalitesine etkide bulunduğu sonucuna varılmaktadır. Ancak, bu araştırmada tek bir genotip dikkate alınmış olup, ileri çalışmalarda genotip farklılığının yetiştirme sistemleri ile birlikte alınmasında yarar vardır.

Traceability in Food Logistics: From Farm to Fork

Usman Mir Khan[1*], Mesut Selamoglu[2]

[1]National Institute of Food Science and Technology, University of Agriculture Faisalabad, Pakistan
[2]Logistics Program, Department of Management and Organization, Bahce Vocational School, Osmaniye Korkut Ata University Bahce, Osmaniye, Türkiye

***Corresponding Presenter's Email:** usmanmirkhan@yahoo.com

Abstract

Traceability is an important cog in the machinery of modern food logistics systems for attaining the twin objectives of transparency, safety, and efficiency along the food supply chain. Traceability systems allow for real-time monitoring, verification, and response by stakeholders in food production and consumption, from farm to fork, to any issues concerning quality or safety. Thus, this study proposes investigating the traceability of food logistics and the ensuing role in food safety, compliance, and consumer trust. The main focus of the paper is on the structure and operation of traceability systems, resulting-from-technologies like barcoding, RFID, IoT devices, and blockchain applications. These technologies promote the tracing of food products through supply chain nodes: producers, processors, distributors, and retailers: while enabling faster corrective action. The analysis of the cases three from developed countries and three from emerging ones reveals best practices and widespread challenges in the adoption of traceability systems. The study also points to the increasing relevance of end-to-end visibility for sustainable and resilient food supply chains. With growing global trade in food and consumer awareness, traceability is no longer a regulatory requirement but also a strategic marketing tool to gain a competitive edge. Hence, the research elaborates that proper traceability improves accountability, risk management, and trust among stakeholders in food logistics operations. The study recommends investments in traceability technologies and alignment with regulations as critical for making food logistics systems evolve in today's increasingly complex global environment.

Abstract

In this study, the species of Potato Cyst Nematode (PKN) populations taken from 38 locations where intensive potato cultivation is carried out in Niğde province were determined by molecular method. *Globodera rostochiensis* (Wollenweber, 1923) Skarbilovich, 1959, named as Golden cyst nematode, and *G. pallida* Stone, 1973 (Tylenchida: Heteroderidae), named as White cyst nematode, are species that cause serious yield losses in potato cultivation in our country and worldwide. *G. rostochiensis*, which was first detected in Bolu province in Turkey in 1985, was also detected in Niğde, Nevşehir, İzmir, and Afyon provinces in the following years. Accurate and rapid species identification is very important in resistant variety development studies, which is the most effective control strategy against *G. rostochiensis* and *G. pallida.* ITS5, PITSp4, PITSr3 primers were used to distinguish nematode species by molecular method. As a result of species identification, *G. pallida* was not detected and all samples were identified as *G. rostochiensis*.

***Key Words*:** Potato Cyst Nematode, Niğde, molecular diagnosis, potato.

Niğde İli Patates Altın Kist Nematodu (*Globodera rostochiensis*) Popülasyonlarının Moleküler Tür Teşhisi

Özet

Bu çalışmada Niğde ilinde yoğun patates yetiştiriciliği yapılan 38 lokasyondan alınan Patates Kist Nematodu (PKN) popülasyonlarında moleküler tür teşhisi yapılmıştır. Altın kist nematodu olarak isimlendirilen *Globodera rostochiensis* (Wollenweber, 1923) Skarbilovich, 1959 ve Beyaz kist nematodu olarak isimlendirilen *G. pallida* Stone, 1973 (Tylenchida: Heteroderidae), ülkemizde ve dünya çapında patates yetiştiriciliğinde ciddi verim kayıplarına neden olan türlerdir. Türkiye'de ilk kez 1985 yılında Bolu ilinde tespit edilen *G. rostochiensis* daha sonraki yıllarda Niğde, Nevşehir, İzmir, Afyon illerinde de saptanmıştır. *G. rostochiensis* ve *G. pallida'*ya karşı en etkili mücadele stratejisi olan dayanıklı çeşit geliştirme çalışmalarında doğru ve hızlı tür teşhisi yapılması oldukça önemlidir. Moleküler yöntemle nematod türlerini ayırmada ITS5, PITSp4, PITSr3 primerleri kullanılmıştır. Tür teşhisi sonucunda *G. pallida* tespit edilmemiş olup tüm örnekler *G. rostochiensis* olarak tanımlanmıştır.

***Anahtar Kelimeler*:** Patates Kist Nematodu, Niğde, moleküler teşhis, patates.

Abstract

Caused by *Magnaporthe oryzae* B.C. Couch, rice blast is considered as the main fungal disease in rice fields in Burkina Faso. Pure essential oils of *Cymbopogon schoenanthus, Ocimum americanum, Ocimum gratissimum* and *Lippia multiflora* were tested in vitro to assess the radial growth and inhibition rate of the fungus using the contact and fumigation methods. For each essential oil, five doses were developed: D2 (0.1 µl/ml), D4 (0.6 µl/ml), D6 (1.2 µl/ml), D8 (1.8 µl/ml) and D10 (2.4 µl/ml). In both tests, two synthetic fungicides namely mancozeb and azoxystrobin at recommended doses of 6.67 µl/ml and 3.33 µl/ml respectively, and an absolute control were used. The results showed that in the contact method, pure essential oils of *O. americanum, L. multiflora, C. schoenanthus* and *O. gratissimum* inhibited 100% of the mycelial radial growth of the fungus at doses D10 (2.4 µl/ml), D4 (0.6 µl/ml), D6 (1.2 µl/ml) and D4 (0.6 µl/ml) respectively. As for the fumigation method, oils of *O. americanum, L. multiflora, C. schoenanthus* and *O. gratissimum* inhibited mycelial radial growth of the fungus by 100% at doses D10 (2.4 µl/ml), D2 (0.3 µl/ml), D6 (1.2 µl/ml) and D8 (1.8 µl/ml) respectively. Mancozeb and azoxystrobin inhibited radial mycelial growth by 100% and 74.1% respectively. These essential oils can be used to control rice blast in the field. This will also reduce environmental pollution.

Key words : *Essential oils, Efficacy, Oriza sativa, Magnaporthe oryzae, Burkina Faso*

Introduction

Rice blast, caused by the fungus *Magnaporthe oryzae*, remains the most damaging fungal constraint to rice production, with damage that can cause yield losses of up to 100% if no protective measures are taken (Zhan *et al.,* 2018 ; Li *et al.,* 2019 ; Savary *et al.,* 2019 ; Kassankogno *et al.,* 2021). The use of chemicals such as tricyclazole to control M. oryzae has been successful in increasing yields (Moinina *et al.,* 2018). However, their application has numerous consequences for human and animal health and the environment. It is therefore necessary to use alternative control methods such as biological control through the use of biopesticides (Yarou *et al.,* 2017 ; Gamsore *et al.,* 2018 ; Toundou *et al.,* 2020). Studies have shown that essential oils possess insecticidal, bactericidal or fungicidal properties (Amarti *et al.,* 2010 ; Hamdani *et al.,* 2015). Also, other authors have shown that Lippia multiflora essential oil has strong antifungal activity, totally inhibiting the mycelial growth of Fusarum moniliforme and *Bipolaris oryzae* at 100 ppm and 400 ppm respectively (Tiendrebeogo *et al.,* 2017). However, the use of essential oils from aromatic plants for the control of M. oryzae remains largely unexplored. With this in mind, the present study was initiated to evaluate the *in vitro* efficacy of *Cymbopogon schoenanthus*, *Ocimum americanum*, *Lippia multiflora* and *Ocimum gratissimum* essential oils for the control of *M. oryzae*. Specifically, the aim is to evaluate the *in vitro* comparative activities of four essential oils on mycelial radial growth of *Magnaporthe oryzae* B.C. Couch, a rice blast pathogen in burkina faso.

Materials and methods

Fungal material

The fungal material used was *Magnaporthe oryzae* strain BF075 from rice leaves collected at the Farakô-Bâ site and isolated at INERA Farakô-Ba's phytopathology laboratory. The choice of this strain is justified by its virulence level (Kassankogno, 2016).

Essential oils

The essential oils of the *C. schoenanthus, O. americanum, L. multiflora* and *Ocimum gratissimum* aromatic plants used for the tests were extracted from the leafy twigs and used in pure without any combination.

Effects of essential oils on mycelial growth of M. oryzae on PDA medium

The essential oils were tested using two methods: the contact or "poisoned food" method (Adam *et al.,* 1998), which involved mixing the essential oils directly into the Potato Dextrose Agar (PDA) culture medium, and the fumigation or micro-atmosphere method, where the essential oils were poured and then spread on the underside of the Petri dish lid (Tonzibo *et al*., 2013). For each type of essential oil, five (05) doses (D) were prepared in the following proportions : D2 (0.1 µl/ml), D4 (0.6 µl/ml), D6 (1.2 µl/ml), D8 (1.8 µl/ml) and D10 (2.4 µl/ml). In both tests, two synthetic fungicides, mancozeb and azoxystrobin, at recommended doses of 6.67 µl/ml and 3.33 µl/ml respectively, and an absolute control were used. Petri dishes were then placed in an incubation chamber. For each method, the thallus diameters (in mm) of colonies in each Petri dish were measured for 14 days after incubation (JAI) at two-day intervals (Sirima *et al.,* 2020 ; Kassankogno, 2016).

- Assessment of mycelial growth : from seven (07) days of pure culture of *M. oryzae*, one (01) explant measuring six (06) mm was removed and placed in the center of the Petri dish containing the culture medium. Mycelial radial growth was assessed by averaging the two (02) perpendicular diameters passing through the middle of the explant (Sirima *et al*., 2020). Three replicates were performed for each concentration.

- Minimum inhibition doses : the inhibition rate (IR) was calculated according to the following formula: $\boldsymbol{TI}_{(\%)} = \left(\frac{T_0 - T}{T_0}\right) \times 100$.. With T0 = mean value recorded in control medium, T = mean value recorded in culture medium containing essential oil or fungicide (Sirima et al., 2020) From these inhibition rates, minimum inhibition doses were determined.

Results

Effects of essential oils on M. oryzae growth on PDA medium

A variation in the radial mycelial growth of *M. oryzae* as a function of the oils and the method used is shown in Figures 1 and 2. Analysis of variance showed a highly significant difference between the radial mycelial diameters of the different essential oils compared with the controls. In the contact method, pure essential oils of *O. americanum, L. multiflora, C. schoenanthus* and *O. gratissimum* inhibited mycelial radial growth of the fungus by 100% at doses D10 (2.4 µl/ml), D4 (0.6 µl/ml), D6 (1.2 µl/ml) and D4 (0.6 µl/ml) respectively. As for the fumigation method, oils of *O. americanum, L. multiflora, C. schoenanthus and O. gratissimum* inhibited 100% of the mycelial radial growth of the fungus respectively from doses greater than or equal to D10 (2.4 µl/ml), D2 (0.3 µl/ml), D6 (1.2 µl/ml) and D8 (1.8 µl/ml). Fungicides based on mancozeb and azoxystrobin inhibited radial mycelial growth by 100% and 25.9% respectively.

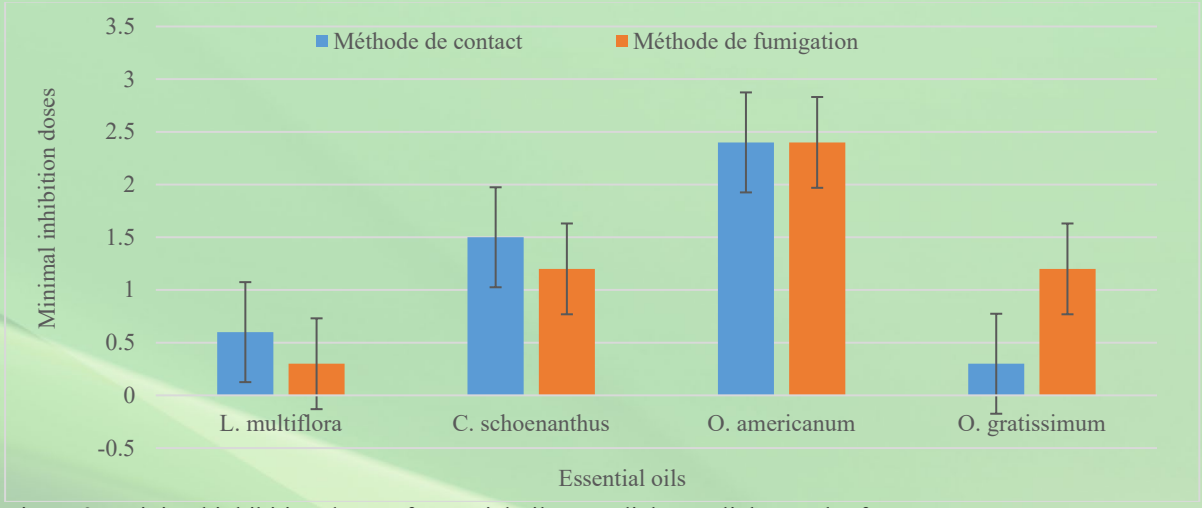

Figure 3 : Minimal inhibition doses of essential oils on radial mycelial growth of *M. oryzae*.

Determination of minimum inhibition doses

The minimum inhibition doses of the various essential oils on radial mycelial growth using the contact and fumigation methods are shown in figure 3.

Analysis of variance showed a highly significant difference between the minimum inhibition doses of the different essential oils. In terms of the parameters evaluated, *O. americanum* essential oil recorded the highest minimum inhibition dose (2.4 µl/ml) in both contact and fumigation methods. In the contact method, *Ocimum gratissimum* oil recorded the lowest minimum inhibition dose (0.3 µl/ml) for all parameters assessed. In the fumigation method, the essential oil of *L. multiflora* applied in pure form recorded the lowest minimum inhibition dose of 0.3 µl/ml on mycelial growth.

Discussion

The effect of essential oils on the growth of *M. oryzae* in vitro varied according to the type of oil and the method used. *O. gratissimum* essential oil was the most effective in inhibiting radial mycelial growth of the fungus. This effectiveness in reducing radial mycelial growth can be explained by its content of major elements, its antifungal properties and its chemical composition, which enable it to stop or slow down the fungus' development (Mohamed *et al.,* 2012). The inhibitory effect of these oils can be attributed to their major compounds, such as 1,8-cineole for *O. americanum* essential oil, or to the synergistic or additive effect of these compounds (Ambindei *et al.,* 2014). According to Sirima *et al.* (2020), the essential oil of *C. schoenanthus* and *L. multiflora* exhibited strong antifungal activity, stopping the mycelial growth of *Alternaria sp* isolates at doses ranging from 5% to 100%.
For Tiendrebeogo *et al*. (2017), the essential oil of *L. multiflora* exhibits strong antifungal activity, totally inhibiting the mycelial growth of *P. oryzae* at 600 ppm. They also showed that this essential oil totally reduced the mycelial growth of F. moniliforme and *B. oryzae* at 100 ppm and 400 ppm respectively. Their work also showed that essential oils were more effective in inhibiting fungal mycelial growth than aqueous plant extracts.
These results can be explained by a probable deactivation or disruption of the fungus's operating system by essential oils. The work of Hamdani *et al* (2015) showed strong 100% inhibition of Fusarium spore germination by *C. aurantium sp* and *F. oxysporum* by *C. sinensis*, while essential oils of *C. limon* and *C. reticulata* stimulated spore germination by 48% and 53% respectively in Alternaria sp. *Magnaporthe oryzae* is a fungus that can infect rice seeds in storage.

Conclusion

The various tests carried out in this study on essential oils and their combinations enabled us to verify their efficacy against *M. oryzae*. All essential oil formulations were effective in inhibiting *M. oryzae*. However, *L. multiflora* oil and *C. schoenanthus* oil used in pure form showed better minimum inhibitory doses on mycelial radial growth of *M. oryzae* spores, with values of 0.6 µl/ml and 1.5 µl/ml respectively. The essential oil of *O. gratissimum* was most effective with a minimum inhibition dose of 0.3 µl/ml. These results attest to the potential of essential oils as a natural means of controlling the pathogen responsible for rice blast. These essential oil formulations can now be tested in real-life conditions to assess their effectiveness in controlling rice blast.

Abstract
The exponential growth of electronic waste (e-waste) has become an urgent environmental and public health concern due to its toxic composition and propensity for illegal disposal. This review synthesizes e-waste generation, composition, and policy responses globally. It discusses the toxicological risks posed by heavy metals, brominated flame retardants, and persistent organic pollutants contained in the majority of end-of-life electronics. The paper then goes on to discuss emerging green technologies for e-waste recycling such as hydrometallurgical leaching, bioleaching, supercritical fluid extraction, and microfactory systems that minimize environmental damage while maximizing material recovery. It also explores the impact of producer responsibility, integration of the informal sector, and eco-design on the evolution of sustainable e-waste management systems. Global policies, for example, Basel Convention and WEEE Directive, are critically discussed alongside problems of transboundary dumping, informal recycling hazards, and inadequate public enlightenment. The article concludes by propounding multi-stakeholder frameworks towards creating secure, efficient, and equitable circular e-waste systems.
Keywords: E-waste, Toxicity, Recycling technology, Bioleaching, Producer responsibility, Circular electronics

Introduction

New technology diffusion, speedy product development, and push consumption have reduced the product life cycle to unprecedented dimensions, resulting in unprecedented generation of e-waste. Global e-waste generation through 2019 was 53.6 million metric tons, 21% growth over five years, as per Global E-waste Monitor 2020. Global e-waste projection is that global e-waste will surpass 74 million metric tons by the year 2030, an virtual doubling over ten years (Ilankoon et al., 2018).

E-waste, for all its vast resource pool, is otherwise dominated by hazard. Many of the different components are made with lead, mercury, cadmium, brominated flame retardants (BFRs), and persistent organic pollutants (POPs), and both disposal and recycling are complicated and risky unless properly carried out. Compounding the issue is that a mere reported 17.4% of the globe's e-waste has actually been gathered and recycled as such, so the rest has to be treated illegally or informally disposed of (Ahirwar & Tripathi, 2021).

The socio-economic complexity of the e-waste problem is also technical and environmental. The poorly equipped developing world is being used as a dumping site for obsolete electronics in illegal or poorly controlled flows. Workers and local communities in the unorganized recycling that provides livelihood for millions are generally exposed to serious health hazards. The resolution of these issues requires an intervention across the entire range by sets of technological, regulatory, economic, and social measures (Lee et al., 2024).

Toxicological Risks and Environmental Impacts

The toxic chemistry of e-waste results from the chemically diverse composition of metals, plastics, glass, and other additive chemicals. Cadmium and lead are heavy metals that are nephro- and neurotoxic and are extremely toxic to extremely vulnerable groups such as children. Neurological damage and impairment of development have been associated with mercury exposure, which permeates switches and flat-panel displays (Lin et al., 2022).

Brominated flame retardants BFRs or plastic additives used as fire retardants are known endocrine disruptors and possible carcinogens alongside metals. They are also classified as persistent organic pollutants and bioaccumulating substances with a suspected causative role in diseases concerning the thyroid, affected reproduction, and neurotoxicity (Darnerud, 2008).

Environmental contamination caused by e-waste is largely caused by careless recycling. Incinerating wires to obtain copper releases dioxins and furans, the most poisonous chemicals at parts per million. Acidic baths used to recover noble metals off printed circuit boards release heavy metals and sulfuric acid into water and land,

respectively. These contaminants change soil chemistry, lower agricultural yields, and destroy aquatic life (Leung, 2019).

No effect on health deterioration. Recyclers also have very high rates of chronic diseases including respiratory disease, bodywide infection, and skin diseases. In the two biggest e-waste dumping grounds Agbogbloshie (Ghana) and Guiyu (China) compared, their children employed at the dumping grounds have lead blood levels very high, which require immediate intervention (Zeng et al., 2016).

Hence, the toxicological and environmental impact of e-waste in the absence of regulation is not only a local but also a global public health phenomenon demanding attention by coordinated global action and regulatory policies (Li & Achal, 2020).

Innovations in Sustainable Recycling Technologies

The ecological cost of native recycling regimes necessitates more sustainable alternatives. Modern technologies seem promising for eco-friendly disposal of e-waste. Hydrometallurgical operations have recently attracted much attention, involving aqueous solutions for the selective dissolution of metals. These operations are characterized by low temperatures of the processing, lower emissions of processes, and high-purity metal recovery options. The new developments include biodegradable solvents and microbial-derived organic acids that make these operations even more environmentally friendly (Huy Do et al., 2023).

Microbial activity helps in bioleaching and metal recovery during e-waste treatment. Some bacterial types oxidize sulfides of metals and release them in pure form such as gold, copper, and nickel. Compared to traditional processes, bioleaching reactions are long but cost-effective, energy-efficient, and environmentally friendly, especially applied at the industrial scale in optimized bioreactors.

Supercritical fluid extraction (SFE) in supercritical carbon dioxide is solvent-free. SFE has shown a selective disruption of the polymers, flame retardants, and noble metals for clean separations under controlled pressure and temperature conditions (Preetam et al., 2022).

Microfactory concepts are changing the game in decentralized recycling of e-waste management. Modular microfactories with automated processes will convert e-wastes into a diverse range of useable products, including metal alloys, engineered plastics, and glass microfibers. The localization of microfactories minimizes logistic emissions and promotes local economy stimulation through the creation of green jobs. The technical possibilities are therefore very reliant on cooperation between the public and private sectors, favourable governmental policies, and continuity in research and development efforts (Moure Abelenda & Aiouache, 2023).

Policy Frameworks, Challenges, and Opportunities

Policy interventions are the backbone for steering towards sustainable e-waste management, with the Basel Convention being an overarching instrument to regulate transboundary hazardous waste so as to ensure that e-waste is not dumped from developed to developing countries. However, the loophole of the export of "second-hand goods" makes enforcement difficult and continues the cycle of environmental injustice (Aycock et al., 2023).

Extended Producer Responsibility (EPR) under which manufacturers are held liable for the end-of-life management of the products relates to the European Union's WEEE Directive, and has thus led to formal collection schemes, recycling standards, and eco-design practices forming. However, most countries will continue to face such problems such as enforcement of the regulation and industry resistance.

Regulatory frameworks are existing, at best, in only a nascent form or completely ineffective in many low- and middle-income countries. Here, the informal recycling economy has thus far become overwhelmingly predominant. This would therefore demonstrate the possibility of strong initiation of lobbying and development activities for policies that can facilitate this informal sector, such as in training and educational initiatives, certification as well as technology assistance (Ezeudu, 2024).

Reinforcement of these international alliances should be through strengthened capacity building, technology transfers and provision of finances to developing countries to help them develop their infrastructures unsustainably for dealing with e-waste.

In addition to that, policies should look at the upstream intervention of product design in the area of durability, reparability, and recyclability as important design considerations. Without such systemic shifts in the production-consumption aspects, little will be achieved with any regulatory changes (Wene, 2015).

The Role of Consumer Behavior in E-Waste Generation

Consumer behavior thus becomes an elemental factor in affecting the size and composition of the e-waste stream. Rapid turnover due to marketing practices, technological obsolescence, and a social perception of the new technologies as a status symbol is much worsened by the speediness of generation or e-waste (Islam et al., 2021). It further induces a throwaway culture planned obsolescence: products are intentionally designed with limited lifespans. Most consumers may throw away devices that are still functional, simply to acquire the latest models, depleting more resources and compounding an already precarious situation.

Education awareness programs aimed at the consumers on the environmental and health hazards posed by e-waste can also change the landscape significantly. Such estimates can empower consumers to be agents of transformation in the circular economy by encouraging repair, reuse, and even responsible recycling behaviors (Wirtu & Tucho, 2022).

The policy instruments include eco-labeling, right-to-repair laws, and buy-back schemes that encourage sustainable consumer consumption. Companies engage in programs like trade-in old electronics or market their products based on easier repairability; such activities enhance loyalty and appreciation among customers while lessening environment footprints. Ultimately, behavioral dimensioning of et-waste involves consumption culture relocation to maintaining a sustainable culture where stewardship and intergenerational equity become priority concerns (Vidal-Ayuso et al., 2023).

Conclusion

E-waste becomes a product of techno-progress. It improves life, but on the other hand, produces a new element that threatens the ecological and social fabric of the earth. E-waste remains the cause of environmental degradation, toxic exposure, and social inequality in any uncontrolled condition. There which means, the crisis, availing a rare opportunity indeed: green recycling technologies advancing, robust policy frameworks strengthened, informal economies integrated, and consumers' mindsets evolving as a whole may pave the way for new sustainability actions (Bakhiyi et al., 2018).

A circular economy in e-waste requires integrated multi-front action: design of electronics for end of life; sound and enforced policy; financial commitment to innovations in technologies; and change in culture for responsible consumption behavior. The future of e-waste management will not be defined just by the ingenuity of technology but by what really commits our ethical being towards environmental justice, social inclusion, and planetary health for generations to come (Xavier et al., 2019).

Abstract

The increasing environmental degradation and biodiversity loss caused by industrial activities have prompted the need for more sustainable logistics practices. Ecological logistics, an emerging interdisciplinary approach, focuses on minimizing the ecological footprint of supply chains while contributing actively to biodiversity conservation. This paper scrutinizes how logistics and supply chain strategies could be structured to support ecological balance and the protection of endangered ecosystems. Through sustainable transportation, green warehousing, and ethical sourcing, the study looks into ecological logistics dimensions. This dimension focuses on low-emission transport, optimized routing, and reduced packaging waste as good environmental responsibility examples. It also analyzes how supply chain actors such as NGO's, governments, and local communities can be partners in developing logistics solutions that contribute positively to biodiversity conservation. In examining the cases, the research draws examples from ecological logistics implementation in the forestry, agriculture, and pharmaceutical sectors. These include habitat-sensitive routing journeys, relocation logistics for endangered species, or monitoring biodiversity via supply chain traceability technologies. Further, the authors discuss how digital tools such as GIS, IoT, and blockchain can further support the visibility and accountability required within the supply chain. Findings show that ecological logistics are realizable and vital for initiating long-term sustainable objectives. Designing logistical strategies with biodiversity in mind could be a potential area to gain an upper hand in competition and meet the legal prerequisites of environmental protection and CSR. Ultimately, this paper favors a shift from the purely efficiency-driven models toward eco-centric systems in logistics management, wherein biodiversity is regarded as a significant stakeholder in supply chain design, not an externality.

Key Words: *ecological logistics, biodiversity conservation, sustainable supply chains, green transportation, environmental responsibility*

Introduction

Over the past decades, the unprecedented loss of biodiversity and the relentless degradation of natural ecosystems have become urgent global concerns, significantly shaping the discourse surrounding sustainable development. Conventional logistics models, often driven by cost-efficiency and operational speed, have historically neglected the profound ecological impacts generated throughout the supply chain. The result has been a steady encroachment on natural habitats, increased carbon emissions, and disruptions to delicate ecological balances. In this context, *ecological logistics* emerges not merely as an environmental compliance measure but as a transformative paradigm seeking to harmonize economic objectives with ecological sustainability. This paper aims to dissect how ecological logistics strategies can serve as an effective bridge between efficient supply chain management and biodiversity conservation, offering both environmental and economic benefits for businesses operating in increasingly eco-conscious markets (Smith & Wood, 2018).

Conceptual Framework of Ecological Logistics

Ecological logistics encompasses a strategic approach that reconfigures logistical processes with the explicit goal of minimizing negative environmental impacts, particularly those affecting biodiversity. Unlike broader sustainability efforts that often focus on singular environmental metrics such as carbon reduction or energy efficiency, ecological logistics elevates biodiversity to the status of a critical stakeholder in supply chain decision-making. This paradigm recognizes that logistics activities, ranging from transportation to warehousing and sourcing, directly influence species habitats, ecosystem services, and the integrity of biological networks. Accordingly, ecological logistics involves proactive measures to avoid habitat destruction, mitigate pollution, and ensure the preservation of ecosystem connectivity. It requires integrating environmental data into logistical planning processes, fostering cross-sector collaborations, and adopting holistic performance metrics that capture ecological impacts alongside economic outcomes (*Ecological Framework*, 2010).

Sustainable Transportation Practices

Transportation logistics remains one of the most significant contributors to environmental degradation, primarily through greenhouse gas emissions, particulate pollution, noise, and habitat fragmentation caused by road and rail networks. Ecological logistics calls for transformative approaches in transportation, including: Low-Emission Vehicles: Transitioning fleets to electric, hydrogen-powered, or hybrid vehicles reduces dependency on fossil fuels and lowers carbon footprints. Such transitions, while initially capital-intensive, often result in long-term cost savings due to reduced fuel and maintenance expenses. Habitat-Sensitive Routing: Logistics planners can leverage geographic information systems (GIS) to design transport routes that deliberately avoid ecologically sensitive areas, such as migration corridors, wetlands, and endangered species habitats. This strategy minimizes direct disturbances to ecosystems while also mitigating risks associated with regulatory non-compliance (Tariq, 2024). Load Optimization: By consolidating shipments and increasing load factors, companies can reduce the frequency of trips, thus lowering cumulative emissions and traffic-related environmental disturbances. Adopting sustainable transportation not only mitigates ecological harm but also aligns organizations with emerging regulatory standards and bolsters their reputation among environmentally conscious stakeholders (Jimenez, 2017).

Green Warehousing and Packaging

Warehousing operations contribute significantly to the environmental footprint of supply chains through energy consumption, material waste, and potential impacts on surrounding ecosystems. Ecological logistics emphasizes a multifaceted approach to green warehousing: Energy-Efficient Facilities: Incorporating renewable energy sources, such as solar panels and geothermal systems, alongside high-performance insulation, significantly reduces greenhouse gas emissions. Smart building technologies, including automated lighting and climate control systems, further enhance operational efficiency. Minimized Packaging Waste: Excessive packaging not only increases material costs but also contributes to solid waste challenges (Bergey, 2005). Ecological logistics promotes the use of recyclable, compostable, or biodegradable materials and encourages packaging designs that reduce material usage without compromising product protection. Biodiversity-Friendly Site Design: Warehousing infrastructure can be designed or retrofitted to minimize land disturbance, preserve natural vegetation buffers, and incorporate green spaces that serve as habitats for local wildlife. Green roofs and rainwater harvesting systems contribute to ecosystem health and water management.

Green warehousing practices yield multiple benefits, including cost savings from reduced energy consumption, enhanced brand image, and compliance with increasingly stringent environmental regulations (Castillo, 2022).

Ethical and Responsible Sourcing

Supply chain sourcing activities have profound implications for biodiversity, particularly when raw materials are extracted from ecologically sensitive regions. Ecological logistics mandates responsible sourcing practices that extend beyond traditional supplier relationships:

Supplier Audits: Companies should conduct thorough assessments of suppliers to ensure adherence to biodiversity conservation standards, legal frameworks, and ethical labor practices. Audits help identify environmental risks and promote continuous improvement among partners.

Traceability Systems: Technologies such as blockchain and RFID enable detailed tracking of raw materials throughout the supply chain, offering visibility into sourcing origins and associated environmental impacts. Traceability ensures accountability and helps companies substantiate sustainability claims (Cox, 2025).

Community Collaboration: Engaging local communities as stakeholders fosters mutual benefits, including the preservation of traditional ecological knowledge and the protection of culturally significant ecosystems. Collaborative efforts can facilitate sustainable harvesting practices and the restoration of degraded habitats. Responsible sourcing is not merely an ethical obligation but increasingly a competitive differentiator, as consumers and regulators demand greater transparency and environmental stewardship from businesses (Agrawal & Lee, 2016).

Role of Digital Technologies

Digital transformation plays a pivotal role in enabling ecological logistics. Advanced technological solutions facilitate environmental monitoring, enhance data-driven decision-making, and improve transparency across complex supply chains:

Geographic Information Systems (GIS): GIS technology supports habitat mapping and route optimization, helping logistics planners avoid ecologically sensitive areas. It provides valuable spatial analysis for assessing the potential impact of logistics infrastructure on biodiversity.

Internet of Things (IoT): IoT devices deployed in vehicles, warehouses, and production facilities collect real-time data on emissions, energy usage, and environmental conditions. This continuous monitoring enables proactive environmental management and timely interventions.

Blockchain Platforms: Blockchain ensures secure, tamper-proof recording of transactions and environmental metrics, providing verifiable evidence of sustainable practices. It builds trust with consumers and regulatory bodies, which increasingly demand traceable sustainability credentials.

These digital tools empower logistics professionals to integrate environmental considerations into operational strategies with unprecedented precision, thereby supporting biodiversity conservation goals (Boulehouache et al., 2012).

Sectoral Applications

The principles of ecological logistics are highly adaptable and have found practical applications across diverse industries:

Forestry: Logistics strategies prioritize habitat-sensitive routing for timber transportation to avoid disturbing wildlife corridors. Companies also employ sustainable harvesting schedules that allow forest regeneration and minimize habitat disruption.

Agriculture: Ecological logistics practices involve traceability systems to monitor inputs such as fertilizers and pesticides, which can have cascading effects on local biodiversity. Sustainable supply chains promote organic farming, integrated pest management, and soil conservation measures.

Pharmaceuticals: Many pharmaceutical products rely on biotic raw materials sourced from sensitive ecosystems. Ecological logistics guides ethical sourcing practices that protect endangered plant and animal species while supporting habitat restoration projects.

These sector-specific implementations illustrate how ecological logistics is not a one-size-fits-all solution but rather a flexible framework capable of addressing unique industry challenges while advancing biodiversity conservation (Hines, 2023).

Conclusion

The mounting evidence of ecological crises underscores the urgency of reimagining logistics systems through an ecological lens. This paper has demonstrated that ecological logistics provides a viable and strategic approach to reconcile operational efficiency with the imperative of conserving biodiversity. By embedding ecological principles into transportation, warehousing, sourcing, and digital technologies, businesses can not only mitigate environmental risks but also secure competitive advantages in markets increasingly driven by sustainability expectations. Importantly, ecological logistics reframes biodiversity not as a peripheral concern but as a core stakeholder whose well-being is integral to long-term economic resilience and ethical business practice. Future research should further investigate cross-sector collaborations, policy frameworks, and technological innovations that can accelerate the mainstream adoption of ecological logistics strategies worldwide.

Abstract

Artificial Intelligence (AI) is increasingly transforming agriculture by introducing advanced methods that enhance productivity and sustainability. Modern AI applications in agriculture encompass several key areas: *Precision Farming*: AI algorithms analyze data from various sources, including satellite imagery and soil sensors, to optimize planting schedules, irrigation, and fertilization, thereby improving crop yields and resource efficiency. *Crop Monitoring and Disease Detection*: Machine learning models and computer vision techniques enable early detection of plant diseases and pest infestations, allowing for timely interventions and reducing crop losses. *Robotics and Automation*: AI-powered robots are employed for tasks such as planting, harvesting, and weeding, increasing operational efficiency and reducing labor costs. *Supply Chain Optimization*: AI assists in forecasting demand, managing inventory, and optimizing logistics, leading to reduced waste and improved market responsiveness. Despite these advancements, challenges persist, including data quality issues, infrastructure limitations, and the need for regulatory frameworks to ensure safe and ethical AI deployment. Addressing these challenges requires collaborative efforts among policymakers, researchers, and industry stakeholders to develop standards and invest in education and infrastructure. This paper explores the current trends and methodologies of AI applications in agriculture, highlighting their potential to transform the sector and contribute to global food security and environmental sustainability.

Keywords: *Artificial Intelligence, Precision Farming, Machine Learning, Agricultural Robotics, Crop Productivity, Sustainable Agriculture*

Introduction

Agriculture remains a foundational pillar of economic sustainability, contributing significantly to long-term economic growth, employment, and national development. Traditionally focused on food and crop production, the agricultural sector has evolved over the past two decades to encompass processing, marketing, and distribution of both crops and livestock. Today, agriculture not only ensures food security but also supports GDP growth, drives trade, provides raw materials for other industries, and serves as a major source of livelihood across many regions. However, the rapid increase in global population, coupled with challenges such as climate change, land degradation, and labor shortages, demands a fundamental shift in how agriculture is practiced. To meet the growing demand for food in a sustainable and efficient manner, innovative technologies must be integrated into agricultural systems. Among these, Artificial Intelligence (AI) stands out as a transformative tool capable of revolutionizing every stage of the agricultural value chain.

Enabled by advances in big data analytics, robotics, the Internet of Things (IoT), drone technology, and affordable sensors, AI is poised to reshape modern farming. By analyzing data on temperature, soil conditions, weather patterns, moisture levels, and historical crop performance, AI can provide predictive insights—such as optimal planting and harvesting times or the best crop selection for a given region. This not only enhances crop yields but also reduces the reliance on water, fertilizers, and pesticides, thereby supporting environmental sustainability.

Furthermore, AI-driven automation improves labor efficiency and worker safety, optimizes supply chains, and ensures food production keeps pace with population growth—ultimately contributing to lower food prices and improved food security.

This paper explores the current trends, methodologies, and challenges in the application of AI in agriculture. It highlights how AI technologies are enhancing productivity, increasing resource efficiency, and paving the way for a more resilient and sustainable agricultural sector [1].

Precision Agriculture

One of the most prominent applications of AI in agriculture is precision farming. Precision agriculture refers to the use of AI algorithms to analyze data collected from various sources, such as satellite imagery, drones, weather

stations, and soil sensors. These AI systems help farmers make informed decisions about crop rotation, planting schedules, irrigation needs, and fertilizer application. For example, machine learning models can predict soil nutrient deficiencies or moisture levels and suggest targeted interventions, thereby improving crop yield and reducing input costs [2].

Moreover, AI-powered tools can generate customized recommendations for specific plots of land, considering microclimatic conditions and soil properties. This leads to better resource management and helps in reducing water wastage and overuse of agrochemicals. According to Kamilaris et al. (2018), such AI-driven approaches can increase yield by up to 25% while lowering input costs by around 20% [3].

Crop Monitoring and Disease Detection

Another area where AI has shown remarkable potential is crop health monitoring and early disease detection. With the help of computer vision, deep learning, and image recognition techniques, AI can identify early symptoms of plant diseases, nutrient deficiencies, or pest infestations by analyzing leaf patterns, color changes, and growth anomalies.

These technologies allow for real-time monitoring through drones or smartphones equipped with AI-powered cameras. By detecting problems early, farmers can take swift action to prevent the spread of diseases, ultimately minimizing losses and reducing the need for harmful pesticides. An example of such a system is Plantix, a mobile application that uses AI to diagnose plant health issues from photos taken by users in the field [4].

Robotics and Automation

AI is also revolutionizing the physical processes of agriculture through robotics and automation. AI-powered robots and autonomous machinery are increasingly used for repetitive tasks such as planting, harvesting, pruning, spraying, and weeding. These machines are capable of working around the clock and in varying weather conditions, significantly reducing the need for manual labor and improving efficiency.

For instance, robots like the “Agrobot” and “Harvest CROO” can identify ripe fruits and pick them without damaging the crops. Weeding robots powered by computer vision and AI can precisely remove weeds without disturbing the surrounding plants. Such innovations not only enhance productivity but also reduce the exposure of human workers to potentially hazardous conditions.

Forecasting and Supply Chain Optimization

AI also plays a vital role beyond the farm—particularly in agricultural forecasting and supply chain management. Predictive analytics powered by AI can forecast crop yields, monitor market trends, and anticipate consumer demand. This helps in planning storage, transportation, and marketing strategies more efficiently, reducing food waste and ensuring better availability of produce in the market.

Furthermore, AI tools can analyze patterns in supply chains to identify inefficiencies and suggest optimal routing for distribution, thus saving time, fuel, and money. AI systems used in logistics are increasingly capable of dynamic adjustment based on weather patterns, road conditions, or market fluctuations [5].

Sustainable Farming and Climate Resilience

AI contributes significantly to the goal of sustainable farming by enabling smart decision-making that minimizes environmental harm. AI-based systems can suggest eco-friendly pest control, optimal irrigation methods, and sustainable crop combinations that enrich the soil. By enhancing the accuracy of climate forecasts and risk assessments, AI also supports climate-resilient agriculture, helping farmers adapt to changing conditions and natural disasters.

For example, IBM’s Watson Decision Platform for Agriculture integrates AI and IoT to provide farmers with a full spectrum of insights—from planting to harvesting—while emphasizing sustainability and risk reduction [6].

Conclusion

AI technologies are not just reshaping how farming is done — they are fundamentally transforming agriculture into a high-tech industry. From precision farming to disease detection, from robotics to supply chain optimization, AI offers comprehensive solutions that improve efficiency, reduce costs, and promote sustainability. As global agricultural demands continue to grow, the adoption of AI will be critical in creating a more productive and resilient food system.

Abstract

Agricultural pests are defined as animals that cause damage and death to crop plants. In recent decades, there has been an increase in the number of pests, including aphids, beetles and locusts, resulting in significant crop losses. Consequently, contemporary agriculture is increasingly reliant on efficacious and secure crop protection products. While various methods of pest control exist, both chemical and biological, it is the former that is more commonly used in practice. These chemical insecticides can exist in a variety of aggregate states (liquid or solid) and are both fast-acting and affordable. However, their significant disadvantage is their ability to accumulate in plants, which can negatively affect the health of consumers.

Consequently, there has been a surge in the development of biological plant protection products, which exhibit a milder and safer action profile. One such agent is a bacterial insecticide based on Bacillus thuringiensis (Bt). This microorganism was first isolated by Berliner in 1915 from dead caterpillars of the miller's fireweed. Subsequent research revealed that the Bt exotoxin (phospholipase C) is responsible for the death of insects, and that its endotoxin, initially non-toxic, is activated in the digestive tract of insects by the action of alkaline proteases and transformed into an active toxin.

Bt insecticides are selective and effective against various pests such as caterpillars, mosquitoes and midges. Due to their targeted activity and environmental safety, Bacillus thuringiensis-based formulations are widely used in biological plant protection. Subsequent reports will address contemporary methodologies for pest management that exhibit high efficiency while causing minimal harm to the environment and human health.

Keywords: Insecticides, Microorganism, Toxins.

Introduction

The widespread increase in agricultural pests in recent decades poses a serious threat to global food supply and sustainable agriculture. Currently, agriculture faces a number of pressing challenges, one of which is to maintain crop yields while ensuring environmental and food security. One of the key factors negatively affecting the productivity of agrocenoses remains pests - insects, mites, nematodes and other organisms that can cause large yield losses and reduce the quality of products. According to the UN Food and Agriculture Organisation (FAO), up to 20-40% of the world's yield is lost annually due to pests, which makes pest control a strategically important task. For many decades, chemical pesticides have been the main method of pest control. Due to their rapid action, wide spectrum of activity and relative ease of application, they have provided stable crop protection under conditions of intensive agriculture.

However, the widespread use of synthetic insecticides has led to a number of serious consequences: establishment of resistant pest populations, destruction of natural ecosystems, death of non-target organisms (including pollinators and natural enemies of pests), contamination of soil and water bodies, and potential threats to human health. These circumstances have necessitated a review of existing approaches to plant protection. With the growing interest in ecologically sound and sustainable agriculture, biological pest control methods are receiving increasing attention. Biological agents are organisms or substances of biological origin that are used to suppress pest populations.

These include bacteria (e.g. Bacillus thuringiensis), entomopathogenic fungi (Beauveria bassiana, Metarhizium anisopliae), viruses (nucleopolyhedroviruses, granuloviruses), parasitoids (trichogramma, horseflies), and predatory insects and mites. The use of such agents provides targeted pest control with minimal impact on the environment and non-target organisms. Biological control can be carried out in various ways: through introduction and acclimatisation of natural enemies, conservation and stimulation of their populations in agrocenoses, as well as the use of biopreparations based on living organisms or their metabolites. Modern biotechnological achievements, including genetic engineering approaches, contribute to the expansion of the arsenal of biological plant protection products and increase their efficiency [1].

The aim of this article is to provide a comprehensive overview of current biological pest management strategies, advantages and limitations. Special attention is given to innovative developments in microbiological preparations, integrated crop protection and the prospects for sustainable agriculture with minimal use of chemicals. The relevance of the topic is due to the need to transition to ecologically balanced farming systems that

meet the challenges of climate change, biodiversity and human health. A comprehensive review of modern biological pest management strategies

Modern approaches to biological pest control represent a multilevel system of measures aimed at reducing the number of pests by means of natural enemies or products of their vital activity.

Biological strategies can be conditionally classified into three main directions: classical (introduction), conservation and applied (or augmentative) biological control. Each of these directions has its own goals, methods of application and area of greatest effectiveness [2].

Classical biological control

The classical strategy consists in the introduction (introduction) of exotic natural enemies of pests into new habitats where the latter lack natural population regulators. It is most effective in controlling invasive pest species. A successful example is the introduction of Encarsia formosa to control whitefly in greenhouse farms. The main advantage of the method is its long-term effect after a single infestation of the enemy, but the effectiveness depends on the degree of adaptation of the biological agent to the new biotope.

Conservation biological control

A conservation strategy aims to preserve and stimulate populations of natural enemies of pests already existing in the agrocenosis. This may include creating favorable habitat for entomophagy, reducing the use of chemical insecticides, ensuring the availability of alternative food sources (e.g. nectar-bearing plants) and conserving landscape diversity. Such measures have proven effective in integrated plant protection systems and contribute to restoring ecological balance in agroecosystems.

Applied (augmentative) biological warfare

The applied strategy consists of mass multiplication of biological agents in laboratory conditions and their subsequent release into the environment. Depending on the objective, inoculative (single release at early stages of infestation) and inundate (mass release at high pest levels) approaches are distinguished. Trichogramma (parasitic webworms) are widely used to control scale pests, as well as entomopathogenic fungi, bacteria and viruses. A significant achievement in recent years is the commercial production of Bacillus thuringiensis (Bt)-based biopreparations with narrow specificity, environmental safety and proven efficacy against a number of insects [3].

Microbiological and viral preparations

Microbiological plant protection agents based on the action of bacteria, fungi and viruses have become increasingly important in the structure of biological protection in recent years. Preparations based on Bacillus thuringiensis are effective in controlling larvae of scales and bivalves. Viral agents such as nucleopolyhedroviruses (NPVs) are used to control caterpillars of pest moths, demonstrating high specificity and safety. The development of preparations based on symbiotic nematodes in combination with bacteria of the genus Xenorhabdus and Photorhabdus is underway, which expands the possibilities of point control of soil pests [6].

Genetic engineering and biotechnology

A significant contribution to biological defence comes from the use of genetically modified organisms. The best known are transgenic plants expressing Bt-toxins that are resistant to a number of pests. Although the use of such crops is a matter of scientific and public debate, they have already proven effective in reducing the use of chemical insecticides, especially in cotton and maize production [3].

Integrated strategies and sustainable agriculture

The most promising approach is Integrated Pest Management (IPM), which combines biological methods with agronomic, breeding and, where necessary, limited use of chemicals. This approach allows achieving high control efficiency while maintaining ecological sustainability and reducing environmental impact. IPM requires systematic monitoring of pest populations, predicting outbreaks and adapting strategies to current conditions.

Advantages and limitations of modern biological pest control strategies

Modern biological pest control methods are considered as an important alternative to chemical pesticides in the transition to sustainable agriculture [4]. However, despite the obvious advantages, biological control is not a universal solution and has its limitations that need to be taken into account when designing and implementing plant protection systems.

*Advantages: E*nvironmental safety. Biological agents are generally highly specific and do not adversely affect non-target organisms, including beneficial insects (pollinators, entomophages), animals and humans. This makes them

attractive in programs to protect biodiversity and reduce anthropogenic pressure on ecosystems. The lack of resistance in pests (if applied correctly) is also an important factor.

Unlike chemical insecticides, to which pests quickly develop resistance, biological agents - especially in integrated strategies - create more complex selection pressures that reduce the likelihood of resistance [5]. Compatibility with organic farming.

Biological products and methods based on the use of living organisms are authorized in most organic certification systems (e.g. EU, USDA Organic), making them indispensable in organic agro-technologies. Selectivity of action.

Most biological agents affect only certain groups of pests, thus preserving beneficial fauna and natural population regulators in agrocenoses. Reduction of residues in products. Biological preparations do not accumulate in plants and the environment, which improves the quality and safety of agricultural products, reduces health risks for consumers and facilitates export to countries with strict phytosanitary requirements.

Limitations: Slow and condition-dependent action.

Unlike chemical insecticides, biological agents often act more slowly, especially under unfavorable weather conditions (high temperature, drought, UV radiation), which can be critical when pest populations increase dramatically. High specificity.

While specificity is an advantage, it also limits the use of a single product against different pest species. This requires accurate diagnosis of the problem and often more complex logistics in application. Storage and transport difficulties.

Many biologics (especially live crops) are sensitive to storage conditions (temperature, humidity), which limits their shelf life and requires strict adherence to transport conditions. The need for an integrated approach and monitoring.

To achieve high efficiency of biological control, a systematic approach is required: monitoring pest numbers, forecasting outbreaks, understanding the biology of the enemy and the agent. This requires qualified personnel and scientific support [7]. Limited number of registered drugs.

In some countries and regions, the market for biological defense products is underdeveloped. There are fewer registered effective and available preparations than chemical analogues, which restrains the widespread adoption of bio methods. Development and implementation costs.

The development and commercialization of new biological agents requires significant investment in research, laboratory production and field trials, which can stifle innovation in this area [8]. Despite some limitations, biological pest management represents an important part of a sustainable and ecologically oriented agricultural system. Given the global challenges - climate change, soil degradation, increasing pest resistance to chemicals - biological strategies are becoming increasingly important. The introduction of integrated plant protection systems combining biological, agronomic and, if necessary, chemical measures is the most rational way to a sustainable and environmentally friendly agriculture of the future [9].

Innovative development of microbiological preparations in the system of integrated plant protection as a basis for sustainable farming with minimal use of chemical agents

Sustainable farming in modern conditions requires transition from intensive use of chemical means of plant protection to more environmentally friendly and safe technologies. One of the key directions of such transition is the development and introduction of microbiological preparations in the system of integrated plant protection. These preparations are based on the use of natural microorganisms - bacteria, fungi, actinomycetes and viruses, which have the ability to suppress phytopathogens, stimulate plant growth, improve soil structure and enhance crop immunity [10]. Innovative new-generation biopreparations are developed taking into account specific agroecological conditions, biological compatibility with crops and effectiveness against certain pests. The most widely used strains are Bacillus subtilis, Pseudomonas fluorescens, Trichoderma harzianum, Metarhizium anisopliae and others.

Thanks to the development of biotechnology, forms of preparations with prolonged action, resistance to temperature fluctuations and UV radiation are created, which increases their practical value. Integration of such preparations into the plant protection system makes it possible to significantly reduce or completely replace chemical fungicides, insecticides and nematicides. This, in turn, reduces environmental pollution, preserves useful soil microflora, improves the quality of agricultural products and contributes to the restoration of the natural balance. The use of microbiological means and requires a systematic approach: monitoring of pathogens, selection of optimal time of treatment, crop rotation and combination with other methods of protection. Thus, innovative microbiological developments are becoming an integral part of biologisation of agriculture and the basis for sustainable, environmentally oriented agricultural production [11].

Conclusion

Modern strategies of plant pest protection are increasingly oriented towards environmentally safe and sustainable approaches, among which biological control occupies a special place. In contrast to the traditional use of chemical insecticides, biological methods are based on the use of living organisms - entomophages, pathogenic microorganisms (viruses, bacteria, fungi), as well as natural regulators - pheromones and plant extracts. Biological means not only provide effective suppression of pests, but also contribute to the preservation of ecological balance in the agro-ecosystem.

One of the key advantages of these methods is the lack of resistance in pests when properly applied, making biological defence a sustainable tool in the long term. Modern biosecurity strategies involve the integration of different approaches: release and conservation of populations of beneficial insects, use of microbiological preparations (based on Bacillus thuringiensis, Metarhizium anisopliae, Beauveria bassiana, etc.), use of pheromone traps and attractants for pest monitoring and management. The development of technologies for mass production of entomophages and biopreparations, as well as precise planning of their application using modern digital platforms, also plays an important role. With global climate change and increasing pest resistance to chemistry, biologicals are becoming an integral part of integrated crop protection strategies. Their use in combination with agronomic measures and modern monitoring systems opens the way to sustainable and environmentally friendly agriculture of the future.

Abstract

Bee venom is a complex biological active product that is produced by the venom glands of honeybees. Its utilisation in the folk medicine of diverse cultures, including those of India, China and Greece, dates back millennia. In the contemporary medical context, the therapeutic potential of bee venom has garnered significant attention, with numerous studies supporting its role as a natural remedy for a wide range of diseases. The chemical composition of bee venom is intricate, comprising over 40 active components, the most significant of which are melitin, apamin, adolapin, hyaluronidase and phospholipase A2. These substances have been shown to possess anti-inflammatory, analgesic and antibacterial properties. Melitin in particular has garnered significant attention due to its remarkable anti-inflammatory properties, thus positioning it as a potential therapeutic agent for conditions such as rheumatoid arthritis, osteoarthritis, and sciatica, among others that affect the musculoskeletal system. In addition, studies demonstrate the potential of bee venom in treating nervous system disorders such as multiple sclerosis, Parkinson's disease and neuropathies. Apitherapy, a therapeutic modality that involves the utilisation of bee-derived products, encompasses both direct bee stings and the application of ointments, creams, and injections containing purified apitoxin. The study of the antitumour properties of bee venom is of particular interest. In vitro studies have demonstrated that melittin, a component of bee venom, can trigger apoptosis (programmed cell death) in cancer cells without significant harm to healthy tissues, suggesting its potential for use in the development of novel anti-cancer therapies. However, it is imperative to exercise caution when utilising this therapy, as it can potentially induce severe allergic reactions, including anaphylactic shock. Consequently, prior to the initiation of any therapeutic intervention, it is imperative to seek the counsel of a medical professional and undergo allergy assessments. The potential of bee venom as a valuable natural resource with a wide range of therapeutic effects is therefore evident. Further study of this substance and its integration into mainstream medicine may lead to new treatments for a range of chronic and intractable diseases.

***Keywords*:** bee venom, chemical composition, disease, treatment

Introduction

Apitoxin, a complex biologically active substance produced by the glands of bees, has been utilized for centuries in folk medicine for the treatment of various human diseases. In recent decades, there has been a notable increase in the scientific interest in bee venom, owing to the substance's diverse pharmacological effects and its potential for the treatment of human diseases. As stated by Smith et al. (2022), bee venom is comprised of a multitude of biologically active substances, including but not limited to melittin, apamin, phospholipase A2, hyaluronidase, and various amino acids. The unique properties of these substances have the capacity to affect the cells and tissues of the body. Recent medical research and clinical trials have demonstrated the efficacy of bee venom in the treatment of inflammatory diseases, including osteoarthritis and rheumatoid arthritis, as well as neurodegenerative disorders, such as Parkinson's disease. Osteoarthritis is a degenerative joint disease, characterized by the destruction of cartilage and alterations in joint structure. The principal symptoms encompass discomfort, impaired mobility and inflammation. In contradistinction to rheumatoid arthritis, osteoarthritis is not associated with systemic inflammation or immune system disorders. Rheumatoid arthritis is an autoimmune disease in which the immune system mistakenly identifies joint tissues as foreign agents and attacks them, causing chronic inflammation. This can result in joint damage and even joint deformity. In addition to the manifestation of joint problems, rheumatoid arthritis has the potential to affect other organs. Moreover, the therapeutic potential of bee venom extends to the fields of cosmetology and dermatology. The anti-inflammatory and antimicrobial properties of bee venom have been demonstrated to be efficacious in the treatment of acne, psoriasis and other dermatological conditions (Smith et al., 2022). Furthermore, the potential of bee venom in oncology is equally promising, with its components demonstrating the capacity to induce apoptosis in tumour cells. However, despite the promising results, the use of bee venom is associated with a number of risks, including the possibility of allergic reactions. In order to avoid such risks, strict monitoring and dosing is required when using it for therapeutic purposes. In this context, further research is required to improve methods for the safe use of bee venom, as well as to better understand its molecular mechanisms of action. The objective of this paper is to evaluate the extant data on the medical use of bee venom, to identify its therapeutic potential and limiting factors, and to discuss the prospects for its further use in clinical practice [1].

Present status of research on the utilization of bee venom

The utilization of bee venom, otherwise referred to as apitoxin, has a long history in folk and traditional medicine. However, it is only in recent decades that scientific research has begun to comprehensively study its therapeutic properties. Recent studies have corroborated the high biological activity of the components of bee venom, with particular emphasis on melittin, which has been shown to possess significant anti-inflammatory, antimicrobial and antitumor properties [2]. In light of recent advancements in biotechnology and pharmacology, the potential of bee venom as a therapeutic agent for the management of oncological, autoimmune and neurological diseases has been a subject of considerable interest. The necessity for new, safer and more effective therapeutic approaches, as well as the growing interest of the scientific community in natural compounds in medicine, renders the topic highly relevant. The utilization of bee venom in therapeutic contexts can be categorized into several primary directions. Its use in oncology is of particular pertinence. In recent years, melittin has attracted the greatest attention from researchers. This is because it is considered to be the main component of bee venom. As demonstrated in, it has exhibited the most significant activity against a variety of malignant tumors, including those affecting the breast, liver, lung and skin [3]. Melittin has been shown to have the capacity to disrupt tumor cell membranes, thereby inhibiting their growth and inducing apoptosis, or programmed cell death. Furthermore, it has been demonstrated that this compound can enhance the effects of chemotherapy drugs such as doxetaxel while concomitantly reducing their toxic effects on healthy vital tissues. The subsequent focus will be on the treatment of inflammatory and autoimmune diseases. The utilization of bee venom in the therapeutic management of rheumatoid arthritis, osteoarthritis, and other inflammatory joint diseases has gained significant traction in recent years. A substantial body of research has repeatedly demonstrated that regular injections of low doses of apitxin have a significant analgesic effect, reduce inflammation, and enhance joint mobility. Research is also ongoing into the use of bee venom in multiple sclerosis, where it shows potential as a neuroprotective and immunomodulatory agent. Another popular application of the technology is in the fields of neurology and dermatology. Its utilization is prevalent in the treatment of diseases affecting both the central and peripheral nervous systems, encompassing conditions such as neuralgia, radiculitis, and paralysis. It is evident that apamin exerts a stimulant effect on the nervous system, albeit one that is mild in nature. In the field of dermatology, research is underway to explore the potential of bee venom as an active ingredient in cosmetic products, with a view to treating conditions such as psoriasis, acne, and promoting skin rejuvenation. In contemporary times, the administration of bee venom can be accomplished through a variety of methodologies. These include the utilization of direct bee stings, the injection of purified venom, the application of ointments and creams, and the formulation of nano preparations and transdermal patches. Contemporary pharmacological formulations enable more precise dosage regulation and mitigate adverse effects. This is widely regarded as one of the most significant advantages of the method of application. However, despite the promising results of this study, the use of bee venom requires caution and should be carried out strictly under the supervision of specialists, taking into account possible allergic reactions and individual intolerance. In the future, the expansion of the potential applications of apitoxin in modern medicine will be driven by in-depth clinical studies and the development of safe pharmacological forms [4].

Thirdly, the therapeutic potential of bee venom will be examined in detail.

The apitoxin is produced by a special gland in the abdomen. The venom itself is transparent and has a bitter taste. It is noteworthy that the odor rarely resembles the smell of ripe bananas. It is highly soluble in water and acids, but almost insoluble in alcohol. The venom contains approximately 30% solids, and its drying process occurs rapidly at ambient temperatures. The resultant solid is of a viscous nature. It is evident that bee venom is a distinctive pharmaceutical agent that has been utilized since the inception of beekeeping. The treatment of bee venom is a distinctive and time-honored technique. It has become one of the most valuable healing methods, having withstood the test of time. The effectiveness of bee venom is measured in units of 0.1 mg, which is equivalent to the amount of venom typically found in a bee sting. Excessive ingestion of bee venom has been demonstrated to induce anaphylactic shock, with the potential for fatal consequences. The pharmaceutical substance is administered in minimal doses for therapeutic purposes. The efficacy of bee venom is attributable to its ability to stimulate the body's innate capacity to counteract the disease with immediate effect. It has been demonstrated that the application of bee venom results in an increase in blood flow at the site of the sting. The process of destruction of microbes and already damaged tissues is initiated by antibodies, defense cells and enzymes. Inflammation caused by the venom is known to dissipate rapidly, with foreign elements and altered chemicals being eliminated from the affected area. It is evident that bee venom exerts a marked influence on the immune, vascular and nervous systems [5]. The following investigation will explore the mechanisms by which bee venom exerts its effects. The efficacy of bee venom is attributable to its ability to stimulate the body's innate capacity for immediate disease resistance. It has been demonstrated that the application of bee venom results in an increase in blood flow at the site of injection. The process of destruction of microbes and already damaged tissues is initiated by antibodies, defense cells and enzymes. The inflammation caused by the venom is known to dissipate rapidly, accompanied by the removal of foreign bodies and altered chemicals from the affected area. The range of applications of bee venom is extensive. It is evident that bee venom exerts a marked influence on the immune,

vascular and nervous systems. Furthermore, it has been demonstrated that the activation of this process results in the production of hormones that are essential for the suppression of pathologies. Furthermore, the venom activates the work of all systems and organs. The bee bath has been employed in the treatment of a wide range of ailments, including diseases of the nervous system (e.g. neuralgia, radiculitis, plexopathy, neuritis), the muscular system, polyarthritis, traumatic lesions, thrombophlebitis, hypertensive diseases, pneumonia, asthma, prostatic diseases, psoriasis, gynecological diseases, trophic ulcers, and eye diseases [6]. Indications for treatment with bee venom. The utilization of bee venom as a component of a multifaceted therapeutic approach is indicated for the management of chronic infectious diseases, which frequently emerge as a consequence of multifarious exacerbations precipitated by immune system deficiencies. It is an effective pharmaceutical agent employed in the treatment of rheumatic diseases for which hormonal therapy is the standard of care. In this particular instance, bee venom constitutes a highly effective alternative, given that, in contrast to hormones, this substance is not associated with the development of dependency. The utilization of bee venom has been demonstrated to be efficacious in the treatment of metabolic disorders of various etiologies. In this case, the stimulation is systemic. Following the conclusion of the treatment sessions, a number of changes to the body are observed. Firstly, the metabolism of lipids is restored to normal levels. Secondly, memory is improved. Thirdly, the blood pressure is normalized. Finally, the salts that are deposited in the spinal and joint regions are dissolved. The utilization of bee venom in the treatment of chronic hepatitis and cirrhosis of the liver has also been documented. The therapeutic benefits of bee stings extend to the treatment of scars, the alleviation of sciatic pain, and the management of sciatic attacks. It is asserted that a multitude of diseases can be remedied through a single session of bee stings. Prior to the administration of venom, it is imperative to seek the counsel of a medical professional. It is imperative to recall that the lethal dose of bee venom is 0.2 g, which is equivalent to 300–500 stings. The effectiveness of this method is contingent upon the subject's weight. However, it should be noted that some individuals are allergic to bee venom, and death can result from a single sting. The therapeutic modality that utilizes bee products, including bee venom (apitoxin), is now designated as apitherapy [7]. This approach is currently employed in both conventional medicine and folk practice, due to the aforementioned properties of the substance. A taxonomy of apitherapy methods has been established. Bee stinging is a conventional technique in which bees inject their venom into specific body parts. The procedure is carried out under the strict control of a specialist to avoid allergic reactions. The application of ointments and creams is an essential component of a comprehensive healthcare regimen. The utilization of ointments and creams containing bee venom facilitates the administration of the therapy in the comfort of one's own home. Examples of such means include "Apizartron," "Virapin," and "Sofya" [8]. These substances have been demonstrated to be efficacious in the treatment of joint diseases, inflammation, and back pain. Injections and ampoule preparations. The utilization of bee venom, administered via a syringe, enables precise dosing of the substance and targeted delivery to specific anatomical regions. This method is employed in the treatment of chronic inflammation and pain. The injection of bee venom into the body is achieved through the utilization of either an electric current or ultrasound, thereby facilitating the application of electrophoresis and phonophoresis, respectively. The efficacy of these remedies extends to conditions such as osteochondrosis, sciatica, and arthritis. Apimassage, a therapeutic modality involving the application of creams containing bee venom, has been demonstrated to promote enhanced blood circulation and muscular relaxation through massage. This method is employed in the treatment of diseases of the musculoskeletal system [9].

It is imperative to exercise caution in the following instance:

Allergic Reactions: Individuals with a history of allergic reactions to bee venom should exercise caution and avoid apitherapy whenever possible, as there is a risk of severe reactions, including anaphylaxis.

A consultation with a physician is necessary. It is imperative for individuals to consult with a physician prior to the initiation of treatment, particularly in cases of chronic conditions or allergies.

Professional supervision: It is imperative that all treatments be administered by a duly qualified professional, thereby ensuring the minimization of potential risks and the maximization of treatment efficacy [7].

The Physical and Chemical Properties of Bee Venom

Bee venom is a complex mixture of more than 50 active components, including:

Proteins and peptides constitute approximately 88% of the dry matter. Melittin, the principal toxic component, exhibits anti-inflammatory and anti-tumor effects. Its concentration ranges from 40 to 50.

Apamin, a neurotoxin, has been shown to block potassium channels.

Phospholipase A2 has been demonstrated to disrupt cell membranes and increase inflammation.

Hyaluronidase, an enzyme that increases tissue permeability, is another potential factor to consider.

Amines;

Histamine, dopamine, and norepinephrine (which play a role in inflammation and pain)

The minerals in question include magnesium (Mg), calcium (Ca), phosphorus (P), and trace elements [10]. The physical properties are summarized in Table 1.

Table 1 - Physical properties and its characterization

Property	Characterization
Shape	When fresh, it is a clear, slightly viscous liquid with a pungent odor; when dried, it is a white or yellowish powder
Color	Transparent or light yellow
Smell	Sharp, irritating, similar to acetic or ammonia
Taste	Bitter and burning
Solubility	It is well soluble in water, poorly in alcohols and fats.
pH	Acidic environment, pH ≈ 4.5 - 5.5
Melting point	There is no exact value, but when heated above 60 ° C, the destruction of proteins begins.
Stability	It quickly loses activity in light, when heated, and when in contact with air.

Conclusion

The utilization of bee venom for medicinal purposes constitutes an ancient practice that is increasingly substantiated by contemporary scientific research. For centuries, the therapeutic use of bee venom in folk medicine has been documented for a wide range of ailments, including arthritis, neurological disorders, skin diseases, and even cardiovascular pathologies. In recent decades, scientific research has confirmed the effectiveness of apitherapy in treating a number of diseases. For instance, the therapeutic application of bee venom has been demonstrated in the treatment of osteochondrosis, sciatica, osteoarthritis, and joint diseases. The therapeutic benefits of bee venom include its capacity to reduce inflammation and pain, enhance blood circulation, and restore mobility. However, the utilization of bee venom is not without contraindications. Apitherapy is a therapeutic modality that has been demonstrated to elicit allergic reactions, including anaphylactic shock. Prudent care is therefore paramount when undertaking this practice. Consequently, individuals contemplating the use of bee venom should seek medical counsel and undergo allergy assessments. It is imperative to meticulously observe the dosage and take into account the unique characteristics of the patient. Therefore, it can be concluded that bee venom has the potential to serve as a therapeutic remedy; however, its utilization must be meticulously regulated. A meticulous examination of the advantages and disadvantages reveals that apitherapy has the potential to enhance conventional therapeutic modalities. However, it is imperative to exercise caution and seek the expertise of a qualified professional to ensure its optimal implementation.

Abstract

With a rise in the world's energy demand and fossil fuel dependency, there has been an urgent need for sustainable and renewable power systems. In this mini-review, recent developments in bioelectrochemical systems (BESs), i.e., microbial fuel cells (MFCs), enzymatic bio-batteries, and photobioelectrochemical platforms integrating synthetic biology and nanotechnology for power generation are discussed. These systems exploit the electrochemical potential of microbial metabolism and enzymatic redox reactions to generate electricity from organic substrates, wastewater, and sunlight. The review is focused on genetic engineering of electroactive microbes, designer enzymes for optimal electron transfer, and nanostructured electrodes for improved efficiency and scalability. It also briefly discusses real-world applications including biosensing, remote power generation, and wastewater treatment with simultaneous energy recovery. The capacity to utilize them as components of decentralized low-carbon energy systems makes them a viable solution to both energy access and environmental sustainability in the climate crisis context.

Keywords: *Bioelectrochemical systems, Microbial fuel cells, Synthetic biology, Renewable energy, Enzymatic bio-batteries, Green electronics*

Introduction

With the rising global energy demands and the associated environmental consequences of fossil fuel burning, green and sustainable renewable green technologies have evolved. While conventionally existing fossil energy sources are still major greenhouses and carbon change emitters, a push towards the setting up of alternative mechanisms technology-friendly as well as greener is the global agenda today. Among the emerging options under investigation, bioelectrochemical systems (BESs) have garnered considerable attention due to their ability to produce electricity directly from organic substrates via biological means (Bajracharya et al., 2016).

Bioelectrochemical systems are a suite of technologies including microbial fuel cells (MFCs), enzymatic bio-batteries, and photobioelectrochemical platforms. Bioelectrochemical systems take advantage of the redox properties of enzymes and microbes to generate electric power from waste-based or renewable feedstocks like wastewater and light. Efficiency and scalability of BESs have greatly enhanced with the development of nanotechnology and synthetic biology, and hence are playing a crucial role in real-life applications (Hamelers et al., 2009).

This review attempts to locate the newest developments within the field of BESs, highlighting synergy between synthetic biology and green electronics towards optimizing the efficiency of energy conversion. It also refers to practical applications and how BESs will be in a position to provide support to decentralized, low-carbon energy systems and especially solving the global climate issue. The increasing global energy demand and the environmental impacts of fossil fuels have seen the creation of green and environment-friendly renewable energy technologies. Whereas fossil energy reserves continue to represent major drivers of greenhouse gases emissions and global change, exploring alternatives that are environmentally friendly, technologically-based is now the concern of international significance. Of these new options sought, BESs have generated considerable attention in that they are capable of deriving electricity from organic substrates by biological conversions directly (Fang et al., 2020).

Recent Developments in Bioelectrochemical Systems

There has been spectacular development in bioelectrochemical systems (BESs) over the past few years, with electrochemical and biological developments of interest. Microbial fuel cells (MFCs) are one of the many configurations, which have emerged as a model system of choice. MFCs use electroactive bacteria to oxidize organic substrates, with electrons transferred to an anode and electricity as a byproduct. Enhancements in metabolic engineering and microbial strain choice have accelerated electron transfer rates to yield greater energy and system stability (Schaetzle et al., 2008).

Another area of high promise is enzymatic bio-batteries, which make use of the purified redox enzymes to catalyze directly on the surface of the electrode. These systems offer biochemical pathway control and are well suited for application for utilization in miniaturized power systems for biomedical and remote-sensing applications. Enzyme stability and efficient electron transfer remain the major challenges (Buaki-Sogó et al., 2020).

Photobioelectrochemical systems are a cross-platform system that consists of photosynthetic microorganisms or light-sensitive enzymes in combination with electrochemical interfaces for the harvesting of solar energy. The platforms are gaining popularity due to their dual function of light energy conversion and bioremediation.

In addition to these, the use of novel materials such as carbon nanostructures, metal-organic frameworks (MOFs), and conductive polymers has also improved electrode conductivity and biocompatibility. All of these individually and collectively have resulted in enhancements in better performance measures such as power density, Coulombic efficiency, and operating life, which enable wider application of BESs to practical applications (Majumdar et al., 2017).

Integration of Synthetic Biology and Nanotechnology

The combination of synthetic biology and nanotechnology has revolutionized the designing of future bioelectrochemical systems (BESs) with the potential to regulate biological and electrochemical processes more precisely. Synthetic biology offers efficient ways of re-designing microorganisms to realize better electron transfer, metabolic yields, and substrate utilization. Genetic engineering of electroactive bacteria such as Shewanella oneidensis and Geobacter sulfurreducens has provided strains overexpressing cytochrome, conductive pili, and biofilm forming ability, all of which have been helpful in enabling electron transfer to the electrodes (Chen et al., 2022).

In the meantime, optimization of BES component structure and function is within the realm of nanotechnology. Nanostructured electrodes including carbon nanotubes, graphene, and nanofibers exhibit high surface area, improved conductivity, and improved microbial adhesion. All these attributes improve efficient electron transfer as well as reduce internal resistance for further improvement in overall system performance. In addition, immobilization of redox enzymes on nanomaterials has improved enzyme stability and efficiency of catalysis in enzymatic bio-batteries (Kim et al., 2024).

The merging of these two disciplines also enables the development of hybrid bioelectronic interfaces in which the biological systems are interfaced with electronic devices. These structures should extend the limits of scaled, miniaturized, and high-performance devices that can find applications in wearable biosensors, autonomous environmental sensing networks, etc.

By leveraging novel nanotechnology and synthetic biology techniques, BESs are being designed to function more effectively, for longer, and multi-dimensionally for a variety of energy and environmental applications, a step towards decentralized and sustainable energy generation (J. Kim et al., 2018).

Applications in Renewable Energy and Environmental Sustainability

Bioelectrochemical systems (BESs) possess tremendous potential for solving the most important problems of renewable energy generation and environmental protection. With their unique feature of generating electricity from organic wastes, wastewater, and solar power, BESs become twin-function technologies with the potential of clean energy as well as environmental sustainability (Wilberforce et al., 2020).

One of the most significant applications of BESs is wastewater treatment and power generation. In microbial fuel cells (MFCs), wastewater organic pollutants are oxidized by electroactive microbes and result in simultaneous pollutant abatement and electricity production. This not only reduces the environmental cost of wastewater discharge, but it also offsets the energy need of traditional treatment plants.

BESs are further explored for application in biosensing, where growth of microbes or electrochemical response is employed as a marker to indicate the existence of toxins, pathogens, or specific chemicals. These systems find great application for remote or real-time monitoring for environmental and biomedical applications (Daniel et al., 2009).

In decentralized power supply and off-grid, photobioelectrochemical cells and enzymatic bio-batteries can power small electronic devices in remote or poor regions. Biodegradable and low impact on the environment render them to be used for low-impact or short-term applications such as disaster relief regions, wearables, and IoT (Mukha et al., 2020).

Besides other uses, BESs also offer carbon-free energy grids, compatible with renewable energy grids. BESs are capable of offering circular energy systems with biomass and solar supply, especially for rural or developing regions lacking conventional energy infrastructure. In these diversified applications, BESs demonstrate green electronics and sustainable design principles and offer a way to integrated solutions to energy shortages and ecosystem degradation (Zhang et al., 2019).

Conclusion

Bioelectrochemical systems (BESs) are a new field of investigating sustainable, decentralized energy sources. By tapping into the intrinsic redox potential of microbes and enzymes, and further enhancing their performance with the aid of synthetic biology and nanotechnology, the systems can be utilized to convert solar energy and organic wastes into edible electricity. This renders BESs not only clean energy generators but also environmental remediation and biosensing multidisciplinary platforms.

Despite recent advances, several issues need to be addressed before large-scale applications. These involve improving the long-term stability of enzyme and biological components, electron transfer efficiency, reducing system cost, and increasing production scale without losing performance. Regulation and public perception concerns may also influence commercialization rates.

Future studies will have to tackle the development of genetically designed microbial consortia, novel bio-nano interfaces, and smart control systems that allow BESs to respond dynamically to environmental changes. Integration with other renewable technology, i.e., solar or wind technology, could also facilitate hybrid platforms of peak energy yield and reliability.

In brief, as the global energy portrait transitions towards sustainability, bioelectrochemical systems are a promising, sustainable alternative. Interdisciplinary research will continue to be crucial in unlocking their complete potential and making them economically feasible components of green energy infrastructure in the future.

Abstract

Traceability is an important cog in the machinery of modern food logistics systems for attaining the twin objectives of transparency, safety, and efficiency along the food supply chain. Traceability systems allow for real-time monitoring, verification, and response by stakeholders in food production and consumption, from farm to fork, to any issues concerning quality or safety. Thus, this study proposes investigating the traceability of food logistics and the ensuing role in food safety, compliance, and consumer trust. The main focus of the paper is on the structure and operation of traceability systems, resulting-from-technologies like barcoding, RFID, IoT devices, and blockchain applications. These technologies promote the tracing of food products through supply chain nodes: producers, processors, distributors, and retailers: while enabling faster corrective action. The analysis of the cases three from developed countries and three from emerging ones reveals best practices and widespread challenges in the adoption of traceability systems. The study also points to the increasing relevance of end-to-end visibility for sustainable and resilient food supply chains. With growing global trade in food and consumer awareness, traceability is no longer a regulatory requirement but also a strategic marketing tool to gain a competitive edge. Hence, the research elaborates that proper traceability improves accountability, risk management, and trust among stakeholders in food logistics operations. The study recommends investments in traceability technologies and alignment with regulations as critical for making food logistics systems evolve in today's increasingly complex global environment.

Key Words: *traceability, food logistics, supply chain, food safety, transparency, farm to fork*

Introduction

The globalization of food markets and the intricate nature of contemporary supply chains have introduced significant challenges to ensuring food safety, quality, and authenticity. Past incidents involving contamination outbreaks, mislabeling, and fraudulent practices have diminished consumer confidence and have highlighted the need for robust transparency throughout food logistics systems. Within this evolving landscape, traceability has emerged as a critical instrument, transcending mere regulatory compliance to become a strategic asset for enhancing brand reputation, managing risks, and fostering consumer trust. This paper delves into the notion of traceability in food logistics, examining its technological foundations, operational processes, and strategic importance in guaranteeing a secure and sustainable food supply chain from farm to fork (Singh et al., 2017).

Conceptualizing Traceability

Traceability in the context of food logistics signifies the systematic ability to monitor and document the journey of food products and their components across every phase of production, processing, and distribution. This encompasses capturing and accessing detailed information concerning the history, origin, and current status of products at diverse points along the supply chain. Distinct from conventional record-keeping practices, modern traceability systems leverage advanced digital tools and integrated data management platforms to enable swift data sharing, secure storage, and real-time availability of information. Beyond addressing food safety by facilitating the rapid identification and removal of contaminated goods, traceability plays a pivotal role in verifying sustainability claims, ensuring regulatory compliance, and optimizing operational efficiency within increasingly complex supply networks (Reddy et al., 2023).

Technologies Enabling Traceability

Several cutting-edge technologies form the backbone of contemporary traceability systems in food logistics. Barcoding systems, though traditional, remain widely used due to their cost-effectiveness and reliability in identifying products and recording data at various supply chain points, even if they are limited in data capacity. More advanced, Radio Frequency Identification (RFID) technology offers superior data storage capabilities and operational advantages, such as non-line-of-sight scanning and the ability to read multiple items simultaneously, which significantly improves efficiency in logistics operations. Meanwhile, the Internet of Things (IoT) has revolutionized real-time monitoring by enabling the continuous collection of data on environmental conditions

like temperature, humidity, and transit times, crucial for maintaining the quality of perishable food items. Additionally, blockchain technology provides a decentralized and tamper-proof ledger system for recording traceability data, offering unparalleled transparency and security, and ensuring that data shared across the supply chain is both immutable and verifiable. Collectively, these technologies establish a robust digital ecosystem that enhances the precision, responsiveness, and collaborative capabilities of traceability systems (Jamkhedkar et al., 2021).

Operational Mechanisms of Traceability Systems

Implementing effective traceability systems necessitates the integration of several operational components working seamlessly together. The process begins with meticulous data capture and integration, whereby information is gathered at every stage of the supply chain, documenting essential details such as product identifiers, batch numbers, origin data, and handling conditions provided by farmers, processors, logistics providers, and retailers. Given the vast amounts of data involved, secure and scalable data storage solutions are imperative, with cloud computing offering substantial advantages in terms of accessibility, flexibility, and protection against data loss. Moreover, efficient traceability depends on well-established information sharing protocols among all actors within the supply chain (Austin & Wojcik, 2010). The use of standardized formats and guidelines, such as those set by GS1, facilitates interoperability and minimizes disruptions in data exchange. A critical feature of traceability systems is their capacity to support rapid recall and response mechanisms in the event of contamination or safety concerns, allowing organizations to swiftly isolate and remove affected products from circulation, thus protecting public health and mitigating financial and reputational risks. These operational mechanisms demand significant investments not only in technological infrastructure but also in workforce training and inter-organizational collaboration to ensure their consistent and reliable functionality (Huang et al., 2014).

Benefits of Traceability in Food Logistics

The adoption of comprehensive traceability systems yields numerous advantages for food supply chains across the globe. At the forefront is the assurance of food safety, as traceability allows for precise monitoring of products, thereby facilitating swift identification and removal of any items compromised by contamination or adulteration, ultimately reducing the scope and impact of recalls. Compliance with regulatory mandates set forth by entities like the European Food Safety Authority (EFSA) and the U.S. Food and Drug Administration (FDA) becomes more manageable through robust traceability practices, which are essential for enterprises operating in global markets. Furthermore, traceability systems enhance risk management by empowering organizations to address operational and reputational threats proactively, underpinned by documented evidence of diligence and compliance (Burke, 2019). From a market perspective, as consumers increasingly prioritize transparency, ethical sourcing, and sustainable practices, traceability emerges as a powerful marketing asset, strengthening consumer trust and fostering brand loyalty. Beyond these strategic benefits, traceability contributes significantly to operational efficiency by improving inventory management, minimizing waste, and refining demand forecasting, thereby optimizing the performance and sustainability of entire supply chains (Stevens, 2019).

Challenges and Barriers

Despite its considerable merits, the implementation of traceability systems is not without significant obstacles, particularly in developing and emerging economies. One of the primary barriers is the high cost associated with deploying advanced traceability technologies, which can be prohibitive for small and medium-sized enterprises (SMEs), thereby limiting widespread adoption and perpetuating disparities between large corporations and smaller actors in the supply chain. Technological integration poses another challenge, as incorporating sophisticated traceability solutions into pre-existing IT infrastructures often requires overcoming issues of compatibility and data harmonization across diverse platforms and legacy systems. Additionally, concerns regarding data privacy and proprietary information discourage some stakeholders from fully engaging in transparent data sharing, due to fears of competitive disadvantage, legal exposure, or potential damage to corporate reputation. Compounding these challenges is the lack of standardized regulations and practices across different countries and sectors, resulting in fragmented systems and operational inefficiencies. Addressing these barriers calls for collaborative policy development, financial incentives to support technological adoption, and comprehensive training programs to build the necessary technical expertise across all levels of the supply chain (Boutros et al., 2014).

Conclusion

Traceability stands as a cornerstone of modern food logistics, serving as a vital mechanism for safeguarding food safety, enhancing supply chain resilience, and cultivating consumer trust. As food supply networks grow ever more complex and interconnected, the importance of reliable, technology-driven traceability systems cannot be overstated. Although challenges persist, particularly in the context of resource constraints and infrastructural limitations in emerging economies, the strategic value of traceability as both a regulatory obligation and a competitive advantage is clear and compelling. This paper has highlighted that investing in traceability

infrastructure, fostering collaborative industry initiatives, and pursuing regulatory alignment are essential for securing the future of sustainable and safe food logistics, ensuring that the journey from farm to fork is transparent, reliable, and worthy of consumer confidence.

Comparison of Composition and Bioactive Properties of Garlic from Gaziantep and Kahramanmaraş

Hatice Kubra SASMAZ[1], Turkan UZLASIR[1], Pınar KADIROGLU[1], Hasim KELEBEK*[1]

[1] *Department of Food Engineering, Faculty of Engineering, Adana Alparslan Turkes Science and Technology University, 01250 Adana/ Türkiye

Abstract

Garlic (*Allium sativum* L.) belongs to the Liliaceae family and is a vegetable of global economic importance due to its distinctive flavour and positive health effects. It is utilised as an essential component in both traditional and modern medicine. In this study, garlic cultivated in the Gaziantep and Kahramanmaraş regions was analysed. There is a lack of detailed studies in the literature comparing the general composition and bioactive properties of garlic from these two regions. The analyses encompassed moisture and protein content, colour characteristics, antioxidant capacity (measured through DPPH, ABTS, CUPRAC, and iron ion chelating capacity), and total phenolic content. Additionally, the sugar profile was assessed via the HPLC-RID method, the amino acid profile using HPLC-PDA, and total sulfur compounds along with allicin content were analysed. The amino acids identified in garlic samples included aspartic acid, glutamic acid, asparagine, serine, glutamine, histidine, glycine, threonine, arginine, tyrosine, cysteine, valine, methionine, tryptophan, phenylalanine, isoleucine, leucine, and proline. The total amino acid content was found to be 488.81 mg/100 g in Gaziantep garlic, whereas it was 417.34 mg/100 g in Kahramanmaraş garlic. In both regions, arginine was identified as the dominant amino acid. The amount of allicin in garlic grown in the Gaziantep region was measured at 2.51 mg/g, with a total sulfur compound amount of 7.84 mg/g. In garlic from the Kahramanmaraş region, the allicin content was measured at 2.37 mg/g, while the total sulfur compound amount was 6.58 mg/g. The findings provide vital insights into the nutritional and functional value of garlic by highlighting the differences in composition and bioactive properties of garlic cultivated in different regions.

Key Words: *Allium sativum L., bioactive properties, antioxidant capacity, allicin, HPLC*

Gaziantep ve Kahramanmaraş Sarımsağının Bileşim ve Biyoaktif Özelliklerinin Karşılaştırılması

Özet

Liliaceae familyasına ait olan sarımsak (*Allium sativum L.*), kendine özgü aroması ve sağlık üzerindeki olumlu etkileri nedeniyle dünya çapında ekonomik öneme sahip bir sebzedir. Geleneksel ve modern tıpta önemli bir bileşen olarak değerlendirilmektedir. Bu çalışmada, Gaziantep ve Kahramanmaraş yörelerinde yetişen sarımsaklar incelenmiş olup, literatürde bu iki yöreye ait sarımsakların genel bileşimi ve biyoaktif özelliklerini karşılaştıran ayrıntılı bir çalışma bulunmamaktadır. Bu eksikliği gidermek amacıyla kapsamlı analizler gerçekleştirilmiştir.Analizler kapsamında; nem ve protein miktarı, renk özellikleri, antioksidan kapasitesi (DPPH, ABTS, CUPRAC ve demir iyonlarını şelatlama kapasitesi ile ölçülmüştür), toplam fenolik madde miktarı belirlenmiştir. Ayrıca, HPLC-RID yöntemi ile şeker profili, HPLC-PDA yöntemi ile amino asit profili, toplam sülfürlü bileşik ve allisin miktarı analiz edilmiştir.Sarımsak örneklerinde aspartik asit, glutamik asit, asparajin, serin, glutamin, histidin, glisin, treonin, arjinin, tirozin, sistein, valin, metiyonin, triptofan, fenilalanin, izolösin, lösin ve prolin amino asitleri belirlenmiştir. Toplam amino asit miktarı Gaziantep sarımsağında 488,81 mg/100 g, Kahramanmaraş sarımsağında ise 417,34 mg/100 g olarak saptanmıştır. Her iki yörede de baskın amino asidin arjinin olduğu tespit edilmiştir.Gaziantep yöresinde yetişen sarımsaklarda allisin miktarı 2,51 mg/g, toplam sülfürlü bileşik miktarı ise 7,84 mg/g olarak belirlenmiştir. Kahramanmaraş yöresinde yetişen sarımsaklarda ise allisin miktarı 2,37 mg/g, toplam sülfürlü bileşik miktarı 6,58 mg/g olarak saptanmıştır.Elde edilen bulgular, farklı bölgelerde yetişen sarımsakların bileşimi ve biyoaktif özellikleri açısından farklılıklarını ortaya koyarak, sarımsağın besinsel ve fonksiyonel değerine yönelik önemli bilgiler sunmaktadır.

Anahtar Kelimeler: *Allium sativum L., biyoaktif özellikler, antioksidan kapasite, allisin, HPLC*

Bu çalışma “123O720” proje numaralı 1001 projesi kapsamında TÜBİTAK (Türkiye Bilimsel ve Teknolojik Araştırma Kurumu) tarafından desteklenmiştir. TÜBİTAK’a teşekkürlerimizi sunarız.

Giriş

Sarımsak (*Allium sativum* L.), *Allium* cinsine ait bir türdür. Bu cins, fizyolojik olarak aktif sekonder metabolitler içeren sarımsak, soğan, arpacık soğanı, pırasa ve frenk soğanı gibi yüzlerce türü kapsamaktadır. Sarımsak tarih boyunca "Rus penisilini", "doğal antibiyotik" ve "bitkisel tılsım" gibi çeşitli unvanlarla anılmıştır (Lidiková ve ark., 2023). Sarımsak, içerdiği biyoaktif bileşenler nedeniyle hem geleneksel tıpta hem de modern tıbbi araştırmalarda önemli bir yer tutmaktadır. Yapılan çeşitli çalışmalar, sarımsağın güçlü antikanser, antimikrobiyal, antialerjik ve antioksidan özellikler taşıdığını ortaya koymuştur (Iciek ve Kwiecień, 2009; Rana ve ark., 2011). Sarımsağın farmakolojik etkileri oldukça çeşitlidir. Antibakteriyel aktivitesi sayesinde patojen mikroorganizmalara karşı etkili bir koruma sağlamakta, kan lipit düzeylerini düşürerek kardiyovasküler sağlığı desteklemekte ve antiinflamatuar etkisi ile kronik enflamasyonu azaltabilmektedir. Bunların yanı sıra, ateroskleroz gelişimini önleme potansiyeli, nöronal koruma sağlama yeteneği ve kalp sağlığı üzerindeki olumlu etkileri gibi biyolojik aktiviteleri, sarımsağı fonksiyonel bir gıda ve terapötik ajan olarak öne çıkarmaktadır (Iciek ve Kwiecień, 2009; Rana ve ark., 2011). Sahip olduğu çok sayıda biyoaktif bileşenin yanı sıra, özellikle tıbbi etkileri yüksek olan organosülfürlü bileşiklerden biri olan allisin, bu biyolojik aktivitelerin ortaya çıkmasında temel rol oynamaktadır (Mollica ve ark., 2018). Sarımsak, çeşitli biyoaktif bileşikler içermektedir (Jang ve ark., 2018). Bu bileşikler arasında organosülfür bileşikleri, allisin, diyalil sülfürler, diyalil disülfür, diyalil trisülfür ve S-alil-sistein sülfoksit (alliin) yer almaktadır. Ayrıca saponinler, fenolik bileşikler, amino asitler, uçucu yağlar, vitaminler, mineraller (germanyum, selenyum, kalsiyum ve demir), enzimler ve bağışıklık modüle edici polisakkaritler de sarımsakta bulunan önemli bileşenlerdendir (Qiu ve ark., 2020; Sasmaz ve ark., 2022; Shang ve ark., 2019).
Türkiye'de sarımsak üretimi yıllara göre değişiklik göstermekle birlikte, Türkiye İstatistik Kurumu (TÜİK) 2023 verilerine göre, en fazla sarımsak üretimi sırasıyla Kastamonu, Gaziantep, Kahramanmaraş, Aksaray ve Tokat illerinde gerçekleşmiştir (TUİK, 2023). Gaziantep ve Kahramanmaraş yörelerinde yetişen sarımsakların bileşimleri ve biyoaktif özellikleri karşılaştırmalı olarak incelenmemiştir. Bu çalışmada, her iki yöreye ait sarımsakların nem ve protein içeriği, renk özellikleri, antioksidan kapasiteleri (DPPH, ABTS, CUPRAC, demir iyonlarını şelatlama), toplam fenolik madde miktarı, şeker ve amino asit profilleri (HPLC-RID ve HPLC-PDA), toplam sülfürlü bileşik ve allisin içerikleri analiz edilerek kapsamlı bir karakterizasyon yapılmıştır. Bu sayede, bölgesel farklılıkların sarımsağın biyoaktif özellikleri üzerindeki etkisi değerlendirilmiştir.

Materyal ve Yöntem

Kimyasallar

Metanol (HPLC grade) ve sodyum karbonat Merck (Darmstat, Almanya) firmasından; psülfürlü bileşikler (L-(+)-alliin, allisin, SAC ve GSAC), şekerler (sakkaroz, glikoz, fruktoz), Sigma Chemical Co. (St. Louis, ABD) firmasından temin edilmiştir. DPPH (2,2-difenil-1-pikrilhidrazil), ABTS [2,2-azinobis-(3-etil-benzotiazolin-6-sülfonik asit)], 3-MPA (3-merkaptopropionik asit), FMOAC (9-Florenilmetoksikarbonil), OPA(o-fitalaldehit) ve Troloks ((+/-)-6-hidroksi-2, 5, 7, 8-tetrametil-kroman-2-karboksilik asit) Sigma-Aldrich Chemical Co. (St. Louis, ABD) firmasından ve etanol Riedel de Haen Co. (Seelze, Almanya) firmasından temin edilmiştir. HPLC analizlerinde mobil fazların hazırlanmasında Elga Purelab Option-Q marka saf su cihazından sağlanan 18.2 MΩ-cm ultra saf su kullanılmıştır. Standart çözeltiler ve diğer hassas çözeltiler günlük olarak hazırlanmıştır.

Materyal

Çalışmada kullanılan sarımsak (*Allium sativum* L.) örnekleri, Türkiye'nin önemli sarımsak üretim bölgelerinden olan Kahramanmaraş ve Gaziantep illerinden temin edilmiştir. Kahramanmaraş örnekleri, Kahramanmaraş ilinin Pazarcık ilçesindeki yerel bir pazardan; Gaziantep örnekleri ise Gaziantep ilinin Araban ilçesinden sağlanmıştır.

Nem ve kuru madde miktarı

Örneklerin nem oranları AOAC (1997)'de belirtilen metoda göre yapılmıştır. Kısaca darası alınan bir petri kutusuna yaklaşık 5 g ± 0,1 ağırlığında örnek tartılmış ve 105 ± 2°C'deki etüvde sabit ağırlığa gelinceye kadar kurutma işlemine tabi tutulmuştur.

Renk özelliklerinin belirlenmesi

Renk ölçümlerinde Hunter Lab Scan (Hunter Associates Laboratory, Inc., Reston, VA, USA) cihazı kullanılarak L*, a*, b* değerleri kaydedilmiştir (Hojjati ve ark., 2012). 'L*' değeri parlaklığı (beyazlık veya açıklık koyuluk); '+a*' değeri kırmızı; '-a*' değeri yeşil; '+b*' değeri sarı ve '–b*' değeri mavi renkleri temsil etmektedir. Bu değerlere bağlı olarak aşağıdaki formüllere göre renk berraklığı (Chroma) ve renk tonu (Hue) değerleri de hesaplanmıştır.
Renk berraklığı = (a*2 + b*2)1/2
Renk tonu = Arctan (b*/a*).

Protein tayini

Ham protein içeriği otomatik yakma, damıtma ve titrasyon ünitesi (Vapodest 45s Gerhardt) kullanılarak Kjeldahl yöntemiyle belirlenmiştir. Titrasyon işleminde harcanan 0.1 N HCl miktarı saptanarak elde edilen değerler kullanılıp örneklerdeki protein miktarı hesaplanmıştır (AOAC International. 2007).

Antioksidan Kapasitenin ve Toplam Fenolik Madde Miktarının Belirlenmesi Antioksidan aktivite analizleri

Sarımsak örneklerinin antioksidan aktiviteleri dört farklı yöntemle değerlendirilmiştir. Serbest radikalleri önleme yeteneğini ölçebilen DPPH (2,2, difenil 1-pikri hidrazil) kullanılarak ve metanol içerisinde gerçekleşen reaksiyonun zamana karşı değişiminin 515 nm'de (Agilent –Cary 60) spektrofotometredeki ölçüm sonuçlarına göre yapılmıştır (Brand-Williams ve ark., 1995; Sanchez-Moreno ve ark. 1998; Kelebek ve ark. 2009).

ABTS yöntemi Saafi ve ark. (2009)'nın metoduna göre yapılmıştır. Bu yöntem için 7 mM ABTS (2,2'-Azino-bis 3-ethylbenzothiazoline-6-sulfonic asit) 2.45 mM potasyumbisülfat ile karıştırılmıştır karanlık ortamda 12-16 saat bekletilmiştir ve daha sonra bu solüsyon sodium asetat (pH 4.5) tamponu ile spektrofotometrede 734 nm dalga boyunda 0.70±0.01 absorbans olacak şekilde seyreltilmiştir. Daha sonra 20 µL örnek 2.98 mL hazırlanan tampon ile karıştırılmıştır. Absorbans 10 dakika sonra spektrafotometrede 734 nm dalga boyunda ölçülmüştür. Elde edilen absorbans değerleri Trolox (10–100 µmol/L) standart eğim çizelgesi ile hesaplanmıştır. Elde edilen absorbans değerleri Trolox (10-100 µmol/L) standart eğim çizgisi ile hesaplanmıştır.

CUPRAC yöntemi Apak ve ark. (2004),'nin metoduna göre yapılacaktır. Bu yöntem için 1.0×10-2 M Bakır (II) klorür çözeltisi ($CuCl_2.2H_2O$), 1 M (pH=7) Amonyum asetat tamponu ve 7.5×10-3 M Neokuproin (2,9-dimetil-1,10-fenantrolin) çözeltisi hazırlanacaktır. Troloks antioksidan bileşiğinin stok çözeltisi ise 1.0×10-3 M konsantrasyonda olacak şekilde hazırlanacaktır. Bir cam tüp içerisine bakır (II) çözeltisi, neokuproin çözeltisi ve amonyum asetat tamponundan sırasıyla 1'er ml eklenecektir. Üzerine örneğin katı veya sıvı olma durumuna (x) göre (katı ise 0.5 ml, sıvı ise 0.3 ml) antioksidan çözeltisi ve (1.1-x) mL distile su ilave edilip tüpler iyice çalkalanacaktır. Toplam hacim 4.1 ml olacak şekilde hazırlanan çözeltiler oda koşullarında ağzı kapalı olarak 30 dakika boyunca bekletilecek ve süre sonunda içinde örnek bulunmayan referans çözeltiye karşı 450 nm'de absorbans değerleri ölçülecektir. Elde edilen absorbans değerleri Trolox standart eğim tablosu ile hesaplanarak sonuçlar mmol trolox/g cinsinden ifade edilecektir.

Örneklerin demir iyonlarını şelatlama kapasiteleri, analizi için öncelikle 2 mL örnek çözeltisi ile 0.1 mL 1 mmol/L $FeCl_2 \cdot 4H_2O$ çözeltisi karıştırılarak 30 dakika süreyle inkübasyona bırakılmıştır. Daha sonra karışıma 0.1 mL 5 mmol/L ferrozin çözeltisi ilave edilerek homojen bir şekilde karıştırılmış ve 10 dakika daha inkübasyon işlemi uygulanmıştır. İnkübasyon sonucunda örnek absorbansı, 562 nm dalga boyunda spektrofotometrik olarak ölçülmüştür.

Toplam Fenolik Madde Miktarı

Toplam fenolik madde analizi, Singleton ve ark. (1999) yöntemine göre yapılmıştır. 100 µl ekstrakt üzerine 7.5 ml distile su ilave edilmiş, 0.5 ml Folin-Ciocalteu reaktifi ilave edilmiş 3 dakika bekletilerek üzerine 1 ml %20'lik sodyum karbonat çözeltisi eklenmiştir ve daha sonra 0.9 ml distile su eklenmiş ve karıştırılmıştır. 1 saat oda koşullarında karanlıkta bekletilmiş ve UV spektrofotometre (Agilent Carry 60) ile 765 nm'de absorbans değerleri ölçülmüştür. Elde edilen absorbans değerleri gallik asit (31.25–500 ppm) standart eğim çizgisi ile hesaplanmış sonuçlar mg /100 gram TPC gallik asit eşdeğerleri (GAE) cinsinden ifade edilmiştir.

Şeker Bileşimi Analizi

Şeker bileşiminin belirlenmesi amacıyla, sarımsak örneklerinden 2 g alınarak üzerine 20 mL saf su ilave edilmiş ve 30 dakika süreyle ekstraksiyon işlemi uygulanmıştır (Sasmaz ve ark., 2022). Örnekler Shimadzu Prominence-i model HPLC cihazına enjekte edilerek analiz edilmiştir. Analizlerde, Bio-Rad firmasına ait Aminex HPX-87H (300 × 7.8 mm) kolonu kullanılmıştır. Taşıyıcı faz olarak 5 mM sülfürik asit çözeltisi kullanılmış ve fazın akış hızı 0.5 mL/dakika olarak ayarlanmıştır. Ayırma işlemi izokratik modda gerçekleştirilmiştir. Örneklerdeki sakkaroz, glikoz ve fruktoz miktarlarının belirlenmesi için refraktif indeks dedektörü (RID) kullanılmış ve kantitatif analizler dış standart yöntemi ile yapılmıştır. Bu kapsamda, her bir şeker bileşiği için beş farklı konsantrasyonda kalibrasyon çözeltileri hazırlanarak standart eğriler oluşturulmuştur.

Amino Asit Analizi

Amino asit analizleri için sarımsak örneklerinden 0.5 g tartılarak, üzerine 10 mL %0.1 N HCl çözeltisi ilave edilmiştir. Örnekler, geri soğutucu altında 110 °C'de 24 saat süreyle hidrolize edilmiştir. Hidroliz sonrasında elde edilen sıvı fazdan 2 mL alınarak 0.45 µm'lik membran filtreden geçirilmiş ve analiz için hazırlanmıştır.Filtre edilen örnekler, Shimadzu Prominence-i model HPLC cihazına enjekte edilmiştir. Analiz öncesinde, amino asitler 3-merkaptopropiyonik asit (3-MPA), ortoftalaldehit (OPA) ve 9-fluorenylmetil kloroformiat (FMOC) reaktifleri ile türevlendirilmiştir. Türevlendirilen örnekler, Shimadzu marka Shim-pack XR-ODS II kolonuna (2 µL enjeksiyon hacmi) enjekte edilerek amino asit miktarı saptanmıştır (Sasmaz ve ark., 2022).

Toplam sülfürlü Bileşiklerin ve Allisin Miktarının Analizi

Örnek ekstraksiyonu için Sasmaz ve ark. (2023) tarafından yürütülen yöntem uygulanmıştır. Analizler, Agilent 1260 LC sistemi ile entegre çalışan bir diyot dizin dedektörü (DAD) ve Agilent 6460 üçlü kuadrupol kütle spektrometresi (Agilent Technologies, Santa Clara, CA, ABD) kullanılarak gerçekleştirilmiştir. Sülfürlü bileşiklerinin tayininde, Phenomenex Luna C18 kolon (250 x 4.6 mm, 5 µm; Torrance, Kaliforniya, ABD) kullanılarak pozitif iyon modunda LC-DAD-ESI-MS/MS tekniği uygulanmıştır. Kromatografik ayırma işlemi için kolon sıcaklığı 25°C'de sabit tutulmuş ve 5 µL'lik enjeksiyon hacmi uygulanmıştır. Mobil faz olarak iki çözelti kullanılmıştır: çözücü A, su ve formik asit karışımından (99:1, v/v); çözücü B ise asetonitril ile çözücü A'nın 60:40 (v/v) oranında karıştırılmasıyla hazırlanmıştır analizde, gradient sistemi kullanılmıştır. Kütle spektrometresi analizlerinde elektrosprey iyonizasyon (ESI) kaynağı kullanılmış olup, nebülizör gaz basıncı 45 psi, kuru gaz akış hızı 15 L/dakika ve kuru gaz sıcaklığı 400°C olarak ayarlanmıştır.

Bulgular ve Tartışma

Kuru madde ve nem miktarının belirlenmesi

Gaziantep ve Kahramanmaraş illerinden temin edilen taze sarımsaklarda yapılan analizler sonucunda, kuru madde miktarları sırasıyla %28,93 ve %29,09, nem içerikleri ise %71,06 ve %70,91 olarak saptanmıştır (Tablo 1). Sasmaz ve ark. (2022) yaptıkları çalışmada Gaziantep ve Kastamonu taze sarımsaklarının nem içeriğini %60,3 ve %65,4 olarak belirlemişlerdir. Kutlu ve ark. (2018) Tunceli dağ sarımsağının özelliklerini araştırdıkları çalışmada, sarımsağın kuru madde miktarını %38,08 olarak saptamışlardır. Taze ve siyah sarımsağın fizikokimyasal ve antioksidan özelliklerinin araştırıldığı çalışmada, taze sarımsağın nem miktarı %64,21 olarak belirlenmiştir (Choi ve ark., 2014). Yapılan diğer çalışmalarda taze sarımsakların nem içeriklerinin %62,31 ile %72,42 arasında değiştiği bildirilmiştir (Kang ve ark., 2016, Resende Nassur ve ark., 2018).

Tablo 1. Sarımsakların genel bileşimleri

	Gaziantep	**Kahramanmaraş**
Nem (%)	71,06±0,57	70,91±0,41
Kuru madde(%)	28,93±0,57	29,09±0,41
Protein (%)	6,78±0,10	6,36±0,17
Renk Parametreleri		
L*	82,71±0,21	77,45±1,72
a*	1,7±0,06	2,32±0,15
b*	14,32±0,73	15,78±1,91
C	14,75±0,15	15,95±1,87
h*	96,90±0,09	98,49±1,08
Şeker Bileşimi (mg/kg)		
Sakkaroz	1276,51±1,32	938,61±1,85
Glikoz	1055,70±0,83	895,58±3,62
Fruktoz	477,17±0,12	463,00±2,53
Toplam şeker	2809,39±2,28	2298,15±5,01

Protein miktarı

Gaziantep ve Kahramanmaraş taze sarımsaklarının protein miktarı Tablo 1'de verilmiş ve protein içerikleri sırasıyla %6,78 ve %6,36 olarak saptanmıştır. Sasmaz ve ark. (2022) yaptıkları çalışmada Gaziantep ve Kastamonu taze sarımsaklarının protein miktarını %7,5 ve %6,8 olarak belirlemişlerdir. Sasaki ve ark. (2007) taze sarımsağın protein miktarını %8,4 olarak, Liu ve ark. (2018) ise %5,32 olarak bildirmiştir. Sarımsakların protein içerikleri genel olarak değerlendirildiğinde Gaziantep ve Kahramanmaraş yörelerine ait sarımsakların protein içeriklerinin literatür verileriyle uyumlu olduğu ve Gaziantep yöresinin protein içeriğinin Kahramanmaraş yöresine kıyasla yüksek olduğu saptanmıştır.

Renk özellikleri

Renk, gıda seçimi ve kabul edilebilirliği üzerinde önemli bir etkiye sahiptir ve genellikle gıda kalitesinin bir göstergesi olarak lezzet, güvenlik ve besin değeri ile ilişkilendirilmektedir (Andrés-Bello ve ark., 2013; Hutchings, 2016). Bir nesnenin kabul/reddinin %62-90 oranında renge bağlı oluştuğu ve tüketicilerin satın alma kararlarını bir ürünle temasın ilk 90 saniyesinde oluşan izlenimlere dayandığı bildirilmiştir (Brennan, 2006). Taze sarımsakların L*, a*, b*, C ve h değerleri Tablo 1'de verilmiştir. L* değeri parlaklığı (beyazlık veya koyuluk); +a*' değeri kırmızı; -a*' yeşil; +b*' değeri sarı ve –b' değeri mavi renkleri temsil etmektedir. Gaziantep ve Kahramanmaraş yörelerinden temin edilen taze sarımsakların renk parametrelerinden L* değeri sırasıyla 82,71 ve 77,45 olarak belirlenmiştir. Renkteki kırmızılığın göstergesi olan a* değeri 1,70 ve 2,32 sarılığın göstergesi olan b* değeri, 14,75 ve 15,95, C değeri 14,75 ve 15,95, h değeri ise 96,9 ve 98,49 olarak tespit edilmiştir (Tablo 1).

Antioksidan aktivite

Gıdalardaki doğal bileşiklerin antioksidan aktivitelerini belirlemek için çeşitli yöntemler bulunmaktadır (Kim, Jung ve ark., 2012). Gaziantep ve Kahramanmaraş taze sarımsaklarının antioksidan kapasitesi DPPH, ABTS, CUPRAC ve demir iyonlarını şelatlama kapasitesi olmak üzere dört farklı yöntemle belirlenmiş ve elde edilen veriler Tablo 2'de verilmiştir.

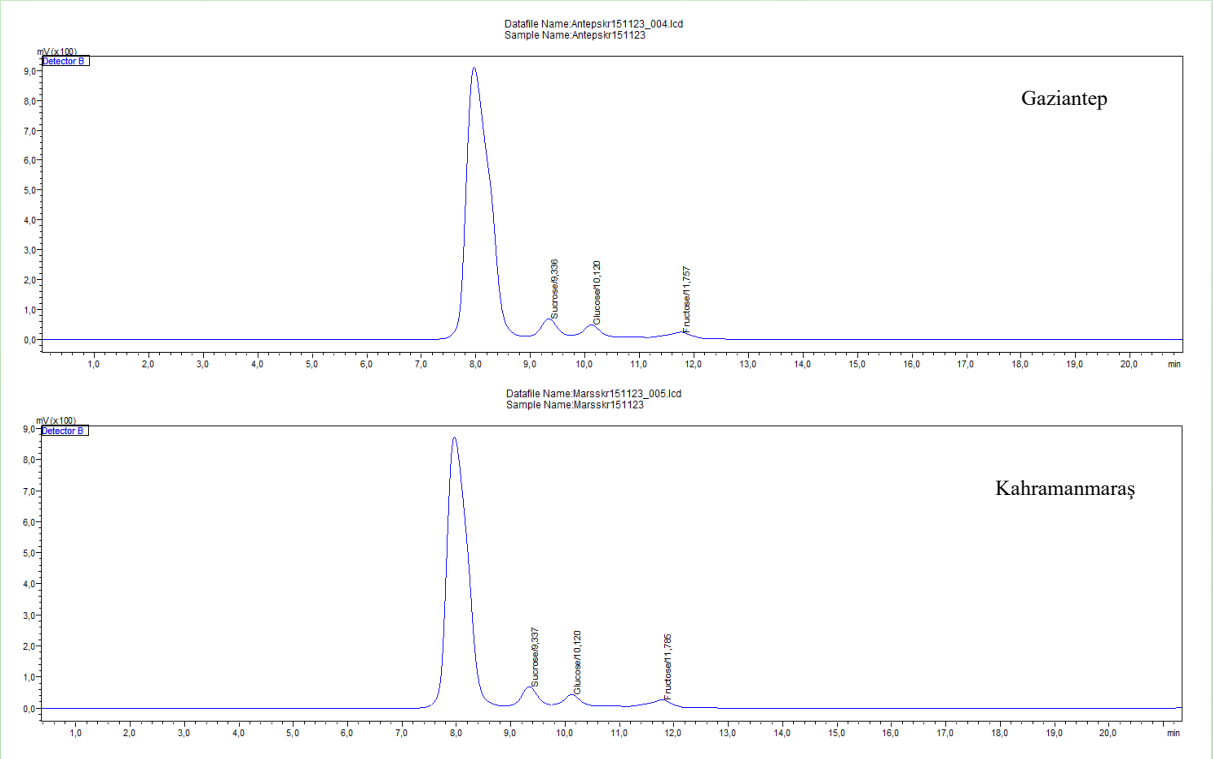
Bitkilerin ve ekstraktların radikal temizleme kapasitesinin belirlenmesinde kullanılan en yaygın yöntemlerden biri 2,2-difenil-1-pikrilhidrazil (DPPH) analizidir. Bu yöntem, uygulanması kolay, tekrarlanabilirliğinin yüksek ve ekonomik olmasıyla bilinmektedir. DPPH yöntemi, DPPH radikalinin antioksidanlar tarafından bir redoks reaksiyonuna bağlı olarak süpürülmesi temeline dayanmaktadır (Carmona-Jiménez ve ark., 2014). Gaziantep taze sarımsağının DPPH yöntemiyle saptanan antioksidan kapasitesi 174,54 µmol Trolox/100g KA, Kahramanmaraş taze sarımsağının ise 146,91 µmol Trolox/100g KA olarak saptanmıştır (Tablo 2).

Tablo 2. Sarımsak örneklerinin antioksidan kapasite ve toplam fenolik madde miktarı sonuçları

	Gaziantep	Kahramanmaraş
Toplam Fenolik Madde[1]	276,97±3,86	252,91±1,79
DPPH[2]	174,54±3,09	146,70±3,12
ABTS[2]	312,15±5,32	307,62±5,02
CUPRAC[3]	62,85±0,81	58,81±1,16
Demir İyonlarını Şelatlama Kapasitesi[4]	63,22±0,02	62,54±0,17

[1] mg GAE /100 g KA, [2] µmol Trolox /100 g KA, [3] mmol Trolox/100 g KA,[4]mg EDTA/100 g KA

ABTS (2,2′-azinobis-3-etilbenztiazolin-6-sülfonik asit) yöntemi, ilk olarak Miller ve arkadaşları (1993) tarafından bildirilmiş olup, ABTS'nin hidrojen persülfat ile oksidasyonuyla oluşturulan, ABTS+ radikalinin, bir antioksidanı stabilize etme yeteneğine dayanmaktadır (Londoño, 2012). ABTS yöntemiyle saptanan Gaziantep taze sarımsağının antioksidan kapasitesi 312,15 µmol Trolox/100g KA, Kahramanmaraş taze sarımsağının ise 307,62 µmol Trolox/100g KA olarak belirlenmiştir. CUPRAC (Bakır II iyonu indirgeme esaslı antioksidan kapasite) yönteminde, 2,9-dimetil-1,10- fenantrolin (Neokuproin-Nc)'in Cu(II) ile oluşturduğu bakır(II)-neokuproin kompleksinin (Cu(II)-Nc) antioksidan bileşikler varlığında 450 nm'de maksimum absorbans veren bakır(I)-neokuproin [Cu(I)-Nc] şelatına indirgenme yeteneğinden yararlanılarak bileşiklerin antioksidan kapasiteleri ölçülmektedir (Apak ve ark., 2014). Gaziantep taze sarımsağında CUPRAC yöntemiyle saptanan antioksidan kapasite 62,85 mmol Trolox/100 g KA, Kahramanmaraş taze sarımsağının ise 58,81 mmol Trolox/100 g KA olarak belirlenmiştir (Tablo 2). Demir iyonlarını şelatlama yöntemiyle saptanan antioksidan kapasite ise Gaziantep yöresinde yetişen sarımsaklarda 63,22 mg EDTA/100 g KA, Kahramanmaraş yöresinde yetişen sarımsakların ise 62,54 mg EDTA/100 g KA olarak saptanmıştır (Tablo 2).



Toplam fenolik madde miktarı

Fenolik bileşikler, bitkilerde bulunan ve sağlık için faydalı olan doğal bileşiklerdir (Amoako ve Awika, 2016). Bu bileşiklerin, antioksidan ve antiinflamatuar gibi birçok biyolojik fonksiyona sahip olduğu bilinmektedir (Tavan ve ark., 2023). Fenolik bileşiklerin insan sağlığı üzerindeki potansiyel faydaları göz önüne alındığında, bu bileşiklerin gıda maddeleri ve ilaç ürünlerinde biyoaktif bileşen olarak kullanımı büyük ilgi görmüştür (Tavan ve ark., 2023). Gaziantep sarımsaklarının toplam fenolik madde miktarı 276,97 mg GAE/100 g KA, Kahramanmaraş sarımsaklarında ise 252,91 mg GAE/100 g KA olarak tespit edilmiştir (Tablo 2, Şekil 4). Yapılan bir çalışmada sarımsakta fenolik bileşiklerin toplam miktarının 3,4 ile 10,8 mg GAE/g arasında değiştiği ve ortalama 6,5 mg GAE/g olduğu bildirilmiştir (Qiu ve ark., 2020). Bir diğer çalışmada ise farklı solventler (metanol, hekzan ve etil asetat) ve farklı sürelerde (35, 50 ve 65 dakika) yapılan ekstraksiyonlar ile taze sarımsaklardaki toplam fenolik madde içeriğinin 38,57 ile 60,38 mg GAE/100g arasında değiştiği ve en yüksek içeriğe 50 dakikalık ekstraksiyon süresinde ve metanol kullanılarak ulaşıldığı bildirilmiştir (Awan ve ark., 2019). Bir diğer çalışmada ise taze sarımsaklardaki toplam fenolik madde miktarı 98 mg GAE/100g olarak belirlenmiştir (Bozin ve ark., 2008). Elde edilen veriler doğrultusunda çalışmamızda belirlenen TFM miktarının Qiu ve ark. (2020)'nin tespit ettiği TFM miktarından düşük, Awan ve ark., (2019) ve Bozin ve ark., (2008)'in çalışma verilerinden ise yüksek olduğu gözlenmiştir. Bunun nedeninin sarımsakların çeşidine, yetiştirilme yörelerine, mevsim koşullarına ve yetiştirme koşullarından (toprak, gübreleme ve sulama vb.) kaynaklı olabileceği düşünülmektedir.

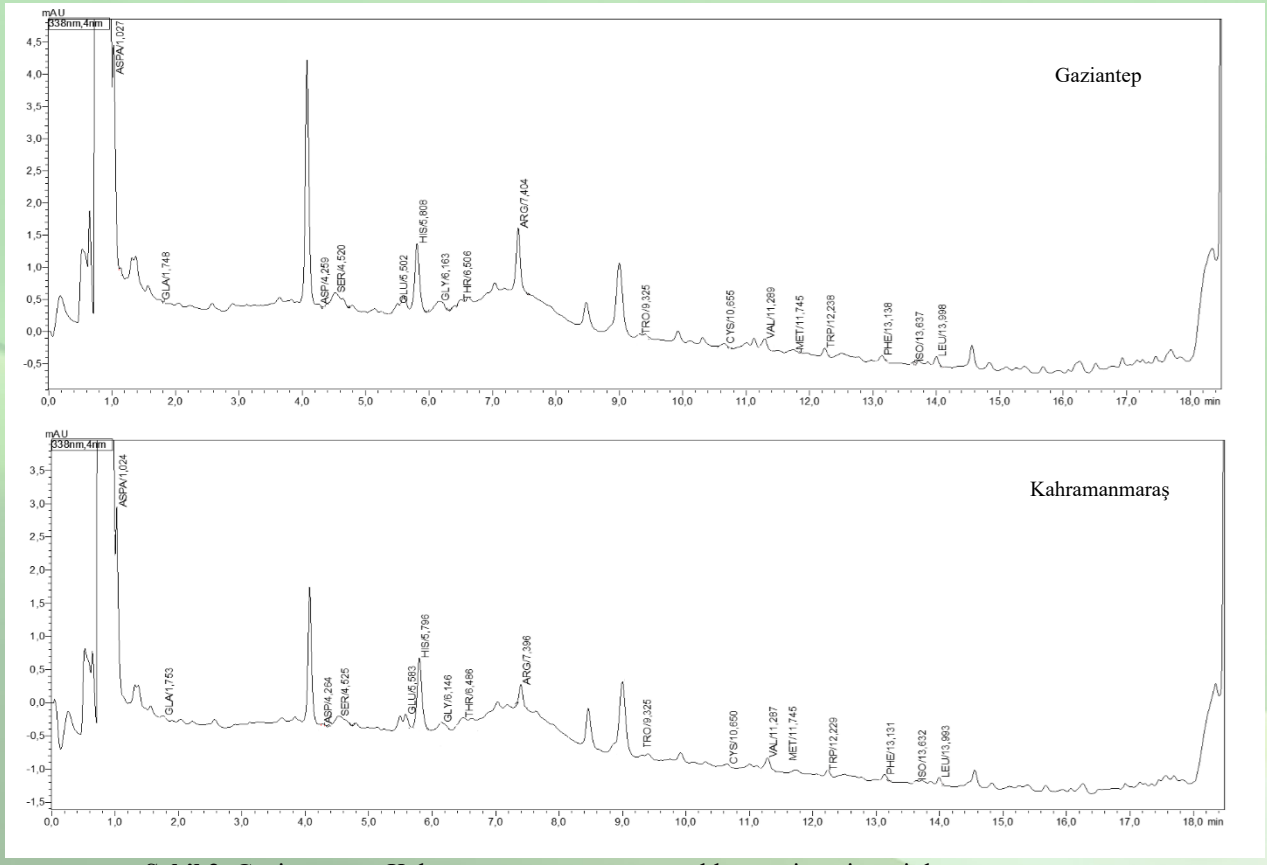
Şeker profili

Taze sarımsağın %26-30'unu karbonhidratlar oluşturmaktadır (Darbyshire ve Henry, 1981). Polisakkaritler, sarımsağın ana bileşenlerindendir ve son yıllarda yapılan klinik çalışmalar, sarımsak polisakkaritlerinin antibakteriyel, antiinflamatuar, antidiyabetik, antitümör ve antiaging (yaşlanmayı engelleyici) potansiyele sahip olduğunu göstermektedir (Li ve ark., 2017). Tablo 1'de her Gaziantep ve Kahramanmaraş yörelerinden temin edilen taze sarımsaklarda belirlenen sakkaroz, glikoz ve fruktoz miktarları verilmiştir. Şekil 1'de belirlenen bileşiklere ait HPLC-RID kromatogramı, verilmiştir. İki yöreden de temin edilen taze sarımsaklarda baskın şeker

sakkaroz olarak saptanmış ve bunu miktarsal olarak fruktoz ve glikozun izlediği tespit edilmiştir. Gaziantep yöresinden temin edilen taze sarımsağın toplam şeker içeriği 2809,39 mg/kg, Kahramanmaraş yöresinden temin edilen taze sarımsağın ise 2298,15 mg/kg olarak tespit edilmiştir (Tablo 1). Bu bulgular, Gaziantep yöresi sarımsaklarının, Kahramanmaraş yöresi sarımsaklarına göre daha yüksek toplam şeker içeriğine sahip olduğunu göstermektedir.Gaziantep ve Kahramanmaraş yöresi taze sarımsaklarının sırasıyla sakkaroz miktarı 1276,51 mg/kg ve 938,61 mg/kg, glikoz miktarı 1055,70 ve 895,58 mg/kg ve fruktoz miktarı ise 477,14 ve 463,00 mg/kg olarak belirlenmiştir. Gaziantep yöresine ait sarımsakların şeker içeriklerinin Kahramanmaraş yöresi sarımsaklarından yaklaşık 1,2 kat yüksek olduğu tespit edilmiştir. Petropoulos ve ark. (2018), Yunanistan'da yetiştirilen sarımsaklarda sakkarozun baskın şeker olduğunu ve miktarının 1,99 ile 3,29 g/100 g arasında değiştiğini rapor etmişlerdir. Bu çalışmada, toplam şeker içeriğinin %97'sini sakkaroz oluştururken, fruktoz daha düşük seviyelerde bulunmuştur. Ayrıca, incelenen genotiplerin sadece üçünde glikoz tespit edilmiştir. Sasmaz ve ark. (2022), taze sarımsaklarda toplam şeker miktarının 1519-1856 mg/100g arasında değiştiğini bildirmişlerdir.

Şekil 1. Gaziantep ve Kahramanmaraş yöresi taze sarımsakların şeker kromatogramı

Amino asit profili



Sarımsak, antimikrobiyal özellikleri (Lanzotti ve ark., 2014), kanser önleyici potansiyeli (Dong ve ark., 2014), kardiyovasküler hastalıkların önlenmesi ve tedavisi (Katsuki, ve ark., 2006) ve antioksidan özellikleri (Fratianni ve ark., 2016) gibi sağlık yararları nedeniyle her geçen gün daha fazla ilgi görmektedir. Amino asitler insan vücudundaki en önemli bileşikler olarak kabul edilmektedir. Bu bileşikler yalnızca proteinlerin temel yapısal birimleri ve bir enerji kaynağı olmakla kalmaz, aynı zamanda nörotransmitterlerin, porfirinlerin, poliaminlerin ve nitrik oksitlerin biyosentezinde de önemli bir rol oynamaktadır (Guo ve ark., 2013). Sarımsaktaki amino asitlerin miktarı ve bileşimi, sarımsağın kalitesi ve besin değeri hakkında bilgiler sağlamaktadır. Yapılan çalışmalar, sarımsağın serbest amino asitler açısından zengin ve amino asit takviyesi için sağlıklı bir besin kaynağı olduğunu ortaya koymaktadır (Yongdoo ve ark., 2005; Lee ve Harnly 2005). Yapılan çalışmalarda sarımsakta baskın amino asittin arjinin olduğu bildirilmiştir (Liu, ve ark., 2018). Arjinin, tüm hücreler tarafından kullanılan yarı esansiyel bir amino asittir. Bu amino asit, ortalama olarak, normal insan diyetindeki toplam amino asitlerin %5-7'sini oluşturmaktadır (Pahlavani ve ark., 2017). Sarımsağın çeşidine ve yetiştirilme koşullarına bağlı olarak amino asit miktarı değişmektedir (Lee ve Harnly, 2005).

Gaziantep ve Kahramanmaraş yörelerinden temin edilen taze sarımsakların aminoasit profili ve miktarlarına ait veriler Tablo 3'de sunulmuştur. Her iki yörenin sarımsaklarında da 18 adet amino asit bileşiği saptanmıştır. Sarımsaklarda aspartik asit, glutamik asit, asparajin, serin, glutamin, histidin, glisin, treonin, arjinin, tirozin, sistein, valin, metiyonin, triptofan, fenilalanin, izolösin, lösin, prolin amino asitleri belirlenmiştir. Toplam amino asit miktarı Gaziantep sarımsağında 488,81 mg/100g, Kahramanmaraş sarımsağında ise 417,34 mg/100g olarak saptanmıştır. Gaziantep ve Kahramanmaraş sarımsaklarında baskın aminoasitin arjinin olduğu saptanmıştır. Gaziantep yöresi sarımsakların arjinin miktarı Kahramanmaraş yöresine göre yaklaşık 1,34 kat daha yüksek

içeriktedir. Arjinin sonrasında aspartik asit, glutamik asit, histidin ve tirozinin baskın amino asitler olduğu saptanmıştır. Bunlar dışında Gaziantep yöresi sarımsağının Kahramanmaraş taze sarımsağına göre asparajin miktarı 1,52 kat, glisin miktarı 1,45 kat, treonin miktarı 1,41 kat, tirozin miktarı 2,59 kat ve sistein miktarı ise 1,76 kat daha yüksek olduğu belirlenmiştir.

Tablo 3. Sarımsak örneklerine ait aminoasit miktarları

Alıkonma zamanı (dk)	Amax (nm)	Aminoasitler (mg/100 g)	Kısaltma	Gaziantep	Kahramanmaraş

Şekil 2. Gaziantep ve Kahramanmaraş taze sarımsaklarına ait aminoasit kromatogramı

Kang (2016) yaptığı çalışmada, sarımsaklarda aspartik asit (23,64 mg/100 g), glutamik asit (17,35 mg/100 g), sistein (2,51 mg/100 g), histidin (111,46 mg/100 g), glisin (157,75 mg/100 g), treonin (2,17 mg/100 g), lizin (3,37mg/100 g), arjinin (30,78 mg/100 g), valin (216,47 mg/100 g), triptofan (203,03 mg/100 g) ve lösin (18,08 mg/100 g) amino asitlerini belirlemişlerdir. Liu ve ark. (2018) tarafından bir diğer çalışmada sarımsaklardaki lösin miktarı 9,2 mg/100 g, izolösin miktarı 14,08 mg/100 g, aspartik asit miktarı 14,66 mg/100 g, glutamik asit miktarı 60,5 mg/100 g, sistein miktarı 3,75 mg/ 100 g, triptofan miktarı 23,51 mg/100 g olarak belirlenmiştir. Bir diğer çalışmada, Liu ve ark., (2020) sarımsaktaki aspartik asit miktarını 30,9 mg/100 g kuru madde (KM), glutamik asit miktarını 32,7 mg/100 g KM, lizin miktarını 154 mg/100 g KM, arjinin miktarını 74,3 mg/100 g KM, valin miktarını 6,4 mg/100 g KM, triptofan miktarını 0,7 mg/100 g KM, lösin miktarını 2,7 mg/100 g KM olarak belirlemişlerdir. Lu, (2017) yaptığı çalışmada sarımsağın amino asit miktarını 19,43 mg/ g olarak belirlemişlerdir.

Toplam sülfürlü bileşik ve allisin miktarı

Sarımsağın insan sağlığı üzerine yararlı etkileri sülfürlü bileşiklere çoğunlukla da allisin (dialil tiyosülfinat, 3-prop-2- enylsulfinylsulfanylprop-1-ene) bileşiğine atfedilmiştir (Amagase, 2006; Okada ve ark., 2008). İnsan sağlığı için önemli bir bileşik olan allisin, sarımsağın biyoaktif ve ana fonksiyonel bileşenidir (Meriga ve ark., 2012; Liang ve ark., 2012). Sarımsaktaki allisin varlığı ve biyolojik özellikleri ilk olarak 1944'te Chester John Cavallito ve John Hays Bailey tarafından bildirilmiş ve allisin bileşiğine "sarımsağın kalbi" denilmiştir (Josling, 2007). LC/MS/MS yardımıyla toplam sülfürlübileşik ve allisin miktarı belirlenmiştir. Gaziantep ve Kahramanmaraş sarımsakları kullanılarak en yüksek allisin içeriğine sahip taze sarımsak belirlenmiştir. Gaziantep yöresinde yetişen sarımsak örneklerinde allisin miktarı 2,51 mg/g, toplam sülfürlü bileşik miktarı ise 7,84 mg/g olarak belirlenmiştir. Kahramanmaraş yöresinde yetişen sarımsak örneklerinde allisin miktarı 2,37 mg/g, toplam sülfürlü bileşik miktarı ise 6,58 mg/g olarak belirlenmiştir. En yüksek allisin ve toplam sülfürlü bileşik miktarına sahip taze sarımsağın Gaziantep yöresinde yetişen taze sarımsak olduğu tespit edilmiştir. Yapılan bir çalışmada sarımsağın gramı başına yaklaşık 2.5 ila 4.5 mg allisin içerdiği bildirilmiştir (Lawson ve Hunsaker 2018).

Tartışma

Bu çalışmada, Gaziantep ve Kahramanmaraş yörelerinde yetiştirilen taze sarımsakların fizikokimyasal özellikleri, biyoaktif bileşen içerikleri ve antioksidan kapasiteleri kapsamlı bir şekilde karşılaştırılmıştır. Elde edilen bulgular, her iki yöre sarımsaklarının önemli besin değerlerine ve fonksiyonel özelliklere sahip olduğunu, ancak bazı parametrelerde belirgin farklılıklar gösterdiğini ortaya koymuştur. Nem içerikleri açısından her iki yöre sarımsakları benzer özellikler göstermiştir. Ancak, Gaziantep sarımsaklarının protein içeriği (%6.78) Kahramanmaraş sarımsaklarına (%6.36) göre daha yüksek bulunmuştur. Antioksidan aktivite sonuçları, her iki yöre sarımsaklarının güçlü antioksidan kapasiteye sahip olduğunu göstermiştir. Şeker profili analizleri, Gaziantep sarımsaklarının toplam şeker içeriğinin (2809.39 mg/kg) Kahramanmaraş sarımsaklarından (2298.15 mg/kg) yaklaşık %22 daha yüksek olduğunu göstermiştir. Amino asit profillerinde ise her iki yöre sarımsaklarında arjininin baskın amino asit olduğu belirlenmiştir. Gaziantep sarımsaklarının toplam amino asit içeriği (488.81 mg/100g), Kahramanmaraş sarımsaklarına (417.34 mg/100g) göre belirgin şekilde yüksek bulunmuştur.
Sülfür bileşikler açısından yapılan analizler, Gaziantep sarımsaklarının hem allisin (2.51 mg/g) hem de toplam sülfürlü bileşik (7.84 mg/g) içeriğinin Kahramanmaraş sarımsaklarına göre daha yüksek olduğunu göstermiştir.
Sonuç olarak, bu çalışma Gaziantep ve Kahramanmaraş yörelerinde yetiştirilen sarımsakların besin değerleri ve biyoaktif özellikleri açısından bazı farklılıklar gösterdiğini ortaya koymuştur. Gaziantep sarımsakları genel olarak daha yüksek protein içeriği, antioksidan kapasite, şeker ve amino asit içeriği ve toplam sülfürlü bileşik içeriği ile dikkat çekmiştir.

Teşekkür

Bu çalışma "123O720" proje numaralı 1001 projesi kapsamında TÜBİTAK (Türkiye Bilimsel ve Teknolojik Araştırma Kurumu) tarafından desteklenmiştir. TÜBİTAK'a teşekkürlerimizi sunarız.

Abstract

Tamarind (*Tamarindus indica* L.), an evergreen tree from the Fabaceae (Leguminosae) family, has garnered attention in both scientific research and traditional medicine due to its rich antioxidant content, natural sugars, organic acids, and phytochemical compounds. Interest in herbal infusions and their applications is growing, especially regarding their bioactive properties and potential health benefits. However, studies on the effects of infusion parameters, such as temperature and duration, on tamarind infusions remain limited in the literature. In this study, we investigated the effect of infusion time (3, 6, and 12 minutes) on the total phenolic content (TPC), antioxidant activity, organic acid profile, and sugar composition of tamarind fruit extract. We evaluated the changes in the antioxidant potential of the samples based on infusion duration using two different methods: DPPH and ABTS, while organic acids were analyzed by HPLC-PDA and sugar composition by HPLC-RID. The highest antioxidant activity, determined by DPPH and ABTS assays, was observed at the 12-minute infusion time, with values of 6780.95 and 7431.33 µmol Trolox/L, respectively. The total phenolic content at this duration was recorded as 2832.02 mg GAE/L. Tamarind infusions contained citric, malic, and tartaric acids as organic acids, along with sucrose, glucose, and fructose as sugars. The highest concentrations of organic acids and sugars were found in the 12-minute infusion. Tartaric acid (51.82 g/L) was identified as the predominant organic acid, while glucose (30.47 g/L) was the most abundant sugar. These findings highlight the potential of tamarind fruit infusions as a promising alternative to conventional herbs. At the same time, their high antioxidant content and beneficial organic acid composition.

Key Words: *Tamarindus indica, Antioxidants, organic acids, Infusions, Sugar profile*

İnfüzyon süresinin *Tamarindus indica*'nın biyokimyasal bileşimi üzerine etkisi

Özet

Fabaceae (Leguminosae) familyasından yaprak dökmeyen bir ağaç olan demirhindi (*Tamarindus indica* L.), zengin antioksidan içeriği, doğal şekerleri, organik asitleri ve fitokimyasal bileşikleri nedeniyle hem bilimsel araştırmalarda hem de geleneksel tıpta dikkat çekmiştir. Bitkisel infüzyonlara ve uygulamalarına olan ilgi, özellikle biyoaktif özellikleri ve potansiyel sağlık yararları açısından giderek artmaktadır. Bununla birlikte, sıcaklık ve süre gibi infüzyon parametrelerinin demirhindi infüzyonları üzerindeki etkilerine ilişkin çalışmalar literatürde sınırlı kalmaktadır. Bu çalışmada, infüzyon süresinin (3, 6 ve 12 dakika) demirhindi meyve özütünün toplam fenolik içeriği (TPC), antioksidan aktivitesi, organik asit profili ve şeker bileşimi üzerindeki etkisi araştırılmıştır. İnfüzyon süresine bağlı olarak örneklerin antioksidan potansiyelindeki değişiklikleri iki farklı yöntem kullanarak (DPPH ve ABTS) değerlendirilmiştir, organik asitler HPLC-PDA ve şeker bileşimi HPLC-RID ile analiz edilmiştir. DPPH ve ABTS analizleri ile belirlenen en yüksek antioksidan aktivite, sırasıyla 6780,95 ve 7431,33 µmol Trolox/L değerleri ile 12 dakikalık infüzyon süresinde gözlenmiştir. Bu süredeki toplam fenolik içerik 2832,02 mg GAE/L olarak kaydedilmiştir. Demirhindi infüzyonları organik asit olarak sitrik, malik ve tartarik asitler ile şeker olarak sukroz, glukoz ve fruktoz içermektedir. En yüksek organik asit ve şeker konsantrasyonları 12 dakikalık infüzyonda bulunmuştur. Bu süre zarfında toplam fenolik içerik 2832,02 mg GAE/L olarak kaydedilmiştir. Demirhindi infüzyonları organik asit olarak sitrik, malik ve tartarik asitlerin yanı sıra şeker olarak sükroz, glukoz ve fruktoz içermektedir. En yüksek organik asit ve şeker konsantrasyonları 12 dakikalık infüzyonda bulunmuştur. Tartarik asit (51,82 g/L) baskın organik asit olarak belirlenirken, glikoz (30,47 g/L) en bol bulunan şeker olmuştur. Bu bulgular, demirhindi meyvesi infüzyonlarının geleneksel bitkilere umut verici bir alternatif olma potansiyelini vurgulamaktadır. Aynı zamanda, yüksek antioksidan içeriği ve faydalı organik asit bileşimine sahiptir.

Anahtar Kelimeler*: Tamarindus indica, Antioksidanlar, organik asitler, İnfüzyonlar, Şeker profili*

Giriş

Demirhindi (*Tamarindus indica* L.- *T. indica*), Fabaceae (Leguminosae) familyasının bir üyesidir ve Dünyada Hindistan, Bangladeş, Sri Lanka, Tayland ve Endonezya gibi Asya ülkeleri ile Afrika ve Amerika olmak üzere 50'den fazla ülkede yetişmektedir (Pal& Mukherjee, 2020). Orta ila büyük boyutlu, yaprak dökmeyen, 24 m yüksekliğe ve 7 m çevreye sahip bir ağaçtır ve meyve yaklaşık %55 pulp, %34 tohum ve %11 kabuk ve tohumu kaplayan lif tabakasından oluşmaktadır (Hemshekhar ve ark., 2011). Tohumlar çok sert, parlak, kırmızımsı veya morumsu kahverengi, meyvenin içine gömülmüş halde bulunmaktadır ve sert bir zar ve liflerle birbirlerine bağlanmaktadır (Şekil 1). Hindistan yılda yaklaşık 0.3 milyon ton *T. indica* yetiştirmektedir ve bunun yaklaşık %30-34'ünü tohum oluşturmaktadır. Meyve özü (pulp) furan türevleri, karboksilik asit, flobatannin, asetik, sitrik, formik, malik, süksinik asit, flavonoidler, pektin, şeker içermektedir ve pulp dünyanın birçok ülkesinde yaygın olarak tüketilmektedir. (Dhasade ve ark., 2009; Tril ve ark., 2014). Tohumlar, kampesterol, *β*-amirin, β-sitosterol, yağ asitleri, tanenler, şeker, musilaj ve polisakkaritler, kardiyak glikozitler ve fenolikler içermektedir (Dhasade ve ark., 2009, Yeasmen& Nazrul Islam, 2015; Ganesapillai ve ark., 2017). Kabuk ise tanenler, saponinler, glikozitler, peroksidaz ve lipitleri içermektedir (Dhasade ve ark., 2009). Polifenoller, örneğin flavonoidler ve fenolikler, bitkinin hemen hemen her bölümünde bulunmakta ve bu da *T. indica*'yı antioksidan içeriği yüksek bir gıda haline getirmektedir(Ganesapillai ve ark., 2017). Meyvenin besin kompozisyonu incelendiğinde protein ~%7.5, nem ~%15.50, yağ ~%3, karbonhidrat ~%70 ve lif ~%4.5 olarak belirlenmiştir (Sadiq ve ark., 2016). *T. indica*, antidiyabetik, hipolipidemik, hepatoprotektif, antimikrobiyal ve antiproliferatif özellikler gibi bildirilen bazı aktivitelere sahiptir (El-Siddig, 2006). Farooq ve ark. (2022) meyvenin posasının C vitamini ve şeker açısından çok zengin olduğunu tespit etmiştir. Bu nedenle şuruplarda, meyve suyu konsantrelerinde, turşularda ve et soslarında kullanılmaktadır. *T. indica*, başta düşük glisemik indekse sahip fruktoz ve hücresel enerji üretimi için temel kaynak olan glikoz olmak üzere, tatlı ve keskin lezzetine katkıda bulunan doğal şekerler açısından zengindir. Bu şekerler sadece enerji sağlamakla kalmaz, aynı zamanda meyvenin genel lezzetinde ve besin değerinde de rol oynamaktadır. Birçok farklı tarif olmasına rağmen genellikle meyve suyu, infüzyon veya salamura haline getirilmektedir (Katare ve Hakrovorty, 2019).

Meyve, karakteristik ekşi tadından sorumlu olan tartarik asit de dahil olmak üzere çeşitli organik asitler içermektedir. Tartarik asit, özellikle *Aspergillus flavus* gibi türlere karşı antifungal özellikleriyle dikkat çekmektedir (Kachapulula ve ark., 2019). *T. indica*'da bulunan diğer organik asitler arasında, sindirime ve metabolik süreçlere yardımcı olarak sağlık üzerinde etkili olan sitrik asit ve malik asit içermektedir. *T. indica*, serbest radikallerin nötralize edilmesinde ve oksidatif stresin azaltılmasında önemli bir rol oynayan galik asit, ferulik asit, kafeik asit ve *p*-kumarik asit gibi fenolik asitler, apigenin, luteolin, kersetin, rutin ve naringenin gibi flavonoidler, C vitamini, *β*-karoten ve lutein gibi karotenoidleri içermektedir. *T. indica*'da tanımlanan diğer temel antioksidan bileşikler ise 2-hidroksi-3',4'-dihidroksiasetofenon, metil 3,4-dihidroksibenzoat ve oligomerik proantosiyanidinlerdir (OPC'ler) (Waqas ve ark., 2013). Bu bileşikler, DPPH serbest radikal temizleme yöntemi de dahil olmak üzere çeşitli analizlerle belirlenen *T. indica*'nın genel antioksidan aktivitesine katkıda bulunmaktadır (Waqas ve ark., 2013). Ayrıca, mirisetin ve prosiyanidin B2 gibi flavonoidlerin varlığı antioksidan profilini daha da geliştirmektedir (Pratiwi ve ark., 2020).

Tamarindus indica, zengin antioksidan içeriği, doğal şekerleri, organik asitleri ve fitokimyasal bileşenleri sayesinde sağlığa birçok fayda sağlayan bir meyvedir. Geleneksel kullanımının yanı sıra, bu faydalar bilimsel araştırmalarla da desteklenmektedir. *T. indica* infüzyonları, özellikle metabolik ve kardiyovasküler hastalıkların yönetiminde destekleyici bir bileşen olarak değerlendirilen çeşitli sağlık yararlarıyla dikkat çekmektedir. Maekawa ve ark. (2022), *T. indica* yapraklarından elde edilen metanolik ekstraktların biyolojik sistemlerde antioksidan seviyelerini artırdığını ve oksidatif stresle ilişkili durumların yönetiminde potansiyel bir diyet takviyesi olarak kullanılabileceğini belirtmişlerdir. Ayrıca, *T. indica* posası infüzyonunun gastrointestinal sağlık üzerindeki etkileri incelenmiş; ülserlere karşı koruyucu etki gösterdiği ve mukozal savunma mekanizmalarını desteklediği rapor edilmiştir (Umar ve ark., 2023). *T. indica*'nın antidiyabetik etkileri de kapsamlı şekilde araştırılmıştır. Meher (2017) ile Purwaningsih ve ark. (2023) tarafından yürütülen çalışmalar, *T. indica* tohumları ve yapraklarından elde edilen ekstraktların diyabetik modellerde kan glikoz düzeylerini anlamlı ölçüde düşürebildiğini ve lipid profillerini iyileştirebildiğini göstermiştir. Bu etkilerin, içerdiği flavonoidler ve saponinler gibi biyoaktif bileşiklerin insülin duyarlılığını artırması ve lipid metabolizmasını düzenlemesiyle ilişkili olduğu düşünülmektedir. Etukudo ve ark. (2024) ise *T. indica*'nın özellikle oksidatif stres ve nörodejenerasyonla ilişkili durumlarda gösterdiği nöroprotektif etkileri vurgulamış; yapısında bulunan flavonoidlerin ve diğer fitokimyasalların, nöronal hücreleri hasardan koruma potansiyeline sahip olduğunu belirtmişlerdir.

T. indica infüzyonu, meyvenin sıcak suda bekletilerek hazırlanmasıyla elde edilen bir özüt veya çaydır. İnfüzyon ile, meyvenin biyoaktif bileşenleri suya geçmekte için sağlık açısından değerli bileşenler içermektedir: Fenolik bileşikler antioksidan ve anti-inflamatuar etkiler göstermekte, flavonoidler hücresel yaşlanmayı yavaşlatmakta ve bağışıklık sistemini güçlendirmekte, organik asitler (tartarik asit, sitrik asit) sindirimi desteklemekte ve bağırsak sağlığına fayda sağlamakta ve mineraller (potasyum, magnezyum, demir) ise kan basıncını düzenlemekte ve kas fonksiyonlarını desteklemektedir (Pratiwi ve ark., 2020; Etukudo ve ark., 2024). Ayrıca *T. indica* meyve özünden

elde edilen antioksidan bakımından zengin ekstraktlar, oksidatif stresle ilgili gen ifadesinin modülasyonuyla ilişkilendirilmiş ve oksidatif hasarla mücadeledeki rollerini daha da desteklemiştir (Razali ve ark., 2010). *T. indica* infüzyonu, antioksidanlar, anti-inflamatuar ajanlar ve diğer biyoaktif bileşiklerden oluşan zengin bileşimi sayesinde sağlığı geliştirmek için umut verici bir yol sunmaktadır. Çeşitli çalışmalardan elde edilen kanıtlar, oksidatif stres, inflamasyon, gastrointestinal sağlık ve metabolik bozuklukların yanı sıra yara iyileşmesi ve enfeksiyon yönetimindeki geleneksel uygulamaların yönetiminde potansiyel kullanımını desteklemektedir.
T. indica infüzyonları ve uygulanan sıcaklık ve süre gibi faktörlerin meyvenin yapısında bulunan ve infüzyon ile suya geçem önemli biyoaktif bileşikler üzerinde etkisi ile ilgili literatürde sınırlı çalışma bulunmaktadır. Bu çalışmada, *T. indica* meyve özünün TPC, antioksidan aktivite, organik asitler ve şeker kompozisyonu üzerine infüzyon süresinin (3, 6, 12 dakika) etkisi incelenmiştir. Örneklerin infüzyon süresine bağlı olarak antioksidan potansiyelinin ne şekilde değiştiği DPPH ve ABTS olmak üzere iki farklı yöntemle belirlenmiştir. Organik asitler HPLC-PDA ile, şeker kompozisyonu ise HPLC-RID kullanılarak değerlendirilmiştir.

Materyal ve Yöntem

1. Kimyasallar

Organik asitler, şeker standartları, 2,2-difenil-1-pikrilhidrazil (DPPH) ve Trolox Sigma-Aldrich Chemical Company'den ve Folin-Ciocalteu reaktifi Merck'ten satın alınmıştır. HPLC sisteminde referans standartlar olarak organik asitler için sitrik (77-92-9), malik asit (6915-15-7) ve tartarik asit (87-69-4), şeker analizi için sakkaroz (57-50-1), glukoz (50-99-7) ve fruktoz (57-48-7) Merck'ten satın alınmıştır.

2. İnfüzyonların hazırlanması

Demirhindi (*T. indica*) Adana'da yerel bir marketten satın alınmıştır. İnfüzyon çaylarda yaygın olarak kullanılan sıcaklık 85ºC ile 100ºC, infüzyon süresi ise 3-15 dakika arasındadır ve bu sıcaklık ve süreler daha önceki çalışmalarımızda da kullanılmış ve iyi sonuçlar elde edilmiştir (Kelebek, 2016; Uzlasir ve ark., 2020). Ayrıca, mevcut literatürden elde edilen koşullar da benzer sıcaklık ve süreler kullanılmıştır (Ariffin ve ark., 2011; Gan ve Ting, 2017; Pan ve ark., 2018; Xiao ve ark., 2017). *T. indica*'ların kabuk, meyve ve çekirdekleri ayrılmış ve infüzyonların hazırlanmasında meyve kısmı kullanılmıştır (Şekil 1).

(a) (b) (c) (d)

Şekil 1. *T. indica* meyve bölümleri (a: tüm meyve, b: kabuk, c: meyve özü (pulp) ve d: tohum)

Beş gram *T. indica* meyve özü tartılarak 250 mL'lik bir behere aktarılmış ve üzerine 100 °C'de 100 mL sıcak su eklenerek 3, 6 ve 12 dakika süreyle demlenmiştir. Elde edilen örnekler, 4 °C'de 15 dakika boyunca 6.500 rpm'de santrifüj edilmiş ve yüksek performanslı sıvı kromatografi (HPLC) analizi öncesinde 0,45 µm'lik membran filtre (Millipore) ile süzülmüştür. İnfüzyon işlemleri ve analizler, üç tekerrürlü olarak gerçekleştirilmiştir.

3. Antioksidan aktivite (AA) ve toplam fenolik madde (TFM) analizleri

3.1 Antioksidan aktivite (DPPH ve ABTS yöntemleri kullanılarak) analizleri

DPPH analizi, Brand-Williams ve ark. (1995) tarafından tanımlanan yönteme çeşitli modifikasyonlar uygulanarak gerçekleştirilmiştir. Kısaca, her bir ekstrakttan 200 µL alınarak 3,9 mL DPPH çözeltisi ile karıştırılmış ve karışım karanlık ortamda, oda sıcaklığında 1 saat süreyle inkübe edilmiştir. Ardından, absorbans değerleri UV-görünür spektrofotometre (Cary 60, Agilent, Malezya) kullanılarak 517 nm dalga boyunda ölçülmüştür. Antioksidan aktiviteler, bir kalibrasyon eğrisi yardımıyla hesaplanmış ve sonuçlar µmol Trolox/L cinsinden ifade edilmiştir.
ABTS radikal süpürme aktivitesi analizi, Re ve ark. (1999) tarafından belirtilen yönteme göre modifiye edilmiş otomatik ağartma yöntemi kullanılarak gerçekleştirilmiştir. İnhibisyon yüzdesi hesaplanmış ve sonuçlar µmol Trolox / L olarak ifade edilmiştir.

3.3 Toplam fenolik madde (TFM) analizi

TFM analizleri daha önce Singleton ve ark. (1999) tarafından belirtilen Folin-Ciocalteu reaktifi kullanılarak tespit edilmiştir. Kısaca, 200 µl infüzyon 0,5 ml Folin-Ciocalteu reaktifi ile 3 dakika boyunca karıştırılmış, ardından 2

ml %20 (w/v) sodyum karbonat eklenmiştir. Karışım daha sonra 765 nm'de absorbans ölçülmeden önce 30 dakika oda sıcaklığında bekletilmiştir. TFM miktarı, mg gallik asit eşdeğerleri (GAE) /L olarak ifade edilmiştir.

4. Organik asit ve şeker analizi

İnfüzyonlar, organik asit ve şeker profillerini tespit etmek ve miktarlarını belirlemek için PDA ve RID dedektörlü HPLC'ye (Shimadzu Prominence-i LC-2030C) enjekte edilmiştir. Analizlerde taşıyıcı faz olarak 0,5 mL/dak akış hızında H_2SO_4 (5 mM) taşıyıcı faz olarak ve formik asit çözeltisi (%0,1) kullanılırken, şeker profili için BIORAD Aminex HPX-87H (300 × 7,8 mm, Bio-Rad; Hercules, CA, ABD) kolon olarak kullanılmıştır (Flores, Hellín ve Fenoll, 2012). Bileşiklerin miktarlarını belirlemek için her bir standart madde için beş farklı konsantrasyonda hazırlanmış ve bileşikler kalibrasyon eğrilerinden ölçülmüştür.

5. İstatistiksel analiz

Bu çalışmada, istatistiksel veri analizi XLStat deneme yazılımı (Addinsoft) kullanılarak gerçekleştirilmiştir. Verilerin içerik seviyelerindeki farklılıklar Duncan testi ile hesaplanmıştır. *P*-değerleri 0.05'ten küçük olan ortalamalar istatistiksel olarak anlamlı kabul edilmiştir.

Bulgular ve Tartışma

1. Antioksidan aktivite (AA) ve Toplam Fenolik madde miktarı (TPC)

Antioksidanlar, reaktif oksijen türlerinin (ROS) neden olduğu hücresel hasarı önleyen veya azaltan bileşiklerdir. *T. indica* infüzyonlarında ölçülen başlıca antioksidan bileşikler; fenolik bileşikler, flavonoidler ve bazı organik asitlerdir. Tablo 1'de, *T. indica* (demirhindi) meyves infüzyonlarının 3, 6 ve 12 dakikalık sürelerle hazırlanması sonucunda oluşan antioksidan aktivite (AA) ve toplam Fenolik madde miktarlarındaki (TPC) değişimleri verilmiştir.

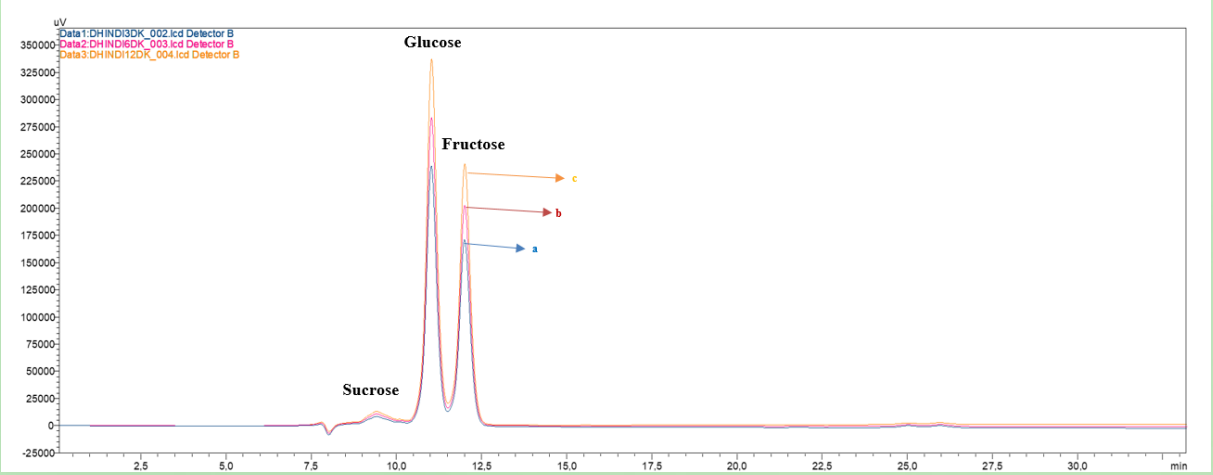
Tablo 1. *T. indica* infüzyonlarının biyokimyasal kompozisyonu

***T. indica* infüzyonları**			
Süre	***3 dakika***	***6 dakika***	***12 dakika***
AntioksidanAktivite			
DPPH (µmol Trolox/L)	2592,38±38,79^{a}	2872,38±48,68^{b}	6780,95±78,68^{c}
ABTS (µmol Trolox/L)	2978,67±19,22^{a}	3432,00±43,41^{b}	7431,33±68,71^{c}
TFM (mg GAE/L)	1777,37±4,24^{a}	2131,36±121,01^{b}	2832,02±6,39^{c}
Şeker Profili			
Sakkaroz (mg/L)	20,33±0,00^{c}	1,13±0,0^{a}	1,41±0,0^{b}
Glikoz (mg/L)	21,45±0,00^{a}	26,18±1,2^{b}	30,47±0,0^{c}
Fruktox (mg/L)	11,88±0,00^{a}	14,30±0,4^{b}	16,90±0,0^{c}
Toplam şeker(mg/L)	*34,35±0,00^{a}*	*41,61±1,6^{b}*	*48,78±0,1^{c}*
Organik Asit Profili			
Sitrik Asit (mg/L)	1,07±0,00^{a}	1,30±0,02^{b}	1,55±0,06^{c}
Tartarik Asit (mg/L)	36,11±0,09^{a}	43,24±0,15^{b}	51,82±0,23^{c}
Malik Asit(mg/L)	4,86±0,00^{a}	6,03±0,04^{b}	7,24±0,06^{c}
Toplam organik asit (mg/L)	*42,03±0,09^{a}*	*50,56±0,21^{b}*	*60,61±0,34^{c}*

± standard deviation

a-c: Aynı satırdaki farklı harfler istatistiksel farklılıkları göstermektedir ($p<0,05$).

3 dakikalık infüzyonda 2592,38 µmol Trolox/L olan DPPH radikal süpürme kapasitesi, 6. dakikada hafif artış göstererek 2872,38 µmol Trolox/L'ye yükselmiş, ancak 12. dakikada 6780,95 µmol Trolox/L ile belirgin şekilde artmıştır ($p<0,05$). Bu durum, infüzyon süresi uzadıkça fenolik bileşiklerin suya daha fazla ekstrakte olduğunu göstermektedir. Literatürde, *T. indica* özlerinin DPPH serbest radikali üzerinde önemli antioksidan etki gösterdiği bildirilmiştir (Sudjaroen et al., 2005). Benzer şekilde, infüzyon süresi arttıkça antioksidan aktivite artışı *Hibiscus sabdariffa* (karkade) gibi bitkilerde de gözlemlenmiştir (Tsai ve ark., 2002).



ABTS yöntemi ile belirlenen radikal süpürme kapasitesi ise 3 dakikada 2978,67 µmol Trolox/L iken 6 dakikada 3432,00 µmol Trolox/L ve 12 dakikada 7431,33 µmol Trolox/L'ye yükselmiştir ($p<0,05$). Bu sonuç, ABTS analizinin daha polar fenolik bileşikleri ölçmede etkili olduğunu ve infüzyon süresinin bu bileşiklerin çözünürlüğünü artırdığını göstermektedir (Re ve ark., 1999). Yüksek ABTS ve DPPH aktiviteleri, demirhindi infüzyonunun inflamasyonu azaltıcı ve yaşlanma karşıtı etkiler potansiyeli taşıdığını göstermektedir.

Toplam fenolik madde (TPC) miktarı incelendiğinde ise 3 dakikada 1777,37 mg GAE/L olan TPC, 6. dakikada 2131,36mg GAE/L'ye, 12. dakikada ise 2832,02 mg GAE/L'ye yükselmiştir ($p<0,05$). Fenolik bileşikler suda çözünürlük özelliği taşıdığından, uzun süreli infüzyonlar ekstraksiyon verimliliğini artırmaktadır (Duenas ve ark., 2005). Yüksek TPC değeri, DPPH ve ABTS sonuçları ile paralellik göstermektedir. Fenolik bileşikler serbest

radikalleri etkisiz hale getirerek DNA, lipitler ve proteinlerin oksidatif hasara uğramasını önlemektedir (Scalbert ve ark., 2005). Kronik hastalıkların (kanser, kardiyovasküler hastalıklar, diyabet, Alzheimer) gelişimini azaltıcı etkileri ise bilimsel olarak gösterilmiştir (Manach ve ark., 2004). *T. indica* meyvesi, gallik asit ve ferulik asit gibi güçlü antioksidan fenoller içermektedir (Sudjaroen ve ark., 2005).

2. Şeker profili

T. indica infüzyonlarında doğal olarak bulunan şekerler sakkaroz, glikoz ve fruktoz, enerji sağlamada temel rol oynasa da, sağlık üzerine etkileri tüketim düzeyine göre değişiklik göstermektedir. Tablo 1'de, *T. indica* (demirhindi) meyves infüzyonlarının 3, 6 ve 12 dakikalık sürelerle hazırlanması sonucunda şeker profilinde meydana gelen değişimler, Şekil 1'de ise HPLC-RID ile belirlenen şeker kromatogramı verilmiştir. Sakkaroz miktarı 3 dakikada 20,33 mg/L iken 6 ve 12 dakikada sırasıyla 1,13 ve 1,41 mg/L olarak önemli ölçüde azalmıştır. Bu azalma, sakkarozun parçalanarak glikoz ve fruktoza dönüşmesi ile açıklanabilir. Glikoz miktarı ise 3 dakikada 21,45 mg/L, 6 dakikada 26,18 mg/L ve 12 dakikada 30,47 mg/L'ye çıkmıştır. Fruktoz değeri de benzer bir artış göstermiştir. Toplam şeker içeriği ise 3 dakikada 34,35 mg/L, 6 dakikada 41,61 mg/L ve 12 dakikada 48,78 mg/L olarak artış göstermiştir. ($p<0,05$). Bu sonuçlar, invertaz enzim aktivitesinin etkisini düşündürmektedir. Demirhindi meyvesinde bulunan doğal enzimlerin, sakkarozu parçalayarak glikoz ve fruktoz üretmesi mümkündür. Bu dönüşüm, infüzyon sırasında sıcaklığın etkisiyle hücre duvarlarının geçirgenliği artmakta ve çözünür şekerler kolaylıkla ortama geçmesi ile açıklanmaktadır (Morton, 1987). Aynı zamanda bu dönüşüm hızlı enerji kaynağı sağlarken infüzyonun tatlılık seviyesini artırmaktadır. Glikoz ve fruktoz hızla emilerek kan şekeri seviyesini yükseltmektedir ve aşırı fruktoz tüketimi karaciğer yağlanması ve insülin direnci ile ilişkilendirilmektedir (Tappy ve Lê, 2010). Ancak doğal meyve kaynaklı fruktoz, lif ve fenoliklerle birlikte tüketildiğinde zararlı etkisi azalmaktadır. Mahmood ve ark. (2014,) *T. indica* meyvesinin düşük kalorili içeceklerde doğal tatlandırıcı olarak kullanılabileceği bildirmiştir.

Şekil 1. HPLC-RID ile belirlenen şeker kromatogramı (a: 3 dakikalık infüzyon süresi ile hazırlanan ekstrakt, b: 6 dakikalık infüzyon süresi ile hazırlanan ekstrakt ve c: 12 dakikalık infüzyon süresi ile hazırlanan ekstrakt)

3. Organik asit profili

Organik asitler, sadece tat profiline katkı sağlamakla kalmaz, aynı zamanda sağlık üzerinde çeşitli etkiler göstermektedir. *T. indica* meyve infüzyonlarının 3, 6 ve 12 dakikalık sürelerle hazırlanması sonucunda organik asit profilinde meydana gelen değişimler Tablo 1'de verilmiştir. *T. indica* infüzyonlarında belirlenen başlıca organik asitler arasında sitrik asit, tartarik asit ve malik asit yer almakta olup, bu bileşiklerin toplam konsantrasyonları infüzyon süresi arttıkça anlamlı biçimde yükselmiştir ($p<0,05$). Bu artış, sıcaklığın ve ekstraksiyon süresinin, meyve matrisindeki organik asitlerin çözünürlüğü ve salınımı üzerindeki etkilerini yansıtmaktadır. İnfüzyonun 3. dakikasında toplam organik asit içeriği 42,03 mg/L iken, bu değer 6. dakikada 50,56 mg/L'ye, 12. dakikada ise 60,61 mg/L'ye ulaşmıştır. Özellikle tartarik asit, 36,11 mg/L'den 51,82 mg/L'ye kadar artarak en baskın asit bileşeni olduğunu ortaya koymaktadır. Bu durum, *T. indica* meyvesinin doğal olarak zengin olduğu tartarik asidin, sıcak su infüzyonları yoluyla etkili bir şekilde ekstrakte edilebildiğini göstermektedir. Benzer şekilde, malik asit miktarı da infüzyon süresiyle birlikte artış göstermiş (4,86 mg/L → 7,24 mg/L), bu da malik asidin sıcaklığa duyarlı fakat çözünürlüğü yüksek bir organik asit olduğunu işaret etmektedir. Sitrik asit ise en düşük konsantrasyon düzeyine sahip olmasına rağmen zamanla anlamlı bir artış göstermiştir (1,07 mg/L → 1,55 mg/L). Bu artış, sitrik asidin bitkisel dokulardan geç difüze olması ve daha uzun süreli ekstraksiyon süreçlerinde açığa çıkmasıyla açıklanabilir. Literatürdeki benzer çalışmalar da infüzyon süresinin organik asitlerin ekstraksiyon verimliliği üzerinde belirleyici olduğunu göstermektedir (Mahmood ve ark., 2014; Tsai ve ark., 2002). Bu bağlamda, *T. indica* infüzyonlarının işlenme parametreleri (özellikle süre ve sıcaklık), ürünün

organoleptik özelliklerinin yanı sıra fonksiyonel içeriğini de doğrudan etkilemektedir. Organik asitlerdeki bu artışlar, yalnızca tat profiline katkı sağlamakla kalmayıp, aynı zamanda sindirim fonksiyonları, mineral biyoyararlanımı ve mikrobiyal stabilite açısından da önemli sağlık katkıları sunmaktadır.

Tartışma

Bu çalışma, *T. indica* meyvesinden hazırlanan infüzyonların farklı sürelerde ekstraksiyonu sonucunda meydana gelen biyokimyasal değişimleri kapsamlı bir şekilde ortaya koymuştur. Elde edilen bulgular, infüzyon süresi ile toplam antioksidan kapasite, toplam fenolik madde içeriği, organik asit profili ve şeker düzeyleri arasında anlamlı korelasyonlar olduğunu göstermektedir. Antioksidan aktivitenin, özellikle 12 dakikalık infüzyon süresinde maksimum seviyeye ulaştığı belirlenmiş; bu durum, fenolik bileşikler ve flavonoidlerin sıcaklıkla çözünürlüğündeki artışla ilişkilendirilmiştir. Organik asit profili açısından en belirgin artış tartarik asitte gözlenmiş; malik ve sitrik asit düzeyleri de infüzyon süresine paralel olarak artmıştır. Bu bulgular, *T. indica*'nın karakteristik ekşi tadını belirleyen asidik bileşenlerin sıcak suda çözünürlüğünün süreye bağlı olarak arttığını göstermektedir. Organik asitlerin bu yoğunluğu yalnızca duyusal kaliteyi artırmakla kalmamakta, aynı zamanda sindirimi destekleyici ve mikrobiyal kontrol sağlayıcı etkiler açısından da önem arz etmektedir.

Şeker profili açısından değerlendirildiğinde, özellikle glukoz ve fruktoz düzeylerinin infüzyon süresine bağlı olarak arttığı belirlenmiştir. Bu durum, sıcaklığın meyve dokularının parçalanmasını teşvik etmesi sonucu serbest şekerlerin çözünebilir hale gelmesiyle açıklanabilir. Bununla birlikte, şekerlerin biyoerişilebilirliğini artıran bu durumun, fonksiyonel içecek formülasyonlarında dikkatle değerlendirilmesi gerektiği vurgulanmalıdır.

Genel olarak bu çalışma, *T. indica* infüzyonlarının biyolojik açıdan aktif bileşenlerinin maksimum ekstraksiyonu için infüzyon süresinin kritik bir parametre olduğunu ortaya koymaktadır. Elde edilen veriler, fonksiyonel içeceklerin geliştirilmesinde *T. indica*'nın potansiyel bir doğal antioksidan ve sağlık destekleyici bileşen kaynağı olarak değerlendirilebileceğini göstermektedir. Bu bağlamda, infüzyon süresinin optimize edilmesi, hem besin bileşenlerinin korunumu hem de fonksiyonel etkilerin maksimize edilmesi açısından büyük önem taşımaktadır.
